Abstract: Investigation of social influence dynamics requires mathematical models that are “simple” enough to admit rigorous analysis, and yet sufficiently “rich” to capture salient features of social groups. Thus, the mechanism of iterative opinion pooling from (DeGroot, 1974), which can explain the generation of consensus, was elaborated in (Friedkin and Johnsen, 1999) to take into account individuals’ ongoing attachments to their initial opinions, or prejudices. The “anchorage” of individuals to their prejudices may disable reaching consensus and cause disagreement in a social influence network. Further elaboration of this model may be achieved by relaxing its restrictive assumption of a time-invariant influence network. During opinion dynamics on an issue, arcs of interpersonal influence may be added or subtracted from the network, and the influence weights assigned by an individual to his/her neighbors may alter. In this paper, we establish new important properties of the (Friedkin and Johnsen, 1999) opinion formation model, and also examine its extension to time-varying social influence networks.

1. INTRODUCTION

During the past decades, there has been a substantial growth of interest in dynamics of social influence networks and opinion formation mechanisms in them. In contrast to the recent research emphasis on multi-agent consensus and coordination, models are being advanced that explain observed behaviors of social groups such as disagreement, polarization, and conflict (Friedkin, 2015; Proskurnikov and Tempo, 2017). An explanatory network science is advancing on the structural properties of social networks (Wasserman and Faust, 1994; Easley and Kleinberg, 2010) and some special dynamical processes over these networks, e.g. epidemic spread (Newman, 2003). At the same time, there is a growing recognition that systems and control theories may substantially broaden the scope of our understanding of the definitional problem of sociology—the coordination and control of social systems (Friedkin, 2015).

System-theoretic examination of social dynamics requires mathematical models that are capable of capturing the complex behavior of a social group yet simple enough to be rigorously examined. In this paper, we deal with one such model, proposed by Friedkin and Johnsen (Friedkin and Johnsen, 1999, 2011; Friedkin, 2015) and henceforth referred to as the FJ model. The FJ model extends the idea of iterative “opinion pooling” (DeGroot, 1974) by assuming that some agents are prejudiced. These agents have some level of “anchorage” on their initial opinions (prejudices) and factor them into any iteration of their opinions. Similar to continuous-time clustering protocols with “informed” leaders (Xia and Cao, 2011), the heterogeneity of the prejudices and its linkage to individuals’ susceptibilities to interpersonal influence may lead to persistent disagreement of opinions and outcomes such as polarization and clustering. With the FJ model, the clustering of opinions does not require the existence of repulsive couplings, or “negative ties” among individuals (Fläch and Macy, 2011; Altafini, 2013; Proskurnikov et al., 2016a; Xia et al., 2016) whose ubiquity in interpersonal interactions is still waiting for supporting experimental evidence (Takács et al., 2016). Unlike models with discrete opinions (Castellano et al., 2009) and bounded confidence models (Hegselmann and Krause, 2002; Weisbuch et al., 2005; Blondel et al., 2009), the FJ model describes the opinion evolution by linear discrete-time equations, and is thus much simpler for mathematical analysis. At the same time, the FJ model has been confirmed by experiments with real social groups (Friedkin and Johnsen, 2011; Friedkin et al., 2016a). The FJ model is closely
related to the PageRank algorithm (Friedkin and Johnsen, 2014; Proskurnikov et al., 2016b) and has been given some elegant game-theoretic and electric interpretations (Bindel et al., 2011; Ghaderi and Srikan, 2014; Frasca et al., 2015). In the recent works (Parsegov et al., 2017; Proskurnikov and Tempo, 2017) necessary and sufficient conditions for the stability of the FJ model has been established; these conditions also provide convergence “on average” of its decentralized gossip-based counterpart (Frasca et al., 2013; Ravazzi et al., 2015; Frasca et al., 2015). A multidimensional extension of the FJ model has been used to describe the evolution of belief systems (Parsegov et al., 2017; Friedkin et al., 2016b), representing individuals’ positions on several mutually dependent issues.

