The CIB conference MISBE2011 - Management and Innovation for a Sustainable Built Environment - was organised in Amsterdam, The Netherlands, in June 2011 by the Department of Real Estate & Housing, Faculty of Architecture, Delft University of Technology, in association with AESOP (Association of European Schools of Planning) and ENHR (European Network for Housing Research). This was also a joint meeting for CIB W055 Building Economics, W065 Organization & Management in Construction, W089 Building Research & Education, W112 Culture in Construction, TG76 Recognising Innovation, TG78 Informality & Emergence in construction, TG81 Global Construction Data.
During the conference an international group of 180 scientists and building professionals from 20 countries on all continents met each other and discussed from a broad perspective recent developments in management, innovation and planning of the built environment. The conference provided a challenging forum and vibrant opportunity for researchers and practitioners to share their research perspectives, research results and experiences on specific new challenges and emerging issues in practice, during the paper sessions and the specific workshops as well.

The Proceedings of MISBE2011 contain the collected papers presented on the International Conference MISBE2011 and cover the following topics:

- Management for sustainable design and construction
- Economics of the built environment
- Collaboration and integration in design and construction
- Innovation in construction
- Construction bidding and contracting
- Value driven design and delivery
- Planning for sustainable urban areas
- New technologies in planning
- Sustainable transformation
- Innovations in (strategic) urban planning
- Supply chain integration & collaboration
- Selecting partners and organizing collaboration
- Global construction data
- Social innovation & participation
- Deconstructing organisational paradoxes

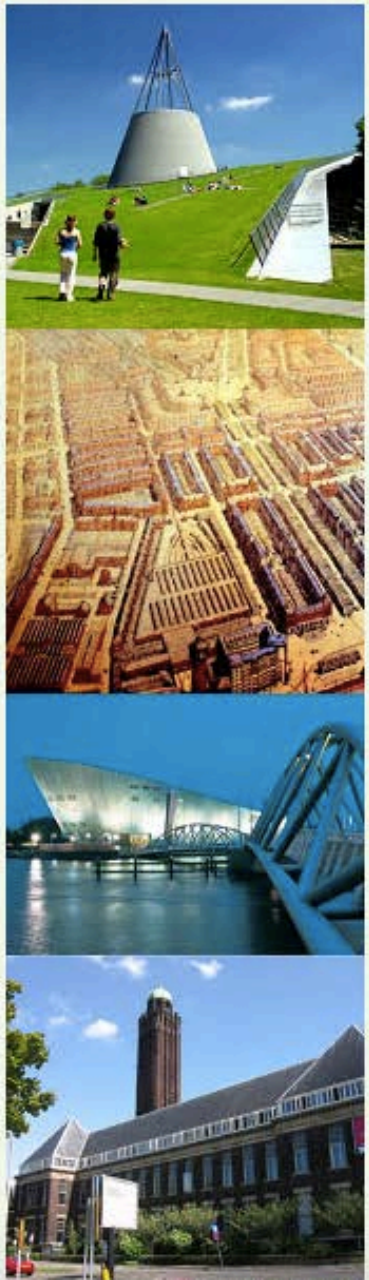
PREFACE

These proceedings contain the collected papers presented on the International Conference "Management and Innovation for a Sustainable Built Enviroment". This conference is organised under the auspices of Working Commissions W55, W65, W89 and W112 of the International Council for Research and Innovation in Building and Construction (CIB), together with the European Network for Housing Research (ENHR) and the Association of European Schools of Planning (AESP).



During the conference an international group of 180 scientists and building professionals from 20 countries on all continents met eachother and discussed from a broad perspective recent developments in management, innovation and planning of the built environment.

The organisers wish to express their gratitude to all those individuals who played an important role in the organisation of MISBE2011. We special thank the members of the local Organisation Committee and all members of the Scientific Committee.

Finally, the conference organisers wish to thank all speakers, participants, session chairs and workshop leaders for their involvement and contributions, making the conference a success.

Abstract
This study examines opportunities for the emergence of SME networks regarding highly energy-efficient housing, as well as the barriers they face.
A theoretical innovation diffusion model is developed from the point-of-view of social and environmental entrepreneurship and sustainable consumption.
The qualitative analysis reflects key elements from the theoretical model and is based on a representative case study of a successful passive house network located in the Belgian Flemish Region. Data were gathered during the emergence of the network, by means of participant observation and action-based (thematic innovation) research. Interviews provided further supplementary information.
The study concludes that the successful emergence of an SME network regarding highly energy-efficient housing requires a holistic approach, in which both enterprises and clients are guided in each step of the innovation-decision process. In their role as intermediaries between clients and firms, change agents should be supported by policy that facilitates networks for innovation diffusion.

Keywords: Buildings; Energy efficiency; Passive house; Innovation diffusion; Enterprise networks.

INTRODUCTION

The importance of high energy efficiency in the construction sector is widely acknowledged. A wide range of innovative energy-efficient solutions are already available within enterprises, and thus at issue is why these innovations are not widespread. The outcomes of research into the barriers to and drivers of technological innovation are expected to speed up the necessary transformation of the housing sector towards energy efficiency (EeB 2009).
Of particular interest are enterprise network structures, since these are known to create an environment of formal relationships and contracts between enterprises, providers and clients and cooperation between enterprises, as well as being supportive for regional economic and social development (Brenner and Fornahl 2003; DeBresson and Amesse 1991; Ornetzeder et al. 2005; Porter 1998). In particular, networks are also known to form a 'locus' for the introduction and diffusion of new technological solutions (Ornetzeder et al. 2005).
Although there are some experiences with case studies of successful emergence of enterprise networks in different fields (see for example: Brenner and Fornahl 2003, Ornetzeder et al. 2005, Porter 1998, Scott 1993), how to implement an SME network for the diffusion of highly energy-efficient housing (and related technology) is not well known: the emergence of network structures to implement certain goals of sustainable development or innovation is a relatively new research field.

Nevertheless there are some parallel research fields, most exemplary on innovation diffusion (e.g. Brenner and Fornahl 2003, Rogers 2003), which can contribute to this research field. Indeed, to examine barriers and drivers for the emergence of SME networks, it is important to understand what drives innovation-decision processes in SMEs and how this relates to SME networks. It can be useful to investigate a case study in order to provide a better understanding how individual change in SMEs can result in collective social innovation. This work therefore studies the emergence of an SME network dedicated to innovation diffusion, using theory of innovation-decision processes.

RESEARCH QUESTIONS

The main research question in this paper is:

How can SME networks aiming at highly energy-efficient housing successfully emerge?
In order to investigate this question the work defines several subquestions, taking the emergence of an existing SME network as a representative case study for empirical research. The following subquestions are addressed in the next sections:

How can the emergence of a network dedicated to high energy-efficiency housing be studied in relation to innovation-decision processes?
To answer subquestion 1, a research model is developed in the next section, and a representative successful case study covering the field of highly energy-efficient housing is selected.

How did SMEs decide to adopt such a network?
In the analysis section, the research model is used to describe the case study.

What were the first steps of the network?
The research model is further used to describe and discuss the first actions of the network.

What can be learnt from the case study?
In the conclusion, the most important findings are summarized.

RESEARCH METHODOLOGY

Theoretical background

In general, there are several bodies of literature that can be relevant for answering subquestion 1, like findings in the fields of (emergence of) enterprise networks and networks for innovation development and social or environmental entrepreneurship (see introduction). A full theoretical overview is beyond the scope of this paper, but further reading can also be suggested considering product-service systems (Mont and Tukker 2006) and the concepts of bounded socio-technical experiments, technological innovation systems and in particular strategic niche management (Ornetzeder and Rohracher 2009). Since the focus of the study was on innovation diffusion, for the examination of decision-processes for the emergence of the case study network, as a general framework Rogers' theory of innovation diffusion was selected (Rogers 2003).
Researchers have been working on a scientific framework for diffusion of innovation since the 1950's. An early milestone is the work of Rogers, describing since 1962 methodologies

for diffusion research that even now are still being used, although in modified forms. The newest edition of this work (Rogers 2003) defines diffusion as the process by which an innovation is communicated through certain channels over time among the members of a social system. The innovation-decision process was defined by Rogers (2003) as the process through which an individual (or other decision making unit) passes from first knowledge of an innovation, to forming an attitude towards the innovation, to a decision to adopt or reject, to implementation of the new idea, and to confirmation of this decision. According to Rogers' model, communication channels, and prior knowledge and conditions, can influence adoption. In the persuasion phase, the decision making unit can be influenced by the perceived characteristics of the innovation.
Rogers' scientific framework of innovation diffusion has also been used by Dutch researchers as a guiding model for market introduction of energy efficiency and sustainable development in the construction industry (Silvester 1996, van Hal 2000; Bos-Brouwers 2010). Damian Miller (2009) recently developed an integrated model for emerging markets, including Rogers' theory and based on four broad perspectives in innovation diffusion research defined by Lawrence Brown (1981): communication, economic history, market development, market infrastructure (see further in Figure 2).

Model development

Networks are known to develop, grow and decline similar to enterprises in innovation diffusion theory (see for example: Brenner and Fornahl 2003). Regarding innovation diffusion it thus makes sense to analyze (emerging) clusters or networks as (innovating) enterprises. However, social networks are also identified by a common goal, by a specific way of communication and action, as well as by a minimal internal institutional (organizational) structure (Fürst 2002). Regarding energy-efficient housing, Ornetzeder et al. (2005) suggested a strong focus on creation of trust and social capital, and learning processes and the need for a center of know-how as most important factors in the emergence of networks of enterprises. Also, social networks tend to focus on steering a paradigm shift, which means they try to influence ways of thinking and representing in order to influence action (Fürst 2002, Ornetzeder et al. 2005).
In the development of the present research model, it is noted that key to the social learning process regarding the implementation of highly energy-efficient housing as an innovation is how to break the so-called 'circle-of-blame' (see Figure 1), and transform it into a learning 'circle-of-innovation' (or circle of trust, see Figure 2).

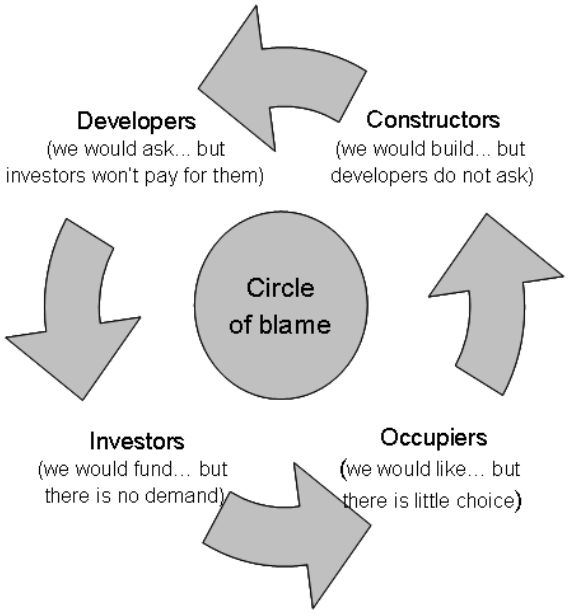

Figure 1: *Circle of blame. Source: SCFG (2000).*

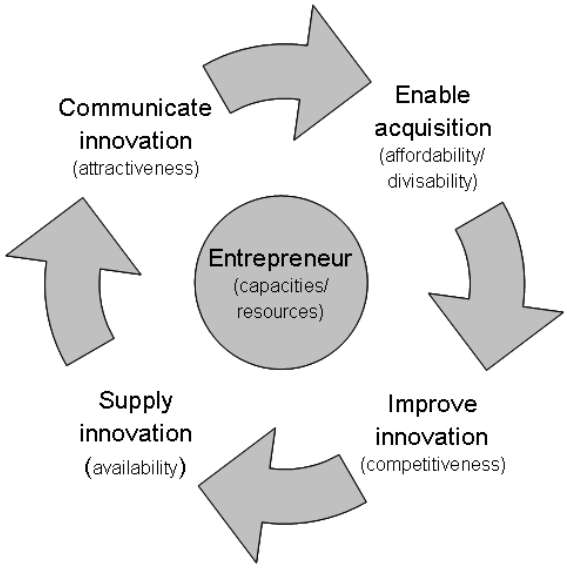

Figure 2: *Integrated analytical framework for innovation diffusion (interpretation based on: Miller 2009).*

A real challenge lies in combining structural technological and system changes (like social and innovation-oriented entrepreneurship as illustrated in Figure 2) with cultural and behavioral changes (like sustainable consumption), possibly by means of intermediary functions or new networks.

Based on a theoretical framework of sustainable consumption Peter Tom Jones and Vicky De Meyere (2009) proposed the 4E-model (see Figure 3, the model has its roots in Stevenson and Keehn 2006; Defra 2008) to explore effective strategies to change behavior towards sustainable consumption. This model can be useful when the research explores actions of the network regarding sustainable consumption.

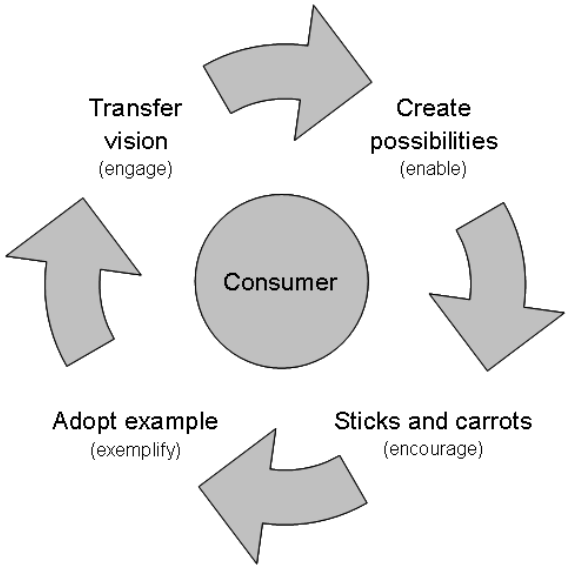

Figure 3: *The British 4E model provides an overview of a mix of complimentary instruments that can change consumption behavior: 'enable', 'encourage', 'exemplify' and 'engage' (interpretation based on the study by Jones and De Meyere 2009).*

In order to analyze the case study the research combines both models from Figure 2 (viewed from the supply side) and Figure 3 (viewed from the demand side).

Selection of a case study

In practice, the promotion of energy efficiency has long been the mandate of national governments and energy utilities. Nowadays, also in the framework of larger 'climate' or 'sustainability' agenda's, a lot of intermediary organizations already work on energy efficiency (Heiskanen et al. 2009), including a variety of governmental and nongovernmental organizations, public-private partnerships and regional or sectorial networks.

In the field of construction of highly energy-efficient housing different authors (Ornetzeder and Rohracher 2009; Mlecnik 2003) noted that nowadays new interest organizations focusing on passive houses shape the socio-technical system by mediating between producers and the policy level and by building systems to transfer these new technologies and practices into the mainstream building sectors. In the case of Austria, the evolving niche of highly energy-efficient passive houses seems to have the potential to profoundly transform existing construction practices (Ornetzeder and Rohracher 2009). Therefore a passive house related SME network was selected for further study.

As a case study, the research qualitatively investigates how an SME network, focused on passive house development, emerged in the Belgian Flemish Region. In 2002 a governmental agency decided to support a thematic innovation platform for SMEs in the construction industry during four years (IWT 2007, Mlecnik 2003) to stimulate thematic innovation in the regional construction industry. The main goal of the network was the diffusion of the passive house concept and technologies in the Flemish Region. Today, the network has shown strong growth and its influence reached even into policy development. While the word 'passive house' was regionally unknown in 2002, today it is an official word in Belgian federal income tax reduction law, hundreds of passive houses are being built every year in the Flemish Region and dozens of companies offer specific products, systems and services for a newly developed regional market of highly energy-efficient housing. Meanwhile the Flemish 'Passive House Platform' (PHP) has evolved from 18 founding members in 2002 to more than 300 members at the end of 2008, of which 158 can be characterized as enterprises, organizations and institutes.

To answer to the research question it can be important to have a rather complete view of the introduction and development of the case study (network PHP), including qualitative details that might be of importance in decision-making and replication of the network initiative. The paper is based on action-based innovation research by the author in the framework of a thematic innovation stimulation project (IWT 2007). Participatory observation in the set-up of the network led to permanent follow-up of the emergence and change of composition of the network. To provide empirical data, introductory interviews were performed amongst the founding and emerging members of PHP (2002-2006), focusing on: What are the characteristics of the member? What is expected from the collaboration with the network? What kind of information and initiatives are needed? What are the observed needs for the future?
The following section analyses the innovation-decision process for the set-up of the SME innovation network.

Limitations of the research
In social sciences the qualitative analysis of case studies has a long tradition, usually because more quantitative approaches are not sufficient or can even lead to wrong descriptions of the encountered phenomena (Ornetzeder et al. 2005). Unlike quantitative approaches of network research, which are usually more focused on interpreting the importance of relationships between members in a network or analysis of clusters, qualitative network research is more focused on interpreting the importance, actions and consequences of the network as a whole.
Organizational innovations tend to have a very specific emergence history which is highly related to local context and side conditions in a social context, which can limit the way a model can be transferred to another region or social context. The action-based research was conducted during the emergence period 2002-2006 of PHP, so starting conditions might be different today. Notably, the European context of energy performance of buildings legislation has changed. Also, interviewees were chosen in function of their relative importance to the introduction and development of the network, which can induce a high focus on the 'innovator' view. It is noted that, meanwhile for addressing the growth market, activities and business model of the examined case study have changed. The growth of the network from innovation to volume market is discussed in another paper (Mlecnik 2011).
The research does not to attempt to conclusively answer what a passive house SME cluster is, or is not, but to review and integrate experiences which may help in understanding the importance of mediators and SME networks as a liaison between sustainable consumers and innovating enterprises. Note that local success of a transfer process of a business model is highly dependent on motivation and competences of the lead actors, resources and social capital generation. However, the business model of the network 'Passiefhuis-Platform' (PHP) is known to have been transferred to other regions, for example to the Walloon Region (with the emergence of the 'Plate-forme Maison Passive') and to the Czech Republic (with the emergence of the 'Centrum Pasivniho Domu'), which makes it worth while to study more deeply.

ANALYSIS OF THE CASE STUDY

Emergence
Exemplify
The discussions between enterprises during the foundation phase of PHP clearly indicated a wish to achieve more sustainable construction on the regional level, based on examples from (and comparison with) other countries. Previous studies (SENVIVV 1998, CIR 2000, Eurima

2003) indicated that for example thermal insulation quality of buildings in the Flemish Region was amongst the worst in Europe. In 2002, there was also no concern from policy to set higher energy performance requirements: the Flemish Region was just confronted with the implementation of the European Performance of Buildings Directive (EPBD 2002) and just started re-inventing energy calculation procedures in collaboration with industry. At first, the EPBD policy approach led to distrust in the fashion of the typical 'circle of blame' (see Figure 1).

Engage

For some companies, this knowledge-action gap was a driver to discuss more effective strategies and business opportunities for sustainable housing, like for example in the IEA SHC Task 28 (2006). Several enterprises defended that to bridge this gap not only a 'circle of trust' – alternatively a 'green circle of naming' (Buck, 2008) – is needed, but also a broader conceptualization of actions for win-win situations and a more appropriate interpretation of knowledge, for example from neighboring countries. A Flemish engineering office, familiar with sustainability issues and studies, was keen on setting a higher energy performance standard in order to promote their services. Instead of trying to steer people's behavior by the (still non-existing) EPBD, they argued that it is necessary to enhance people's knowledge about the existence of solutions. They argued that in order to translate energy consciousness into consumer action, people not only need to know about the state (and energy coefficient) of the houses, but also about the root causes of the problem like insufficient thermal insulation, leaky construction details, improper use of solar gains and (health problems due to) lack of ventilation. It was observed that some non-profit organizations in the Flemish Region promoted for example renewable energy systems (ODE-Vlaanderen vzw) or sustainable construction materials (VIBE vzw), but that the root causes were insufficiently addressed by these promoters.

Enable

Keeping the root causes of the problem in mind, visions and socio-environmental possibilities and strategies towards change were developed. The engineering office played a key role in providing competences and resources for this development, using a small but subversive unit within the larger organization - what Rogers calls a 'skunkworks': an especially enriched environment that is intended to help a small group of individuals design a new idea by escaping routine organizational procedures (Rogers 2003: 149). An existing but dormant non-profit organization (Energie Duurzaam vzw) was used to pioneer the development of the social innovation, and an R&D worker was selected and given special resources, working on a crash basis to create the innovation and to find support for it.

Encourage

From innovation diffusion literature it is known that the availability of positive information is important in innovation adoption decisions (O'Neal et al. 1973). Energie Duurzaam collected answers from individual SMEs interested in profiling themselves in best energy-efficiency. The R&D worker could rely on the connection network of the engineering office to find motivated individuals within companies. In-depth interviews with possible key stakeholders led to initial knowledge diffusion, and further persuasion and decision of some companies to adopt an SME network. The adoption process was further formalized in regular meetings between interested companies, in order to gain confidence and to develop a common vision. This common vision – diffusion of knowledge to stimulate high energy-efficiency in buildings - was formalized as a goal for a non-profit organization, to be erected. Instead of

protesting against slow policy development, the psychology of change was defined as a framework including positive community building, and positive feedback loops as strategies.
Once a proposal for a common vision was developed and set into statutes of a non-profit organization, it was presented to a larger group of possible stakeholders, including companies from the sustainable building sector, as well as traditional building companies and prominent building research institutes. As expected, traditional companies and even the building research institutes were at first reluctant, but the decision was left to them if they wanted to join the movement. However, to join the movement, they were asked to formalize their intent and write consent to stimulate innovation for high energy-efficiency by means of a letter signed by their director.

Competences/ resources
A first barrier to tackle was the exact meaning of 'energy efficiency' in order to attract competences. It was obvious from the different discussions that the enterprises wanted to distinguish themselves from companies that care less regarding energy efficiency. So most companies agreed to set a higher standard, even compared to 'low energy', such as a factor four energy reduction, or even including other sustainability criteria. The engineering office proposed to examine the example of the passive house concept as a high energy-efficiency target, since they recently discovered that in Germany hundreds of passive houses had already been built, which consumed less than a factor four compared to the proposed new energy performance legislation in implementation of the European Performance of Buildings Directive (EPBD). In further meetings it became clear that the passive house standard was best documented (be it in German) with directly available performance criteria, available technologies for import and diffusion, and available tools for energy calculation (which were still missing for normal EPBD calculation). In this framework the decision fell to adopt the passive house standard as a first concept for promotion during the first years of the non-profit organization.
A second barrier was the funding of the non-profit organization. At the organizational level an energy efficiency network can be conceptualized as commercializing a non-profit organization. Many non-profits remain fearful of commercial operations undercutting their social mission (Dees 1998; Fowler 2000), and this was also apparent in the discussion with possible stakeholders. Many enterprises were reluctant to join formally with possibly large member contributions without a clear view how the organization would be able to support itself. It was formalized that a viable business would be the best option to generate a dependable income to pay for network actions: the benefits energy efficiency networks create are public, but they are nonetheless incurring private costs.
Also, since mostly small and micro-enterprises were interested to develop such a competitive niche market, the organization could not rely on substantial member contributions. Funding opportunities were searched and a resource channel of the Institute for the Promotion of Science through Technology (IWT, Flemish Community) was considered as a viable option. To obtain resources the companies had to engage in stimulating thematic innovation and a substantial number of SMEs (more than 10 according to the grant programme) had to co-contribute. Since this would allow 80% funding for more than 2 full-time employees during four years, the SMEs decided to cover the remaining 20% with membership fees. Further, a distinction was made in membership fees according to the size of the company (small, medium or large enterprise, and later also micro-enterprises as a separate category), to allow the micro- and small enterprises, showing wild ideas and clear motivation for innovation, to participate.
After one year of preparatory work, this action led to the foundation of PHP in October 2002 with 18 members, just before the official IWT funding application was submitted. The

number of founding members, the inclusion of a large enterprise as opinion leader, and the transparency and multi-disciplinarity of the organization, created a highly visible signal towards the construction industry with diverse media attention. PHP was erected to be the first multidisciplinary organization in the construction industry involving members such as architect's offices, engineering offices, distributors, materials producers, system providers, installers, contractors, and so on. It was decided that the management can change as rapid as the expected evolution: every two years a number of members of the management board would be chosen amongst the members. A first management board was selected to represent and guard the holistic approach, including a contractor, a climate system provider, an installer, an architect, an engineering office and an individual representing possible owners.

First steps

Concerning the motivation of the innovators to join the network, the interviewees mentioned to be vision driven expecting to get a jump on the competition, not by lower product cost, but by faster time to market, more customer service, or some other business advantage. As a result of the emergence trajectory, they were prepared to champion the passive house concept against resistance and to bear bugs and setbacks that accompany innovation. The innovator group included mostly micro- or small enterprises, e.g. the passive house design offices, engineering offices, contractors, installers and suppliers involved in the first demonstration projects.

In contrast to the single-issue focus of other existing organization in the Flemish Region - for example ODE-Vlaanderen and VIBE - PHP started from a holistic perspective on what has to be done. Instead of fear, guilt and shock as motives for action, hope, optimism and pro-activity were stimulated by developing an attractive vision for future innovation, focusing on the many examples of SME innovation developments in for example Germany and Austria. Thus, like in Austria (Ornetzeder and Rohracher 2009), passive houses in the Flemish Region have been very much developed in a bottom-up fashion without central steering but requiring a high degree of coordination and intermediation processes, with similar initiatives for the development of technical guidance, dissemination of information, development of certificates and quality assurance, and so on.

Table 1 illustrates that the general elements of the social marketing activities of the employees of the network during the first years included innovation specific information provision, the approach to include more enterprises (especially SMEs), the reinforcing of innovation as well as building up a regional and communal identity towards possible clients.

Compared to Austria (Ornetzeder and Rohracher 2009), a stronger focus was put from the beginning on providing innovation directly to SMEs. In the first two years the collective action was stressed, promoting the integrated holistic approach of the passive house concept. It was made clear to the individual companies that they could benefit by using the passive house concept as a 'coat-hanger' for their own products, systems and services.

Considering both the entrepreneur and the consumer perspective, in the first years 'engage' and 'exemplify' were clearly the main focus since the market had to be introduced. For most companies, 'exemplify' meant that the passive house technologies and solutions had to be demonstrated. This was tackled by the employees of the network by organizing a small conference and technology fair soon after the erection of the platform. This enabled companies to network and brainstorm about possible demonstration projects. Two holistic demonstration projects were kick-started by individuals from the leading engineering office, who decided to build their own house in the passive house standard. As consulting engineers they could rely on their opinion leadership in order to convince architects and contractors to participate in their project. Once the demonstration projects were available, construction site

and building visits convinced other actors. In the mean time, bus tours were organized by the network to visit key demonstration projects and companies in nearby Germany.

