Abstract—Test-Driven Code Review (TDR) is a code review practice in which a reviewer inspects a patch by examining the changed test code before the changed production code. Although this practice has been mentioned positively by practitioners in informal literature and interviews, there is no systematic knowledge of its effects, prevalence, problems, and advantages.

In this paper, we aim at empirically understanding whether this practice has an effect on code review effectiveness and how developers’ perceive TDR. We conduct (i) a controlled experiment with 93 developers that perform more than 150 reviews, and (ii) 9 semi-structured interviews and a survey with 103 respondents to gather information on how TDR is perceived. Key results from the experiment show that developers adopting TDR find the same proportion of defects in production code, but more in test code, at the expenses of fewer maintainability issues in production code. Furthermore, we found that most developers prefer to review production code as they deem it more critical and tests should follow from it. Moreover, general poor test code quality and no tool support hinder the adoption of TDR. Public preprint: [https://doi.org/10.5281/zenodo.2553127], data and materials: [https://doi.org/10.5281/zenodo.2553139].

I. INTRODUCTION

Peer code review is a well-established and widely adopted practice aimed at maintaining and promoting software quality [4]. In a code review, developers other than the code change author manually inspect a code change to find as many issues as possible and provide feedbacks that need to be addressed before accepting the code in production [8].

The academic research community is conducting empirical studies to better understand the code review process [42], [41], [4], [27], [43], as well as to obtain empirical evidence on aspects and practices that are related to more efficient and effective reviews [49], [32].

A code review practice that has only been touched upon in academic literature [47], but has been described in gray literature almost ten years ago [56] is that of test-driven code review (TDR, henceforth). By following TDR, a reviewer inspects a patch by examining the changed test code before the changed production code.

To motivate TDR, P. Zembrod—Senior Software Engineer in Test at Google—explained in the Google Blog [56]: “When I look at new code or a code change, I ask: What is this about? What is it supposed to do? Questions that tests often have a good answer for. They expose interfaces and state use cases”. Among the comments, also S. Freeman—one of the ideators of Mocks [46] and TDD [11]—commented how he covered similar ground [22]. Recently, in a popular online forum for programmers, another article supported TDR (collecting more than 1,200 likes): “By looking at the requirements and checking them against the test cases, the developer can have a pretty good understanding of what the implementation should be like, what functionality it covers and if the developer omitted any use cases.” Interviewed developers reported preferring to review test code first to better understanding the code change before looking for defects in production [47].

Despite these compelling arguments in favor of TDR, we have no systematic knowledge on this practice: its effectiveness in finding defects during code review, its prominence in practice, and what are its potential problems/advantages. This knowledge can provide insights for both practitioners and researchers. Developers and project stakeholders can use empirical evidence about TDR effects, problems, and advantages to make informed decisions about when to adopt it. Researchers can focus their attention on the novel aspects of TDR and challenges reviewers face to inform future research.

In this paper, our goal is to obtain a deeper understanding of TDR. We do this by conducting an empirical study set up in two phases: An experiment, followed by an investigation of developers’ practices and perceptions.

In the first phase, we study the effects of TDR in terms of the proportion of defects and maintainability issues found in a review. To this aim, we devise and analyze the results of an online experiment in which 92 developers (77 with at least two years of professional development experience) complete 154 reviews, using TDR or two alternative strategies (i.e., production first or only production). Two external developers rated the quality of the review comments. In the second phase, we investigate problems, advantages, and frequency of adoption of TDR—valuable aspects that could not be studied in the experiment. To this aim, we conduct nine interviews with experiment participants and deploy an online survey with 103 respondents.

Key findings of our study include: With TDR, the proportion of functional defects (bugs henceforth) found in production code and maintainability issues (issues henceforth) found in test code does not change. However, TDR leads to the discovery of more bugs in test code, at the expenses of fewer issues found in production code. The external raters judged the quality of the review comments as comparable across all review strategies. Furthermore, most developers seem to be reluctant to devote much attention to tests, as they deem production code more important; moreover applying TDR is problematic, due to widespread poor test quality (reducing TDR’s applicability) and no tool support (not easing TDR).
II. RELATED WORK

To some extent, TDR can be considered as an evolution of classical reading techniques [6], as it shares the general idea to guide code inspectors with software artifacts (i.e., test cases) and help them with the code review task.