In this paper, we further develop the mathematical theory of the FJ model, obtaining explicit estimates for its convergence speed. We also examine an extension of the classical FJ model, describing a natural time-varying social influence process. Such an extension is important since during opinion dynamics on an issue, arcs of interpersonal influence may be added or subtracted from the network, and the influence weights assigned by an individual to his/her neighbors may alter. An example of such an evolution is the dynamics of individuals’ reflected appraisals (Jia et al., 2015; Friedkin et al., 2016a; Chen et al., 2016).

2. PRELIMINARIES AND NOTATION

We denote matrices with capital letters $A = (a_{ij})$, using lower case letters for their scalar entries and vectors. The symbol $1_n$ denotes the column vector of ones $(1, \ldots, 1)^\top \in \mathbb{R}^n$, and $I_n$ is the identity $n \times n$ matrix. For two vectors $x, y \in \mathbb{R}^n$ we write $x \leq y$ if $x_i \leq y_i \forall i$. The spectral radius of a square matrix $A$ is denoted by $\rho(A)$, the matrix is Schur stable if $\rho(A) < 1$. A non-negative matrix $A$ is substochastic if $\sum_j a_{ij} \leq 1$ for any $i$. Any such matrix has $\rho(A) \leq 1$ due to the Gershgorin disk theorem (Horn and Johnson, 1985). A substochastic matrix $A$ is stochastic if $\sum_j a_{ij} = 1 \forall i$; when $A$ is sized $n \times n$, the stochasticity implies that $A1_n = 1_n$ and $\rho(A) = 1$.

A (weighted directed) graph is a triple $G = (V, E, W)$, where $V = \{v_1, \ldots, v_n\}$ stands for the set of nodes, $E \subseteq V \times V$ is the set of arcs, and $W$ is a (weighted) $n \times n$ adjacency matrix, i.e. $w_{ij} > 0$ when $(i, j) \in E$ and otherwise $w_{ij} = 0$. Henceforth we assume that $V = \{1, 2, \ldots, n\}$ and thus the graph $G = G(W)$ is uniquely defined by its adjacency matrix $W$. We denote an arc $(i, j) \in E$ by $i \rightarrow j$ and call the value $w_{ij}$ its weight. A chain of arcs $i_0 \rightarrow i_1 \rightarrow \cdots \rightarrow i_{r-1} \rightarrow i_r$ is a walk of length $r$ from node $i_0$ to node $i_r$.

3. THE FRIEDKIN-JOHNSEN MODEL

The FJ model describes a network of social influence (Friedkin and Johnsen, 2011), consisting of $n$ individuals, or social agents indexed $1$ through $n$. The agents’ opinions are represented by scalars $x_i \in \mathbb{R}$, constituting the vector of opinions $x = (x_1, \ldots, x_n)^\top$. The process of social influence is described by two matrices: a stochastic matrix of interpersonal influences $W \in \mathbb{R}^{n \times n}$ and a diagonal matrix $\Lambda = \text{diag}(\lambda_{11}, \ldots, \lambda_{nn})$ of individual susceptibilities $\lambda_{ii} \in [0; 1]$ to the interpersonal influence. At each step, the vector of opinions changes as follows

$$x(k + 1) = \Lambda W x(k) + (I_n - \Lambda) u, \quad k = 0, 1, \ldots$$

The elements $u_i$ of the constant vector $u$ stand for the agents’ prejudices; the original FJ model (Friedkin and Johnsen, 1999; Friedkin, 2015) assumed that $u_i = x_i(0)$.

In the special case where $\Lambda = I_n$ the model (1) reduces to DeGroot’s iterative “opinion pooling” (DeGroot, 1974), providing a discrete-time consensus algorithm (Ren and Beard, 2008). At each step, an agent sets its new opinion to be the convex combination of its own and others’ opinions

$$x_i(k + 1) = \sum_{j=1}^{n} w_{ij} x_j(k) \forall i \iff x(k + 1) = W x(k).$$

The influence weight $w_{ij}$ shows the contribution of $j$th opinion on each stage to the $i$th opinion on the next stage.