Target group	*SME network actions*	*Number of actions 2003-2004*	*Number of actions 2005-2006*
Companies and clients	Company and demonstration project visits	70	67
	Technical publications	7	37
	Lectures/ seminars	22	45
	Newsletters	8	12
	Promotional publications	5	43
	Web site actions	1	6
Mainly companies	Networking actions for companies	18	16
	Actions for membership	1	4
	Larger innovation networking initiatives	4	7
	Technology watch (innovation support)	2	8
	Innovation studies	4	7
	Stimulating international cooperation + partner search	5 + 2	10 + 2
	Grant application support	2	9
	Guidance of innovation projects	4	4
Mainly clients	Answering technology questions	300	450
	Guided question transfer	100	60

Table 1: *Activities of the SME network PHP according to year of activity. Based on: (IWT, 2007).*

Media attention of the 'first houses without heating' spurred enthusiasm and requests for providing more information to interested companies and clients. Innovator-clients appeared to be highly receptive to the proposed solution due to their environmental concern. The clients who adopted first were usually from the upper middle class and could reserve an extra budget for realizing the concept. In comparison, later clients wanted to be well informed and followed workshops and visited demonstration projects in order to form an opinion. They usually also rationalized the passive house concept compared to the perspective of another low energy option. However, their final decision appeared also to be highly influenced by other parameters like the experienced comfort during visits of the demonstration project.
After the first four years, the declining media attention for passive houses (gap from innovation to growth market), led to new business development. Figure 4 exemplifies the business model development of PHP, summarizing Figures 2 and 3. Amongst other, a stronger focus was set on quality assurance of passive houses.

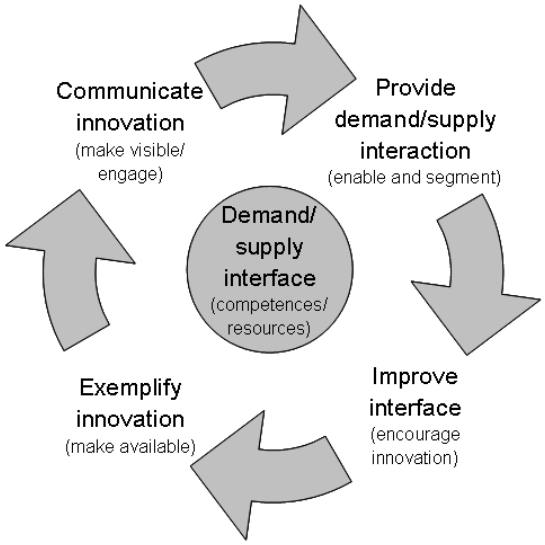

Figure 4: *Business model development of a change agency/ SME network in order to encourage innovation through demand/supply interaction.*

CONCLUSION

The model developed for innovation diffusion studies of SME networks focused on highly energy-efficient housing, and the application of the model on a case study, provide interesting new insights. Member-companies can be engaged by exemplifying opportunities and by positive communication focusing on their shared common meanings, beliefs and mutual understanding. A holistic approach promoting an integrated concept and involving actors from different disciplines on a regional level has the advantage that the SME network can also excel in, for building projects necessary, heterophilous and neutral communication. Innovative passive house technologies and services appear to be suitable as a focus for the emergence of an SME network focusing on highly energy-efficient housing. The role of such an SME network as a 'change agent' and formal gate-keeper between innovation-push and demand-pull, can be envisaged.

For emerging networks it is important to define 'interventions' as coherent objective in the innovation phase to bring about behavior change in order to produce identifiable outcomes and transitions. An SME network for the diffusion of highly energy-efficient housing can emerge on several activities. It can stimulate persuasion and a favorable attitude towards innovation by providing detailed information to both clients and innovating companies. It can help the individual with engaging in activities that lead to a choice to adopt the innovation, for example by providing or directing to further personal training. It can help the individual (or other decision making unit) with the implementation, for example, directing to established or certified professionals. Finally, it can help in providing confirmation when the individual (or other decision making unit) seeks reinforcement of the decision already made. The case study shows that guiding the client or the innovating company through the whole decision-taking process with suitable responses in each step of the decision process can contribute to success.

The study exemplifies that the role of motivated agents from an SME network is imperative for steering innovation-decision processes towards the implementation of passive houses, both for enterprises and for clients. This role could have never been achieved without support by innovation policy that facilitated the set-up of a specific thematic network for innovation diffusion.

ACKNOWLEDGEMENTS

Funding for thematic innovation stimulation during the period 2003-2007 was obtained within the project number 020506 entitled 'Passiefhuis-Platform' by IWT, the agency for innovation by science and technology of the Flemish Community.

ADVANCEMENT OF SUSTAINABLE DEVELOPMENT, CONTRACTING, DESIGN, AND SUPPLY BUSINESSES VIS-A-VIS CONSTRUCTION MARKETS

Pekka Huovinen, Aalto University, Strategic Management in Construction
Finland
pekka.huovinen@aalto.fi

Abstract
The background involves the multiplication of Porter's (1980) five forces framework and the prior design of the 8-arena framework for capturing complexity of managing businesses within each of hundreds of (inter)national construction markets. In turn, the aim of this theoretical paper is to advance environmental sustainability as part of managing the four primary businesses. The sustainability of construction-related business management is enabled by implanting drivers into each of the eight competitive arenas. In life-cycle contracting and development businesses, the novel drivers include the coupling of object development ideas with sustainability advantages. In design-build contracting businesses, such drivers include the re-engineering of value chains with all tiers of designers, subcontractors, and suppliers. In design businesses, such drivers include the transformations of design firms into long viewers, path dependency breakers, stock-specific programmers, object-specific planners, impact blockers, and impact cause tracers. In supply businesses, such drivers include the adoptions of cradle-to-cradle certifications, product formula renewals, and full responsibility takings over the life-cycles of supplied units. In the future, practitioners and researchers alike could adopt this high-sustainability 8-arena framework.

Keywords: building products, business management, construction, design, sustainability

INTRODUCTION

Built environments and their sustainable advancement are herein approached from **a business management viewpoint** as follows. One of the generic definitions on sustainability is adopted and quoted, followed by a brief review of the recent perceptions and concepts for managing businesses in sustainable ways in various contexts outside and inside built environments. This review justifies the aim-setting for the paper as a whole and its focus on the advancement of sustainable development, contracting, design, and supply businesses.

In general, **sustainable** is defined to be capable of, relating to, or designating forms of human economic activity and culture that do not lead to environmental degradation, especially avoiding the long-term depletion of natural resources (OED 2011). On the one hand, an indicative, cross-industrial survey resulted in the finding that only 54% of the 335 managers assessed that their firms are extremely or very concerned about sustainable performance as part of supply chain management. Overall, these firms still focus mainly on **cost and financial concerns**. Moreover, the respondents are not yet convinced by academics, consultants, and others who argue that sustainability improvements may in fact help the bottom line, instead of cutting profits (Prokesh 2010).

On the other hand, the top management in many leading firms are perceiving that environmentally friendly businesses truly determine how successful they will be in the long run and, thus, **long-term goals** are being set along the dimensions of sustainability (Orange 2010). For example, Unilever has declared that they will run their supply chains fully sustainably by the year 2020. In practice, such advancements will require technical,

management, process, and cultural innovations as well as the engagement of all units and people within globally scattered organizations (Senge in Prokesh 2010). Typically, Nidumolu et al. (2009) advocate that pioneering business managers adopt **a generic, 5-stage process** for becoming sustainable, i.e. (i) viewing compliance as opportunity, (ii) making value chains sustainable, (iii) designing sustainable products and services, (iv) developing new business models, and (v) creating next-practice platforms.

Herein, **the focal contexts** involve the four coinciding spheres of (inter)national built environments, capital investment markets, real estate markets, and construction markets. These spheres deal with the design, implementation, services, and life-cycle aspects of both existing object stocks and new, object-specific investments in various sectors, i.e. natural resources utilization, energy supply, telecommunications, transportation, other infrastructure, manufacturing, and general building. Later, only the term **"construction markets"** is used to encompass all these spheres.

Some years ago, Fergusson and Langford (2006) postulated that as **environmental strategies** are developed, competencies in managing environmental issues will grow and lead to improved business performance. Based on the thin evidence in the UK context, they initially verified **the three propositions**, i.e. (a) UK firms are considering environmental issues within their strategic management at least informally in compliance with legislation and contractual obligations, (b) improved environmental performance is increasingly, with a varying rate, included within strategic management plans, and (c) at least more proactive firms are managing environmental responsibility at a strategic level to gain competitive advantages. Recently, Jones et al.'s (2010) survey resulted in the similar, low-sustainability findings in the US engineering and construction industry. It is herein assessed that such low-sustainability states in managing firms and their businesses are prevailing today across the construction globe.

Thus, **the aim of this theoretical paper** is to advance environmental sustainability inside firms and as part of managing their development businesses, contracting businesses, design businesses, and supply businesses in construction markets, respectively. **The three sub-aims** are as follows: (i) to re-introduce the 8-arena framework that Huovinen and Kiiras (2005a-c, 2006, 2007, 2009) have designed for capturing complexity of managing a business across the eight competitive arenas that are embedded inside each of targeted (inter)national construction contexts, (ii) to implant the high-sustainability drivers into the six of these competitive arenas and as part of the managing of each of the four primary businesses, and (iii) to conclude with some remarks on the future advancement of high-sustainability business management, including the validation of the 8-arena framework and the implanted high-sustainability drivers.

The management of the four primary businesses in highly sustainable ways is herein defined to encompass the utilization and development of natural resources in ways which are compatible with the maintenance of these resources, and with the conservation of the natural and built environments, for current and future generations (applying OED 2010). Sustainability calls for incorporating environmental and green concerns into business-level management, but sustainability is causally related to bottom lines and social issues, too. Similarly, project-level management is - along managing contract, quality, schedule, budget issues - considering how every project (or capital investment object) will impact communities, environments, and businesses (applying Fister Gale 2009).

PRIOR MULTIPLICATION OF PORTER'S FIVE FORCES FRAMEWORK VIS-A-VIS CAPTURING COMPLEX COMPETITION IN CONSTRUCTION MARKETS

Within the strategic management literature, **Porter's (1980/1998) five forces framework** offers a generic frame of reference for any firm who aims at attaining its business goals in its industry. This framework applies to high-tech, low-tech, and service industries, including global and local construction industries or markets. There are five basic forces that are attached to one focal competitive arena, at a time.

In turn, Huovinen and Kiiras (2005a-c, 2006, 2007, 2009) have redefined and multiplied Porter's five forces in order **to understand and explain competition** between various stakeholders within several causally interrelated, upstream and downstream arenas and across them in any construction market. In this paper, this multiplication of Porter's five forces into the 8-arena framework is re-introduced as follows.

It is argued that each construction market consists of **the eight competitive arenas with incumbents** who are interacting as procurers and sellers as follows: (1) rivalry among focal sellers in their base arena, (2) the bargaining power of clients in the next downstream arena, (3) the bargaining power of subcontractors, sub-designers, and suppliers in chained upstream arenas, (4) the threats of substitute offerings, and (5) the threats of entrants (Figure 1).

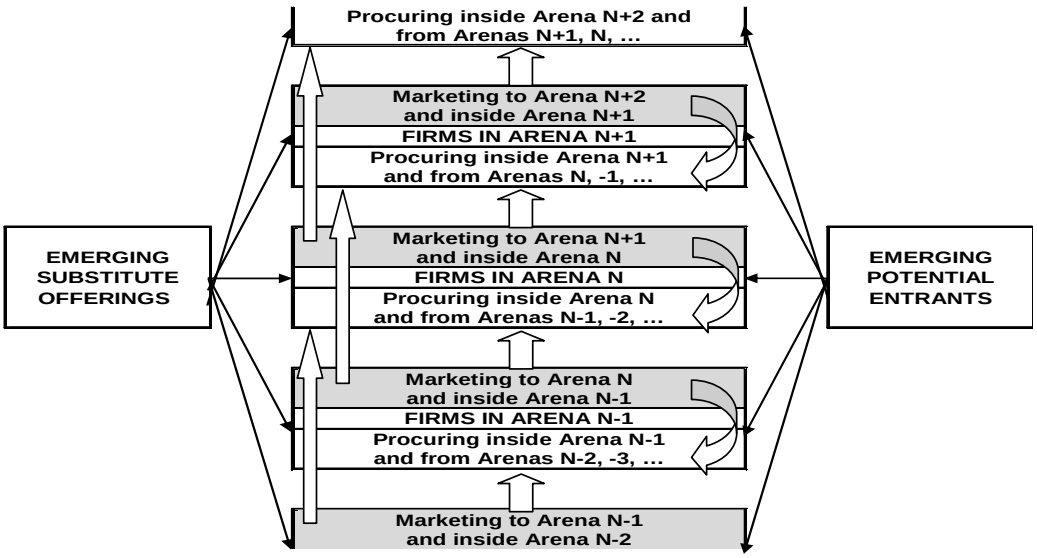

Figure 1: *Incumbents as procurers and sellers across targeted arenas in a focal construction market (Huovinen and Kiiras 2005a; applying Porter 1980/1998).*

It is axiomatic that each procurement route, which each procurer (client) chooses, determines the rules of competition and the nature of marketing in a coupled upstream arena. In turn, a set of marketing routes couple the related duos or trios of downstream arenas into value adding chains even project by project. Each incumbent occupies **the two principal roles** of a procurer and a seller in its base arena. As a seller it interacts via marketing routes with targeted clients in downstream arena(s). As a procurer it acquires inputs via procurement routes from upstream arena(s) and from inside the same arena(s).

The most downstream arena, i.e. **Arena 1 of Uses** involves stakeholders who use **capital object stocks**, including building stocks and infrastructure stocks, as part of built environments. Users occupy and operate individual capital objects, e.g. buildings and pieces of infrastructure over their life cycles. In turn, these various spaces, utilities, and structures enable users to fulfill their purposes and compete for the best effectiveness of their primary operations in a country, an economy, or a society. Many stakeholders are assuming a dual role, i.e. such users act also as the owners (in Arena 2) of the objects that they occupy or exploit.

Arena 2 of Ownership includes stakeholders who own capital objects and stocks. The two primary owner groups are as follows. Owner users compete in terms of (a) enabling the most effective use of and operations related to their objects and (b) earning the best value for their invested capital under long-term ownerships. Professional owners compete for achieving the same goals through speculative or long-term ownerships and renting stocks to desired users as tenants (in Arena 1).

Arena 3 of Life-Cycle Services includes firms who compete for providing various services to owners (in Arena 2) and users (in Arena 1) over (the contract periods of) the life cycles of capital object stocks. The two primary service groups include real estate management services as well as operation and maintenance (O&M) services.

Arena 4 of Capital Investing includes stakeholders who invest in, initiate, and manage their new, modernization, and renovation investments in various sectors. In the short or middle term, these capital investors compete for the highest possible returns through selling their objects to versatile owners (in Arena 2). The four primary investor groups are developers, owner investors, venture capitalists, and financiers. Investors' procurement strategies and routes determine the existence of two other arenas, by each object. On the one hand, many investors are realizing their capital investments by handing out single ("turnkey") contracts to the most competent contractors around (in Arena 5). On the other hand, several investors can themselves manage capital object-specific processes and, thus, hand out multiple subcontracts to firms (in Arena 6) for carrying out all designs, procurements, construction works, and installation works.

Arena 5 of Wholes includes principal contractors and CM consultants who compete for taking full responsibilities via single contracts for the design and implementation of investors' (in Arena 4) object-specific investment plans. Primary competitor groups consist of system, general, turnkey, and design-to-build contractors as well as construction management (CM) firms. Typically, these contractors of wholes (a) arrange competitive biddings and hand out a set of engineering and design contracts to the best designers and a related set of subcontracts for trade-specific works to the best subcontractors, or (b) package first design, procurement, and works into sub-systems, arrange systemic biddings, and hand out contracts to the most advanced sub-system contractors (in Arena 6).

Arena 6 of Parts includes designers and subcontractors who compete for the realization of the parts of investment objects via multiple contracting. The two primary client groups include capital investors (in Arena 4) and contractors of wholes (in Arena 5). Competitor groups involve engineers and designers of various disciplines as well as sub-system, plant, machinery, equipment, main, HEVAC, specialty, and trade contractors.

Arena 7 of Prefabricated Products includes suppliers and traders who compete for delivering versatile prefabricated building products and components to principal contractors

and CM consultants of wholes (in Arena 5), contractors of parts (in Arena 6), and assemblers of components (inside the same Arena 7). By definition, suppliers and traders of these inputs do not take responsibility for works at sites. The three broad supplier groups are building product suppliers, component suppliers, and construction equipment suppliers.

The most upstream arena, i.e. **Arena 8 of Construction Materials** includes suppliers and traders who compete for delivering all kinds of materials such as copper, steel, wood, glass, stone, sand, and ceramics to product or component suppliers (in Arena 7) or directly to contractors at sites (in Arena 6; or even Arena 5).

New substitute offerings may emerge related to one or several primary arenas even in the short term. Annually, **potential entrants** decide to target new construction markets. In each market, entrants may try to enter only one arena or two or more arenas concurrently based on their arena strategies, respectively. In addition, there are **other (in)directly competing stakeholders** such as financiers and traders as well as **supporting stakeholders** such accountants, administrators, lawyers, promoters, trainers, and transporters.

In principle, all procurers have **important latitude** to rethink and influence the internal structure and boundaries of focal arenas and to position themselves relative to other actors. Even leading procurers can never stop learning about their markets and upstream arenas, rivals in base arenas, procurement routes, and building environments in order to improve their performance (applying Porter 1980/1998: xi-xii, xiv).

Indeed, each of these 8-arena sectors and markets are facing **sustainable or green standards battles** in global, international, continental, and national contexts. Such battles are over what constitutes sustainable or green construction and built environments in the first place. It is herein posited that major developers, contractors, designers, and suppliers should become actively involved in debates and shaping rules and standards. Otherwise, managers and their businesses will be assessed sooner or later against sustainability standards that they cannot meet such as the certification of Leadership in Energy and Environmental Design (LEED) also outside the USA (aligning with Unruh and Ettenson 2010).

Within the demand side (in Arenas 1-2), pioneering owners and users will set the required levels of sustainable, societal developments and built environments. In the EU-wide context, one of the exemplary initiatives is the Energy-efficient Buildings (EeB) PPP with a roadmap towards the realization of the challenging vision, i.e. by the year 2050, most buildings and districts could become energy neutral and have a zero CO2 emission. A significant number of buildings would then be energy positive, thus becoming real power plants, integrating renewable energy sources, clean distributed generation technologies, and smart grids at district levels. The rate of change of the built environments will be realized through the six planned intervention or natural mutation moments, i.e. (i) the renovation of energy infrastructures, (ii) new building additions, (iii) refurbishment, (iv) large maintenance, (v) HVAC system replacements, and (6) demolition (EC 2010).

In the next three sections of this theoretical paper, this author is sharing his foresights on the sustainable developments **in the supply side (in Arenas 3-8),** i.e. leading and pioneering firms will implant high-sustainability drivers into and across focal competitive arenas as part of managing their four businesses, respectively, within targeted (inter)national construction markets and contexts (Fig. 2).

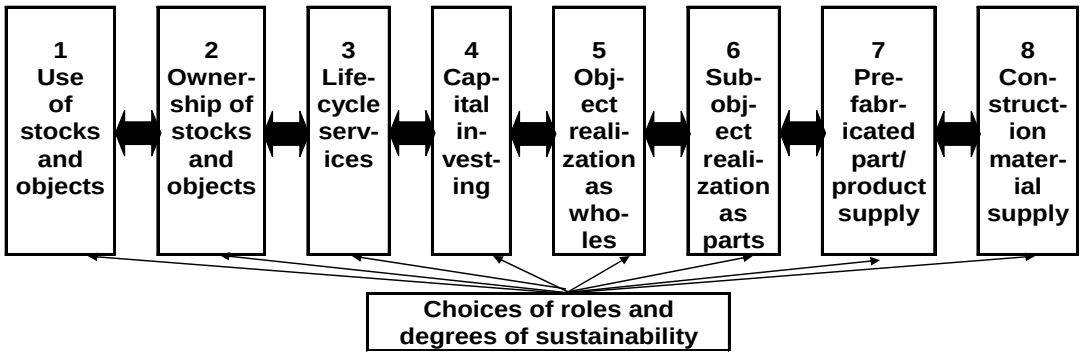

Figure 2: *Choices of stakeholders occupying Arenas 1-8 within each construction market.*

IMPLANTING ENVIRONMENTAL SUSTAINABILITY INTO ARENAS 4-6 AND 3 AS PART OF MANAGING DEVELOPMENT AND CONTRACTING BUSINESSES

Construction contractors are choosing their businesses, respectively, from among many alternatives such as life-cycle, PPP, and other financing-based contracting, object development as well as design-build, main, specialty, and trade contracting, complemented with life-cycle services, in building and infrastructure sectors within (inter)national contexts. New objects are being constructed and the existing ones are being renovated.

The future implanting of high-sustainability drivers into each of (inter)national construction markets will take place **when firms are managing their development businesses and contracting businesses** in targeted arenas as follows (in part applying Fister Gale 2008, 2009) (Fig. 3):

- In life-cycle, PPP, and other financing-based contracting businesses (Arena 4b), firms are orchestrating the planning and realization of object-specific sustainability programs through all internal organizational layers and the 2-5 tiers of external contractors and suppliers. Life-cycle management involves a capital investment ideation, the early crafting of alternative object scopes with sustainability advantages, the sub-setting of high-sustainability goals, and the continuous measurement of impacts on sustainability against these goals as part of a total progress via delivery, use, and maintenance processes (and stages).
- In object, property, and infrastructure development businesses (Arena 4c), developers are launching similar organizational penetrations. In addition, developers are using filters for pre-screening each potential object-specific party in terms of trustworthiness, loyalty, performance, and necessary competencies. Developers are relying on value adding parties to innovate on their behalf. Object-related parties need to trust each other for any sustainable initiative to work.
- In CM contracting and CM consulting businesses (Arena 5a), CM firms are securing buy-ins from all contracted parties according to sustainability plans. CM firms make sure that each designer, sub-contractor, and supplier is actually doing what they say they are doing in conformance with high-sustainability. For this monitoring, CM teams tailor and use a reliable metrics. Open relationship networks are built in order to communicate on a real-time basis and to find viable solutions when something goes wrong.

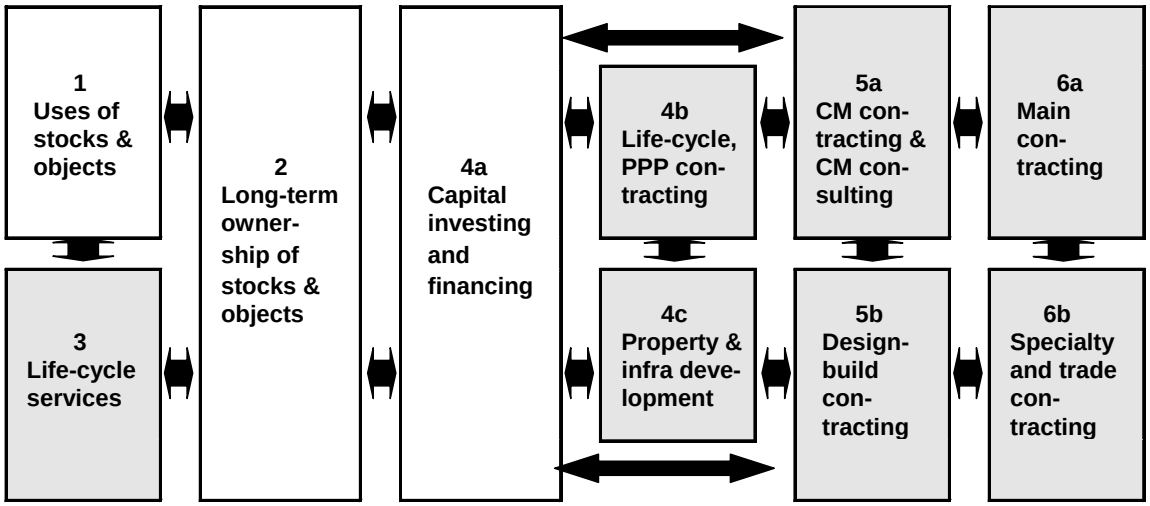

Figure 3: *Implanting of high-sustainability as part of managing of development businesses (in Arenas 4b-c), contracting businesses (in Arenas 5a-b and 6a-b), and life-cycle service businesses (in Arena 3).*

- In design-build contracting businesses (Arena 5b), DB contractors are collaborating with leading designers in order to offer high-quality, high-sustainability, and cost-effective object solutions. Sustainability is one of key drivers for the re-engineering of DB value delivery chains that encompass all tiers of designers, subcontractors, and suppliers. Self-assurance procedures are endorsed.
- In main contracting businesses (Arena 6a) and specialty & trade contracting businesses (Arena 6b), such contractors are planning their dual sustainability management systems that are compatible with their clients' systems (in Arenas 4-5) and their suppliers' systems (in Arenas 7-8). Specialty contractors are improving sustainability that is embedded in their sub-supply chains and the tiers of suppliers.
- In life-cycle services businesses (Arena 3), leading providers are having the in-depth understanding of the types and degrees of the negative and positive impacts of alternative existing and novel solutions on stock-specific and object-specific sustainability, where and when impacts actually occur during each stage. They cultivate intelligence upon how alternative changes made in the particular upstream and downstream stages of life-cycles decrease and even block negative impacts.

In the future, developers ensure their competitive edges by integrating **eco-investing principles** into capital objects and development processes. Likewise, contractors ensure their competitive edges by implanting **eco-contracting principles** into objects as wholes and parts as well as contracting processes (applying Orange 2010).

Typically, **Skanska AB** of Sweden is enhancing green offers for advanced clients. The foundational focus of Skanska Green Business is exclusively on the refurbishment of existing office buildings and it includes green solutions for more energy efficiency. Skanska can cut energy consumption in half in existing buildings. Energy-efficient designs include such features as low-speed, high-efficiency ventilation systems, efficient waste heat recovery systems, the use of district heating and cooling, super-insulated windows, the use of parking facilities as heat sinks in winter, energy-efficient elevators, and low-energy lighting with daylight and occupancy sensors (Fasth 2010).

IMPLANTING ENVIRONMENTAL SUSTAINABILITY INTO ARENAS 6, 5, AND 3 AS PART OF MANAGING DESIGN BUSINESSES

Design firms are choosing their businesses, respectively, from among many alternatives such as societal and urban planning, architectural, feasibility study, engineering, design, consultation, assessment, and inspection services, complemented with programming expertise and software selling, in building and infrastructure sectors within (inter)national contexts. New and under-renovation capital objects are being investigated, designed, and enabled.

The future implanting of high-sustainability into each of (inter)national construction markets will take place **when firms are managing their design businesses in targeted arenas via eight sustainability (S) drivers** as follows (in part applying Fister Gale 2008, 2009) (Fig. 4).

Foresights, visions, and other long views (S1) on sustainable developments up to the years 2030, 2040, and 2050 (and even beyond) are being prepared by specialized teams and experts inside design firms for public and private stakeholders (in Arenas 1-4). Reports contain cross-sectional and longitudinal views on the focal, more or less sustainable states of affairs. Long views are based on the modeling of alternative, causally interrelated developments in societies, built environments and natural environments, resources, and technologies. Thus, design firms deepen their systemic understanding on sustainability in part by collaborating with top universities and research institutes.

Scenarios and forecasts (S2) on more and less sustainable futures are being crafted by teams and experts inside design firms for public and private stakeholders (in Arenas 1-4). Development path dependencies are embedded within each of alternative scenarios on sustainability and paths with milestones leading towards such alternatives. Scenarios are over-viewing the best and worst futures that, in turn, are being guessed by involved stakeholders along the dimensions of sustainability. Forecasts are highlighting likely long- and short-term net changes in sustainability and they are justified by the most recent and historical evidence. In turn, a set of assumptions are underlying each scenario and forecast. Thus, design firms ensure their expertise in part by recruiting both seasoned experts with their deep, tacit knowledge and young talents with their minds open for novel approaches.