Scenario-based inspections. Among reading techniques, Porter & Votta [37] defined the scenario-based approach, based on scenarios that provide inspectors with more specific instructions than a typical checklist and focus on a wider variety of defects. They discovered that such technique is significantly more useful for requirements inspectors. Later on, Porter et al. [58], [59] and Miller et al. [53] replicated the original study confirming the results. Other studies by Fusaro et al. [23] and Sandahl et al. [44] reported contradictory results, however without providing explanations on the circumstances leading scenario-based code inspection to fail. A significant advance in this field was then provided by Basili et al. [7], who revisited the original scenario-based as a technique that needs to be specialized for the specific issues to be analyzed. They also defined a new scenario-based technique called perspective-based reading: The basic idea is that different aspects of the source code should be inspected by inspectors having different skills [7]. All in all, the papers mentioned above, provided evidence of the usefulness of reading techniques; their similarities with TDR, give an interesting rationale on why TDR could bring benefits.

Ordering of code changes. Research on the ordering of code changes is also related to TDR. In particular, Baum et al. argued that an optimal ordering of code changes would help reviewers by reducing the cognitive load and improving the alignment with their cognitive processes [10], even though they made no explicit reference to ordering tests. This may give theoretical value to the TDR practice. Code ordering and its relation to understanding, yet without explicit reference to tests or reviews, has also been the subject of studies [25], [12].

Reviewing test code. Many articles on classical inspection (e.g., [29], [54]) underline the importance of reviewing tests; however, they do not leave any specific recommendation. The benefits of reviewing tests are also highlighted in two case studies [30], [55]. Already in Fagan’s seminal paper [17], the inspection of tests is discussed, in this case noting fewer benefits compared to the inspection of production code. Winkler et al. [55] experimented with writing tests during inspection and found neither large gains nor losses in efficiency and effectiveness. Elberzhager et al. [10], [15] proposed to use results from code reviews to focus testing efforts. To our knowledge, in academic literature TDR has been explicitly referred to only by Spadini et al. [47]. In a more general investigation on how test files are reviewed, the authors reported that some practitioners indeed prefer to review test code first as to get a better understanding of a code change before looking for defects in production code. Our work builds upon the research on reviewing test code, by investigating how reviewing test code can(not) be beneficial for the whole reviewing process.

III. METHODOLOGY

In this section we describe the research questions and the methodology we follow to conduct our study.

A. Research Questions

This study has two parts corresponding to two research questions. In the first part, we design and run an experiment to investigate the effects of TDR on code review effectiveness. We measure the effectiveness as the ability to find bugs and maintainability issues during a code review (i.e., the main reported goal of code review [4]). Hence, our first research question:

RQ1. Does the order of presenting test code to the reviewer influence the code review’s effectiveness?

More formally, the goal of the experiment is to test the following null hypotheses:

H0_pc_miu: For production code, there is no difference in the proportion of found maintainability issues between the different review practices (TF and PF).
H0_pc_bugs: For production code, there is no difference in the proportion of found bugs between the different review practices (TF and PF).
H0_tc_miu: For test code, there is no difference in the proportion of found maintainability issues between the different review practices (TF and PF).
H0_tc_bugs: For test code, there is no difference in the proportion of the number of bugs found between the different review practices (TF and PF).
H0_review_time: There is no difference in time required for a review between the review practices (TF and PF).
H0_review_quality: There is no difference in the review qualities between TF, PF, and OP.

Subsequently, we investigate the prominence of TDR and developers’ perception toward this practice, also focusing on problems and advantages. To do so, we conduct semi-structured interviews and deploy an online survey. Hence, our second research question:

RQ2. How do developers perceive the practice of Test-Driven Code Review?

B. Method – RQ1: Design Overview

Figure [4] depicts the flow of our experiment. We follow a partially counter-balanced repeated measures design [19], augmented with some additional phases.

1) We use a browser-based tool to conduct the experiment and answer RQ1. The tool allows to (i) visualize and perform code reviews, and (ii) collect data from demographic-like questions and the interactions that participants have with the tool. The welcome page provides information on the experiment to perform and requires informed consent.

2) After the welcome page, an interface is shown to collect demographics as well as information about some confounding

61 participants completed both reviews

Figure 1. Experiment steps, flow, and participation

Figure 2. Example of the review view in the browser-based experiment UI, showing the code change. In this case, the treatment is PF, thus to see the test code, the participant must click on the ‘Toggle Shown Code’ button.

Figure 3. Example of the review view in the browser-based experiment UI, showing the code change. In this case, the treatment is TF, thus to see the production code, the participant must click on the ‘Toggle Shown Code’ button.