The FJ model (1) also employs the mechanism of convex combination, allowing some agents to be prejudiced. If $\lambda_{ii} < 1$ then agent $i$ is “attached” to its prejudice $u_i$ and factors it into any opinion iteration, replacing (2) by

$$x_i(k + 1) = \lambda_{ii} \sum_{j=1}^{n} w_{ij} x_j(k) + (1 - \lambda_{ii}) u_i \forall i.$$  

When $\lambda_{ii} = 1$, the $i$th agent’s opinion is formed by the DeGroot mechanism (2), otherwise its prejudice influences each stage of the opinion iteration. Agent $i$ with $\lambda_{ii} = 0$ is “totally prejudiced” and its opinion is static $x_i(k) \equiv u_i$.

Under the assumption $u_i = x_i(0)$, adopted in the FJ model, any agent with $w_{ii} = 1$ (and thus $w_{ij} = 0 \forall j \neq i$) retains its opinion constant $x_i(k) = u_i$ independent of $\lambda_{ii}$, and one may suppose, without loss of generality, that $w_{ii} = 1 \iff \lambda_{ii} = 0$.

In the original model from (Friedkin and Johnsen, 1999) an even stronger coupling condition $w_{ii} = 1 - \lambda_{ii} \forall i$ was adopted for parsimony in the model’s empirical applications. In this paper, we do not assume this condition to hold, so $\Lambda$ and $W$ are independent except for the non-degeneracy condition (4). Notice that each FJ model corresponds to the substochastic matrix $\Lambda = \Lambda W$; for the models satisfying (4) this correspondence is one-to-one. A substochastic matrix $A$ is decomposed as $A = \Lambda W$, where

$$\lambda_{ii} = \sum_j a_{ij} \quad \text{and} \quad w_{ij} = \begin{cases} a_{ij}/\lambda_{ii}, & \lambda_{ii} > 0, \\ 1, & i = j \text{ and } \lambda_{ii} = 0, \\ 0, & i \neq j \text{ and } \lambda_{ii} = 0. \end{cases}$$

The stability criteria for FJ models may thus be reformulated for substochastic matrices, and vice versa.

For us it will be convenient to discard the standard assumption $x(0) = u$ and consider $u$ as some constant external “input”, independent of the initial opinion $x(0)$. A central question concerned with the FJ dynamics (1) is its convergence of opinion vectors to a finite limit

$$x^\infty = \lim_{k \to \infty} x(k).$$
A sufficient condition for convergence is the Schur stability: if \( \rho(AW) < 1 \) then the opinions converge to
\[
x^\infty = Vu, \quad V = (I - \Lambda W)^{-1}(I - \Lambda).
\] (6)

It is known (Friedkin, 2015) that for any Schur stable FJ model the matrix \( V \) is stochastic and, obviously, \( x^\infty \) from (6) is the only equilibrium of the system (1). Generally, the Schur stability is not necessary for convergence, e.g. the DeGroot model (2) is never stable but converges when e.g. W is primitive (i.e. irreducible and aperiodic) (DeGroot, 1974; Gantmacher, 2000).

Henceforth we are primarily interested in Schur stable FJ models, where the steady opinion is unique and given by (6). The Schur stability is a “generic” condition if at least one prejudiced agent exists, and holds, for instance, for a strongly connected influence networks \(^2\), as implied by the following lemma (Parsegov et al., 2017).

**Lemma 1.** The matrix \( AW \) is Schur stable if and only if each node in the graph \( G(W) \) either belongs to the set
\[
S_A = \{i : \lambda_{ii} < 1\}
\] (7)
or connected to a node from \( S_A \) by a walk, i.e. any agent is either prejudiced or influenced by a prejudiced individual.