Life-cycle knowledge on individual capital objects and object stocks (S3) is being itemized and accumulated inside design firms and then offered as programs and tools for long-term owners, investors, and developers (in Arenas 1-5) in order to enable effective, stock-level sustainability management. Stock-specific programs include criteria for assessing the degrees of sustainability of alternative existing and new objects to be included in focal stocks. Programs include metrics for comparing the life-cycles and stages of each object inside focal stocks. All this is being synthesized into the rating of stock-specific sustainability indexes. Thus, design firms advance their expertise in part by continuous learning about portfolio management, technology platforms, and alike.

Life-cycle knowledge on individual objects (S4) is being systemized inside design firms and then offered as plans and tools for owners and other key stakeholders (in Arenas 2-5) in order to enable effective object-specific sustainability management. Object planning is coupled with tools for taking sustainability into account as part of feasibility analyses, goal-setting, investment management, design management, PM, process management, FM, and other maintenance management. Moreover, pre-structured plans include also the design and rating of pre-planned roles that parties assume from investment ideas to the end of life-cycles

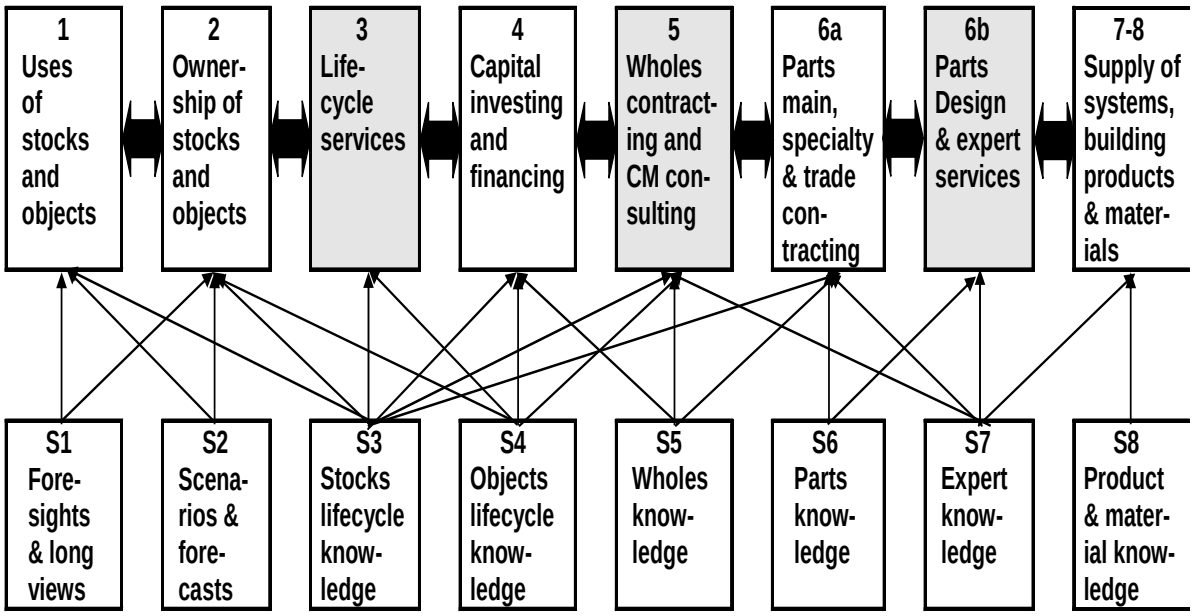

Figure 4: *Implanting of high-sustainability via the eight drivers (S1-S8) as part of managing of design businesses (in Arena 6b), CM consulting businesses (in Arena 5), and life-cycle service businesses (in Arena 3).*

(including reuses). Knowledge covers impacts on environment, biodiversity, fair trade, stakeholder health, and human rights. Thus, design firms also collaborate with and sub-contract external experts in order to master and offer complete knowledge.

Knowledge on wholes (S5) is being cultivated inside design firms and then offered (i) to investors and developers (in Arena 4) who are realizing their objects through single contracts (e.g. PPP, turnkey, design-build, and CM) as well as (ii) to related contractors and CM consultants (in Arena 5) in order to enable effective whole-specific sustainability management. Knowledge on a complex project as a whole and its impacts on communities and environments is a valuable part of avoiding negative impacts, mitigating risks, increasing revenues, and better managing costs. Thus, core design firms extend their expertise bases towards sustainability in CM consulting businesses and managing contracts of wholes.

Knowledge on parts (S6) is being deepened inside design firms and then offered (i) to investors and developers (in Arena 4) who are realizing their objects through multiple part-specific contracts (e.g. trade-based contracts) as well as (ii) to chained contractors and designers (in Arenas 5-6) in order to enable effective part-specific sustainability management. The depth of knowledge on part-specific sustainability is often decisive when parts at hand are being designed and specified. Thus, specialized design firms invest in their own expertise on sustainability. These specialists are also attractive partners in the eyes of other design firms and contractors.

Expert knowledge on sustainability measurement (S7) is being accumulated inside design firms and then offered to contractors, designers, and suppliers (in Arenas 5-8) for the auditing, testing, and verifying the degrees of sustainability as part of the assurance and proving of the conformance or the detection of non-conformance between sustainability

requirements and delivered products and materials. Thus, many design firms specialize towards measurement (and testing) and nourish such hands-on knowledge as part of their total knowledge reservoirs.

Knowledge on systems, structures, products, components, and materials (S8) is being accumulated inside design firms and then offered to suppliers and traders (in Arenas 7-8) and contractors (in Arenas 5-6) in order to enable effective part-specific sustainability management. Technical systems (e.g. elevators, HEVAC systems) consist of structures, products, components, and materials. Part-specific knowledge on sustainability is composed of the three aspects of the making of a particular part, its content, and its use or performance over a life-cycle. Thus, design firms extend and deepen their expertise in order to cover all targeted parts (e.g. components) or they specialize and focus on one or some of them. Specialization is also taking place along the dimension of materials, e.g. sand, concrete, wood, metals, fibers, plastics, glass, and their composites.

In the future, being green and sustainable will mean taking into consideration the entire life-cycles of objects in built environments when designing them. **Eco-intelligence** is a core competency underlying all high-sustainability drivers (S1-S8) in design businesses. When architects, urban planners, and engineers start to utilize the intelligence of natural systems, they can create societal systems, infrastructures, built environments, and single objects that are essentially waste-free and allow nature and societies to successfully coexist (applying Orange 2010).

Typically, **Pöyry Group** of Finland perceives that a sustainable world will not happen by itself. It must be created and new engineering solutions must be developed. This is where Pöyry can contribute and make a real difference by designing realistic and innovative solutions that consider all aspects of sustainability. Pöyry's in-depth expertise extends to the fields of energy, industry (e.g. pulp & paper), urban & mobility and water & environment. The concept of Balanced Sustainability is about improving resource efficiency. This concept involves finding solutions to improve energy, water, material, and supply chain efficiencies while improving overall returns on investments (Pöyry Group 2011).

IMPLANTING ENVIRONMENTAL SUSTAINABILITY INTO ARENAS 7-8, 6, AND 3 AS PART OF MANAGING SUPPLY BUSINESSES

Suppliers and traders are choosing their businesses, respectively, from among many alternatives such as the supply and trading of prefabricated building and infrastructure systems, building products and components as well as construction materials, complemented with life-cycle services, in building and infrastructure sectors within (inter)national contexts. Systems, products, and materials are being delivered for new and under-renovation objects.

The future implanting of high-sustainability drivers into each of (inter)national 8-arena markets in each of respective contexts will take place **when firms are managing their supply businesses in targeted arenas** as follows (in part applying Fister Gale 2008) (Fig. 5):

- In system supply businesses (Arena 7a), the keen understanding of sustainability is prevailing across suppliers' organizations and supply chains. Cradle-to-cradle (C2C) and similar certifications indicate truly that all human and environmental health

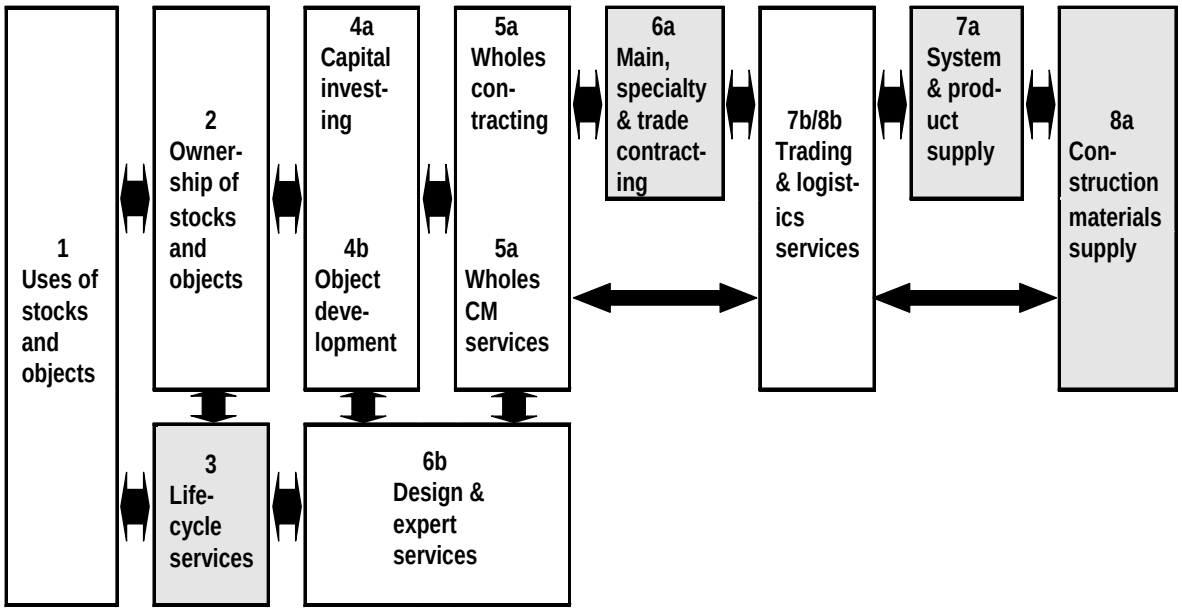

Figure 5: *Implanting of high-sustainability as part of managing of supply businesses (in Arenas 7a and 8a) complemented with contracting businesses (in Arena 6a), and life-cycle service businesses (in Arena 3).*

criteria are being constantly monitored to ensure that materials-based systems are not harmful and that elements can be recycled, remanufactured, or composted. Often this means getting all members in supply chains to agree on changes in their ways of making products and giving system managers access to their product formulas.

- In building product supply businesses (Arena 7a), C2C certifications are forming foundations that, in turn, have to be realized by choosing viable materials together with secondary and tertiary suppliers and by engaging such suppliers with product assemblers' own sustainability vetting processes. In addition, pioneering product suppliers are creating advantages in terms of using sustainable processes and raw materials, offering sustainable packaging, providing more energy-efficient and less polluting products, minimizing energy consumption, advertising environmental impacts, and engaging in product stewardship by taking back products after the ends of their lives.
- In construction material supply businesses (Arena 8a), C2C certifications are likewise prevailing. In particular, material suppliers are training their organizations to participate clients' sustainability programs, e.g. by analyzing, compiling, and handing over lists that cover each ingredient, chemical, etc. Non-disclosure agreements are being signed in the case of proprietary ingredients.
- In main, specialty, and trade contracting businesses (Arena 6a), suppliers are diversifying their core businesses into contracting businesses along their respective parts of supply. New kinds of part-centered (e.g. system-centered and product-centered) contractors become fully responsible for the conformance of their parts' contents and quality, their local assembly or erection operations at sites, and the performance and use of their parts over life-cycles, respectively. Pioneering suppliers are overcoming hurdles for such entries by competency acquisitions, training, piloting, etc.

- In life-cycle service businesses (Arena 3), suppliers complement their core businesses with in-depth services that are based on the understanding of life-cycles of focal parts consisting of systems, products, components, and materials, respectively. Such suppliers are selling their knowledge on sustainability and providing their services for extending the life-cycles of their own or similar offerings in highly sustainable ways. For some parts and sub-parts (and their suppliers), the highest sustainability-increasing or -decreasing impacts occur in the extraction of raw materials. For others, major impacts occur during use and disposal.

In the future, it seems that suppliers and their value and sustainability adding supply chains will involve materials that are perpetually circulated and, once used, can be disposed of in any natural environment and decompose into the soil. Instead of ending up in a landfill, systems, products, components, and materials can be circulated in endless cycles. For suppliers and traders, thinking in terms of cradle-to-cradle design, versus cradle-to-grave design, can be revolutionary. Typically, pioneering **wholesalers and retailers** as gatekeepers will launch market-wide ratings and labeling systems that survey suppliers about their ecological footprints and score building products and construction materials based on how environmentally and socially sustainable they are (applying Orange 2010).

In turn, **internationally leading suppliers** will adopt the toughest external and internal common norms because this actually allows them both to gain leaderships and to save money. Internally, the enforcement of a single norm at a supplier's all manufacturing units allows to exploit economies of scale and to optimize supply chain operations (applying Nidumolu et al. 2009).

Typically, **KONE Elevators** of Finland is seriously responding to a fact that elevators and escalators can account for 2-10% of a building's energy consumption. KONE wants to be the innovation leader in eco-efficient solutions for its industry. Great potential is seen in further reducing the impacts of buildings on natural environments by offering innovative and energy efficient solutions. In the year 2009, KONE released a range of elevators which reduced energy consumption by 30% compared to its previous volume models. KONE is annually re-setting more demanding targets in terms of improving the energy-efficiency and the eco-efficiency over the life-cycles of its products and minimizing its operational carbon footprint (KONE 2010).

CONCLUSIONS

It is herein suggested that **pioneering firms and other key stakeholders** adopt the theoretical, 8-arena framework in order to foresee, envision, set realistic aims, and also attain these aims vis-a-vis the realization of high environmental sustainability across (inter)national businesses, built environments, capital investment sectors, and construction markets at desired future points in time.

In turn, this author is planning to conduct **a series of empirical investigations in order to validate the 8-arena framework and the novel to-be-implanted high-sustainability drivers** concerning leading firms in each of the four primary businesses with targeted (inter)national contexts. Besides, other interested researchers and parties may use the 8-arena framework as **a diagnostic tool** for assessing the current and future degrees of environmental sustainability in focal contexts and preparing their recommendations to key private and public

stakeholders for the enhancement of respective businesses and competitive arenas in highly sustainable and effective ways in the future.

In practice, **the market-wide implanting** of one or several high-sustainability drivers into the eight competitive arenas needs to be planned so that each implanting event corresponds to a focal (inter)national context in terms of current higher and lower degrees in sustainability versus the targeted higher degrees, local environments, owners and investors with their life-cycle preferences, investment programs, and procurement strategies, firms with their sustainable, competitive rationales as well as other private and public stakeholders with their development agendas, legislations, and supporting roles.

So far, most difficulties in **actual sustainability advancements** can be traced down to the fundamental errors of focusing on parts - like energy saving technologies in the case of transiting from fossil-fuel economies to clean-tech economies - rather than on built environments, sectors, markets, and causally routed arenas as a whole. Besides sustainable technologies, many innovative business models, market adoption strategies, and government policies will be needed. A case in point, **the Masdar Initiative** was launched in Abu Dhabi in the year 2006 in order to develop a clean-tech sector and to realize **the world's first carbon-neutral city**. It is too early to say whether Masdar will be successful (Johnson and Suskewicz 2009). Indeed, it is herein perceived that the concept of City of Masdar corresponds well to the adoption of the 8-arena framework for any market-wide or sector-wide renewal and implanting process. Their 5-dimensional business model includes (i) sectoral and area development, (ii) high-sustainability investing in new technologies and solutions, (iii) the design and supply of new systems and products, (iv) carbon strategy development and realization, and (v) sustainability focused university-level research and education.

Finally, it seems that pioneering business management teams keep expanding their expertise by **cross-partnering** between developers, contractors, design firms, and suppliers not to talk about other stakeholders that have in-depth or extensive knowledge on sustainable built environments. Aligning with Senge (Prokesh 2010), it would perhaps be more effective to focus on managing in hands-on, environmentally non-harmful ways - and at the same time to use the word "sustainability" as little as possible because it is too generic.

MANAGING OF CONSTRUCTION-RELATED BUSINESSES IN ENVIRONMENTALLY SUSTAINABLE WAYS - A FOCUSED REVIEW OF 62 CONCEPTS

Pekka Huovinen, Aalto University, Strategic Management in Construction
Finland
Pekka.Huovinen@aalto.fi

Abstract
The on-going literature review has revealed a platform of the 62 construction-related business management (BM) concepts, published mainly via the journals between the years 1990-2009. The aim of this paper is to enhance the managing of construction-related businesses in highly environmentally sustainable ways. A focused review resulted in the expected findings, i.e. environmental sustainability is so far being taken into account only by the 8 (13%) BM concepts within the 62-concept population. Academic and practicing concept designers can incorporate sustainability into BM concepts as a dimension, an element, an attribute of managing, and/or a criterion in business decision making. In turn, sustainability is herein enhanced by designing a 5-element, high-sustainability BM concept. The five pioneering firms are used to highlight sustainable elements such as offerings with no negative impacts, business processes with minimal carbon footprints, core competitiveness nurturing based on sustainability foresights, business framing with high-sustainability rules, and dealings with sustainable collaborators. CIB related researchers can both individually and jointly incorporate sustainability in their existing and new BM concepts. It is envisioned that this reviewer be able to report on higher sustainability in managing by the year 2015.

Keywords: business management, construction, design, literature review, sustainability

INTRODUCTION

The background involves **the on-going literature review** that has revealed the 62 construction-related business management (BM) concepts, published mainly via the journals between the years 1990-2009 (e.g. Huovinen 2010). The reviewer argues that **BM is the most challenging, evolving, and critical area (or level) within strategic management** both in general and across various private and public contexts (Huovinen 2003). Herein, **built environments** are seen to be coupled with capital investment, real estate, and construction markets that deal with design, implementation, services, and life-cycle aspects of both existing object stocks and investments in new objects across the utilization of natural resources, energy supply, telecommunications, transportation, other infrastructure, manufacturing, and general building concerns. Later, the term **"construction markets"** is used to encompass all these built environments and concerns.

The main aim is to enhance the managing of construction-related businesses in highly environmentally sustainable ways in the future. The three sub-aims are as follows. (i) The unique review of a population of 62 construction-related BM concepts, published mainly via journals between the years 1990-2009, is briefly introduced. This reviewer explores especially **the degrees of environmental sustainability** that the authors have incorporated inside each of their respective BM concepts. Next, the key finding is being told for the sake of the setting of a meaningful, second sub-aim. Namely, this focused review reveals that only 1 (2%) BM concept deals with sustainability to a medium degree and 7 (11%) BM concepts take sustainability into account to a low degree.

In other words, it seems that the existing construction-related BM concepts are not advancing sustainability. Thus, (ii) **an exemplary, 5-element, high-sustainability BM concept** is being designed in this paper. Each element is illustrated with the pioneering action of a globally leading firm in its targeted construction markets. Finally, (iii) some future actions are put forth in order to enhance high-sustainability BM in the contexts of built environments.

62-CONCEPT PLATFORM AND EIGHT SCHOOLS OF THOUGHT ON BM

The review consists of **the three review rounds** that have been carried out in the years 2003, 2006, and 2010. The same limitations have been re-adopted to maintain the validity and to expose any major developments. Hart's (1998) literature review **guidelines** have been relied upon. The method for the reviewing of conceptual literature, i.e. the replicable ways of searching, browsing, in-/excluding, retrieving, inferring, moderate coding, describing, and analyzing the construction-related conceptual data is introduced in Huovinen (2003, 2006).

The volumes of **the 20 construction-related journals** (1990-2009) and those of **the 42 management journals** (1990-2008) have been browsed comprehensively. This is so because peer reviewers apply the most rigorous criteria when they are pre-reviewing manuscripts for publishing in scientific journals. Otherwise, the degrees of the comprehensiveness of the search has varied markedly via the other formal channels, i.e. (i) generic and construction-related management books and reports, (ii) chapters in edited, generic and construction-related management books, (iii) generic and construction-related management journals, (iv) generic and construction-related management conference proceedings, and (v) generic and construction-related management databases. This author will submit the itemized lists of all the publication channels on request.

In this short paper, the 62-concept population can only be overviewed in terms of the following three questions. **Question 1. What is the relatedness of the 62 concepts to one or several of eight schools of thought on BM?** Generic BM research involves the eight schools of thought: (1) Porterian school, (2) resource-based school, (3) competence-based school, (4) knowledge-based school, (5) organization-based school, (6) process-based school, (7) dynamism-based school, and (8) evolutionary school (Huovinen 2008). During the three review rounds, each of the BM concepts could be assigned to one of the eight schools based on the authors' rationales and replies to the question "What is the primary way (element) of managing that will enable managers to set challenging business goals and also to attain them?", within their root references. The combined share of 15 Porterian concepts, 14 organization-based concepts, 10 knowledge-based concepts, and 10 dynamism-based concepts is 79%. Overall, none of the schools (and their key generic concepts) has triggered a coherent, published flow of construction-related BM concepts or applications. The temporal pattern is emerging and fragmented. Only the 10 (16%) new concepts have been published via the journals between the years 2006-2009 (Table 1). **Question 2. What is the relatedness of the 62 construction-related BM concepts to one or several applied scientific fields?** 32 (52%) concepts are primarily related to construction management, 11 (18%) concepts are related to project management, 11 (18%) concepts are related to corporate real estate services, and 8 (13%) concepts are related to industrial management and international marketing. Overall, no established research traditions or groups exist in the area of construction-related BM. Only 7 (11%) concepts have been designed by the authors who are affiliated with the business schools. Clearly, construction is outside the interests of generic management researchers vis-à-vis alternative contexts and application areas.

Table 1: *Relatedness of the 62 construction-related BM concepts (published between the years 1990-2009) to the eight schools of thought (Huovinen 2010).*

School of thought on BM	Concepts published btw 1990-2002 (1st review)		Concepts published btw 2003-2005 (2nd review)		Concepts published btw 2006-2009 (3rd review)		All concepts	
	No.	(%)	No.	(%)	No.	(%)	No.	(%)
1 Porterian school	11	(29%)	0	(0%)	4	(40%)	15	(24%)
2 Resource-based school	1	(3%)	0	(0%)	0	(0%)	1	(2%)
3 Competence-based school	3	(8%)	0	(0%)	2	(20%)	5	(8%)
4 Knowledge-based school	7	(18%)	3	(21%)	0	(0%)	10	(16%)
5 Organization-based school	9	(24%)	4	(29%)	1	(10%)	14	(23%)
6 Process-based school	0	(0%)	4	(29%)	3	(30%)	7	(11%)
7 Dynamism-based school	7	(18%)	3	(21%)	0	(0%)	10	(16%)
8 Evolutionary school	0	(0%)	0	(0%)	0	(0%)	0	(0%)
Sum	38	(100%)	14	(100%)	10	(100%)	62	(100%)

Question 3. For what primary contexts, i.e. industries, businesses, or sectors have the authors designed their 62 concepts, respectively? 21 (34%) concepts address construction or building, 21 (34%) project-based business, contracting, complex product systems, or combined engineering, purchasing, and construction (EPC) projects, 10 (16%) real estate development and services, and 5 (8%) capital investments-based businesses, 4 (6%) design and consulting services, and 1 (2%) building products supply.

ASSESSED DEGREES OF SUSTAINABILITY INSIDE THE 62 BM CONCEPTS

In general, OED (2011) defines **sustainable** "to be capable of, relating to, or designating forms of human economic activity and culture that do not lead to environmental degradation, especially avoiding the long-term depletion of natural resources". Herein, **sustainability in construction-related BM** is defined to encompass the utilization and development of natural resources in ways which are compatible with the maintenance of these resources, and with the conservation of the natural and built environments, for current and future generations (applying OED 2011). Sustainability calls for incorporating environmental and green concerns into business level management, but sustainability is causally also related to bottom lines and social issues. Similarly, project level management is - along managing contract, quality, schedule, and budget issues - considering how every project (or capital investment object) will impact communities, environments, and businesses (applying Fister Gale 2009).

In this paper, sustainability is approached according to the above mentioned definitions. For the focused review, **the four degrees of environmental sustainability** were pre-defined as follows. A particular BM concept may take environmental sustainability into account to:

- a high degree, i.e. sustainability is one of the primary elements along one, several, or all dimensions of BM such as a business goal, a key attribute of offerings, competitive

advantages, and strategies as well as an edge of competitiveness and a key performance indicator of business processes, organizations, project portfolios, etc.

- a medium degree, i.e. sustainability is one of the supportive elements along one, several, or all dimensions of BM
- a low degree, i.e. sustainability is only an implicit part of a firm's offerings and underlying expertise in built environments and/or it is taken into account only as one requirement or tendency in clients' buying behavior, one criterion in stakeholders' decision making, one factor in environmental analyses, etc.
- no degree, i.e. the authorship is silent vis-a-vis environmental sustainability, no single 'thing' is explicitly written along this dimension in the reference.

Overall, this sub-review revealed that only 1 (2%) BM concept deals with sustainability to a medium degree and 7 (11%) BM concepts take sustainability into account to a low degree. No high-sustainability BM concepts belong to the 62-concept population. **The concept-specific results** are compiled in Tables 2-8, by each of the 7 schools of thought on BM (there are no construction-related, evolutionary BM concepts). Within these tables, the identified, original terms are quoted. When such a quotation is coupled with a statement "no degree", this implies that the authors are using, respectively, the terms sustainable, sustainability, environment(al) only in the spheres of strategic, business, and project management or real estate development. Therein, sustainability refers to the continuity of a focal firm, unit, or other entity and environments refer to business environments and work environments. The references in the text refer only to the authorship and its BM concept presented in the respective, resultant tables. This reviewer will submit a complete list of the 58 references containing a population of the 62 construction-related BM concepts on request.

Only one dynamism-based, construction-related BM concept is taking sustainability into account, but to a medium degree as follows (Table 5). **Chinowsky with Meredith (2000)** have defined the seven areas of a firm’s strategic management within a feedback framework (wheel) including (1) vision, mission, and goals, (2) core competencies, (3) knowledge resources, (4) education, (5) finance, (6) markets, and (7) competition. Within a civil engineering organization, these strategic management activities are a process to ensure that a constant focus is retained on the core purpose of existence. The framework allows leaders to formulate strategic concepts. In particular, they emphasize that re-examining a firm’s strengths requires a move beyond the thoughts of current, short-term profit centers, to a focus on the objectives the organization can potentially achieve over a sustained period of time and effort. Leveraging human resources into core strengths along a competency spectrum provides an organization with confidence, knowledge, and abilities to pursue objectives with the greatest possibility to succeed. **A medium degree** of sustainability is incorporated as (i) a firm's environmentally sensitive core designs that are based on many support strengths and, in turn, (ii) core designs enable the design of project-specific solutions. (iii) Environmental engineering is one of the surface characteristics of core competencies. (iv) An environmental area is designed as one of a firm's knowledge areas. (v) Environmental testing is listed as a competency (Chinowsky with Meredith 2000: 130, 142, 146).