C. Method – RQ1: Browser-Based Experiment Platform

As previously mentioned, we adapt and use a browser-based experiment platform to run the experiment. This has two main advantages: On the one hand, participants can conveniently perform code reviews; on the other hand, the tool assists us when gathering data from the demographic questions, conducting the different treatments, and collecting information for the analysis of co-factors. To reduce the risk of data loss and corruption, almost no data processing is done on the server: instead, participants’ data is recorded as log records and analyzed offline.

The tool implements a GUI similar to other browser-based code review tools (e.g., GITHUB pull requests): It presents a code change in the form of two-pane diffs. An example of the implemented GUI is reported in Figure 2. Review remarks can be added and changed by clicking on the margin beneath the code. The tool logs many user interactions, such as mouse clicks and pressed keys, which we use to ensure that the participants are actively performing the tasks.

We propose two of the three treatments to keep the experiment as short as possible, thus stimulating a higher response rate, as also recommended by Flanigan et al. This choice does not influence our observations, as the random selection balances the treatments (see Table IV).
D. Method – \textbf{RQ}$_1$: Objects

The objects of the study are represented by the code changes (or patch, for brevity) to review, which need to be properly selected and eventually modified to have a sufficient number of defects to be discovered by participants.

\textbf{Patches.} To avoid giving some developers an advantage, we use a code base that is not known to all the participants of the experiment. This increases the difficulty of performing the reviews. To keep the task manageable, we ensure that (i) the functional domain and requirements are well-known to the participants and (ii) there is little reliance on special technologies or libraries. To satisfy these goals, we select an open-source project. \textbf{JPACMAN-FRAMEWORK:} The project consists of 42 production classes (≈2k LOC) as well as 13 test classes (≈600 LOC), it received 103 pull requests in his history, and has a total of 17 contributors.

To select suitable patches, we screen the commits of the project and manually select changes that (1) are self-contained, (2) involve both test and production code, (3) are neither too complicated nor too trivial, and (4) have a minimum quality, \textit{e.g.}, not containing dubious changes.

The selected patches are those of commits 6d7c14d and 698ac7d. In the first one, a new feature is added along with the tests that cover it. In the second one, a refactoring in the production code is applied and a new test is added.

\textbf{Seeding of bugs and maintainability issues.} Code review is employed by many software development teams to reach different goals, but mainly (1) detecting bugs (functional defects) and (2) improving code quality (\textit{e.g.}, finding maintainability issues), (3) spreading knowledge \cite{9,31,49,4}.

Since the online experiment is done by single developers, we measure code review effectiveness by considering only the first two points, detecting bugs (functional defects) and maintainability issues. To this aim, we seed in the code bugs and maintainability issues. Examples of injected bugs are a wrong copy-paste and wrong boundary checking. For maintainability issues, we mainly mean “\textit{smells that do not fail the tests}” \cite{21}, \textit{e.g.}, a function that does more than what it was supposed to do, wrong documentation or variable naming.

Concerning the nature of faults, one bug was real and identified some commits later. The other six were manually injected, based on standard errors such as handling corner cases and null pointer exceptions.

In the end, the two patches contain a total of 4 bugs and 2 issues (Patch 1) and 5 bugs and 3 issues (Patch 2). The total number of bugs per file (4 and 5) is higher than in the real-world code; indeed, in our experiment, we opted for a higher density of errors to ensure an attainable number of participants, and reduce confounding factors in the experiment. The reason is that if the number of errors in the code is too low, the statistical power decreases, and many more participants are needed to measure an effect. Moreover, if subjects must read too much correct code, the effects such as “reading speed,” become stronger confounding factors.

E. Method – \textbf{RQ}$_1$: Variables and analysis

We investigate whether the proportion of defects found in a review is influenced by the review being done under a \textbf{TF}, \textbf{PF}, or \textbf{OP} treatment, controlling for other characteristics.

The first author of this paper manually analyzed all the remarks added by the participants. Our tool explicitly asked and continuously highlighted to the participants that the primary goal is to find both bugs and maintainability issues; therefore, each participant’s remark is classified as identifying either a bug or an issue, or as being outside of the study’s scope. A remark is counted only if in the right position and correctly pinpointing the problem.\textsuperscript{2}

By employing values at defect level, we could compute the dependent variables at review level, namely proportions given by the ratio between the number of defects found and the total number of defects in the code (dependent vars in Table \ref{tab:1}). The dependent variables are then given by the average of \(n_j\) binary variables \(y_i\), assuming a value 1 if the defect is found and 0 if not, where \(n_j\) is the total number of defects present in the change \(j\), so that the proportion \(\pi_j\) results from \(n_j\) independent events of defect finding and \(y_i\) are binary variables that can be modeled through a logistic regression.