4. **SCHUR STABLE FJ MODELS: OPINION CLUSTERING AND CONVERGENCE SPEED**

In this section, we derive some advanced properties of Schur stable FJ models (1), satisfying the condition from Lemma 1. We answer the following two questions, related to such models’ dynamics:

- do the final opinions \( x^\infty \) reach consensus or disagree?
- what is the convergence speed in (5)?

4.1 **Consensus and disagreement in the FJ model**

One can expect that for a general FJ model the consensus of the steady opinions \( \hat{x}_1^\infty, \ldots, \hat{x}_n^\infty \) typically should disagree, whereas their consensus is an exceptional situation. This is confirmed by the following consensus criterion.

**Theorem 2.** Let the FJ model (1) be stable. Then the consensus of final opinions \( \hat{x}_1^\infty = \ldots = \hat{x}_n^\infty \) is reached if and only if \( u_i = u_0 \) for some \( u_0 \in \mathbb{R} \) and any \( i \in S_A \). In this case \( x_i^\infty = u_0 \forall i \). This holds e.g. when \( S_A = \{i\} \) has only one element, i.e. only one agent is prejudiced.

The values \( u_i \), where \( i \not\in S_A \) and thus \( 1 - \lambda_{ii} = 0 \), obviously do not influence the value of \( x^\infty \) and may be arbitrary. Note that when consensus is not established, the number of “clusters” in the vectors \( u \) and \( x^\infty \) do not correlate. For instance, if \( u_1 = 1 \) and \( u_i = 0 \forall i > 1 \) then \( x^\infty \) is the first row of \( V \) and its elements are usually all different.

4.2 **Convergence speed of the FJ model**

In this subsection we give an explicit estimate of the spectral radius \( \rho(AW) \), which also determines the convergence speed in (5): \( |x(k) - x_\ast| = O(\rho^k) \) as \( k \to \infty \). We start with introducing some definitions and notation.

---

2 This property can be also reformulated as follows: an irreducible substochastic matrix is Schur stable (Meyer, 2000, Exercise 8.3.7).
The time-varying FJ model (TVFJ) is as follows
\[ x(k + 1) = \Lambda(k)W(k)x(k) + [I_n - \Lambda(k)]u. \] (10)

We assume that the matrices \( \Lambda(k), W(k) \) on each stage of the opinion evolution are known and have the same structure, as for the classical model (1), i.e. \( \Lambda(k) \) is diagonal, \( 0 \leq \Lambda(k) \leq I_n \) and \( W(k) \) is stochastic. Given the initial condition \( x(0) = x^0 \) and the prejudice vector \( u \), let \( x(k|x^0,u) \) stand for the solution of (10). The averaging mechanism of (10) provides several useful properties.

**Lemma 7.** Any model (10) has the following properties:

1. if \( x^0 = u = u_i, \Lambda_i \), then \( x(k|x^0,u) = u_i 1_n \), \( \forall k \);
2. if \( x^0, u \in [m,M]^n \), then \( x(k|x^0,u) \in [m,M]^n \), \( \forall k \);
3. if \( x^0 \leq x^1 \) and \( u \leq u^1 \), then \( x(k|x^0,u) \leq x(k|x^1,u^1) \), \( \forall k \);
4. for any perturbations \( \delta x^0, \delta u \in [m,M]^n \) one has \( x(k|x^0+\delta x^0,u+\delta u) - x(k|x^0,u) \in [m,M]^n \).

Here \( m, M, u \) stand for some real scalars.

Applied for \( M = -m = \varepsilon \), statement 4) in Lemma 7 implies robustness of the trajectories against small perturbations in \( x^0 \) and \( u \). Note that this property does not depend on the asymptotical (Schur) stability of the system (10). For a general neutrally stable system, such a robustness does not hold as illustrated by the simplest counterexample \( x(k + 1) = x(k) + u \).