Among the 15 Porterian BM concepts, there are two low-degree concepts (Table 2). **Veshosky (1995)** has used Porter’s (1980/1998) generic competitive strategies as a basis for developing an analytical framework and applying this to the design segment of the A/E/C industry in the USA. The content and use of the cost leadership, the differentiation, and the focus on a niche have been elaborated. He has concluded that the formulation and implementation of explicit business strategies appear likely to be superior to strategies that

occur by default. **A low degree** of sustainability is indicated as environmental systems and facilities among a firm's project types as well as core competencies for managing hazardous waste (Veshosky 1994: 43-45). In turn, **Huovinen (2001)** has designed a competitive strategy framework for technology-intensive contractors. It is based on the idea of creating the best fit between the primary decision maker, i.e. the focal investor with its need and investment process and the most competent contractor with its solution and delivery process. The framework consists of four areas: (a) business scope and objectives, (b) marketing and sales, (c) investment solution, and (d) contract fulfilment. **A low degree** of sustainability is designed as one of clients' decision making criteria, i.e. environmental impacts are taken into account when choosing winning solutions or bids (Huovinen 2001: 73).

Among the 14 organization-based BM concepts, there are two low-degree concepts as well (Table 3). **Flanagan (1994)** envisioned that, by the year 2000, a successful construction company will have many desired features of a service provider, i.e. flat, lean, quick to respond to change, IT intensive, expert resources (lockers), shared design skills (by chambers), marketing intensive, more global in outlook, i.e. acting locally but thinking globally, alert to financing issues, involved in project creation, complex as well as technologically sensitive and driven. **A low degree** of sustainability is designed as follows: (i) Environmental consciousness and sustainability are among the 11 forces that drive strategies, (ii) in design, external impacts on surroundings, e.g. energy, traffic, waste, and ecology are becoming more important, and (iii) successful companies are concerned about the environment and the community (Flanagan 1994: 312, 316, 318). In turn, **Huovinen and Hawk (2003)** have designed a collaborative client-supplier relationship model for globally operating building product suppliers. **A low degree** of sustainability is implanted as a product's environmental impacts among the 11 decision making criteria that clients use for choosing winning bids (Huovinen and Hawk 2003: 158).

Among the 10 knowledge-based BM conceps, there is only one low-degree concept (Table 4). **Love et al. (2002)** have introduced a model for long-term learning alliances, total quality management (TQM), and integrated supply chains in construction. One of the sub-models consists of systems thinking, learning culture, knowledge and communication, changing mental models, joint learning structure/processes, and the development of learning relationships. A long-term learning alliance improves the ability of staff, i.e. to become more productive and less likely to make mistakes. One of the goals is to attain a successful project that can enhance the reputations of all parties. **A low degree** of sustainability is designed as taking into account the ethical consideration of the social and environmental responsibility in such cooperative alliances (Love et al. 2002: 12).

Among the 7 process-based BM concepts, there is only one low-degree concept (Table 6). **Anderson and Merna** (2005) have designed a framework for managing new business development processes in the case of firms offering project management services. **A low degree** of sustainability is implanted as environmental management among the 11 domains of development (Anderson and Merna 2005: 175). Among the 5 competence-based BM concepts, the assessment resulted in identifying no degrees of sustainability (Table 7). Instead, sustainability is being taken into account to a low degree within the only resource-based BM concept (Table 8). **Lowendahl (1997/2000)** has designed the three generic strategies, the four resource types, the four dimensions for resource-based differentiation, and the three phases in the evolution in the case of professional service firms. **A low degree** of sustainability is indicated as environmental protection among alternative targeted markets (Lowendahl 1997/2000: 106).

Table 2: *Assessed degrees of sustainability inside the 15 Porterian, construction-related BM frameworks, published between the years 1990-2009 (the 1st school).*

Author (year)	Applied concept and its focal context	Assessed degree of sustainability based on the key quotations (page number)
Betts, Ofori (1992)	Applying Porterian concepts in construction firms in the UK	No degree, "sustainable strategies" and "business environments" are mentioned.
Winch, Schneider (1993)	2x2 matrix: strong delivery, experience, ideas, ambition in UK architectural practices	No degree, "competitive environments" is mentioned.
Veshosky (1994)	Analytical, applied framework for the design segment of the A/E/C industry in the USA	**Low:** Environmental systems (43) and facilities (44) as project types, hazardous waste related to core competencies (45).
Jennings, Betts (1996)	New generic strategy model to UK quantity surveying practices with IT support	No degree, "external environments surrounding business arenas" and "sustain-able competitive advantages" are mentioned.
Roulac (1999)	Real estate value chain as part of development in the USA	No degree, "environment is essence of experience and creativity" is mentioned.
Roulac (2001)	8 strategies, 7 contributions to advantages in the US real estate	No degree, "work environments enhance productivity" is mentioned.
Pinto et al. (2000)	Project supplier's value chain	No degree
Huovinen (2001)	Competitive strategy in technology-intensive contracting	**Low:** Solutions' environmental impacts as one of clients' decision making criteria (73)
Langford, Male (2001)	Adapted 5 forces shape the UK industry structure	No degree, "relationships between firms and environments" is mentioned.
Rapp (2001)	Adapted 5 forces (incl. speedy response) and a client value chain in the US construction	No degree, "environmental opport-unities and threats as part of a SWOT or 5 forces analysis" is mentioned.
Kale, Arditi (2002)	Mode (cost, quality, time, inno-vation) and scope (geography, delivery systems, clients) in the US construction industry	No degree, "environmental determinism vis-a-vis explaining firm performance " is mentioned.
Milosevic, Srivannaboon (2006)	Framework for aligning PM and a firm's business strategy in US engineering, industrial firms	No degree
Singer et al. (2007)	Model for combining real estate and competitive strategies in Dutch multinational companies	No degree, "work environments that stimulate productivity" is mentioned.
Chiang et al. (2008)	Volume building strategy of contractors in Hong Kong	No degree, "sustainable sources of competitive advantages" is mentioned.
Heywood, Kenley (2008)	Sustainable competitive advantage model for corporate real estate in Australia	No degree, "sustainable competitive advantages and competitiveness" and "environmental changes" are mentioned.

Table 3. *Assessed degrees of sustainability inside the 14 organization-based, construction-related BM concepts, published between the years 1990-2009 (the 5th school).*

Author (year)	Applied concept and its focal context	Assessed degree of sustainability based on the key quotations (page number)
Leinberger (1993)	Managerial systems change strategy in the US real estate	No degree
Flanagan (1994)	Successful construction company in the year 2000 (based in the UK)	**Low:** Environmental consciousness and sustainability are among 11 forces that drive strategies (312). In design, external impacts on surroundings, e.g. energy, traffic, waste, ecology) are becoming more important (316). Successful companies are concerned about the environment and the community (318).
Artto (1999)	Organizational model for PM in a project-oriented company	No degree, "multi-project environments" is mentioned.
Bennett (2000)	7 partnering pillars balance competition and cooperation in the UK construction industry	No degree, "companies that survive long-term" and "networks interact with their environments" are mentioned.

DESIGN OF A HIGH-SUSTAINABILITY CONCEPT FOR MANAGING BUSINESSES IN CONSTRUCTION-RELATED CONTEXTS

In general, Nidumolu et al. (2009) advocate that pioneering business managers in their various contexts adopt **a generic, 5-stage process** for becoming sustainable, i.e. (i) viewing compliance as opportunity, (ii) making value chains sustainable, (iii) designing sustainable products and services, (iv) developing new business models, and (v) creating next-practice platforms.

For the management of businesses in construction-related contexts, environmental sustainability is herein incorporated as the primary sub-elements into a BM concept (applying Huovinen 2002). It is proposed that the successful management of a business in a construction-related context be based on the adoption of **a 5-element, high-sustainability business system**. The two elements through which a viable firm interacts with its competitive offering markets are redefined first, then the three more internal elements follow (Figure 1).

Offerings and competitive strategies with no/low negative impacts on environments
A firm advances its competitive strategies and offerings (the front-line element 1) in order to offer the best solutions to targeted clients and managing all the contracts to be won for high client satisfaction, the highest degrees of sustainability, and high firm profitability. By definition, **offerings with no/low negative impacts** enable a firm to pre-empt or over-satisfy client needs, excel among competitors, and meet its business-specific, high-sustainability goals in the short term. In practice, the valuable knowledge on sustainability needs to be recreated on a continuous basis and then differentiated into strategies and customized into offerings. Typically, the top management of **KONE Elevators** of Finland is aware of a fact that elevators and escalators can account for 2-10% of a building's energy consumption. KONE wants to be the innovation leader in eco-efficient solutions for its global industry. A great potential is seen in further reducing the impacts of buildings on the environment by offering innovative and energy efficient solutions. In the year 2009, KONE released a range of elevators which reduce the energy consumption by 30% compared to the previous volume models (KONE 2010).

Business processes with minimal carbon footprints
A firm integrates its business processes (the process element 2) to ensure the targeted level of operative effectiveness. In practice, a firm’s business processes and contract tasks are managed as a dynamic, IT-supported matrix where teams play integrative, flexible roles. By definition, **business processes with minimal carbon footprints** allow a firm both to ensure and to increase the targeted effectiveness across contracts to be won. In practice, generic and contract-specific, high-sustainability knowledge needs to be integrated and virtualized before leveraging it into a firm's processes. Typically, **the top management of HOCHTIEF** of Germany has itemized a set of the goals for cutting carbon emissions together with their clients in the area of active climate protection such as (i) cutting company carbon emissions in Germany and the UK by 5.0% by the year 2011 by lowering office power consumption (2008 base year), (ii) cutting Turner's (the subsidiary's) carbon emissions in the USA by 5.0% in the next five years (2006 base year), (iii) switching the major office locations in Germany fully over to green power, (iv) offering green power to construction sites, and (v) cutting business trips by 2.5% by the year 2011 through the greater use of communication technologies (HOCHTIEF 2010). In turn, **KONE** is annually re-setting more demanding targets in terms of improving the energy-efficiency and the eco-efficiency over the life-cycles of its products and minimizing also its operative carbon footprint (KONE 2010).

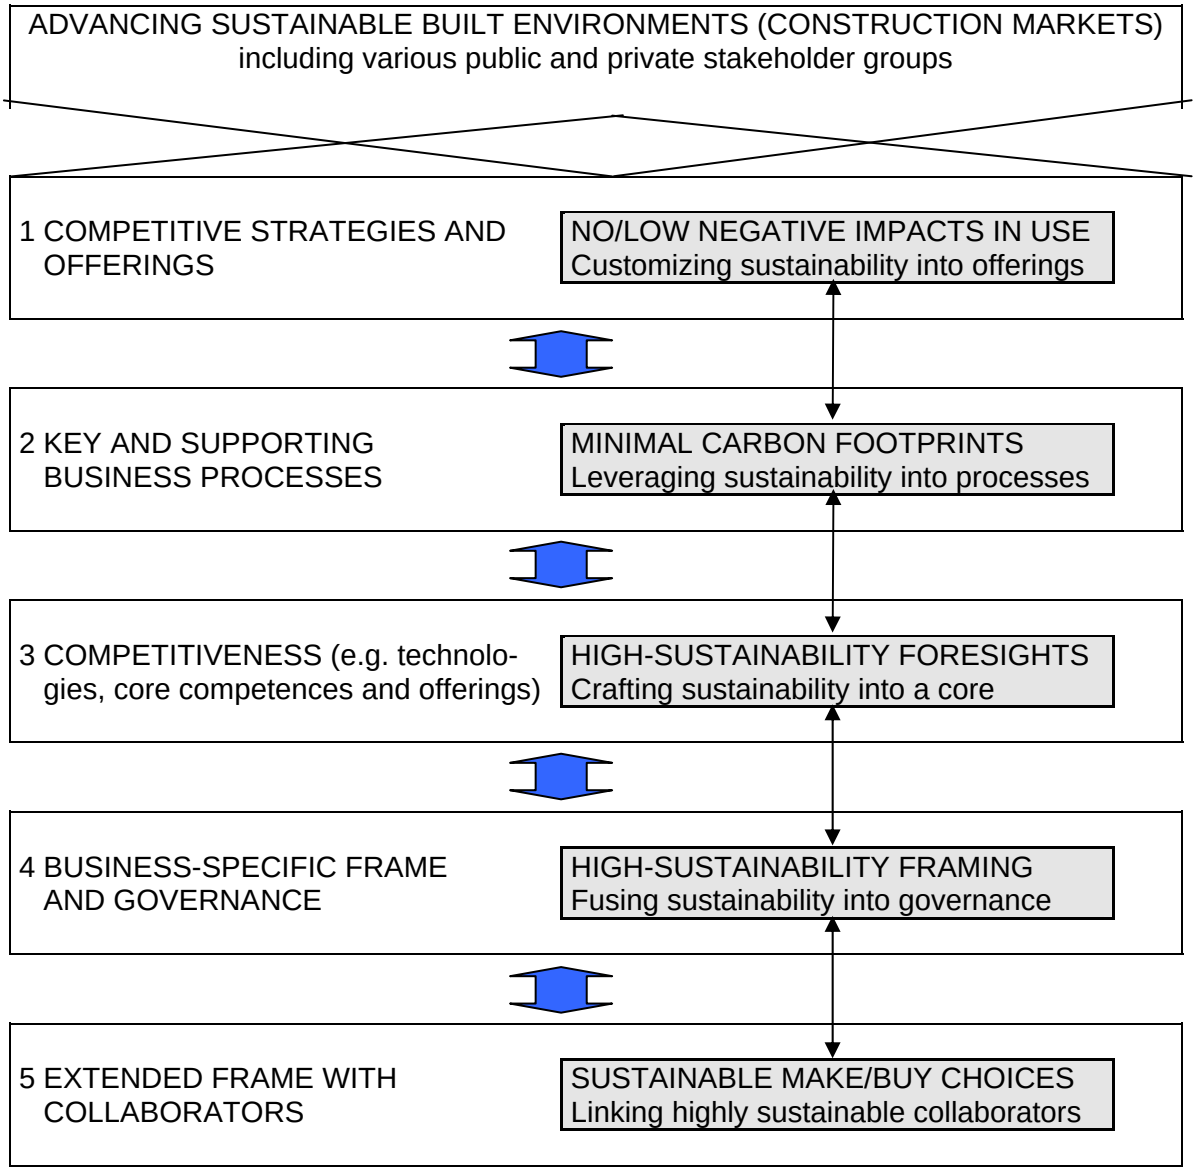

Figure 1: *Management of a 5-element business in high-sustainability ways vis-a-vis the advancement of built environments across the globe (applying Huovinen 2002: 336).*

Core competitiveness based on high-sustainability foresights

A firm nurtures its core technologies, competences, and offerings (the back-end element 3) in order to create competitive advantages and to prolong the current edge as long as possible. By definition, **a firm's competitiveness** is being nurtured based on its high-sustainability foresights that involve business opportunity perceptions, technology foresights, a technology platform, a core competence architecture, a core offering portfolio, and innovation paths. In practice, such foresightful knowledge on sustainability needs to be acquired or invented, rechecked continuously, and then comprehended before crafting it into technologies, core competences, and offerings. Typically, **Pöyry Group** of Finland perceives that a sustainable world will not happen by itself. It must be created and new engineering solutions must be developed. This is where Pöyry can contribute and make a real difference by designing realistic and innovative solutions that consider all aspects of sustainability. Pöyry's in-depth

expertise extends to the fields of energy, industry (e.g. pulp & paper), urban & mobility and water & environment. The concept of Balanced Sustainability is about improving resource efficiency. It involves finding solutions to improve energy, water, material, and supply chain efficiencies while improving the overall return on investments (Pöyry Group 2011).

High-sustainability framing and governance of a firm's businesses

A firm frames each of its businesses both externally and internally (the frame element 4) in order to optimize each business system's (unit's) existence and outcomes that add value to business performance and firm shareholding. The framing takes place along an inter-dependent set of legal, financial, venturous, organizational, institutional, social, and sustainable dimensions. By definition, **a high-sustainability framing** covers firm ownership, top management, business venturing, financing, and the preferred ways of firm-market interactions. In practice, knowledge on sustainability needs to be self-produced or bought, and then updated many times before it is fused into owners' and top management's decisions on business scopes. Typically, the top management of **Skanska AB** of Sweden is leading their corporation in order to be best-in-class regarding margins, the safest firm in the industry, and the leading "Green construction and development company" in the year 2015. The new business plan for 2011-2015 outlines the green future for Skanska (Karlström 2010).

Extended, business-specific frames with sustainable collaborators

A firm's extends its business-specific frames by engaging itself in collaboration (the extended frame element 5) with various domestic, foreign, global, and local stakeholders. The extent and depth of each collaborative relationship vary according to business-affecting goals agreed upon between parties. Forms include partnerships, networking, and similar new forms of physical and virtual collaboration in the long term. By definition, **sustainable collaboration** includes the synergistic ways of make/buy choices, opportunity exploitation, benefit balance, and risk avoidance. In practice, this (originally tacit) internal knowledge on sustainable collaboration is first explicated and documented before it can be exchanged between one, more, or all elements within collaborators' business systems. Typically, **Nokia Siemens Networks (NSN)** is positing that environmental leadership can be a differentiator for their customers, i.e. farsighted operators who are prepared to reduce energy usage, to improve network and system designs, and to create environmental sustainability for the entire business. In turn, NSN takes a holistic approach to environmental performance over product lifecycles. NSN foresees that the adoption of environmentally sustainable business strategies requires an overhaul of each "old way" of doing things. NSN integrates environmental issues into procurement processes. NSN is encouraging its networked suppliers to take a full environmental responsibility for their operations. NSN ensures that its suppliers embrace sustainable practices. Supplier and collaboration agreements include specific requirements such as using a documented environmental management system, meeting standards for raw materials content, and monitoring the environmental performance (NSN 2008).

CONCLUSIONS

Concerning interested researchers, it is suggested that **high-sustainability BM concepts be advanced** so that they meet the following criteria in terms of serving as (a) a foundation of a meaningful communication vis-a-vis environmental sustainability, (b) a perspective or a way of looking at the empirical BM world related to construction markets and built environments, (c) a means of classifying and generalizing sustainability-focused BM situations, e.g. stating the conditions when the management's (and other key stakeholders') efforts are likely to be

successful and those conditions under which their efforts are likely to be carried out in vain, and (d) a component of a theory or a model and thus of an explanation, prediction, and prescription for high-sustainability BM in construction-related contexts (applying Ghauri and Gronhaug 2002). In particular, CIB related researchers are herein encouraged to incorporate environmental sustainability in their existing and new BM concepts through joint and individual efforts in the future. In turn, this author will follow up the emergence of both generic and construction-related BM concepts on an annual basis. It is envisioned that higher sustainability vis-a-vis business managing can be reported upon already by the year 2015.

Concerning practicing business managers in construction-related firms, some recommendations are put forth so that managers take into account **high-sustainability throughout all business transactions** in terms of (i) envisioning the preferred states and ways of managing environmental sustainability issues, e.g. in the years 2015 and 2020, (ii) embedding high-sustainability into the setting of business goals, (iii) incorporating high-sustainability into BM thinking as a major decision making criterion, and (iv) adding the minimization of negative impacts on natural and built environments onto dual agendas for business performance enhancement and competitiveness development.

SYSTEM INNOVATION FOR SUSTAINABLE BUILT ENVIRONMENTS: THE CASE OF LIGHT EMITTING DIODES

SHULING LU
School of Construction Management and Engineering, University of Reading
Whiteknights, Reading, Berkshire, RG6 6AW, United Kingdom
s.lu@reading.ac.uk

Abstract
The United Kingdom (UK) government policy is increasingly directed at transforming the built environment to an environmentally sustainable one. The government, for example, has set a target for a reduction in carbon emissions by 80% by 2050 compared to 1990 levels. A large number of new policies and regulations are being introduced to minimise the impact of the built environment and the construction industry on the environment. These pressures are inducing a large amount of product and process innovation across distributed networks: manufacturers, suppliers, installers, clients, users, and so on. To address this challenge, this research suggests that the explicit adoption of a multi-level perspective of sustainable transition management as a way forward. The key point of the multi-level perspective is that transitions or long-term changes come about through interplay between processes at different levels in different phases. This model consists of three levels: socio-technical landscape, regime, and technical niches. This paper reports on an ongoing research project which is tracking, real time, the start-up and growth of a company which is developing and introducing a range of leading edge light emitting diode (LED) technologies. Interim results will be presented with the focus being on the distributed interaction between the principal actors: a LED module manufacture, a luminaire (light fitting) manufacture and a range of end users.

Keywords: High technology, light emitting diodes (LEDs), multi-level perspective, system innovation

INTRODUCTION

The United Kingdom (UK) government policy and regulation is increasingly directed at making buildings far more environmentally sustainable. A key source of environmental burden from buildings is lighting, which accounts for around 20% of the UK's energy consumption (Climate Change Act 2008; Carbon Trust, 2007a). The future consumption trend is upward, despite improvements in energy efficiency per lumens output. Projections indicate that the "global demand for artificial light will be 80% higher by 2030" (IEA, 2006: 26) and that particular "energy demand for domestic lighting … [will] … double between 2005 and 2030" (IEA, 2010: 14). The shift to more sustainable consumption patterns is not solely a technical matter; rather, it involves myriad changes in the institutional context, as well as the design, operation and use of lighting at building and urban levels. But appropriate technological innovation to develop more environmental sustainable lighting technologies is central to any credible, long-term effort to improve the situation. The current situation, for example, is one where "of the 628 million lamps installed in UK homes, around 60% use inefficient tungsten filament technology" (DEFRA, 2008: 7).

Light emitting diodes (LEDs) are poised to make a significant contribution to carbon reduction (BIS and DECC, 2009: 47) and "appear to have the greatest scope for improvement and may yet transform the global lighting market" (IEA, 2006: 42). This resonates with the Ad-hoc Advisory Group (2008: 12) which stated that, potentially, more than 50% of the electrical energy could be saved per year in the near future by switching to LED lighting.

LEDs are solid-state semi-conductor devices that produce light. LED technology has significant functional and environmental benefits over traditional lighting technologies such as incumbent incandescent and halogen technologies (TSB / DIUS, 2007). They have several major benefits [1]. First, LEDs have a practical operational life of '50,000 hours' (Carbon Trust, 2007b: 12) compared with 1000 or 2-4000 for incandescent and halogen lamps respectively. This can potentially reduce maintenance cost. Second, LEDs exceeds the energy efficiency of conventional lighting technologies. For example, white LEDs are over 400% more efficient than incandescent lamps and 300% more than halogen (TSB / DIUS, 2007).

The better functional performance of LEDs, compared to incumbent technologies, is clear. But superior technical performance of a particular technology is no guarantee that it will become the dominant technology. Systems innovation (which adopts a multiple level, multiple actor perspective) is an important new stream of theory which is providing new insights into the innovation diffusion process; particularly ushering in a better understanding of why (and under what conditions) niche or disruptive technologies become (or do not become) established technologies in a given sector or technology field (for example, see Geels and Schot, 2007; Rotmans et al., 2001).

This paper reports on an ongoing exploratory research project which is tracking, real time, the start-up and growth of a company which is developing and introducing a range of leading edge LED technologies. A systems innovation approach is adopted to reflect on the interim results. The results reveal the pivotal institutional barrier of LEDs not being supported by national and international standards, as well as the obstacle of high capital cost in the procurement decisions at a local level. The interim results give tentative support of the value of using a systems innovation approach to understand uptake and diffusion a new technology. There is a need for significantly more theorising and empirical work in a built environment context to develop the descriptive and explanatory utility of systems innovation. This paper is structured as follows. Section 2 briefly discusses the multi-level perspective of sustainable transition management. Section 3 sets out the research questions and an overview of the research methodology. Section 4 presents the interim results with the focus being on the distributed interaction between the principal actors. Finally, discussion and conclusion are drawn.

MULTI-LEVEL MODEL OF INNOVATION AND SYSTEM TRANSFORMATION

Innovation theory and empirical evidence has long stressed that new technologies are the emergent outcome of a range of interconnected institutional and organisational activities. The linear view of innovation, for example, where new technologies are pushed into the market has been all but discredited. Further, there is recognition that the shift from the current, unsustainable trajectory of societies to sustainable paths cannot be achieved in a fragmented, ad-hoc fashion. There is a need for co-ordinated policy and action across a range of diverse domains and levels. In response to this agenda the multi-level view of system innovation is being developed. Geels and Schot's (2007) multi-level perspective of 'socio-

technical systems' on technological process innovation in the built environment distinguishes three conceptual levels: socio-technical landscape, socio-technical regimes, and technical niches (Geels and Schot, 2007; Geels, 2005) (see Figure 1). Each level is discussed below.

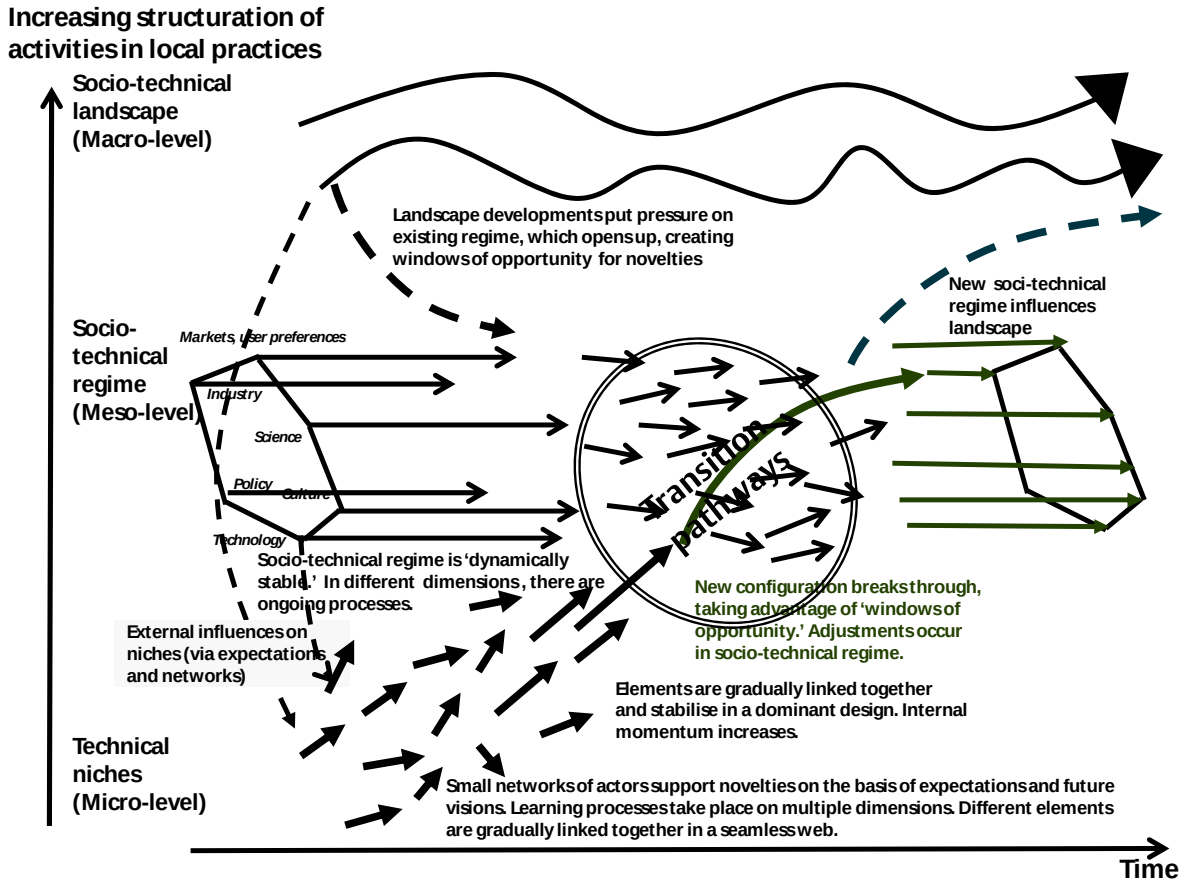

Figure 1: A dynamic multi-level perspective on system innovations (adapted from Geels and Schot, 2007: 401)

First, socio-technical landscape (macro) level represents the broader political, social and cultural values and institutions (such as standards, regulations) that form the deep structural relationships of a society and only change slowly (decades). The landscape guides actors' perceptions and activities. Within this landscape, there are socio-technical regimes and technical niches.