\[\pi_j = \sum_{i=1}^{n_j} \frac{y_i}{n_j}\]  \hspace{1cm} (1)

\textsuperscript{2}To validate this coding process, a second author independently re-coded the remarks and compared his classification with the original one. In case of disagreements, the two authors opened a discussion and reached a consensus. We compute the Cohen’s kappa coefficient  \cite{13} to measure the inter-rater agreement between the two authors before discussion: we find it to reach 0.9, considerably higher than the recommended threshold of 0.7 \cite{13}.
The main independent variable of our experiment is the review strategy (or treatment). We consider the other variables as control variables, which include the time spent on the review, the review and programming practice, the participant’s role, the reviewed patch (i.e., P1 or P2), and whether the review is the first or the second being performed. In fact, previous research suggests the presence of a trade-off between speed and quality in code reviews [26]: following this line, we expect longer reviews to find more defects; to check this, we do not fix any time for review, allowing participants to perform the task as long as needed. Moreover, it is reasonable to assume that participants who perform reviews more frequently will also find a higher share of defects.

We run logistic regressions of proportions, where \( \text{Logit}(\pi_j) \) represents the explained proportion of found defects in review \( j \), \( \beta_0 \) represents the log odds of being a defect found for a review adopting PF (or OP) and of mean TotalDuration, IsFirstReview, etc., while parameters \( \beta_1 \cdot \text{Treatment}_j \), \( \beta_2 \cdot \text{TotalDuration}_j \), \( \beta_3 \cdot \text{IsFirstReview}_j \), \( \beta_4 \cdot \text{Patch}_j \), etc. represent the differentials in the log odds of being a defect found for a change reviewed with TF, for a review with characteristics \( \text{TotalDuration}_{j-mean} \), \( \text{IsFirstReview}_{j-mean} \), \( \text{Patch}_{j-mean} \), etc.

\[
\text{Logit}(\pi_j) = \beta_0 + \beta_1 \cdot \text{Treatment}_j + \beta_2 \cdot \text{TotalDuration}_j + \beta_3 \cdot \text{IsFirstReview}_j + \beta_4 \cdot \text{Patch}_j + \ldots (\text{other vars and } \beta \text{ omitted}) 
\]  

(2)

F. Method – RQ2: Data Collection And Analysis

While through the experiment we are able to collect data on the effectiveness of TDR, we cannot collect the perception of the developers on the prevalence of TDR as well as the motivations for applying it or not. Hence, to answer RQ2, we proceed with two parallel analyses: We (i) perform semi-structured interviews with participants of the experiment who are available to further discuss on TDR and (ii) run an online survey with the aim of receiving opinions from the broader audience of developers external to the experiment.

Semi-structured interviews. We design an interview whose goal is to collect developers’ points of view on TDR. They are conducted by the first author of this paper and are semi-structured, a form of interview often used in exploratory investigations to understand phenomena and seek new insights on the problem of interest [53].

Each interview starts with general questions about code reviews, with the aim of understanding why the interviewee performs code reviews, whether they consider it an important practice, and how they perform them. Then, we ask participants what are the main steps they take when reviewing, starting from reading the commit message to the final decision of merging/rejecting a patch, focusing especially on the order of reviewing files. Up to this point, the interviewees are not aware of the main goal of the experiment they participated in and our study: We do not reveal them to mitigate biases in their responses. After these general questions, we reveal the goal of the experiment and we ask their personal opinions regarding TDR. The interview protocol is available [2].

During each interview, the researcher summarizes the answers and, before finalizing the meeting, these summaries are presented to the interviewee to validate our interpretation of their opinions. We conduct all interviews via Skype. With the participants’ consent, the interviews are recorded and transcribed. Later, we analyze the interviews applying a Grounded Theory approach [14]: we use Descriptive Coding as first cycle coding, and Pattern coding as second cycle. We first summarize in a short phrase the essential topic of each passage from the interviews; then we identify explanatory codes to create emergent themes that we discussed among the authors. Overall, we conduct nine 20/30-minute interviews; Table II summarizes the demographics of the participants.

Online survey. We create an anonymous, 4-minute, online survey with two sections. In the first one, we ask demographic information of the participants, including gender, programming/reviewing experience, policies regarding code reviews in their team (e.g., if all changes are subject of review or just a part of them), and whether they actually review test files (the respondents who answer “no” are disqualified). In the second section, we ask respondents (i) how often they start reviewing from tests vs. production files and (ii) to fill out a text box explaining the reasons why they start from test/production files. The questionnaire is created using a professional tool [1] and is spread out through practitioners blogs (e.g., REDDIT) and through direct contacts in the professional network of the study authors, as well as the authors’ social media accounts on Twitter and Facebook. Furthermore, we neither revealed the aim of the experiment nor provided incentives to participate.