Henceforth we are primarily interested in asymptotically stable TVFJ models, which means, as usual, that \( x(k|x^0,0) \rightarrow 0 \) for any initial condition \( x^0 \), i.e.
\[ \Lambda(k)W(k)\Lambda(k-1)W(k-1)\ldots\Lambda(0)W(0) \rightarrow 0, \text{ as } k \rightarrow \infty. \] (11)

Unlike the stationary case, the asymptotical stability in general does not imply the convergence (5). For instance, let two stationary Schur stable FJ models with matrices \( (A_1,W_1) \) and \( (A_2,W_2) \) corresponding to different matrices \( V_1, V_2 \) (defined by (6)). Due to (6), when \( (\Lambda(k),W(k)) \) switches between \( (A_1,W_1) \) and \( (A_2,W_2) \) with sufficiently large dwell time, \( x(k) \) oscillates between \( V_1 u \) and \( V_2 u \). Nevertheless, two “relaxed” versions of the convergence condition remain valid for asymptotically stable models (10).

**Lemma 8.** The following conditions are equivalent:

1. (stability) the system (10) is asymptotically stable;
2. (containment) for any \( x(0) \), \( u \in \mathbb{R}^n \) one has
   \[ \min_j x_j(k) \leq \liminf_{k \to \infty} x_j(k) \leq \limsup_{k \to \infty} x_j(k) \leq \max_j u_j; \]
3. (consensus) if \( u = u_k 1_n \), then \( x(k) \rightarrow u \) as \( k \rightarrow \infty \).

Lemma 8 establishes an important relation between the TVFJ model and algorithms of multi-agent control, namely, protocols for leader-following consensus (Ren and Beard, 2008) and containment control (Ren and Cao, 2011). Adding a “virtual” agent \( n + 1 \) whose opinion is static \( x_{n+1}(k) \equiv x_{n+1}(0) \) and the “augmented” opinion vector \( \hat{x}(k) = (x_1(k), \ldots, x_n(k), x_{n+1}(k)) \), the system (10) with \( u = x_{n+1}(0)1_n \) can be rewritten as follows
\[ \hat{x}(k + 1) = \hat{\Lambda}(k)\hat{x}(k), \quad \hat{\Lambda}(k) = \begin{bmatrix} \Lambda(k)W(k) & (1_n - \Lambda(k)1_n) \\ 0_{1 \times n} & 1 \end{bmatrix}. \] (12)

Lemma 8 states that stability of the model (10) is equivalent to establishing consensus in (12) \( x_i(k) \rightarrow \) for any initial condition \( \hat{x}(0) \). This implies the following stability condition.

**Lemma 9.** Suppose that \( \varepsilon > 0 \) exists such that the matrix \( \hat{\Lambda}(k) = (\hat{a}_{ij}(k)) \) at any time \( k \geq 0 \) satisfies the conditions \( \hat{a}_{ij}(k) \in [0,\varepsilon] \), then the model (10) is stable if a period \( T \geq 1 \) exists such that in the graph \( G[\hat{\Lambda}(k) + \varepsilon \hat{\Lambda}(k+T-1)] \) each node is connected to node \( n + 1 \) by a walk. This holds e.g. if the condition from Lemma 1 is valid at any time.

**Proof.** Thanks to the standard consensus criterion for time-varying directed graphs (Blondel et al., 2005; Ren and Beard, 2008), the assumption of Lemma 9 entail consensus in the augmented network (12), which, in turn, is equivalent to stability of the model (10) due to Lemma 8.

The assumptions of Lemma 9, typically adopted to prove the convergence of multi-agent coordination algorithms (Ren and Beard, 2008; Ren and Cao, 2011), are however very restrictive for networks of social influence. In particular, the process of reflected appraisal (Friedkin et al., 2016a) often leads to the situation where some self-confidence weights \( w_{ii} \) asymptotically vanish.