Second, socio-technical regime (meso) level represents "the prevailing set of routines or practices that 'actors' and institutions use and that create and reinforce a particular technological system" (Foxon et al., 2010: 1204). These practices include: "engineering practices; production process technologies; product characteristics, skills and procedures … all of them embedded in institutions and infrastructures" (Rip and Kemp, 1998 cited in Foxon et al., 2010). Regime accounts for "the stability of existing large-scale systems (in transport energy etc.)" (Schot and Geels, 2008: 545). Within the existing regime, incremental, often product, innovation is generated.

Finally, technical niches (micro) level is where "market niches provide early footholds for radical innovation" (Geels, 2008: 522). Micro-level niches are 'protected spaces' where new technologies, new novelties etc emerge. Geels (2005: 450) further comments that it is difficult to create radical innovations within socio-technical systems because of the stabilising mechanisms. Radical innovations tend to be encouraged through regulation and/or financial incentives (such as taxes and R&D subsidies). For instance, the UK government is currently guaranteeing high prices for electricity produced by microgeneration technologies [2] to encourage the R&D, uptake and diffusion of such technologies.

The key point of the multi-level perspective is that transitions (long-term changes) come about through the interplay between processes at different levels in different phases. As a consequence, transition pathways [3] (see Figure 1) need to be created and managed to encourage the adoption and diffusion of 'niche' new technologies so that, overtime, they become the dominant technology. Geels (2005) argue that radical innovations emerge (the transition is) through three phases. In the first phase, radical innovations emerge in niches, often outside of the existing regime. There are no stable rules (e.g. dominant design) and actors improvise, and engage in experiments to work out the best design and find out what users want. The networks that carry and support the innovation tend to be small. Innovations at this stage do not form a threat to the existing regime. In the second phase, the new innovation is used in small market niches, which provide resources for technical development and specialisation. The new technology develops a technical trajectory of its own and rules begin to stabilise (e.g. a dominant design). But the innovation still forms no major threat to the regime, because it is used in specialised market niches. New technologies may remain stuck in these niches for a long time (decades), when they face a mis-match with the existing regime and landscape. As long as the regime remains stable, niche innovations have little chance to diffuse more widely. The third phase is characterised by wider breakthrough of the new technology and competition with established regime, followed by a stabilisation and new types of structuring. The multi-level perspective of transition management emphasises that "both internal niche-dynamics and external developments at regime and landscape level are important for wider breakthrough and diffusion" (Geels, 2005: 452) and transition pathways arise through the dynamic interaction of technological and social factors at these different levels.

RESEARCH QUESTIONS AND METHODOLOGY

The ongoing research is guided by the following research questions:

1. How does the lighting supply chain (including LED module manufacturer, luminaire manufacturers, specifiers and end-users) engage with new LED technology?

2. What are the drivers and barriers underlying end-users decisions to adopt / reject such technology?

The project brought together representatives from the key parts of the supply chain: LED module manufacture, luminaire (light fitting) manufacturer and end-users. A brief description of each project partner is presented below.

The LED module manufacturer, a small LED lamp manufacturer based in California in the United State of America, funded in July 2007, is a start-up company. Its business model is to

design and manufacture LED light modules that allows light fitting manufacturers to add significant value in multiple applications and markets which leverage their existing channels.

The luminaire (light fitting) manufacturer and installer, established in 1982, is an established original equipment manufacturer (OEM). It works with module (lamp) manufacturers and end users to produce standard and bespoke products and systems for a range of indoor and outdoor applications.

End-users include three technical and four non-technical end-users. Technical end-users include three specifiers (hereafter specifiers 1, 2 and 3). The specifier 1 was formed in 1978 and is one of the UK's largest mechanical and electrical (M&E) building services engineering consultancy practices. It specialises in bespoke building services engineering solutions to a wide range of market sectors, including healthcare, education, research, local government, pharmaceutical and commercial clients. The specifier 2, based in Scotland, is privately owned firm. The firm provides M&E building services engineering consultancy services. Specifier 3, also based in Scotland, is an electrical contractor.

Non-technical end-users include an airport operator, a property group, a regional museum, art gallery and archives service and an in-house maintenance function of a marina. The airport operator is the country's largest UK-owned airport operator. The pilot site (an airport) was located in North West England. The property group, founded in 1958, is an international property group with broad skills across the property value chain. The property group operates three core businesses: project management and construction, property investment management and property development. The pilot site (a shopping centre), opened in 1999, is Europe's largest combined retail and leisure destination. The third one is a major regional museum, art gallery and archives service. The organisation is responsible for twelve museums, galleries and heritage sites. The pilot site (a museum) is located in North East England. Finally, an in-house maintenance function of a marina. The marina opened in 2010 and is situated in Scotland. Its facilities include deepwater, sheltered berthing and built facilities, including accommodation, restaurants and bars and shops.

Data collection techniques include interviews, meetings, workshops and company documentation.

INTERIM RESULTS

This section is structured into two sub-sections: barriers to the adoption of LEDs technologies and enablers for the adoption of LED technologies.

Barriers to the adoption of LED technologies

1. High initial capital cost / high purchase cost

It is clearly LEDs has far better functional performance than the existing lighting technologies (e.g. tungsten and compact fluorescent lights), but the high capital costs was a major barrier. The 'high initial capital cost' of LEDs is clearly demonstrated by the comments of the luminaire manufacturer and end users. One of managing directors of the luminaire manufacturer, for example, expressed his concerns towards this barrier:

"As an overview, taking it above this [LED] technology, when it was going through 'how do we get sustainable energy efficient technology in the marketplace, there is a tremendous

amount of negativity in the actual purchasing process of taking this technology on because of the initial capital cost, and that's the biggest barrier we face with this."

The 'high initial capital cost' strongly links to the second barrier discussed below.

2. Decoupled capital and maintenance budgets
When the capital and maintenance budget is disjoined within the client system, the adoption of LEDs appears to be impossible. This is evident in one of managing directors of the luminaire manufacturer, stating that:

"Where [a local authority] have the capital budget for expenditure is absolutely nothing to do with the maintenance budget, nor are they linked. Until the people who are in charge of the budgets for this link the two together to get an overall saving, their short termism is costing the country millions."

3. Lack of standards
Standards are playing an essential role in the growth of the LED lighting market and the rate of adoption of LED lighting in various applications. Without standards, performance comparison can be difficult or impossible, and specifications cannot be traced to a meaningful reference. This can make customers and specifiers uneasy about using LED lighting for their projects even niche actors' perceived that LEDs is fully developed. One of the end-users (specifier 2), for example, was skeptical of claims of LEDs' long life by saying:

"… the first criteria would have to be 'can I trust the life' … that would be the first one because you get quoted lots of things … a golden number of 50,000 hour life on a LED … it's easy to quote a number … it's hard to prove that number, I guess, isn't it?"

The importance to comply with regulations is further reinforced by one of end-users (specifer 1), stating that:

"… my experience here with people who have used LEDs has been quite open … our engineers here are very open, forward thinking solutions. We do work within the realms of British Standards."

Lack of standards, particularly play a key barrier for the deployment of LEDs products in the construction sector. One of managing directors of the luminaire manufacture, for instance argue that unless the LED products is specified, otherwise, it will not be introduced into the construction projects.

".. when we're dealing with the design and build marketplace, the whole criterion of that is to get the most competitive tender in that satisfies your remit with a twelve month period, and this technology [LED], unless it is written in under design and build specification that it must have certain points, then it will never go in because the contractor will not pay eighty / one hundred pounds for a luminaire when he can buy ten or twenty pounds for a luminaire, and he doesn't care after twelve months of the problem.

4. Lack of awareness or enthusiasm of electrical engineers (e.g. lighting designers)
Electrical engineers can be significant influencers on LED purchases both by the choices they make for lighting fixtures in new construction, so lack of awareness or enthusiasm on their part can be a barrier to LED technology adoption. The resistance to change in designers and

clients to use LEDs, in part, because it would mean disrupting and changing the existing 'regime' or 'way of doing things.' Another managing director of the luminaire manufacturer, for example, indicated the challenge to introduce a radical technology (rather than incremental technology) into the development of new products:

"Our approach to product, because the lighting market place and engineers are conservative people who get very comfortable with certain pieces of technology, to move them radically in different direction becomes a problem to them … so it's easier for them to embrace the idea of a low voltage or a diachronic replacement … let's try and replicate something that works, that is more in their comfort zone to get a higher market uptake."

Specifiers seek to offer leading-edge technology to their customer. LEDs are transforming their offer but at the same time introducing new challenges. Specifier 1, for instance, noted that:

"… there are always conflicting requirements, and the hardest one to reconcile is when it's a personal conflict. I don't mean personality, a personal conflict of somebody in a design team might prefer something else because they've used it in the past on another project and it was a really good result so they like that. You suggest something new, perhaps, and they may … I wouldn't say reluctance, but there may be a bit of 'Is it okay? Do I really want to move to that?"

5. Lack of awareness or knowledge of LEDs from clients

What was interesting is that, in most cases, the client itself does know what it wants prior to installation. It is only when the lighting installation is in place that the client knows whether it was the right or wrong solution. This situation is amplified in the case of LEDs as this is, in most cases, a totally novel technology for the client. The lack of awareness/knowledge of the client about the LED product is evident in the one of managing directors of the luminaire manufacturer and installer, stating that:

"I don't know a single end user who would have any awareness at all [of LEDs]. In the old days when we used to talk about metal halides, people had firsthand experience … now, with this, it's just not on their radar …"

6. No experience or having bad experience of clients of using LEDs

No experience or having bad experience of clients of using LED has negative impacted on the adoption process. This is demonstrated by one of the end users (specifier 1), stating:

"Sometimes a university … may have a small project that doesn't actually involve us, a small value project where they've bought a few LEDs, tried them, bad experience, and they're not experts in the LED or lighting field, so they may just go with that as a bad experience and think 'I'm not going to use them again.' So that's the kind of barrier that we might see."

<u>Enablers for the adoption of LED technologies</u>

1. Whole life cycle costing

The 'whole life cycle costing' was considered as an important factor in introducing LED products into the project. Specifier 1 stated how the end user was convinced by deploying the new LED technology:

"The good thing for us is the energy departments … specifically at University of … their energy department is quite keen on using new technologies that save energy. With those product if I can save at least thirty or forty percent for certain types of products then it make sense to do so."

That can be said that the concept of the 'whole life cycle costing' is addressing the both the 'high initial capital cost' and 'disjointed capital and maintenance budgets' barriers.

2. Reduction in maintenance works and low maintenance cost

The benefits of long life of LED products clearly demonstrate in the reduction of maintenance works and costs. This benefit to reduce the maintenance work was demonstrated by specifier 1, quoting how the new LED product was adopted by the end user:

"That was an architect. I showed it to the maintenance team after that meeting on site because I got to know them there, showed them the products, and the first thing they said was 'Great. That means I won't need to keep changing [lamps] that I keep changing every few months."

3. The important role of specifiers

The important role of specifiers in helping end users' acceptance towards new LED product is evident in specifier 1:

"Quite often when I employed as the specialist and are very seldom challenged on the design of the lighting, other then the way it appears with the design team, because the design team predominantly will include an architect. The architect on this one, I showed him the products because I was interested in it, of course, and I showed him the kind of output you get with LEDs and it was met with nothing but extremely open arms, such is the effect that the architect believed he would try to find as many jobs as he possibly could to use them on.

This is particularly when there is no LED standard in place. Specifier 1, for example, described the reason why he adopted the LED technology in his projects:

"It's very difficult that one, isn't it, because it's hard to give me any concrete evidence for anything. I have to rely on the experts who are supplying it and whatever warranty they might provide to me. So on this project it's a five year warranty, and that's all I can really go on, actually."

The interactions within social-technical regimes also present a challenge in the transition. One of managing directors of luminaire manufacturer and installer, for example,

"When you talk about end users, …you talk to people who are lighting professionals and that's what they do, they'll embrace it, but, again, how well they communicate it to their client because, at the end of the day, the client after a while glazes over and just thinks 'Oh yes, it looks nice. It's pretty.' He doesn't know why it's pretty."

DISCUSSION AND CONCLUSION

The findings, when viewed through the multi-level perspective, bring into the sharp focus two key, interrelated issues. First, at a technical niche level, the current generation of light emitting diodes (LEDs) demonstrate clear functional benefits, but are significantly hampered by their high initial cost compared to incumbent lighting technologies (Unger, 2011). The

specifiers may be engaging with client systems to win the argument concerning whole life cycle cost attributes. But this engagement is very limited and patchy. Clients are locked into existing technologies and installation / maintenance routines which often lock-out consideration of the LEDs option. Second, at a social-technical landscape level, the specifiers are being hampered in two respects. Specifiers themselves may be locked in to particular lighting solutions. Further, where specifiers do consider LEDs, the lack of standards and certification schemes for the technology introduces too much uncertainty and risk.

This exploratory paper advocates that a broadening of the debate beyond the flat, linear view of, say, the traditional new product development to a multi-level perspective provides policy makers potential levers to bring about more effective system innovation. In this case, the LEDs technology itself is not the bottleneck – it is the way clients and specifiers are locked into old technologies and practices. The lock-in is further aggravated by the absence of LEDs standards and certification schemes. This is, in many respects, a somewhat common-sense message: technological innovation is not without context, it is embedded within landscape institutions and regime networks. But in the clamour for new sustainable technologies, this message is too often lost in the noise and, as a consequence, the system innovation required is not being progressed. In summary, LED technology, to substitute the incumbent, less environmentally-friendly lighting technologies, requires more robust transition pathways which are created and supported by legitimising standards and new knowledge sets for specifiers.

Finally, to reiteate, this exploratory paper has mobilised the multi-level perspective to construct a better, albeit partial, understanding of why and how new technologies (in this case LEDs) are adopted and diffused. We advocate that significantly more theoretical and empirical research should be undertaken to investigate whether the multi-level perspective has real purchase and traction in a construction context to move the sector to an environmental trajectory.

ACKNOWLEDGMENTS

The author is grateful to the Construction Knowledge Exchange (CKE) (www.cke.org.uk) who funded the 'Demand led Light Emitting Diodes (LED) lighting new project development for the retail sector' project on which this paper is based. The author would also like to express her gratitude to all interviewees for their contribution of time, resources and, most of all, enthusiasm. Without their co-operation and support this study would not have been possible.

NOTES

[1] For more discussions on LEDs technologies, see Held (2009), Carbon Trust (2007b).

[2] The term 'microgeneration' is understood to be the "… onsite generation of low- and zero-carbon heat and electricity in domestic, public and commercial properties (Bergman and Jardine, 2009: 6).

[3] Transition pathways are defined by "the interactions between the internal regime dynamics and wider landscape factors and niche alternatives, which destabilize the incumbent regime and eventually give rise to a new regime" (Foxon et al., 2010: 1207).

SUSTAINABLE PLANNING AND LAND VALUATION. NEW FORMS OF SUBURBAN GROWTH IN AREAS OF THE SPANISH MEDITERRANEAN COAST

Abstract
The present study analyzes residential models in coastal areas with large influxes of tourism, the sustainability of their planning and its repercussion on urban values. The project seeks to establish a methodology for territorial valuation through the analysis of externalities that have influenced urban growth and its impact on the formation of residential real estate values.
This will make it possible to create a map for qualitative land valuation, resulting from a combination of environmental, landscape, social and productive valuations. This in turn will establish a reference value for each of the areas in question, as well as their spatial interrelations. These values become guidelines for the study of different territorial scenarios, which help improve the sustainable territorial planning process.
This is a rating scale for urban planning. The results allow us to establish how the specific characteristics of the coast are valued and how they can be incorporated into sustainable development policies.

Keywords: territorial valuation; sustainable planning; suburban growth

INTRODUCTION. CURRENT SITUATION

The urban territorial structure of developed countries has changed significantly over the past several decades, due to service sector expansion, transportation improvements (Leinfelder,2007) and population growth, prompting the regeneration and planning of suburbia, which goes beyond a territorial transformation as it also involves social, political and economic changes. These transformations have made the regeneration and planning of ample suburban fabrics necessary, and have provoked a profound territorial, social, political and economic transformation.

The discourse about the meaning of city and countryside is not unique for all the countries. The European RURBAN-project conclusions (Overbeek, 2006) indicate a dominant planning discourse. This sets that city and countryside are two separate entities that need a complementary and simultaneously opposite policy: new developments are concentrated in urban areas, while the open space is safeguarded against new developments.

On a territorial level, these changes have caused the classic appraisal models for urban value to lose validity. In this context, how are the countryside and the city valued?
North-West-European countries share a rural tradition in which agriculture and the environment are central elements within the urban planning. As a consequence, countryside is

highly valued as a space for production and consumption and the city and urbanisation are perceived in a more negative way. In contrast, the Mediterranean rural tradition approaches the countryside negatively and perceives city and urbanisation quite positively because it stimulates economic development.

However the traditional political dichotomy in simple categories ‘city’ and ‘countryside’ is being questioned increasingly. It ignores the complexity and stratification of society (Halfacree, 2004). The relations between places and activities have become very complex in network society and concern different spatial scales at the same time (Leinfelder, 2007).

Most of development possibilities are in open space where there are now areas of environmental interest. This stance has led to the devaluation of the environmental potential of many areas of the Spain’s Mediterranean coast due to the intense pressure of the tourism industry. In these locations, the significant increase in residential land has contributed to a gradual loss of the territory’s environmental values. The main problem is that the economy of these areas is based on tourism linked to environmental values. The primary purpose of encouraging the preservation of environmental values may not be financial, but financial justification for these actions is nearly always required (Crompton, 2007)Therefore there is a contradictory situation and it is remarkable how planning has not taken clear role for open space in ‘network urbanity’ (Leinfelder, 2007).

Currently, land value responds to more than just accessibility factors and urban hierarchical structuring. It is also defined by its capacity to support marketable real estate products and the market value of said goods. This market value is determined by a set of qualities or attributes that cannot be traded independently, but rather only as an integrated market unit. The group of variables that affects each choice has a direct impact on the property appraisal process (Kauko, 2008). Its analysis is fundamental to understanding the complex system of urban development and growth.

Given this scenario, it seems particularly relevant to develop innovative methodologies that specify tools and techniques capable of meeting developmental and land management requirements on a regional and local scale. The offer has a spatial location, which must be considered for the market analysis (Gutiérrez and Gould, 1994).

The main goal of this study is to rehearse new techniques for sustainable development planning using technological applications. The analysis of externalities that have had an influence on urban growth and the appraisal of residential real estate products will help establish a methodology for land valuation.

The work creates different outlines for urban valuation. The result is approximate to an economic valuation on a territorial scale. It analyzes the impact of the urban and natural attributes that make a city attractive. This analysis is supported by economic, social, environmental and urban planning concepts, and is used to explain the variability of urban land values.

In order to determine whether the planning previsions will adequately meet the requirements of the demand, we must explore to what extent the differential characteristics of these products adapt to the level of significance or valuation of their territorial location. This differentiation of municipalities allows us to study the integral characteristics of a location’s real estate market.

These formulas have been amply used in studies applied to the housing market. In Spain, however, there are few known experiments to this effect. Additionally, this project’s proposal

is of particular interest due to the dynamic development of this area over the past several years, its marked suburban character destined for second homes and the significant influence of tourism on its expansion.

OBJECTIVES

The purpose of classifying urban development models is to identify their fundamental characteristics by establishing the requirements for competitiveness and sustainability that must be met in order to guarantee territorial progress in the economic, social and spatial sphere.

To this effect, the investigation is linked to fields of study related to urban planning, management and valuation; and proposes a global study with different objectives.

- To identify and analyze the different factors used to formulate the obtained real estate values.
- To systematize a process for land valuation through the analysis of externalities that have had an influence on urban growth.
- To determine the interaction between urban value and land value, assessing the sustainability of real estate activities.

SCOPE OF ANALYSIS

Traditional settlements and New forms of suburban growth

The scope of the study is the Spanish Mediterranean coast, and more specifically the area known as Vega Baja del Segura, which is made up of 27 municipalities. This area boasts a large diversity of landscapes and ecological factors, and has historically maintained a clear distinction between urban and rural spaces. This dichotomy has drastically changed over the past decades. The tourism industry has created a large demographic and economic growth, which has provided the incentive for an extremely dynamic land market.

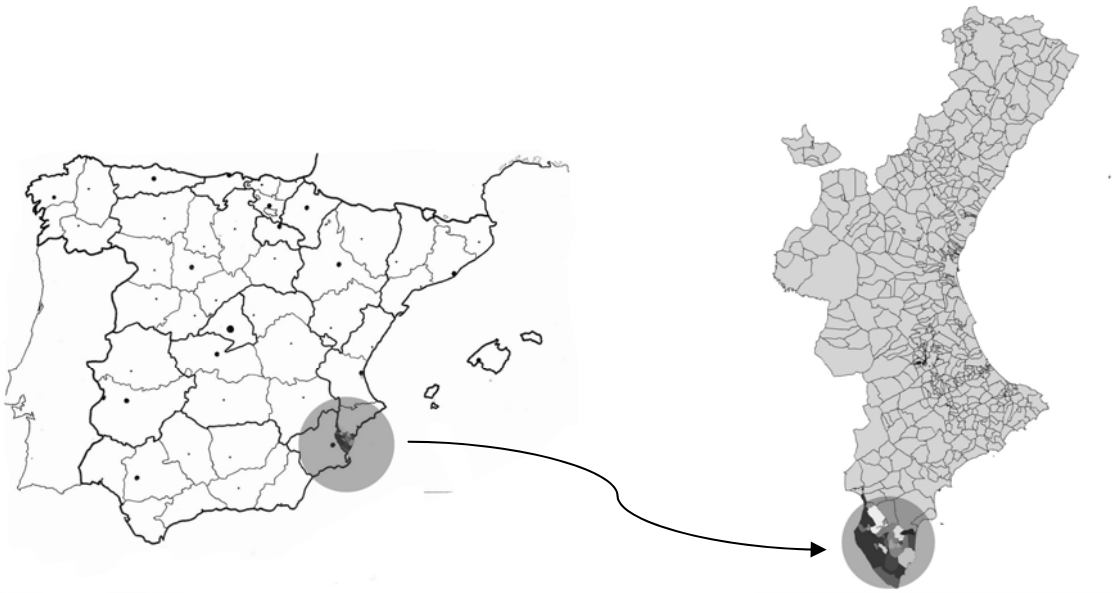

Figure 1: *Location of the scope of Vega Baja del Segura in Spain. Source: the authors*

This growth has caused a marked transformation in the traditional settlement criteria, implanting a new and more complex system that has caused the rural environment to gradually take on a quasi-urban morphology from urbanization processes and facilities. The clear distinction that has traditionally existed between the settlement patterns of the agrarian and urban populations has disappeared. People don't perceive rural areas as a mosaic of independent zones on an urban planning. These are perceived in a qualitative and integral way as an attractive setting for living and recreational activities (Leinfelder,2007). The implementation of new uses, activities and lifestyles that are typically urban in nature, has led to a growing homogenization of the suburban space and a progressive mixing of the urban meshwork with rural structures.

The residential model that responds to this phenomenon is one of low-density housing developments, which penetrate inland towards a town's interior from the coast. This new model results in a significant scattering of the population, giving the area the lowest population density in the province.

According to this approach, the old system of traditional settlements with their marked rural character and center in Orihuela can be distinguished from a new model that has developed from the coast towards the interior, organized hierarchically from the center of Torrevieja. The dialectic process between both systems has produced the current distribution model whose principal characteristic is homogenization. This has led to the development of typically urban lifestyles in very small nuclei in the interior, and typically rural values in urban structures.

Figure 2: *Network of settlements. Source: the authors.*

In conclusion, the settlement system in the Vega Baja del Segura should be analyzed from a territorial point of view, due to the complications that arise in trying to establish a border between rural and urban settlements. The rural sphere cannot be considered as independent of the urban sphere, given that it is a functional, hierarchical space that has intense interaction with the entire network of cities in the Vega Baja.

Population system and economic model

This process has occurred in conjunction with a clear modification of the population structure and the area's production sectors, creating an economic model in the Vega Baja that reflects the strong impact of the large-scale establishment of the tourist sector on an area with strong agricultural roots and a marginal industrial sector. Tourism has become a strategic industry for generating wealth, with extremely significant effects on the area's economy.

The economy of the Vega Baja del Segura is traditionally rooted in agriculture. This impeded the formation of a social structure during the nineteenth and beginning of the twentieth centuries, and has prevented a true industrialization of the area. The agrarian economy experienced a crisis in the sixties, due to the aging and lack of alternatives for a largely uneducated population. However, the Vega Baja has traditionally boasted natural conditions favorable to the strong development of the tourism industry. Factors such as climate, the coast and the landscape resulted in a massive influx of tourists since the 1960s, reaching a spectacular level in the mid 1980s. This was especially true in the town of Torrevieja. This development of the tourism industry provoked an extremely significant increase in population, both on and near the coast, turning the town into a well-known destination for sun and beach within the Community of Valencia and the rest of Spain.

The clear consequence of this development was an increase in local incomes, sparking a significant expansion in the construction sector and converting the service sector into the pillar of the local economy. One factor that intensifies the influence of tourism on other secondary sectors like industry and construction tied to real estate promotion, is that this type of tourism is not centered on hotels, but rather on a type of tourist who spends large portions of the year in the area and is therefore in the market for a second home. This circumstance has brought about a tourism model characterized by a minimal presence of hotels, a predominance of offers for a second residence and an undeclared, non-hotel based offer.

This model initiated a migration of agricultural laborers towards the main population centers and created strong ties between the active population and the construction sector. Additionally, the model attracted an older population, in large part from the rest of the European Union, who made this town their vacation destination or the site of their long-term second residence.

A population pyramid that demonstrates a clear tendency towards a narrowing of its base and a significant widening of cohorts of an advanced age indicates significant distortions with regards to the average age of the population. This results in an increment in the aging rate and a modification of production sectors. The services demanded by this population are limited; a phenomenon that makes it difficult to propel the industrial sector as it stagnates the dynamic of labor demands and thereby blocks the economic development of the zone.

In the area's interior, where elderly immigration is less intense, the classic aging process of rural economies is taking place, pushing young laborers to other areas and clearly throwing the population pyramid out of balance.

Over the past few years, construction has been seriously affected by the financial and real estate crisis triggered in mid 2007. One of the first victims of this phenomenon was employment in the Spanish construction industry. The dependence of this area's economy on the service and construction sectors has meant significant increases in the rate of unemployment, mainly affecting the migrant population.