We collected 103 valid answers, which complement the semi-structured interviews. Among the respondents, 5% have one year or less of development experience, 44% have 2 to 5 years, 28% have 6 to 10 years, and 23% more than 10 years.

IV. Results – RQ1: On The Effects Of TDR

A total of 232 people accessed our experiment environment following the provided link. From their reviews (if any), we exclude all the instances in which the code change is skipped or skimmed, by demanding either at least one entered remark or more than 5 minutes spent on the review. We also remove an outlier review that lasted more than 4 standard deviations from the mean review time, without entering any comments.
After applying the exclusion criteria, a total of 92 participants stay for the subsequent analyses. Table III presents what the participants reported in terms of role, experience, and practice. Only 5 of the participants reported to have no experience in professional software development; most program daily (79%) and review code at least weekly (62%). Table IV shows how the participants’ reviews are distributed across the considered treatments and patches. Despite some participants completed only one review and the aforementioned exclusions, the automated assignment algorithm allowed us to obtain a rather balanced number of reviews per treatment and by patch.

### A. Experiment results

Table V shows the average values achieved by the reviews for the dependent variables (e.g., ‘ProdMaintIssuesProp’) and the average review time, by treatment. The most evident differences between the treatments are in: (d1) the proportion of maintainability issues found in production code (PF and OP) have an average of .21 and .18, respectively, while TF of 0.08), and (d2) the proportion of bugs found in test code (TF has an average of 0.40, while PF of 0.17).

By applying a Wilcoxon Signed Rank Test, we tested and rejected H₀ₚₑₘᵢₛ (p < 0.01) and rejected H₀ₑₜₗₐₜ₅ᵦₛ (p < 0.01). On the contrary, based on the same test, we accept H₀ₚₑₗₜ₅ᵦₛ and H₀ₑₜₗₐₜ₅ᵦₛ (the minimum p is higher than 0.38). Applying again a Wilcoxon Signed Rank Test rejects H₀ₑᵥₑᵦᵣᵦᵣₒᵦ₅ᵦₘₖₑₐᵦ₅ᵦₘₖₑₐᵦₑᵦ₅ᵦₘₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₑₐᵦₑᵦ₅ᵦₘₐ
B. Assessing code review quality

After having found differences in bugs/issues found with TF, we check whether the different treatments (TF, PF, OP) influence the quality of the review, i.e., we intend to test H₀\text{review quality}. To this aim two external validators manually classify each review, rating each comment. These validators have more than 5 years of industrial experience in code review and have collaborated in many open-source projects. We request them to go through each of the code reviews done by the developers involved in the experiment and rate each comment aimed at fixing a defect or maintainability issue in the production or test code using a Likert scale ranging between ‘1’ (very poor comment) and ‘5’ (very useful comment). They also give a score to each comment that is outside the scope (i.e., a comment that does not fix any of our manually injected defects), plus a final overall score for the review. Each validator performs the task independently, and then their assessments are sent back to the authors of this paper. The validators are unaware of the treatment used in each review. A set of 33 reviews is classified by both authors, so that we can measure their inter-rater agreement using Cohen’s kappa [13]. To mitigate the personal variability of the raters, we cluster their ratings into three categories: ‘below average review comment’, ‘average review comment’ and ‘good review comment’. Then, we check the raters’ agreement. The result shows that in all ratings there is at least a substantial agreement between the validators: production issues ($κ = .69$), test issues ($κ = .78$), production bugs ($κ = 1$), test bugs ($κ = .77$).

To test H₀\text{review quality}, we apply an ANOVA on the independent variables score (e.g., productivity issues) and the dependent variable review practice (for each independent variable in separation). We find that for no score the independent variable is a significant factor (productivity issues $p=.62$; test issues $p=.30$; productivity bugs $p=.25$; test bugs $p=.37$). Hence, we accept H₀\text{review quality} and conclude that raters do not see a difference in the quality of the reviews across treatments.

**Finding 2.** There is no statistically significant difference between the quality of the reviews made under the three considered treatments, according to two external raters blinded to the underlying treatments.

V. RESULTS – RQ₂: ON THE PERCEPTION OF TDR

We interview some of the participants of the experiment on what they perceive as advantages and disadvantages of TDR. We also survey 103 developers to enrich the data collection with people that do not participate in the experiment and can provide a complementary view on TDR. In this section, we report the answers obtained during our interviews and surveys. We summarize them in topics, covering both advantages and disadvantages of this practice. We refer to the interviewees by their ID shown in Table [I].