The following two counterexamples demonstrate that in presence of agents with \( \Lambda_{ii}(k) w_{ii} = 0 \) Lemma 9 is not valid, in particular, Schur stability of any matrix \( \Lambda(k)W(k) \) does not imply the stability of the model (10). We start with two simple counterexamples: in one of them, the matrix \( \Lambda \) is fixed while \( W \) is switching, in the other the matrix \( W \) is fixed and \( \Lambda \) switching.

**Example 1.** Consider \( n = 3 \) agents with \( \Lambda(k) \equiv \text{diag}(0,1,1) \) and let the matrix \( W(k) \) switch as follows
\[ W(2m) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad m = 0, 1, \ldots \]

The dynamics (10) implies that \( x_1(k) \equiv u_1 \) and
\[ \begin{cases} x_2(k+1), x_3(k+1) = \{ (u_1,x_2(k)), k = 2m, \\ x_3(k), u_1 \}, k = 2m + 1. \end{cases} \]

Therefore, we have \( x_2(0) = x_2(2) = \ldots = x_2(2m) \forall m \) and \( x_2(k) \not\rightarrow 0 \) as \( k \to \infty \) when \( u_0 = 0 \) and \( x_2(0) \neq 0 \).

**Example 2.** Consider the TVFJ model with \( n = 2 \) and
\[ W(k) = \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix}, \quad \Lambda(2m) = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad \Lambda(2m+1) = \begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix}. \]

The dynamics (10) can then be rewritten as follows
\[ x_1(k+1), x_2(k+1) = \begin{cases} (u_1,x_2(k)), k = 2m, \\ (x_1(k), u_2), k = 2m + 1, \end{cases} \]
entailing that \( x_1(0) = x_2(2) = \ldots = x_2(2m) \forall m \) and thus \( x_1(k) \not\rightarrow 0 \) as \( k \to \infty \) when \( u_0 = 0 \) and \( x_2(0) \neq 0 \).

In Examples 1 and 2 the switching model (10) appears to be not asymptotically stable in spite of the Schur stability of the two possible values \( \Lambda(k)W(k) \): the joint spectral radius (Lin and Antsaklis, 2009) of these matrices equals to 1. This critical situation, where the results of classical switching systems theory (Lin and Antsaklis, 2009) are not
Let introduce the sets
\[ \Lambda_u \]
\[ \{i : w_{ij}^k \geq \varepsilon \text{ for some } j \in J_k-1\} \]
\[ \Lambda^{(k)} = \Lambda \text{ and } W^{(k)} = W \text{ for any } k = 0, \ldots, s, \]
\[ \text{the set } J_k \text{ contains all such indices } i \text{ that } d_{ik}(s, \Lambda, W) \leq j. \]
\[ \text{Definition 10. The class } \mathbf{CFJ}[\delta, \varepsilon, s] \text{ consists of all sequences } \{(\Lambda^{(k)}, W^{(k)})\}_{k=0}^s \text{ such that } J_s = \{1, 2, \ldots, n\}. \]

The following result is proved similarly to Theorem 5.

**Lemma 11.** For any sequence \( \{(\Lambda^{(k)}, W^{(k)})\}_{k=0}^s \) from the set \( \mathbf{CFJ}[\delta, \varepsilon, s] \) the matrix \( P \triangleq \prod_{k=0}^s \Lambda^{(k)} W^{(k)} \) has row sums \( \leq 1 - \delta\varepsilon^s \), that is, \( P I_n \leq (1 - \delta\varepsilon^s) I_n. \)

Using Lemma 11, the following sufficient condition for asymptotic stability is immediate.

**Theorem 12.** Let real \( \delta, \varepsilon > 0 \) and an integer \( s \geq 0 \) exist such that the sequence \( \{(\Lambda^{(k)}, W^{(k)})\}_{k=0}^s \) contains infinitely many subsequences \( \{(\Lambda^{(k)}, W^{(k)})\}_{k=m}^{m+s} \) from \( \mathbf{CFJ}[\delta, \varepsilon, s] \). Then the model (10) is asymptotically stable.