METHOD OF ANALYSIS

In order to reach the goals of this project, a methodological study was carried out relating to a description and quantification of the different aspects that define the territory and effect the evaluation of the real estate product. As a base of analysis, we will use data from the real estate market itself, establishing links between territory and urban value. This implies a detailed and reliable study of values on the sale of finished products and a complete characterization of the territory using ecological, landscape, productivity and environmental criteria.

The evaluation is considered from a double perspective: territory and real estate. How do territorial characteristics determine urban value? Does the distribution of existing urban values respond to territorial characteristics? Does real estate development respond to sustainable territorial guidelines? And, using spatial market analysis, where can we, or should we, establish new supply points (Beaumont, 1991)?

The analysis was carried out using a tool similar to GIS (GeoMedia Professional). This provided agile information management and the creation of maps that represent the qualitative value of each part of the territory, defining areas of fragility and potential for urban developments. This process allows us to define whether or not the distribution of urban values is related to the land valuation and if it meets criteria for territorial sustainability.

The analysis is structured into the following phases:

- Sample selection
- Database design and sample description
- Database processing. Spatial distribution of variables
- Land valuation. Areas of fragility and potential

Sample selection

The first phase of the study is based on the selection and systematization of a set of data obtained through market research carried out in the area of the study. The analytical validity is based on the quality of the information used as a reference for obtaining the market value, and the reliability of the geographical data and spatial precision.

The sample has been stratified into two subsamples based on the typology (multi-family and single-family), due to the fact that they constitute different real estate offers, in which the potential buyers look for incomparable features and therefore present differentiated valuations.

The market study brings together a sufficiently representative sample of finished properties already for sale, both in the primary and secondary markets, with an age of less than 10 years. The research is transversal in character. The data is from a homogenous period of time where

variables such as sale prices and the preferences and needs of potential buyers do not vary significantly. The data was collected between January and August of 2009. The field work was carried out through the compiling of data specific to the present study (73%), market studies for mortgage valuations (21%), market studies for appraisals, expert valuation reports and viability studies (6 %), carried out over the same period.

The utilized data was sufficiently representative and appropriately corrected from unconditional offers. The information was verified and all data that differed unjustifiably from the average market value for the area or that was incomplete, was discarded (Roca, 1987).

The 3,845 pieces of data that made up the original sample were whittled down to a market study consisting of 3,300 units of information, from throughout the entire area. It is a representative sample of the different zones distributed in the following manner.

TOWN	**MULTI**-FAMILY	**SINGLE**-FAMILY
Albatera	73	18
Algorfa	20	8
Almoradí	82	11
Benejúzar	10	7

Database design and characterization of the sample

The group of properties chosen for the basis of the analysis has been qualified using more than 200 variables. The characterization of the sample has a dual aspect that on one side will determine those physical characteristics that qualify the constructed element and on the other, those directed at the characterization of the territory.

In this phase, we attempted to define all of those pieces of data that permit the differentiation of the real estate product from a point of view that is both territorial and related to the demand criteria. This process helped to stratify the sample using criteria of homogeneity, making it possible for us to subsequently conduct explanatory analysis.

The variables or factors for analysis can be grouped together into four families; the first two directed at the characterization of the property and the remaining two at the characterization of the territory:

1 market variables and valuation
2 intrinsic or typological attributes linked to the constructed element and characteristic aspects of the area
3 extrinsic or location related attributes linked to the censual units
4 extrinsic or location related attributes linked to the property

In Family 1, "Market variables and valuation", different defined aspects include the surveyed sale price, unitary market price and repercussion value of the land. The information sources include real estate agents, specialized publications and real estate and individual's websites. The variables obtained from the surveyed market values were compiled by the authors for the purpose of the study.

In Family 2, "Typological variables", the defined aspects include housing programs, construction quality, characteristic typology and occupation levels for properties used as homes, among others. We obtained the characteristic typological variables referring to the territorial scope or censual unit from the data provided by the 2001 Census conducted by the National Institute of Statistics, or compiled by the authors using said data.

Family 3, "Extrinsic territorial variables", takes into account environmental, economic, social and urban structure factors, with reference to the land unit or censual unit where the sample is located. The characteristic typological variables were obtained from the 2001 Census data conducted by the National Institute of Statistics or compiled by the authors from said data.

In Family 4, "Extrinsic values of the variables", the analyzed factors mainly had to do with the environment, infrastructures and facilities with reference to each sample. The variables were obtained through the compilation of field data by the authors.

Database processing. Distribution of spatial variables.

The resulting data set is introduced in an appropriately coded Excel database, and transformed into factors that will determine the final classification of each part of the territory. To this end, the property register mapping for each town was used as the basis, creating a reliable starting point for geo-referencing each sample, for the subsequent production and quality control of the relevant themes.

The use of GIS as a tool for scientific research (Moldes, 1995) is derived from its capacity to respond to spatial questions (Gutierrez and Gould, 1994). The use of GIS technology makes it possible to create complex maps that represent a territory's total qualitative value. This in turn will orient and sensitize with respect to the distribution of values that can be geographically located on a territory, and effectively support the implantation of necessary protection regulations. The GIS data structures detect fragile or vulnerable areas within each scope, in addition to areas with greater potential for growth.

On the other hand, by using the sample obtained during the data collection process, we can find out the market value segmentation for residential housing products in the analyzed area,

both with regards to single-family and multi-family homes. We can determine if there is a link between territorial valuation and the spatial distribution of property values by using the link between the total quality valuation map and the land value map.

The following is a list of the available information that has been incorporated into a Geographic Information System. It is divided into five areas. The following variables were taken into consideration in order to define the territorial valuation:

AREA 1 ECONOMIC

- Weight of unemployment rate
- Socioeconomic condition by homes
- Active population rate / dependent population rate
- Sector / field of activity

AREA 2 ENVIRONMENTAL

- Type of landscape
- Conservation value of the territory
- Buffer of influence from the golf course
- Buffer of influence from the beach

AREA 3 POPULATION

- Average education level
- Average age
- Percentage of Spanish / foreign population

AREA 4 INFRASTRUCTURES AND FACILITIES

- Buffer of influence from transportation infrastructure
- Sanitation facilities

AREA 5 EDIFICATORY TYPOLOGY

- Characteristic residential typology
- Seasonal variation
- Vacant homes index
- Average home size

Territorial valuation. Areas of fragility and potentiality

Valuing the quality of a territory means stipulating a reference value for each of its comprised areas. The concept of “value” incorporates a broad spectrum of different valuations or factors that condition its determination. Once said value has been determined, it becomes possible to estimate the impact of the different actions planned on the territory and articulate mechanisms that will guarantee the preservation of its values.

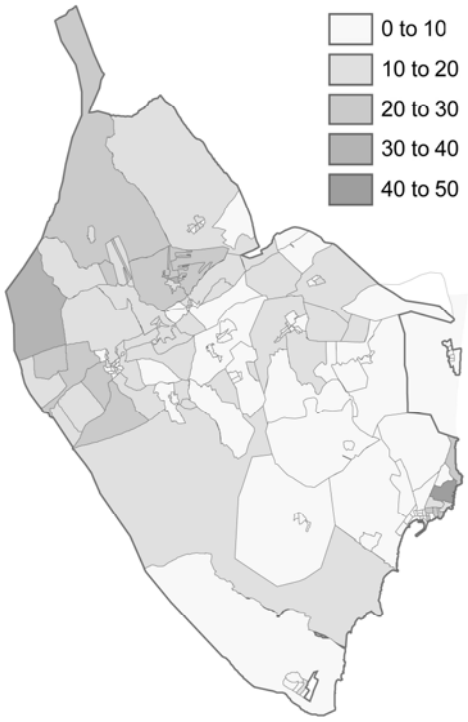
In this sense, all planning tools should take into consideration an impact evaluation of the actions planned for the territory and how consumers value them. The evaluation of an action’s viability should be based on technical, economic, environmental and social criteria.

The variables included in the five highlighted areas (environmental, economic, population, facilities and typology) were subject to a range of analysis. Using this analysis, different maps were then established by theme, constituting the degree of vulnerability or fragility of

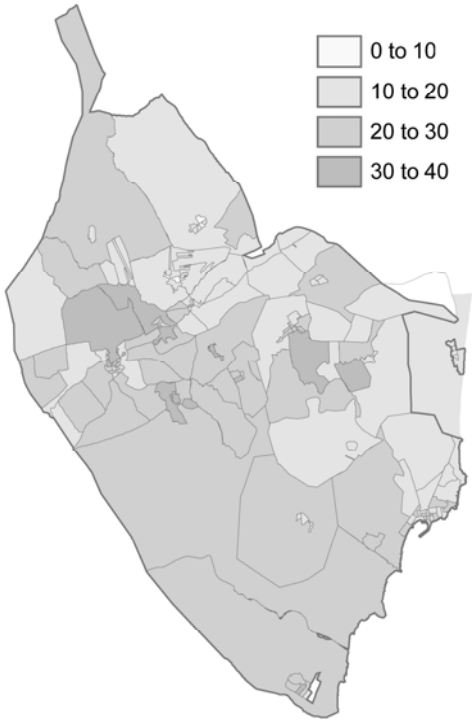
the territory in each of the areas. The superimposition of said maps allows us to make a qualitative valuation map for the territory.

This map established a value reference for each of the areas, as well as for their spatial interrelationships. In this way, the value becomes a guideline for the study of the different territorial zones offering an integral vision of the area with regards to territorial planning.

Once the social demands have been recognized, as well as environmental and economic potentials, we will be in the proper position to establish guidelines that will contribute to improving the sustainable planning process for the territory. In order to qualitatively estimate each of the dimensions of the total value, hierarchical scales with value ranges will be applied to the thematic maps (Moldes, 1995), using said measurement as a reference for determining the critical areas and the areas with a potential for development.



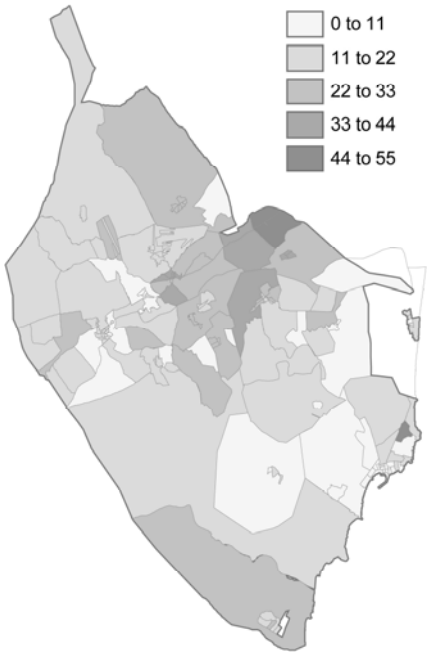
One example of these types of applications (Laurini and Thompson, 1991), was used in the selection of suitable areas for new residences in a part of Maryland where the selection criteria were based on the proximity of fire stations, secondary schools, distances from main highways and flood lands. Also of note are the territorial guidelines established to determine the most suitable area for housing developments in Randstand, Holland (Geertman and Toppen, 1990).



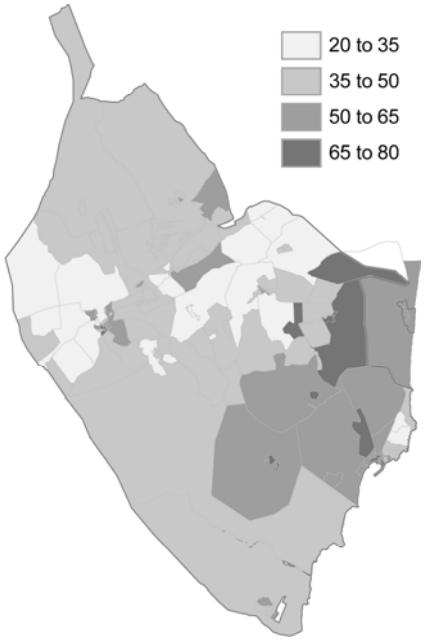
RESULTS. MAP OF TERRITORIAL VALUATION

The final goal of the executed analysis is to determine which areas are fragile, and which have the potential for development. The objective is to create a tool that makes planning decisions easier and favors the selection of the most ideal location with regards to the necessities of each demand profile. The results will therefore be displayed keeping this objective in mind.

Economic fragility



The analysis of the characteristic production sectors for each censual unit makes it possible to detect a clear a renunciation of the historic economic motor of the province: agriculture. The economic model is headed down a new road, that of the tourism and real estate sectors. This makes looking back impossible, given that much of the cultivation areas have been transformed into land susceptible to urbanization. An increasing withdrawal of the agricultural sector can be observed towards the area’s northeast, as well as a significant advance of the construction sector as it colonizes the vacated fields (Fig. 7).

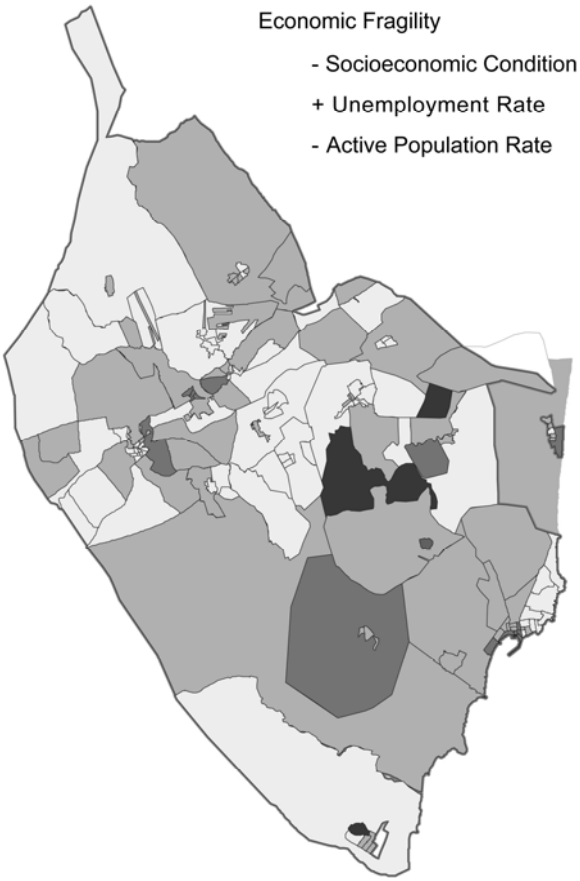


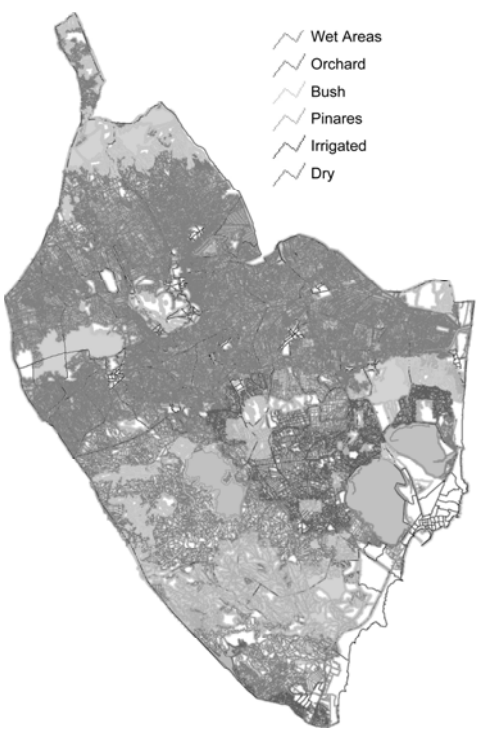
Figures 6 and 7: *Impact on the agrarian sector and construction sector within the area's economic structure. Source: the authors.*

An incipient interest in industry can also be observed (Fig. 8) next to the nucleus of Almoradí. This is sparked by the potential of the network of infrastructures and the strong implantation of the service sector (Fig. 9) in the pre-littoral strip that runs alongside Torrevieja.

Figures 8 and 9: *Impact on the industrial sector and service sector within the area's economic structure. Source: the authors.*

The new structuring of the production sectors demonstrates a clear reflection of the average socioeconomic levels of the homes and the unemployment and active population rates, while provoking a highly significant fragility from an economic point of view. The coastal and pre-coastal strips are transformed into areas with a strong economic dependence on residential tourism and its related real estate activity. The current economic situation has truly compromised the sustainability of this structure.





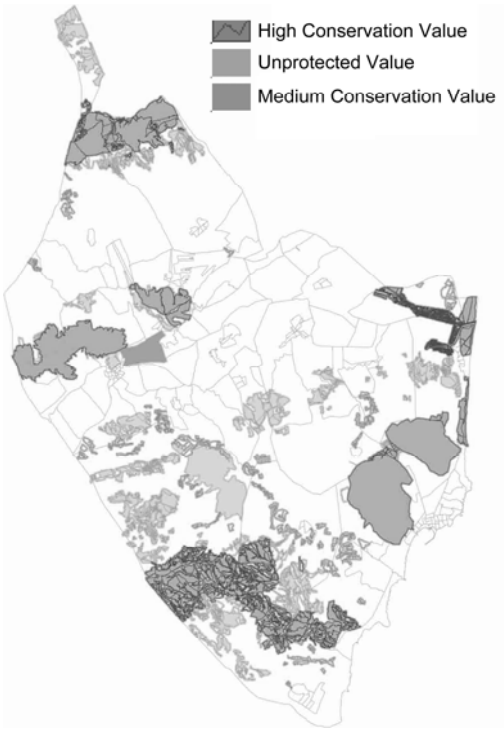


Figure 10: *Thematic map of economic fragility. Source: the authors.*

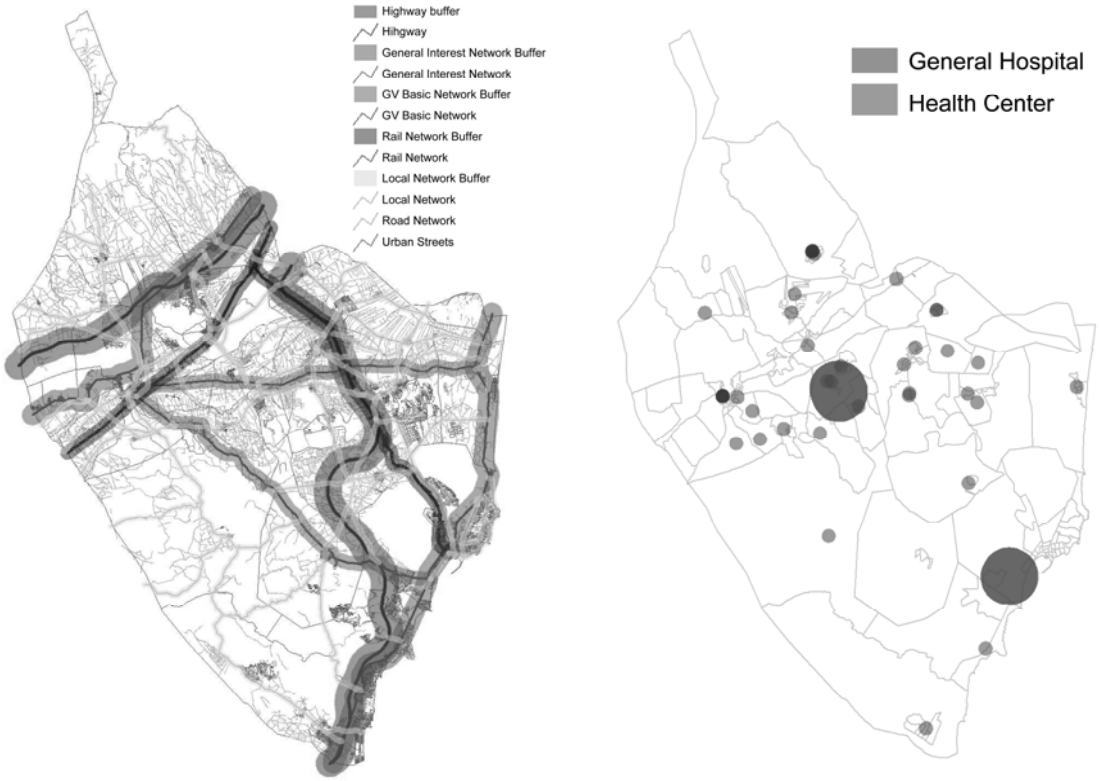
Environmental fragility

The coastal strip has been losing many of its original and potential environmental values as a result of the massive urbanization process that has reached the very edge of the coast. The most environmentally fragile areas are located on the pre-littoral strip. Here, there are highly valued areas for conservation, without any protection statues, that have been covered with golf courses in an effort to maintain a rural framework while opening the door to intense residential development (Fig. 11 and 12).

Figures 11 and 12: *Landscapes and value for land preservation. Source: the authors.*



The loss of the landscape due to the "invasion" of constructed areas provokes critical situations that can be observed on the "Environmental fragility" themed map (Fig. 13). It also illustrates the need to redirect development and not stand in the way of the environmental potential, which has been significantly depleted due to the expansion practices of land markets.

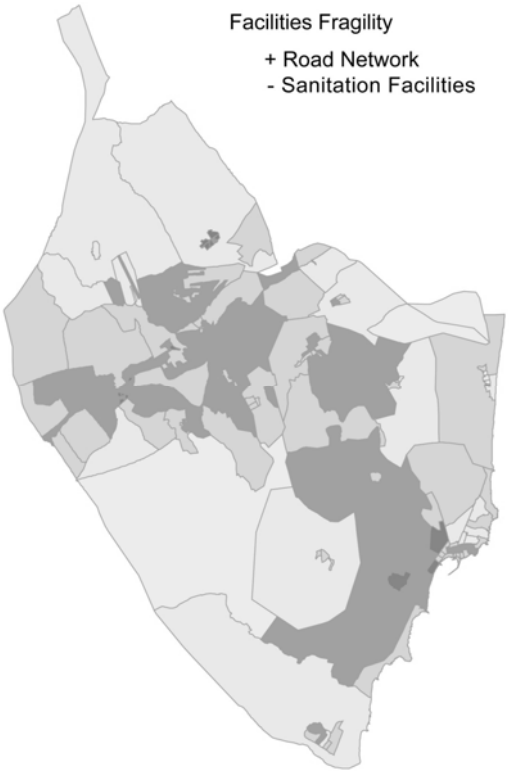
Figure 13: *Thematic map showing environmental fragility. Source: the authors.*

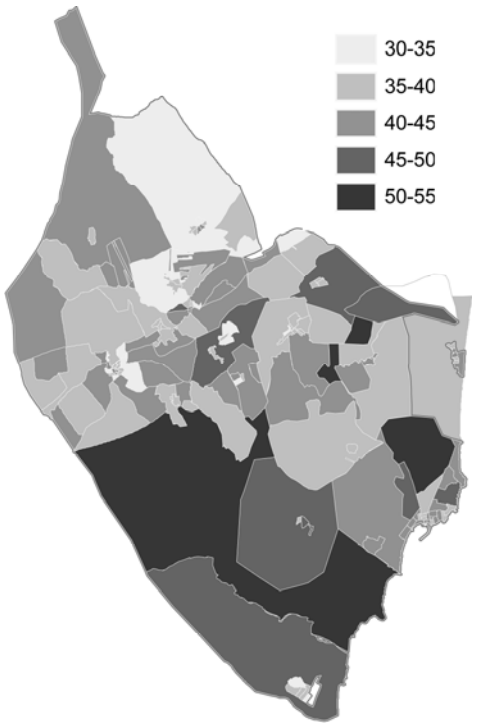
Facilities fragility

A structural and functional analysis of the existing road network makes it possible to detect two corridors that can be considered structurally important to the area (freeway AP-7 Alicante-Cartagena, N-340 and N-332). This also makes it possible to identify the areas, which, in theory, pose more accessibility or interconnection problems, as well as the roads that present the best potential conditions from a functional point of view (Fig. 14). This analysis has been linked to the area's sanitation facilities, detecting significant scarcities in the pre-littoral strips around Orihuela Costa and Montesinos.

Figures 14 and 15: *Areas affected by the road network and sanitation facilities. Source: the authors.*

However, from a non-residential point of view, this fragility is tied to surroundings with construction activity and very high market values. Therefore, within the framework of sustainable territorial development, it is essential to conduct non-residential analysis before development. Additionally, developments cannot be planned without establishing their large-scale viability (Fig. 16).





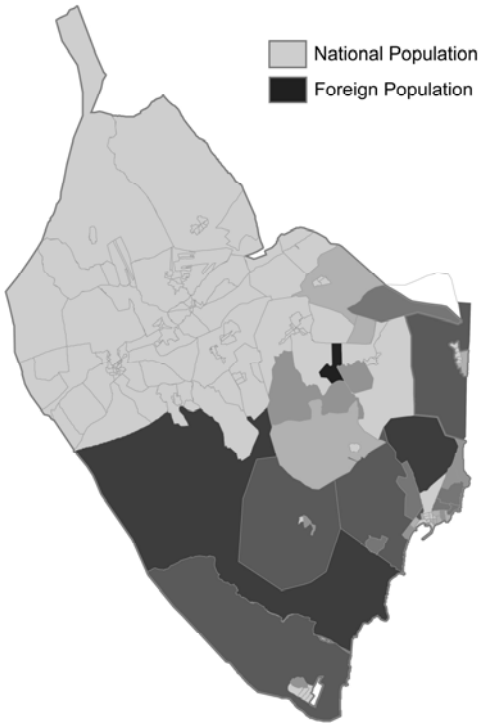


Figure 16: *Thematic map of facilities fragility. Source: the authors.*

Population fragility

The analysis of the social sphere leads to the question of whether or not we are really looking at a potentially sustainable population structure. The population features have caused a break in the economic model that clearly divides the area into two realms. The coast is crowded by a population with an average age, socioeconomic level and education level that is superior to that of the area as a whole.

Figures 17 and 18: *Average age of the population and percentage of foreign-Spanish population. Source: the authors.*

Education levels (Fig. 19) are higher near towns and the pre-littoral strip, due to older (Fig. 17), often foreign (Fig. 18), residential tourists, as opposed to local inhabitants. This structure is easily vulnerable to relevant changes, given that this type of inhabitant, while not temporary, is unstable, and has an uncertain renewal index.

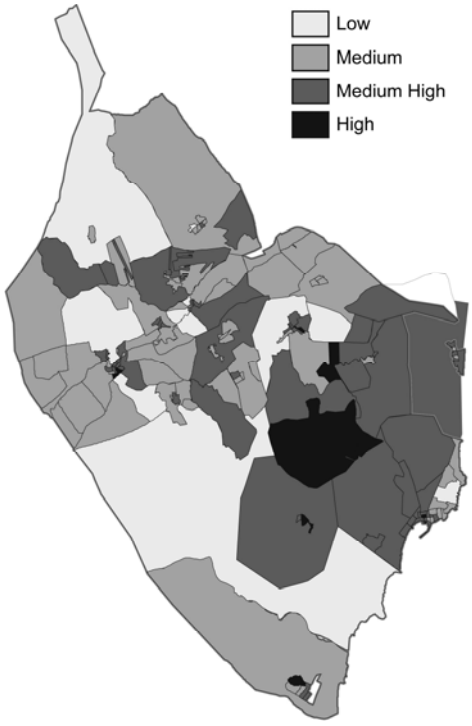

Figure 19: *Average education level. Source: the authors.*

Within this context, there are fragile areas (Fig. 20) with important issues of imbalance with regards to the modification of the population structure.