A. Adoption of TDR in practice

The majority of the respondents applies TDR only occasionally: 5% (5) reported that they always start from test code, 13% (13) almost always, 42% (43) occasionally/sometimes, 27% (28) almost never, 13% (13) never.

B. Perceived problems with TDR

When analyzing data coming from surveys and interviews, we discover a set of blocking points for the adoption of TDR. They can be grouped around four main themes, i.e., perceived importance of tests, knowledge gained by starting reviewing from tests, test code quality, and code review tool ordering, that we further discuss in the following. Themes are discussed based on the frequency of appearance in the survey.

**Tests are perceived as less important.** From the comments left by the participants of the survey, it seems clear that test code is considered much less important than production code and that, as stated by one participant, they “want to see the real change first”. This strong opinion is confirmed by other 15 participants for example, a participant explains that s/he starts “looking at production files in order to understand what is being changed about the behavior of the system. [S/he] views tests as checks that the system is behaving correctly, so it does not seem possible to evaluate the quality of the tests until I have a clear understanding of the behavior”. While the semi-structured interviews confirmed this general perception around tests, they also add a more practical point to the discussion: P₁,₂−₅,₇ state that they need to prioritize tasks because of time, and often higher priority is given to the production code.

A closely related factor contributing to this aspect is the tiredness associated with reviewing code for a long time. As reported by one of the survey participants, “the longer you are reviewing, the more sloppy you get [...]. I would rather have a carefully reviewed production file with sloppy test than vice versa”. In other words, when performing multiple code review at once, developers often prefer to pay more attention to the production code than test files.

13 participants also report that is the production code to drive tests rather than the opposite. A clear example of this concept is enclosed in the following participant’s quote: “To me, tests are about checking that a piece of software is behaving correctly, so it doesn’t make sense to me to try to understand if the tests are testing the right conditions if I do not understand what the code is supposed to do first.” Finally, another aspect influencing the perception that developers have of tests is the lack of testing experience. One of the participants affirms that “not everyone in my team has lots of experience

It should be noted that in the survey we gave the possibility to leave open comments; having 15 or more participants agreeing on exactly the same theme indicates a noteworthy trend.
with testing, so usually just looking at the production code will
tell me if there will be problems with the tests.” Thus, having
poor experience in testing practice might bias the perception of
the advantages given by tests in the context of code review.

Tests give less knowledge on the production behavior.
Both interviewees and survey respondents report that the main
advantage of starting with production code is that they can
immediately see the feature and how it is changed, and only
later they will check if it is properly tested. For example,
a survey respondent says: “I want to understand what the
production code does, form my own opinion of what should
be tested, and then look at the tests afterward.” From the
interviews, P3 also adds that it is hard to capture all the
possible behaviors with tests, while looking to production code
first helps him/her figuring out the failure modes before seeing
what the tests the developer proposed are.

Nevertheless, an interesting trend emerges from our results.
Despite most developers claim that tests cannot give enough
knowledge to review a change, six of them declare that the
decision of start reviewing from test code basically depends
on the degree of knowledge they have of the production code
under test. As explained by a survey participant, “If I am
familiar with the topic and the code, I will start with the
production files. Otherwise I will choose the test files”. In
other words, tests only seem to be useful in time of need, i.e.,
when a developer does not have any other instrument to figure
out the context of the proposed code change.

Tests have low code quality. 4 participants mention poor test
code quality as a reason to not apply TDR in practice. The use
of tests in a code review has the prerequisite that such tests
can properly exercise the behavior of the production code.
One of the participants, when explaining why s/he prefers
starting from production code, reports that “sometimes the
tests are bad and it is easier to understand how the code
behave by looking at the feature code”. This is also confirmed
by the semi-structured interviews: the main obstacle when
reviewing tests first is the assumption that the test code is
well written [P1,5,6,9]. Both P1 and P9 said that most of
the times they prefer to start from production because they
assume developers do not write good tests. P1 says “Usually,
I start from production and maybe the reason is that many
of the projects where I worked do not have that many tests”.
Even if the tests are present, sometimes reviewers find them
difficult to understand: According to P6, “… the test needs
to be written in a clear way to actually understand what’s
going on.” The solution to this problem—according to our
interviewees—is to impose test rules, e.g., all the changes
to the production code should be accompanied by tests [P2,5].
P5 says that “if [tests] are not good, I will ask to modify them.
If they are not even present, I will ask to add them and only
after I will review the patch”.