The condition of Theorem 12 can, evidently, be reformulated as follows: any infinite “tail” \( \{(\Lambda^{(k)}, W^{(k)})\}_{k=r}^\infty \) (where \( r \geq 1 \)) contains a subsequence from \( \mathbf{CFJ}[\delta, \varepsilon, s] \). This condition does not require stability of any matrix \( \Lambda^{(k)} W^{(k)} \) and allows e.g. to have \( \Lambda^{(k)} = I_n \) for some \( k \).

6. PROOFS

In this section, we prove our main results.

6.1 Proof of Theorem 2

We start with the sufficiency part. Suppose that \( u_i = u_0 \forall i \in S_\Lambda \). One may assume that \( u_i = u_0 \forall i \in S_\Lambda \) since for \( i \notin S_\Lambda \) the value of \( u_i \) has no effect on \( x^\infty \). Since \( V \) is row-stochastic (Friedkin, 2015), \( x^\infty = V (u_0 I_n) \), which proves consensus. To prove necessity, assume that \( x^\infty = u_0 I_n \) for some \( u_0 \in \mathbb{R} \). Using (6), \( (I_n - \Lambda)x = u_0 (I_n - \Lambda) I_n = u_0 (I_n - \Lambda) I_n \). In view of (7), \( u_i = u_0 \forall i \in S_\Lambda \).

6.2 Proofs of Theorems 5, 12, Lemma 11 and Corollary 6

We start with a useful technical lemma. Given a sub-stochastic matrix \( A \), the number \( \hat{a}_i = 1 - \sum_j a_{ij} \geq 0 \) is said to be the deficiency of the \( i \)th row. From the Gershgorin disk theorem (Horn and Johnson, 1985) it is obvious that \( \rho(A) \leq \max_{1 \leq i \leq n} \left[1 - \hat{a}_i \right]. \)

**Lemma 13.** Let \( A \) and \( B \) be sub-stochastic \( n \times n \) matrices, \( C = AB \) and \( \hat{a}_i, \hat{b}_i, \hat{c}_i \) stand for the respective deficiencies. Then the following statements hold for any \( i = 1, \ldots, n \):
\[ \hat{c}_i = \hat{a}_i + \sum_{j=1}^n a_{ij} \hat{b}_j. \]

**Proof.** Denote the \( i \)th row of \( B \) and \( C \) with respectively \( b_i \) and \( c_i \), we have \( c_i I_n = \sum_j a_{ij} b_j I_n = \sum_j a_{ij} (1 - \hat{b}_j) = 1 - \hat{a}_i - \sum_j a_{ij} \hat{b}_j \), which entails (13).

**Proof of Theorem 5.** For brevity, we denote \( A \triangleq \Lambda W \) and put \( d(i) \triangleq d_{ik}(s, \Lambda, W) \). We are going to prove the following statement via induction on \( m \): if \( d(i) \leq m \) and \( \hat{c}_i \geq \delta \varepsilon d(i) \), then \( \hat{c}_i \geq \delta \varepsilon d(i) \) for \( m = 0 \) the claim is obvious: when \( d(i) = 0 \) one has \( i \notin S_\Lambda \) and \( \hat{c}_i = \hat{a}_i \geq \delta \). Assuming that the statement has been proved for \( m-1 \geq 0 \), we have to prove it for \( m \). Denoting \( B = A^{m+1} \), one has \( C = BA \). If \( d(i) \leq m - 1 \), then \( \hat{c}_i \geq \hat{b}_i \geq \delta \varepsilon d(i) \) thanks to (13). If \( d(i) = m \), there exists \( j \) such that \( d(j) \leq m - 1 \) and \( v_{ij} \leq \varepsilon \). Denoting \( C' = WB \), (13) implies that \( \hat{c}_i \geq \varepsilon W \hat{c}_j \geq \delta \varepsilon^m \). Since \( C = \Lambda C' \), we have \( \hat{c}_i \geq \hat{c}_j' \) which proves our statement for \( m \). Substitution \( m = \infty \) yields \( \rho(A^{1+\varepsilon}) = \rho(A) \leq 1 - \delta \varepsilon^s \) by definition of \( \mathbf{CFJ}[\delta, \varepsilon, s] \).