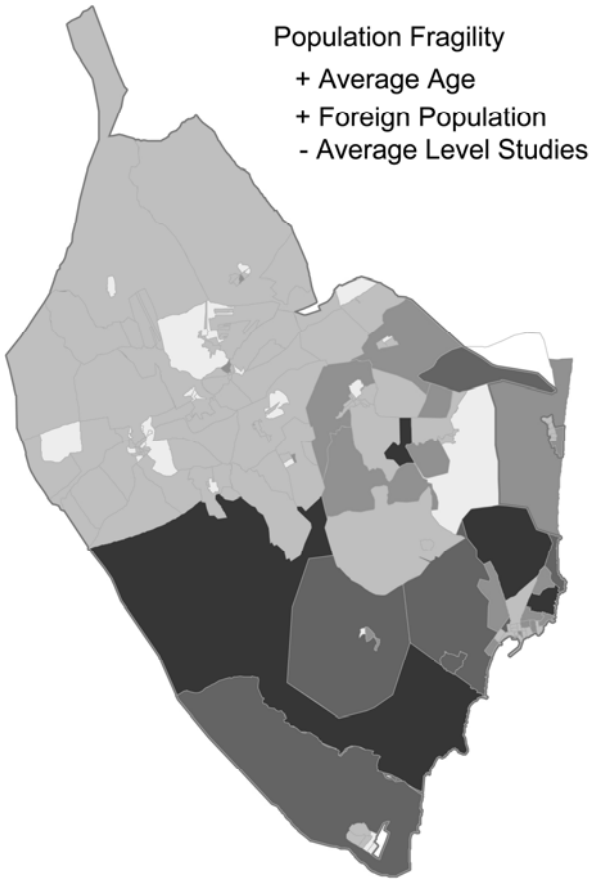

Figure 20: *Thematic map showing population fragility. Source: the authors.*

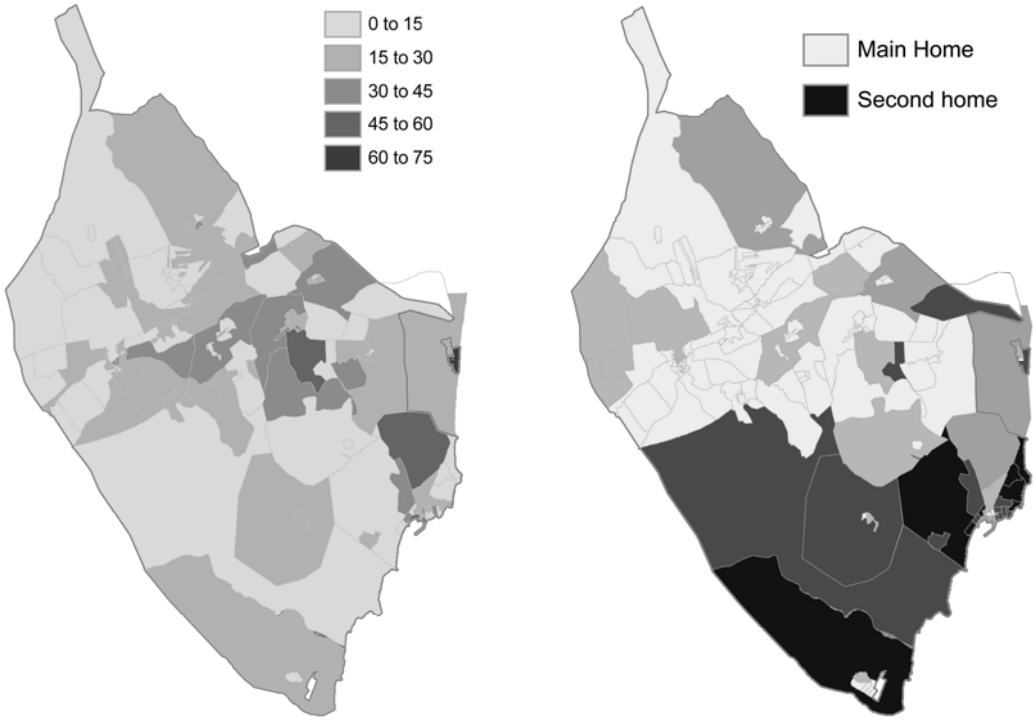
Typological characterization



The single-family home is strengthened as the characteristic typology (Fig.21). The multi-family unit is relevant in urban centers and in the areas surrounding the town of Torrevieja. However, a trend has emerged towards a two or three-story apartment with a ground floor that has a garden, patio or solarium, imitating a single-family typology while maximizing the profitability of the land. The smallest home-size averages (Fig. 22) are located in those areas where the multi-family typology has greater significance.

Figures 21 and 22: *Characteristic building typology and average size of homes. Source: the authors.*

There is a significant percentage of empty homes (Fig. 23) in the town of Torrevieja and the pre-littoral strip where the colonization process of the countryside, through real estate promotions destined for second homes in previously unpopulated areas, has been most intense. In towns like Almoradí, Dolores, Algorfa, and Catral, the cultivation of un-irrigated crops has been substituted for urbanistic developments that have left a large percentage of homes vacant.

The seasonal variation (Fig. 24) is very apparent, given that there is a clearly discernable area destined for second homes in the southern coastal areas and another of primary residences towards the interior.

Figures 23 and 24: *Index of vacant homes and seasonal variation. Source: the authors.*

Territorial valuation and urban value

The superimposition of the thematic maps pertaining to environmental (Fig. 13), non-residential (Fig. 16), and population (Fig. 20) fragility allows create a map that shows the valuation of the territory. This evaluation will allow us to establish later the aptitude of the territory for receiving real-estate developments. In parallel, a spatial distribution has been established for both single-family and multi-family market values (Fig. 25 and 26).

Figure 25 and 26: *Spatial distribution of single-family and multi-family market values. Source: the authors.*

The highest market values are found in areas close to the coast that have been subject to intense urban developments destined for second homes. Notwithstanding, these coastal and pre-coastal zones are the most fragile from a territorial point of view. (Fig. 27)

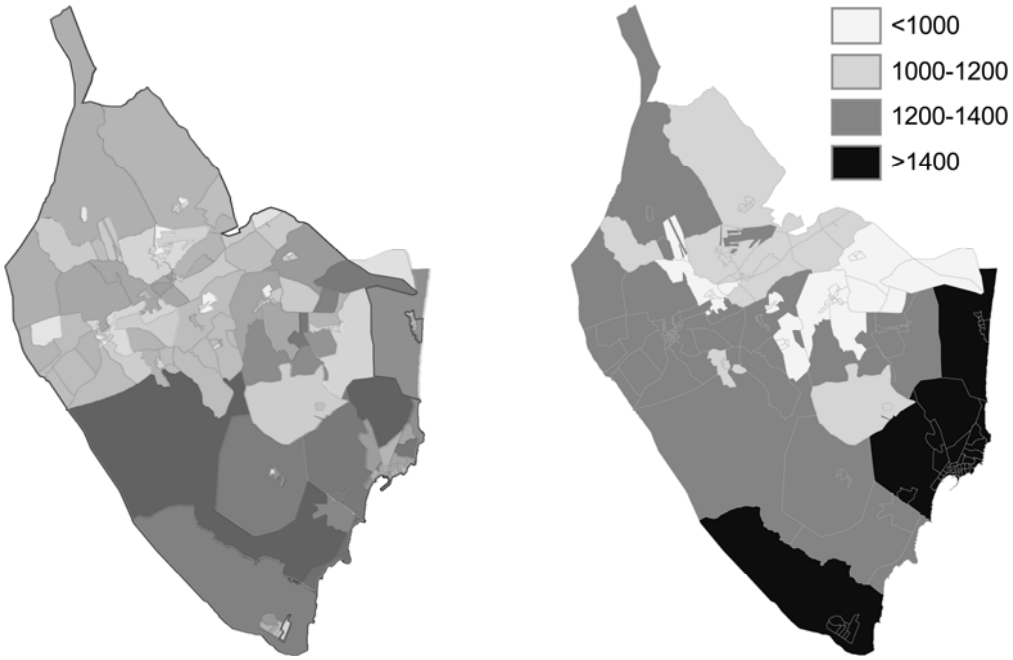


Figure 27 and 28: *Map of territorial fragility and real estate valuation. Source: the authors.*

CONCLUSIONS

The area known as the Vega Baja del Segura has undergone an intense transformation process due to the development of the real estate and tourism sectors. This has led to new demands, which are being met through a complex interaction process made up of legal statutes and political decisions, and without a clear renunciation of its "rurality". The area's development is an unequivocal example of the expansionist policies of the land market that have played out along the Spanish coast during the last two decades. The result has been a significant increase in residential land and a gradual loss of the territory's environmental values.

A justification for keeping the rural spaces alive can be found in the paradigm of sustainability, understood to be a safeguard for the environment. The medium is used as a mechanism for nature conservation and the endowment of green spaces, and as support for resources having to do with the landscape, recreation and tourism; not to mention as an indispensable space for creating areas or discontinuity between urban agglomerations.

Rural spaces are now fulfilling a new function. The different areas must be maintained in a sustainable manner a network of essential elements for achieving a balance between territory, the environmental and the landscape. This will be able to answer to an aspiration that modern societies demand as a fundamental component of quality of life.

The proposed valuation system is a tool for the global evaluation of a territory. Its usefulness is in demonstrating the territory's critical points in order to contribute to its sustainable development. The conflicts and opportunities can be evaluated through the logic of the resulting relationships. The result is a map of global valuation that points out environmental limitations, societal demands and economic potentialities. The area of Vega Baja del Segura has undergone a growing number of interventions that have been detrimental to the sustainable integration of the medium's more disturbing elements. The qualitative valuation of the territory has made it possible to detect its drastic division into two zones that are leading to a clear break in the area's structure. This break was mainly caused by factors relating to population and economic issues, which have had a decided influence on the area's development.

The obtained valuations are practically mimetic with regards to variables like the percentage of foreign-Spanish population, average age of the population and the seasonal variation. This demonstrates the clear dependence between the typological characteristics of the real estate product and the population structure.

What would be the development process for this model, based on suburban growth linked to tourism and construction, if this clear structure were drastically modified? Does this constitute a merely immediate problem, or does it open a breach in the area's structure that will be extremely difficult to resolve? Should the territorial value be protected or consumed?

It should be pointed out that the highest market values, linked to the very intense urban developments that have taken place over the last few years, are associated with those zones where they are overlapped by the greatest environmental, economic and population-based fragilities. We therefore find ourselves in a real estate market that doesn't truly respond to the territorial characterization, but rather to extraterritorial conditions that have defined both the population and economic structure.

To find adaptable solutions to the existing offer, it is necessary to make viable the renovation of the population structure or to carry out economic changes. The search for answers to these

questions points out the need to redirect development, without obviating the potentiality of the area. An indispensable tool for achieving these objectives is the designing of an urban planning that contributes to a sustainable development and adjust to the real needs of the territory. .

Abstract

For many years the issue of how to design buildings which can adapt to changing demands has posed a considerable challenge. This debate has had renewed significance given the emergence of the sustainability agenda and the need to extract additional value from built assets through life. Developing a better understanding of how buildings change over time is arguably crucial to informing architects concerned with extending the life of buildings. This paper critically reviews literature on adaptability, together with that relating to knowledge feedback and architectural practice, in order to construct a theoretical platform for understanding how knowledge of how buildings change can be used to inform design decisions. A pilot case study is used to illustrate the ways in which buildings change could be captured to inform adaptable designs in the future. The work reveals a lack of knowledge in how buildings change and how, if this was fed back to architects, it could support design decisions that might increase the life of many buildings.

Keywords: building appropriation, adaptability, design decisions, feedback, sustainability

INTRODUCTION

Designing for adaptability has had renewed significance since the emergence of the sustainability agenda and the need to extract additional value from built assets through life. Beadle et al. (2008) argue that "adaptable buildings have the ability to change use with market conditions, enabling them to have a longer useful life". Russell & Moffatt (2001) emphasise that the building stock is a key resource that needs to be managed correctly in order for it to be sustainable - as urban areas everywhere are experiencing problems related to poor use of buildings, and high flows of energy and materials. This is supported by Bijdendijk in (Leupen et al. 2005), who claims a sustainable building has two qualities: it can accommodate change (i.e. individual values) and holds preciousness (i.e. collective values) through its exterior and shared spaces. As Graham (2005) summarizes, "A sustainable building is not one that must last forever, but one that can easily adapt to change". Thus, the

creation of a more sustainable environment can be augmented by adaptable design strategies that produce a level of building malleability, and which allow for a variety of changes to be accommodated. Thus, developing a better understanding of how buildings change over time is arguably crucial to informing architects concerned with extending the life of buildings.

The research examines the hypothesis that real accounts of change over time will provide designers with a more informed perspective towards designing for adaptability. It investigates the extent to which current feedback mechanisms provide an effective method for doing so and what new or revised mechanisms could be developed to address this need. In order to address these issues, the paper critically reviews literature on adaptability, feedback, and architectural practice, as links between the three could provide insights into improving the design of adaptable buildings by understanding what parameters are critical and how changes to them can be captured and implemented in future design decisions.

ADAPTABILITY

The section expresses an overarching understanding of adaptability, focusing on how buildings accommodate change and how this could be improved by reviewing the different parameters that allow buildings to better accommodate change. There are various definitions of adaptability, however, the overriding message of many of these reflects the ability of a building to respond to or accommodate change, whether this is specifically focused on user needs, or some wider reaching criteria, such as the state of the market (Schmidt III et al. 2010). The working definition of adaptability that will be used for this report is - *a building's ability to accommodate change throughout time, fundamentally extending its life.*

A distinction can be made between buildings that have been designed for adaptability and ones that have not. However, buildings that have stood the 'test of time' tend to be a mixture of the two, signifying that not all buildings designed for adaptability escape obsolescence and some buildings that were designed with no explicit consideration for adaptability can be adapted over time. Using a streetscape in New York City between 1865 and 1990, Brand (1994) highlights for every building that has stood the test of time there are seven that have not. This failure to survive is termed 'building obsolescence' and the cause of this can be wide ranging, including changes in legislation, technology, economic conditions or architectural style (Mansfield & Pinder 2008). Essentially the building has been unable to accommodate change rendering it no longer of use. From this, it is possible to see that there needs to be an understanding of what allows certain buildings to be adapted rather than demolished and vice versa. Understanding how buildings can or can't accommodate change will provide interesting lessons that could be fed back to help move beyond pre-described ideas of designing for adaptability, which have endured mixed success.

As a general perception in order to add adaptability into the design of a building there is a need to over specify mechanical and electrical plant sizing, floor area provision, structure, etc (e.g. Finch 2009, Ellison & Sayce 2007). This is combined with identifying physical aspects (e.g. durability of materials, span depth, floor to floor height) and specific technical solutions (e.g. moveable partitions, drop ceilings, raised floors) (Schmidt III et al. 2010, Fuster et al. 2009, Matsumura et al. 2006, Durmisevic & Brouwer 2002, Madden & Gibb 2008). In addition, understanding the configuration of a building and the interactions between its components can provide insight into how a building will endure change (Schmidt III et al. 2009). Layers provide a way of thinking about the building that link both time and the building's material form, conceiving components as different 'layers' of longevity. As Duffy (1990) clearly articulates, 'There isn't such a thing as a building… a building properly

conceived is several layers of longevity of built components'. Brand (1994) expanded upon Duffy's (1990) layers concept to include the total building (Table 1). While the table below shows the differing lifespan of components ranging from daily to eternal, it does not make any correlation with different types of change a building may go through and how architects may start to understand them.

Layer	Description	Timescale
Site	Geographic setting of building	Eternal
Structure	The load bearing elements including foundations	30 – 300 years
Skin	The exterior surfaces that provide a weather protecting layer	20 years
Services	The working guts of a building – HVAC, electrical, plumbing, sprinklers etc	7 – 15 years
Space Plan	The internal layout – internal partitions, doors etc	3 – 30 years
Stuff	Furniture, equipment, personal positions of occupants	Daily

***Table 1**: Building layers and time (adapted from Brand 1994)*

Schmidt III et al. (2010) expand the concept of layers by linking them to six different strategies or types of changes for thinking about adaptability (Table 2). This provides a more comprehensive idea of how buildings evolve over time, while not attempting to predict what may happen to buildings - it is simply linking different types of change with how often and to what parts they are likely to change.

Strategy	Type of change	Building layer(s)	Frequency of change
Adjustable	Change of task	Stuff	High
Versatile	Change of space	Stuff, Space	High
Refitable	Change of performance	Space, Services, Skin	Moderate
Convertible	Change of function	Space, Services, Skin	Moderate
Scalable	Change of size	Space, Services, Skin, Structure	Moderate/low
Moveable	Change of location	Structure, Site	Low

***Table 2:** Adaptable strategies and layers (adapted from Schmidt III et al. 2010)*

The consideration of the proposed layers and strategies suggest a framework for which specific examples of changes accrued can fit into and may enhance design decisions towards a more adaptable designed solution. It is therefore crucial that this understanding of change over time is fed back to architects.

FEEDBACK

Leaman & Bordass (1993) suggest that "Good design seemingly creates opportunities out of apparent constraints; Bad design seems to deny opportunities". But how is it possible to tell what is good or bad design without feedback?

This section explores the literature pertaining to feedback and how this has been used to inform design decisions. A number of publications examining the evaluation of buildings

(Gorgolewski 2005, Preiser 2005), show how feedback could be integrated into every stage of a building's lifecycle, for example, through building log books, Sea trials, POEs or DQIs. However, in practice most architects and contractors have shown little interest in learning how their buildings actually perform in use (Bordass 2005).

According to Bordass & Leaman (2005) there are currently five different categories of feedback techniques ranging from a type of audit where quantitative methods are used to measure the buildings technical performance, to package and process techniques which incorporate both quantitative and qualitative methods. These methods include: an in-house team to support the clients moving in and solving any small problems that may become chronic irritants such as the Soft Landings approach (Bordass 2005); a design review (Cook 2007); and a workshop with all major stakeholders (Preiser 2005). It is important also to note that the methods can also be distinguished by who they're carried out by - between users or an expert (Bottom et al 1998). User feedback offers an occupants' subjective perception of the space, where as expert feedback is aimed at objectively quantifying building characteristics. These feedback techniques are meant to gain a holistic view of the building in use; however, they do not currently include techniques that explicitly document how buildings change over time.

An example of a technique from the audit category is the CIBSE TM22 (Bordass et al. 2001). This technique, mainly aimed at service engineers, is a method of surveying and reporting the energy use of a building at any time. Given the data collected, it can also calculate the anticipated savings due to a change in use, which is valuable for engineers, but offers less value to architects, who are unlikely to use it due to its specific role in telling engineers the performance data of the building.

An exemplar from the discussion category is the Learning from Experience (LfE) handbook (Bartholomew 2003). This technique uses interviews to review and reflect on projects. Intended for large construction organisations, it is excellent at transposing tacit knowledge gained on the project to the rest of the organisation. Its main focus is on the business case and where money can be saved. It does, however, ask three main questions that could be very useful for feeding back and documenting change to architects. These are: what happened; why did it happen; and, what can be done better? These provocations could be adapted to look at change within the building, e.g. what has changed? Why has it changed? How could this improve future design?

There are many different approaches within the questionnaire category, including the AUDE POE Guide and Building Use Studies, which are aimed at the client and the users' perception respectively. The majority of these approaches are limited by the fact that a questionnaire cannot explore the building in any depth; in order to gain any depth the questions would have to be qualitative in nature. One questionnaire method that offers some insight is the Design Quality Indicators (DQI) survey (Gann et al. 2003). This user focused technique starts off as a questionnaire, but also includes workshops to discuss the findings with the stakeholders in order to gain a fuller understanding of the meaning behind the data collected. The survey is designed so that these workshops can be conducted at any stage in the project from the preparation and briefing phase to the building-in-use phase. The two most important phases for this research are expected to be the design phase and the use phase, and these are also identified as key phases in the original DQI methodology, because in these phases all of the main stakeholders are brought together to discuss how improvements could be made, allowing for a much broader remit of subjects to be explored. During the design workshop, materiality and the needs of the user are the key focus. During the use phase workshop, the

impact of the building design on the users is discussed and recorded, implicitly a workshop of this kind will produce some explanation of what has changed within the building and why. However, the DQI methodology does not attempt to understand these changes using a verified framework. Nor does it explicitly feed this knowledge back to the architect with the purpose of improving future design decisions. This could be due to the focus of the workshop relating to how to improve the users' environment, rather than how architects can improve future work.

One of the most successful feedback tools used in recent years is based on the PROBE studies (Derbyshire 2001). This tool is essentially an amalgamation of some of the approaches discussed above, mainly looking at user satisfaction, energy consumption and manageability (Blyth & Worthington 2000). What made this so successful was that it managed to publish all of its results in the public domain, meaning that the knowledge could be transferred further than just the participating companies. However, in the context of this work, because this tool is very much based in the engineering field, it is not expected to offer much insight regarding how architects design decision-making might be informed in pursuit of adaptable solutions.

The major problems with existing feedback techniques are that they are all based around two objectives; the technical performance of a building and the improvement of the users environment. They are also currently based around a single point in time, only DQIs are strategically set up to be implemented at different points in time. However, they are still based around a prescribed set of questions aimed at the user's perception none of which may be valued by architects, who instead of looking at the shortcomings of a completed building would much rather move on to the exciting task of a new assignment (Blyth & Worthington 2000). It is therefore important to understand how feedback mechanisms could match architectural values, and how this link could allow for an effective feedback tool that engages the enthusiasm of architects. It is also worth noting that in order for feedback techniques to be successful, champions of feedback need to make a more persuasive case to a broader range of stakeholders as well including clients, developers and occupants on the added value or real savings that can be gained from feedback (Zimmerman & Martin 2001).

ARCHITECTURAL PRACTICE

This section attempts to express the link between architectural practise and feedback pertaining to how buildings change. An architect's values are what set them apart from other professions when it comes to the concept of designing buildings (Cohen et al. 2005), and shape why architects design the way they do. These values can come from an architect's education or experience, and motivate the decisions and guide the behaviours of the designer. Broadly, values are defined as principles, standards, and qualities that guide actions. (Le Dantec & Do 2009).

Most architectural values are based in the visual arena (aesthetics, visual perception, beauty); this is hardly a surprise considering the nature of architectural work and what they are creating (Till 2009). The idea of timelessness or time standing still is also articulated; suggesting most architects ignore time to focus on the aesthetic fixation and immediate functional performance of buildings (Schmidt III et al. 2010). This is likely to create a fundamental barrier to the idea of learning from feedback in the conventional sense. However, it is not suggested that architects do not want to learn per se. This is backed up in their values, when Schön (1984) states that architects are always learning in the sense that architects learn by doing in order to build up their experiences, therefore they are continually

learning through experience. This is supported with what is found in modern practice where architects engage in CPD (continuing professional development) events, lunch seminars, and evening training courses typically aimed at improving computer skills; knowledge of new materials/ regulations; or learning about architectural theories, practices and buildings. Ethics and a feeling of social responsibility are also mentioned (Till 2009), which shows that architects should be open to learning in order to improve the built environment.

Clearly, these values can have a significant impact on how architects design, so it is important to understand how these values develop, in order to conceive how best to affect design decisions. Architectural education is a very important concept to explore; it sets the foundation as to how architects learn both during education and in practice, providing insight into how value systems are shaped. Cuff (1991) insists that architectural education has, for a considerable amount of time, been very much based around learning how to be creative and thinking for yourself; while Lawson et al. (2003) adds that 'knowing by doing' is a readily accepted method of educating within architecture.

A strong criticism of the education system is that "adaptive use is the destiny of most buildings, but it is not taught in architectural schools" (Brand 1994). Most programs emphasis innovation and novelty (Glasser 2000), very little education goes into how to change existing buildings, so there is no knowledge taken forward from education into practice in this area (Kohler & Hassler 2002). Perhaps an answer as to why architectural education and practice are different lies in the fact that, within architectural education it is expressed that it must not mimic the real world in all aspects, as it serves a very important creative and exploratory purpose and if they weren't taught this within education, architects would not be able to apply this conceptualisation in practise (UIA 2005). An additional argument for why education can't directly mimic practice is that the complex web of social interactions that are played out by architects in practice may be hard to replicate in an educational environment (Demirbas & Demirkan 2003).

The above arguments seem to suggest that, intentional or not, there is a missing link between education and practice. It is understood that architectural education must be used as a time to expand creative knowledge; however, the content of that exploration could incorporate an improved understanding about how buildings change. This could still match the underlying problem solving nature of the education (UIA 2005) and might generate creative solutions to current adaptability issues.

Although the value system is shaped in education, it is also instilled within practice; therefore it is also important to examine the literature surrounding architectural practice. There are many problems in practice that not only act as a barrier to learning but can also reduce the quality of the buildings that are produced. A fundamental problem with project-catered organisations is often there is a need to work with new teams, including clients and contractors (Macmillan et al. 2002), which can reduce levels of trust, and the need to build a relationship becomes key, rather than learning, as would be typical of more mature relationships.

A more recent issue is the shift in power within the construction industry from architects to contractors (Kieran & Timberlake 2004). This often means that the architect is merely a subcontractor (Krygiel & Nies 2008), which could be a barrier to 'architectural' feedback; if the client only wants the architect to create the aesthetics of the building. With re-use and refurbishment of existing buildings becoming increasingly important to sustainability (Pearce 2004), and sustainability becoming increasingly important to clients, it could be argued that

architects could regain this power if they had an increased understanding of how buildings can change over time.

A repetition of mistakes because of a lack of learning from past projects is a recurring theme within the literature (Bordass & Leaman 2005). Heylighen et al. (2007) argue that architects (and the building industry in general) have a tendency to disregard past projects in order to concentrate on future ones. This is also reinforced by the way contracts are framed and finished at the end of construction (Barlow & Koberle-Gaiser 2009). In order to incorporate a way to understand time and change in current architectural practice, it is important that lessons are learnt from the entire building stock and how it has changed, so that design decisions in pursuit of creating adaptable solutions can be better informed.

METHODOLOGY

The pilot case study served as a tool to inform and refine data collection plans (Yin 2004). The aim was to gain a holistic understanding of the building and to explore whether there were any lessons to be learnt and fed back to the architects. Qualitative data was collected for this preliminary exercise through semi-structured interviews with major stakeholders of the Nottingham science park; this included the architect, the building manager and developer.

The interviews covered a range of questions geared at uncovering stakeholder values and roles along with understanding what changes were planned for in the design process and what changes have already occurred in use. The questions were based around gaining information in relation to the six strategies presented earlier as they would be used to organise and analyse the different types of changes. Data from each interview was then coded and a thematic content analysis was conducted in relation to each of the adaptable strategies outlined in an attempt to answer the research question posed at the start of this paper - How might design decision-making in pursuit of adaptable solutions be informed?. Through analysis of the interviews the provocations presented at the end of each adaptable strategy are an initial attempt to glean lessons from the data.

CASE STUDY

Nottingham Science Park

The Nottingham Science Park is a speculative office development constructed by the developers Blueprint and designed by the architects Studio Egret West. It was completed in 2008 and is located on the outskirts of Nottingham in the area of Beeston opposite Nottingham University. The development offers a range of spatial sizes (1000 to 20,000 sq ft sized offices), fit out levels (shell & core to full lab spec), design (grade A office to bespoke solutions) and leases (flexible lease terms to suit individual requirements).