Code review tool ordering. The final disadvantage is related
to a practical problem: current code review tools present code
changes following an alphabetic order, meaning that most of
the times developers review following such order. This is
highlighted by 15 survey participants and confirmed by the
interviewees. For example, P3 says: “If there is a front-end, we
do not have integration tests for all the features, so sometimes
I do manual testing. In this case, I would stick with the order
of GitLab. I think GitLab present tests later than production,
so I generally start from that”. Interestingly, this point came
up also from 35% of the survey respondents who do not apply
TDR, that indicated they start from production code because
they simply follow the order given by the code review tool.
According to interviewees P3 and P4, they follow the order of
GitHub because in this way they are sure to have reviewed all
the files in the patch, while going back and forth from file to
file may result in skipping some files.

Finding 3. Perceived problems with TDR: Developers
report to (1) consider tests as less important than pro-
duction, (2) not being able to extract enough knowledge
from tests, (3) not being able to start a review from tests
of poor quality, and (4) being comfortably used to read
the patch as presented by their code review tool.

C. Perceived advantages of TDR
We identify two main themes representing the major per-
ceived advantages of adopting TDR, i.e., the concise, high-level
overview tests give on the functionalities of production code
and the ability of naturally improving test code quality. We
discuss those aspects based on the frequency in the survey.

TDR provides a black-box view of production code. 18
of the respondents explain that the main advantage they
envision from the application of TDR is the ability of tests
to provide a concise, high-level overview of the functional-
ities implemented in the production code. In particular, one
participant reports: “If I read the test first without looking
at the production implementation, I can be sure that the
test describes the interface clearly enough that it can serve
as documentation.” Moreover, developers appreciate that few
lines of test code allow them to contextualize the change. Most
interviewees agreed that starting reviewing tests allows them
to understand better the code change context [P2–8]. P3 says:
“I think starting from tests helps you in understanding the
context first, the design, the “what are we building here?”
before actually looking at “they implemented it”. The
common feeling between the interviewees is that tests better
explain what the code is supposed to do, while the production
code shows how the developer implemented it [P1–4,6,7]. P1
says: “When you are reviewing complex algorithms it is nice
to immediately see what type of outputs it produces in response
to specific types of input.”

TDR improves test code quality. Three of the survey par-
ticipants explicitly report that tests must be of good quality
and a practice like TDR would enable a continuous test code
quality improvement; as one put it: “Tests are often the best
documentation for how the production code is expected to
function. Getting tests right first also contributes to good TDD
practices and the architectural values that come with that”. In other words, the developers report that, in situations where reviewers inspect tests first, the improvement of test code quality have to necessarily happen, otherwise reviewers could not properly use tests as documentation to spot problems in production code. As a natural consequence, TDR would also enforce tests to be updated, thus producing overall benefits to the system reliability.

Furthermore, one participant reports TDR to be efficient “because it captures and should capture all the bugs”: even if we obtain this kind of feedback by a small number of developers, it is still interesting to remark how some of them perceive the potential benefits of TDR, which we empirically found (RQ1), as being more effective in terms of test bugs discovered—while spotting the same proportion of production bugs. The semi-structured interviews confirm all the aspects discussed so far. Most of the interviewees agreed that TDR somehow helps reviewers to be more focused on testing. According to P5: “I think it would encourage the development of good tests, and I think better tests mean more bugs captured. So yes, in the end, you may capture more bugs”. P6 and P8 also say that when reviewing the production code the reviewer already knows what the code is tested for, so it could be easier to catch not covered paths. For example, P3 refers to happy vs. bad paths: “starting from the tests you think a little bit on the cases that apply, so for example if they only test the happy path and not the bad path”.

Finding 4. Perceived advantages of TDR: Developers report that TDR (1) allows them to have a concise, high-level overview of the code under test and (2) helps them in being more testing-oriented, hence improving the overall test code quality.

VI. THREATS TO VALIDITY

Construct validity. Threats to construct validity concern our research instruments. Most constructs we use are defined in previous publications, and we reuse existing instruments as much as possible: The tool employed for the online experiment is based on a similar tool used in an earlier work [2].

To avoid problems with the experimental materials, we employed a multi-stage process: After tests among the authors, we performed three pre-tests with external participants, and only afterward we started the release phase.

One of the central measures in our study is the number of defects and maintainability issues found. The first author seeded the defects, and later checked by the other authors. Nevertheless, we cannot rule out implicit bias in seeding the defects as well as in selecting the code changes.

We asked the participants to review test and production code separately, using a “Toggle shown code” button to switch between them. However, we cannot ensure that all the participants used this button correctly (or used it at all). To mitigate this, we analyzed the results mining only the shown code (e.g., the second part of the review would not exist), obtaining very similar results: Hence we can conclude that this threat is not affecting the final results.