**Corollary 6** is immediate from Theorem 5 since a stable FJ model belongs to \( \mathbf{CFJ}[\delta_0, \varepsilon_0, n-1] \).

**Proof of Lemma 11.** Similarly to proof of Theorem 5, one proves via induction on \( m = 0, 1, \ldots, s \) that for any \( i \in J_m \), the \( i \)th row of the matrix \( P_m \triangleq \prod_{k=0}^m \Lambda^{(k)} W^{(k)} \) has validity \( \geq (1 - \delta \varepsilon^m) \varepsilon^m \). For \( m = 0 \) the claim is trivial. Assuming that it holds for \( m - 1 \), let \( A = \Lambda^{(m)} W^{(m)} \) and \( B = P_{m-1} \). If \( i \notin J_m \) then either \( i \notin S_\Lambda \) and hence \( \hat{a}_i \geq \delta \) or such \( j \) exists for which \( v_{ij} \geq \varepsilon \), and \( \hat{b}_i \geq \delta \varepsilon^{m-1} \). Using (13), one now proves the claim for \( m \) in the same way as in Theorem 5.

**Proof of Theorem 12** is immediate from Lemma 11. Let \( P(m) \triangleq \prod_{k=0}^m \Lambda^{(k)} W^{(k)} \). Notice that if \( P(m-1) I_n \leq \theta I_n \), then \( \{(\Lambda^{(k)}, W^{(k)})\}_{k=m}^{m+s} \) belong to \( \mathbf{CFJ}[\delta, \varepsilon, s] \), then one has \( P(m) I_n \leq (1 - \delta \varepsilon^s)^r \). Therefore \( P(m) \rightarrow 0 \) as \( m \rightarrow \infty \).

6.3 Proofs of Lemmas 7 and 8

**Proof of Lemma 7.** Statements 1)-3) are proved using induction on \( k \). For instance, if \( x_i(0) \leq M \) and \( u_i \leq M \) for any \( i \), then \( x_i(1) \leq M \forall i \) due to (10). Therefore, \( x_i(2) \leq M \) and so on. Statement 4) follows from (2) due to the linearity of (10): \( x_i[|x_i^0 + \delta x, u + \delta a|] = x_i(|x_i^0, u| + x_i[|\delta x, \delta a|]. \)

**Proof of Lemma 8.** Implications 2)\( \Rightarrow \)3) and 3)\( \Rightarrow \)1) are obvious (the first of them is proved by putting \( u_i = u_k \) and the second one by taking \( u_i = 0 \). To prove the implication 1)\( \Rightarrow \)2), note that the limits \( \lim inf x(i) \) and \( \lim sup x(i) \) do not depend on \( x(0) \) due to stability. Assuming that \( x(0) = 0 \), the claim follows now from statement 2) in Lemma 7 by substituting \( m = \min_i u_i \) and \( M = \max_i u_i \).

7. CONCLUSIONS

In this paper, important system-theoretic properties of the Friedkin-Johnsen (FJ) model of opinion dynamics (Friedkin and Johnsen, 1999) are considered such as stability
and convergence speed. We also examine the extension of the FJ model to the case of time-varying social influence and give sufficient conditions for its stability. The time-varying FJ model can be further extended to the case of multidimensional opinions, representing the agents' positions on several interrelated issues (belief systems); for static FJ model such an extension is discussed in (Parsegov et al., 2017; Friedkin et al., 2016b). In our future works we are going to validate the applicability of the FJ model to opinion dynamics in large-scale online social networks.