A major threat is that the artificial experiment created by us could differ from a real-world scenario. We mitigated this issue in multiple ways: (1) we used real changes, (2) we reminded the participant to review the files as they would typically do in their daily life, and (3) we used an interface very similar to the common Code Review Tools GUIs.

Furthermore, to validate the reviews done by the participants, we involved two external validators. The only information they had at their disposal when rating the reviews was the patch and the comments of the participants, i.e., they did not know what treatment it was, the duration of the review, and all the other information we collected. Thus, the rate given by the validators was based on their personal judge and past experience in code review. To mitigate this issue, we involved two validators that have strong experience in Java and MCR: one had worked for many years in a large Russian-based SE company, and the other validator holds a Ph.D. in SE and has worked in many OSS.

Internal validity - Credibility. Threats to internal validity concern factors we did not consider that could affect the variables and the relations being investigated. In an online setting, a possible threat is the missing control over participants, which is amplified by their full anonymity. To mitigate this threat, we included questions to characterize our sample (e.g., experience, role, screen size). To identify and exclude duplicate participation, we logged hashes of participant’s local and remote IP addresses and set cookies in the browser. Furthermore, to exclude participants who did not take the experiment seriously, we excluded experiments without any comments in the review and manually classified the comments to delete the inappropriate ones.

We do not know the nature of the population that did our experiment, hence it might suffer from self-selection bias. Indeed, it could be possible that the sample contains better and more motivated reviewers than the population of all software developers. However, we do not believe this poses a significant risk to the validity of our main findings since we would expect stronger effects with a more representative sample. Furthermore, as depicted in Table [V] the participants’ experience is quite various, with a 30% lower than 2 years and 50% with more than 6.

External validity - Transferability. Threats to external validity concern the generalization of results. A sample of 93 professional software developers is quite large in comparison to many experiments in software engineering [45]. However, it is still small compared to the overall population of software developers that employ MCR. We reduce this issue by interviewing and collecting the opinions of other developers 103 who did not participate in the experiment.

Statistical conclusion validity. A failure to reach statistically significant results is problematic because it can have multiple causes, e.g., a non-existent or too small effect or a too small
of novel techniques that can exploit a set of metrics (e.g., change type or past modifications of the developer on the code under review) to automatically recommend the order that would allow the reviewer to be more effective: this would lead to new adaptive mechanisms that take into account developer-related factors to improve the reviewability of code [39].

Test code quality. A critical enemy of TDR seems to be the poor quality of test code [3, 51]. Many interviewees and survey respondents indicated this as the main reasons to not apply TDR. If tests are poorly written or incomplete, it becomes almost impossible (or even dangerous) to start reviewing from test code, as it is harder to spot errors in production code. However, this would create a vicious cycle, in which tests are reviewed less and less carefully, thus gradually losing quality. Furthermore, we believe that the programming language can potentially influence TDR: in fact, the availability of testing frameworks (e.g., JUnit) affects this practice, and the readability of tests (which may also depend on the framework and language) can also do it. A possible solution consists of enforcing the introduction of code of conducts that explicitly indicate rules on how to review tests [50].

The development of a good team culture in which test code is considered as important as production code should be a must for educators. Indeed, as previous work already pointed out [4, 31, 47], good reviewing effectiveness is found mostly within teams that value the time spent on code review: hence, practitioners should set aside sufficient time for reviewing all the files present in the patch, including test code.

VIII. Conclusion

In this paper, we empirically investigated a code review practice mentioned among practitioners’ blogs and only touched upon in academia: Test-Driven Code Review. We performed a study set up in two phases: an experiment with 92 developers and two external raters, followed by a qualitative investigation with nine semi-structured interviews and a survey with 103 respondents. Among our results, we found that with TDR the quality of the review comments does not change and neither does the time spent and the proportion of found production bugs and test issues. TDR leads to the discovery of more bugs in test code, at the expenses of fewer maintainability issues found in production. We report that developers see the application of TDR as problematic because of the perceived low importance of reviewing tests, poor test quality, and no tool support. However, test first review is also deemed to offer a concise, high-level overview of a patch that is considered helpful for developers not familiar with the changed production code.

IX. Acknowledgment

This project has received funding from the European Union’s H2020 programme under the Marie Skłodowska-Curie grant agreement No 642954. A. Bacchelli and F. Palomba gratefully acknowledge the support of the Swiss National Science Foundation through the SNF Project No. PP00P2_170529.