Figure 1: *Exterior perspective*

Figure 2: *Internal layout*

Adaptable Strategies

Adjustable

Most of the rooms can be reconfigured as none of the furniture is fixed. However this could be a larger undertaking than first realised as when an office is fit out electrical plugs are positioned under the desk layouts through the raised floor. If this layout was to change the electrical plugs would have to be moved also. Another related issue is the fact that fresh air comes through ducts in the raised floor so these would have to be moved away from the underside of desks for user comfort. Both of these reduce the adjustability of the office space; however, it is still feasible compared to providing fixed furniture. *Could alternative electrical and ventilation solutions been provided to ease the shifting of furniture?*

One of the changes that have already occurred within the building is the addition of a carpet to the mezzanine floor as it was found that people walking on the hard floor caused too much noise for the adjacent meeting rooms. *What is the appropriate level of acoustics for the meeting room and other areas? Could the walls been detailed differently initially to accommodate the hard wood floors?*

Versatile

The science park is very flexible as stated by the owner, “We wanted a very flexible layout with a notion of a central hub with a series of pods going off it.” The park can be split from a series of small offices of around 1000 sq ft to the occupation of a full floor.

One interesting point which could hinder versatility is the management of how the offices are split up. For example if a company wanted to expand yet the management had put another office in the adjacent section it would not be possible to simply knock down the partition wall, the expanding company would have to be relocated or given a separate office. *Is it possible for the configuration of space to be designed so that the segregation of offices is optimal? Are there different operational processes that could improve the configuration of space?*

Refittable

The science park has a very high specification of services within it, these services have been designed so they can be divvyed up into different sections, which help with the versatile aspects of adaptability; however, it could also be argued that a major refit would be aided by

the design as long as it was a similar configuration as to what is there now. The ability to add extra ventilation has already been brought into question when one of the clients requested a laboratory section to their space. This request was granted however the solution for adding additional ventilation was clearly not considered before the request as there is a ventilation tube now stuck through an open window. Reasons for this stem back to the envisaged uses of the building not including laboratories.. This request was however said to be easy in the sense that the raised floor could be removed to incorporate the additional loading strength. However another issue was the insurance implications for the building, the building itself could sustain this type of activity however the insurance was an issue as it was built predominately as an office building, this clearly wasn't thought about. *Are there any uses that would require extra services? What is the strategy for refitting the services of the building?*

The cladding could also be refitted easily as it uses a dry connection fitted to insulation, however when asked whether this was a consideration when writing the brief for this project the developer stated that it was "post rationalisation". The architect also added that it 'could' be very easy to re-clad the building, but didn't see this as a likely scenario. *As the skin of a building is envisioned to last approximately 20 years and the structure intended to last much longer (in regards to Brands layers) shouldn't there be a strategy to replace the cladding? Would an easily removable skin aid in the external maintenance of the building?*

Convertible

Convertible strategies involve changing the use of a building. In terms of the science park, it wasn't envisaged in the brief and would be very difficult for many reasons. Location would be a major reason as it is located next to another science park (opposite a university) and out of town, so there is very little demand from within the retail, accommodation, or entertainment sector. The structure itself probably could lend its self to residential in that it can be split into small sections, however there would be very limited local amenities. Planning constraints (e.g. zoning), building regulations (e.g. fire regulations), and zoning of services could also limit this. The structure could accommodate interactive classrooms with in it; however it wouldn't be able to accommodate a split level lecture theatre, so it wouldn't be ideal for an education building. In terms of other university uses, it could be converted into administrative space or a place for non laboratory research. *What functions could this building be equipped to change to with minimal effort? What is needed to accommodate a wider range of uses? What uses could the surrounding area support? Does the lack of public transport affect the diversity and livelihood of the location?*

Scalable

In terms of the scalability of this building, it is built to a set size and there is no plan to ever extend it. If the foundations were overdesigned it would be able to take an extra floor, however, the majority of the plant is on the roof meaning that it would be a major job to refit these elsewhere. *If the park is very successful how does it accommodate the additional space demand?* In terms of location and according to the master plan of the site there is a further plot that could be used to build a replica if the science park proved very successful. *Are there any planning restrictions on what can and can't be built on this site?*

Moveable

The movable strategy has no relevance to this project.

DISCUSSION

In pursuit of answering the research questions several points can be summarised from the work undertaken. It has been put forth that architects are much more interested in the aesthetics of a building rather than how it may change in the future, rendering adaptability (i.e. real appropriation/change) a still poorly understood topic by architects. Current feedback mechanisms are too focused on the building's performance characteristics and not on its physical reshaping. They do not match an architect's complex value system, which is why architects appear disinterested about learning from them. In addition, conventional education and design processes for architects don't value the building as a dynamic process, but as a static finished object.

The above points have lead to the assertion that there are no current mechanisms that communicate the changes in a building's life back to architects in a way that matches well with current values/processes. This argument has been positioned by the literature and exploratory case study by exploring how adaptability can be stratified in time as a series of strategies and layers, how current feedback mechanisms don't communicate changes in the built form, and how current mindsets and processes of stakeholders undermine attempts to feed knowledge back.

In the pursuit of adaptable solutions it remains critical that an effective feedback mechanism, which takes into account architects values and ways of working, be developed in order to better inform future design decisions. This method must support accessibility of explicit knowledge, rather than tacit knowledge, to ensure that any understanding of change has a tangible impact on the profession. The case study illustrates this by showing a number of provocations that, if thought about during the briefing/design stage, could have affected the composition of the building itself. They may not have changed the overall aesthetic of the building but may have improved the configuration and relationships of some elements. This mechanism could compliment other techniques that are currently implemented when a building is in use (e.g. DQIs) by adding an understanding of the changes that have occurred within the building through the adaptable strategies and framework. The next step in the research is to suggest a feedback technique that would best match architectural values.

CONCLUDING REMARKS

Developing a better understanding of how buildings change over time is arguably crucial to informing architects concerned with extending the life of buildings. It shouldn't be an attempt to predict what buildings may change into in the future as, "all buildings are predictions and all predictions are wrong" (Brand 1994), but rather an attempt to construct a platform for capturing and understanding how knowledge regarding the way buildings change can better be used to inform design decisions. This can be supported by understanding how buildings change - by defining different types of changes and how they relate to the different physical elements - by understanding the available methods for knowledge to be transferred from the operational phase of buildings back to the producers of buildings and by understanding the processes and values the producers hold.

Adaptability can no longer be seen as a 'one size fits all' solution and should be developed with the complexity it affords; lessons can and need to be learnt from the building stock in its entirety, which should only improve the design of adaptable buildings in the future.

ACKNOWLEDGEMENTS

The authors would like to thank all the interviewees for their wiliness to participate in the research. This research project is funded by the EPSRC through the Innovative Manufacturing and Construction Research Centre at Loughborough University.

Abstract
It is not sustainable for construction projects in Singapore to rely merely on a Singaporean workforce due to the low participation rate of indigenous workers. A typical construction site in Singapore thus comprises migrant workers from several countries. This gives rise to the need for diversity management on construction sites to ensure social sustainability. The aim of this research is to examine styles that project managers adopt when managing multi-cultural migrant workers in construction projects. The specific objectives are to: investigate the socially sustainable managerial practices adopted by project managers when dealing with migrant construction workers from China, India and Thailand; and identify if there are any differences in management practices when dealing with migrant construction workers from different countries. The research method is questionnaire survey, and data were collected from project managers who had managed migrant workers in Singapore. In-depth interviews were also conducted to confirm the statistical results. The research found that project managers tend to use task-oriented more than relation-oriented management style to achieve social sustainability. The management practices that are significantly implemented include requiring workers to be punctual, giving assertive instructions, providing close supervision and enforcing rules so that social sustainability can be maintained on construction sites.

Keywords: Social sustainability, diversity, leadership, management.

INTRODUCTION

A construction project usually requires a large number of workers. In Singapore, relying on indigenous workers to undertake construction work is not sustainable because Singaporeans eschew this sector of the economy. Official statistics show that the construction sector in Singapore is the most reliant on migrant workers as it attracts only 6.1% of resident workforce (Singapore Department of Statistics, 2000). On a typical site, construction

workers may hail from countries like Bangladesh, China, India, Indonesia, Malaysia, Philippines, Sri Lanka and Thailand. This suggests the need for construction projects to be managed in a socially sustainable manner, taking into account cultural diversity as a result of the workers coming from different countries.

Gilbert et al. (1996) defined social sustainability as practices to ensure that the cohesion of society and its ability to work towards common goals are maintained, and that individual needs should be met. Using inappropriate management practices can render projects to be managed in a socially unsustainable manner, which would result in serious consequences such as stress among the workforce, confusion, frustration and conflict which translates into lower morale, productivity, quality problems and higher accident rates (Loosemore and Lee, 2002). It is thus essential for project managers to apply appropriate management practices in order to effectively lead a multi-cultural construction workforce in a socially sustainable manner.

The aim of this research is to examine leadership styles of project managers when managing multi-cultural migrant workers in construction projects. The specific objectives are to: investigate the socially sustainable managerial practices adopted by project managers when dealing with migrant construction workers; and identify if there are any differences in management practices when dealing with migrant construction workers from different countries. The purpose of identifying leadership styles and management practices is to inform project managers who are going to manage sites with migrant workers from several countries on the more effective practices and styles to achieve social sustainability.

The scope of research covers Singapore resident project managers' management of migrant construction workers from mainland China, India and Thailand on construction sites in Singapore. It is widely observed that the largest percentage of migrant workers come from Singapore's nearest neighbour, Malaysia, though published statistics is not readily available. Malaysians have similar culture to Singaporeans due to geographical proximity and historical links, and therefore, they are excluded from this study. Chinese, Indian and Thai workers are the next three major nationalities on Singapore's construction sites and are therefore selected for this study. The terms Chinese, Indian and Thai in this paper refer to workers' nationalities. Singapore resident project managers, who are the subject matter experts to inform this research, are project managers, construction managers and supervisors who are Singaporeans or permanent residents of Singapore who are not from India, China or Thailand, and who had personally supervised migrant workers from these countries. For brevity, they are generally referred to as 'project managers'.

LITERATURE REVIEW

The effectiveness of a project manager is a vital component in the success of construction projects (Enshassi and Burgess, 1991). Anderson (1983) defined effectiveness as the manager's ability to supervise and manage subordinates. Laufer and Jenkins (1982) suggested that management has a direct and indirect impact on the level of productivity. The direct impact can be achieved by planning and controlling construction activities while the indirect impact is attained through a good interrelationship between managers and their subordinates that may raise the motivation of the work force. In Singapore, project managers have the additional responsibility of managing cultural diversity among migrant construction workers to ensure social sustainability.

The most common cross-culture management challenge is to facilitate culturally-diverse people to work together which requires special skills and sensitivities (Child, 1994). Cross-cultural management studies have provided several leadership styles to cope with cross-cultural differences. Among these, Contingency Theories (Fiedler, 1964; Hersey and Blanchard, 1969) appear to be the most relevant.

Contingency Leadership Theories

Fiedler's (1964) Contingency Theory of Leadership asserts that group performance is contingent on the leader's psychological orientation and on three contextual variables: group atmosphere; task structure; and leader's power position. Further, group performance is a result of interaction of leadership style and situational favorableness. Leadership effectiveness is the result of interaction between the style of the leader and the characteristics of the environment in which the leader works.

Hersey and Blanchard's (1969, 1977) Situational Leadership Theory rests on two fundamental concepts: Leadership Style and the individual or group's Maturity level. It states that there is no single 'best' style of leadership. Effective leadership is task-relevant and the most successful leaders are those who adapt their leadership style to the maturity of the individual or group they are attempting to lead or influence.

Based on contingency theories, two leadership styles are identified: task-oriented leaders; and relation-oriented leaders (Enshassi and Burgess, 1991). **Task-oriented** leaders are those who are mainly concerned with planning, work organization, control, efficiency, and productivity, while **Relation-oriented** leaders are those who give priority to managing internal relationships among employees and themselves, and to an understanding of cultural differences between their subordinates (Enshassi and Burgess, 1991). Task-oriented leaders are predicted to be most effective in either highly favorable or unfavorable situational conditions while relation-oriented leaders should be more effective in the intermediate range of favorableness (Barrow, 1976).

Managing cultural diversity

Cultural diversity has been studied by Hofstede (1980, 1984, 2001). He operationalized culture into 4 dimensions: power distance; uncertainty avoidance; individualism vs collectivism; and masculinity vs femininity, and subsequently added long-term orientation. He has provided indices of these dimensions for many countries, including China, India, Thailand and Singapore. The indices for the countries are different from each other, suggesting cultural dissimilarities among these nations, leading to differing values, beliefs and practices among the migrant workforce on construction sites in Singapore.

Project managers should understand the cultural differences of their subordinates in order to be effective as cultural heterogeneity has a considerable impact on their effectiveness. Low and Leong (2001) designed an Asian organizational managerial framework to manage cultural diversity. They found that an effective leader possesses the ability to influence group members towards the achievement of goals. Thus, effective management of a culturally diverse workforce ultimately contributes to the overall effectiveness of the manager and productivity of the company.

In managing a culturally diverse workforce, differences in cultural traits among workers of different countries have to be recognized in order to understand their mindsets and behaviour, so that supervisors can manage migrant workers effectively. This calls for managers to

develop and implement practices aimed at improving the effectiveness with which the organization utilizes diverse work force, i.e. diversity management. Gilbert et al. (1999) defined diversity management as a complete organizational cultural change designed to foster appreciation of demographic, ethnic and individual differences. It is argued that the challenges within competitive, dynamic and increasingly global markets are best met by an effectively managed workforce that has a diverse experience and knowledge (McCuiston et al., 2004; Seymen, 2006). Bergen et al. (2005) found positive impact of diversity while Curtis and Dreachslin (2008) found diversity impacts performance negatively.

Gap in knowledge

Many leadership studies in construction have been undertaken. Muller and Turner (2010) examined the leadership competency profiles of successful project managers. Toor and Ofori (2008) put forward authentic leaders as a new breed of construction project leaders who possess positive values, lead from the heart, set highest levels of ethics and morality and go beyond their personal interests in the well-being of their followers. These and many other studies did not address cross-cultural management in detail, and did not study management of construction workers. Wong et al. (2007) investigated cross-cultural leadership perceptions and power relationships of Chinese and Western expatriate project managers in multinational construction firms in Hong Kong. While they studied intercultural interactions, it was at the professional level, and not how construction workers are managed.

To effectively manage migrant workers from different cultures, it is important to know what leadership styles and management practices should be adopted. Otherwise, problems such as poor productivity and communication difficulties caused by different work ethics, culture and customs between managers and migrant workers would arise (Son, 2005). However, despite the need for project managers to manage a culturally diverse workforce, insufficient studies have been done to identify the more effective practices to manage migrant construction workers from different nations and different cultures. One study by Han et al. (2008) of foreign construction workers focused on their low performance due to regulations, qualifications and management systems. The study did not investigate leadership styles for migrant workers from different nations.

It is not known if different leadership styles need to be adopted for migrant workers from different countries. There is a lack of information and empirical data with respect to the effectiveness of project managers in managing multi-culture migrant workers. The fieldwork was therefore undertaken to investigate the practices adopted to manage migrant workers and explore how project managers may be more effective in cross-cultural management on construction sites.

RESEARCH METHOD

The research adopted a two-pronged approach: questionnaire survey and in-depth interviews. The purpose of the questionnaire survey was to test whether the managerial styles identified from the literature review are adopted by project managers when dealing with migrant construction workers, and whether the practices differ when migrant workers come from different countries. The purpose of the interviews was to confirm and elaborate on the statistical results.

The data collection instrument comprised a questionnaire which was pre-tested. The first part

of the questionnaire contained demographic questions, while the second part contained structured questions relating to practices adopted in managing workers of different nationalities, developed based on the literature review. The respondents were required to rate the extent to which the practices described the way they managed migrant workers from mainland China, India and Thailand on construction sites in Singapore. The majority of the questions required respondents to rate on a 5-point scale, where 1= strongly disagree; 3= neutral; and 5= strongly agree.

The population comprised project managers, construction managers, professionals and supervisors who had supervised migrant workers in Singapore. The sampling frame was government registered construction firms. Emails and follow up telephone calls to 90 randomly selected Singapore registered construction firms were made to invite participation in the study. 32 responded via a mixture of emails and face-to-face interviews, giving a response rate of 36%.

The second research prong involved face-to-face in-depth interviews with three subject matter experts who had personally supervised migrant workers extensively. They have worked in the construction industry for more than 8 years.

RESULTS AND DATA ANALYSIS

Characteristics of the sample

The characteristics of the interviewees are shown in Table 1.

***Table 1**: Demographic characteristics of respondents*

Description	Frequency	Percentage
Designation		
Senior Management	4	13
Middle Management	20	62
Professional	8	25
Gender		
Male	32	100
Female	0	0
Experience (years)		
Up to 10	11	34
11 – 20	15	47
> 20 years	6	19
Nationalities of workers supervised		
China	31	97
India	32	100
Thai	24	75
Malaysia	30	94
Philippines	23	72

All the respondents are Singapore residents and had supervised at least 4 different nationalities of migrant workers. The majority of the respondents are in middle management (site managers, project/construction managers, site supervisors and site engineers) and had

more than 10 years of experience in the construction industry (average = 15 years). None of the respondents belong to these 3 nationalities.

Qualities of effective project managers in diversity management

The t-test results on the qualities required for the effective management of migrant workers are shown in Table 2. The results show that with the exception of 'ability to gain authority over workers by instilling fear', all the other qualities are significantly important ($p < 0.05$). Effective project managers need to, in descending order of importance: be able to give clear and firm instructions; posses high technical ability; be able to build and maintain relationship with workers; be able to understand the language spoken by migrant workers; be able to understand culture variation; and be able to motivate workers.

The findings show that the top two qualities relate to task-oriented leadership style, indicating that this style is important for managing a multi-cultural migrant work force effectively. Relation-oriented leadership styles, though important, are perceived to be of lower importance, given their relatively lower means. Gaining authority by instilling fear is not emphasized (mean= 2.44; p= 0.001). This may be due to the prevalence of high collectivism and low individualism in the cultures of migrant workers (Hofstede, 1980). High collectivism culture would place high emphasis on building relationships and therefore it is not appropriate to control these workers by instilling fear. Instilling fear is also not correct as people may find ways to get back at their managers and hide information to protect themselves from punishment (Maccoby et al., 2004).

***Table 2**: Qualities required in managing a foreign workforce*

Quality	Mean	Std. dev	T-value	Sig. (2-tailed)	Leadership style
Ability to give clear and firm instructions	4.66	.483	19.416	.000	Task-oriented
High technical ability	4.28	.634	11.428	.000	Task-oriented
Ability to build and maintain relationship with workers	4.22	.832	8.285	.000	Relation-oriented
Understanding the language used by the foreign workers	4.06	.669	8.984	.000	Relation-oriented
Understanding cultural variation within the work force	3.75	.880	4.822	.000	Relation-oriented
Motivating workers by linking rewards to performance	3.53	.950	3.164	.003	Relation-oriented
Ability to gain authority over workers by instilling fear	2.44	.878	-3.626	.001	Task-oriented

Leadership styles of project managers

Based on two leadership styles (task-oriented and relation-oriented), 14 management practices were operationalized. Respondents were asked to rate on a 5-point scale the extent to which they practiced each of these on different nationalities of migrant workers. The means and t-test results for each nationality of workers are shown in Table 3.

For the t-test, the population mean was fixed at 3 (on a 5-point scale) and the significance level for the two-tailed test was set at 0.05. If the t-test results showed that $p < 0.05$ and the *t*-value is positive, the null hypothesis is rejected. It is then concluded that the management

practice is used significantly frequently. If the *t* value is negative, and $p < 0.05$, it is concluded that the management practice is significantly seldom adopted.

To find out if project managers' use significantly different practices to manage different nationalities of construction workers, independent-sample *t* test of equality of means was conducted. Three independent-sample *t* tests were conducted to compare differences in managing: Chinese and Indians (test 1); Chinese and Thais (test 2); and Indians and Thais (test 3). Results show that there is no significant differences in the way project managers manage workers of different nationalities. This is despite Hofstede's (2001) indices showing that Chinese, Indians and Thais have dissimilar cultures. The absence of dissimilarity among people of different cultures was also detected by Wong et al. (2007) when they compared the leadership styles of Chinese and Westerners working in Hong Kong. One possible explanation for the lack of significant difference is that the migrant workers have made intercultural adjustment (Wong et al., 2007), negating the need for project managers to manage each nationality differently. Another explanation is that the project managers are unaware that they need to manage cultural diversity. This may not be the case as Table 2 shows that respondents had indicated that understanding cultural variation within the work force is an important quality for project managers. The third explanation is that project managers prefer to have one style of management for all workers on the same construction site (equal strokes for different folks) so that there is no perception of unfairness.

***Table 3**: One sample t-test results on management practices*

		Chinese			Indians			Thais

DISCUSSION

Management practices relating to task-oriented leadership style

Respondents were asked the extent to which seven management practices relating to task-oriented leadership described the style they adopt in managing migrant construction workers.

Six of these were significantly practised by project managers on the three nationalities of construction workers. These are: supervising closely (T1); giving clear and assertive instructions (T2); reiterating and enforcing rules (T3); emphasizing on getting high quantity of work to be done (T5); insisting on punctuality (T6); and expecting subordinates to follow instructions without debate (T7). The results suggest that project managers use task-oriented leadership style to a significant extent. This agrees with Giritli and Oraz (2004) who found that management personnel in the construction industry perform the authoritative style of leadership more frequently than all other styles.

Only one task-oriented management practice was significantly not applied by project managers to all three nationalities of workers – using threats and punishments to encourage good work (T4). The finding supports the concept that discipline should be the last recourse to reinforce the application of safe work practices when all else (training, guidance and encouragement) failed (Hislop, 1999). Teo and Ling (2010) have also found that introduction of penalties and punishments for offenders/ repeat offenders do not help in enhancing worksite safety.

Management practices relating to relation-oriented leadership style

Respondents were also asked the extent to which they applied seven other management practices relating to relation-oriented leadership style. Four of these practices were used by project managers to manage all three nationalities: maintain good relationship with subordinates (R1); be friendly and approachable to subordinates (R3); be fair and impartial with subordinates (R4); and encourage feedback from subordinates (R7). The finding suggests that relationship cultivation by project managers is important, which agrees with Wong et al. (2007) who also found the importance of interpersonal relationships for effective leadership.

Table 3 shows that project managers try to make their Chinese and Thai workers be as satisfied as possible with their work (R2), but do not practice this with their Indian workers. This may be because Indian nationals have higher individualism score (48) than Chinese and Thai nationals (both at 20) (Hofstede, 2001). This is discussed later.

Two practices are not significantly used by project managers for all 3 nationalities: holding staff meetings to discuss work related problems (R5) and befriending workers to encourage good work (R6). As construction sites are not immune from disputes and complaints, holding staff meetings to discuss problems may turn the meetings into a complaints session. Those who had no problems may also be affected by the complaints, leading to lower morale. One subject matter expert shared that instead of holding meetings, project managers prefer to hold face-to-face discussions with the worker who is upset. He shared that:

> "We prefer to talk to the aggrieved worker to address his complaints and get to the root of the problem. This grievance resolution method goes as close to the source as possible. It also prevents collective bargaining or class-action suit."

As for eschewing friendship with subordinates, this is consistent with the finding that project managers prefer the task-oriented leadership style. Friendship is not encouraged because project managers may fear that their subordinate-friend might try to take advantage of the friendship, or that it may be awkward for project managers to boss people whom they have social ties with (Nefer, 2008).

Power distance

Hofstede's (2001) scores for power distance for China, India, Thailand and Singapore are 80, 77, 64 and 74 respectively, suggesting that these countries are large power distance societies as compared to the UK and USA which have 35 and 40 points respectively. The people in large power distance societies accept a hierarchical order in which everybody requires no justification for his position while people in small power distance societies expects power to be equally distributed and demand justification for power inequalities (Hofstede, 1984). With the high power distance culture of Chinese, Indian and Thai workers, Table 3 shows that project managers are employing appropriate task-oriented leadership style like close supervision (T1) and enforcing rules to maintain discipline (T3). Workers from these 3 countries are more likely to uphold hierarchies and comply with authorities as they come from high power distance cultures. It appears appropriate for project managers to apply more authoritative leadership styles when managing these workers.

Even though the three nationalities have relatively large power distances, project managers still significantly try to be as fair and equal as they can in dealing with workers (R4). The results show that project managers do not encourage good work through friendships with workers (R6). This is consistent with the high power distance that the Chinese, Indian and Thai workers are used to. These workers would be comfortable with the hierarchical management structure. Singaporean project managers are also comfortable to exercise task-oriented leadership style with a vertical organizational structure because Singapore also has a high power distance index. There is therefore a good fit between the task-oriented leadership style displayed by project managers and migrant workers' acceptance of this style based on power distance indices.

Uncertainty avoidance

Hofstede (2001) found that Chinese, Indians, Thais and Singaporeans' uncertainty avoidance scores are 30, 40, 64 and 8 respectively. The scores suggest that these 3 nationalities of construction workers are more uncomfortable with uncertainty and ambiguity than Singaporeans. The findings in Table 3 suggest that Singapore project managers are well aware of this, and try to reduce uncertainty for their migrant workers by strict rules and measures such as insisting workers come to work punctually (T6) and supervising closely (T1). Insisting on punctuality appears to be very important practice as it is ranked first for managing Indian and Thai workers, and third for managing Chinese workers. Punctuality has been found to be one of the 'red flags' to indicate an employee is in serious trouble, which may eventually lead to pronounced behavior changes such as hostility toward authority, being chronically disgruntled, finding fault, blaming others for misfortunes, making destructive criticism, and threats (Magyar, 2003). Project managers' emphasis on punctuality is therefore the right management practice.

Uncertainty is also avoided or reduced by giving clear and assertive instructions (T2). This practice is ranked first for managing Chinese workers. While these migrant workers may be able to tolerate some unfairness due to the propensity to accept a hierarchical order (high power distance), project managers are mindful not to create dissatisfaction (R2) because they have low uncertainty avoidance.

The results in Table 3 support Hofstede's (2001) uncertainty avoidance findings. Chinese, Indian and Thai construction workers appear to require rigid codes of belief and behavior. People from societies with high uncertainty avoidance usually reject deviant persons and ideas (Hofstede, 1984), and favour structure and predictability and conflict is frowned upon (Gold, 2005). The findings also show that even though Singapore project managers have

very high tolerance for ambiguity, they have flexibly minimized uncertainty for their migrant workers in order to accentuate their job performance. This indicates the practice of contingency leadership style (Hersey and Blanchard, 1969).

Individualism vs collectivism

India's individualism score is 48, while China, Thailand and Singapore have the same score of 20, as against the UK and USA's scores of 89 and 91 respectively (Hofstede, 2001). The relatively low score for China, Thailand and Singapore suggests that people from this collectivism social framework expect their relatives, community, or other interest groups to look after them in exchange for unquestioning loyalty (Hofstede, 1984). They are also less individualistic at the work place. As Indians have the highest individualism score among the 3 groups, Table 3 shows that project managers do not significantly try to make them as satisfied as possible with their work. The higher individualism may cause some Indian workers to care more about themselves, leading to weak relationships with co-workers. Project managers may have therefore deemphasized satisfying Indian workers as much as possible so as not to encourage more individualist behaviors.

The interviewees shared that they have observed high collectivism within a nationality group. The workers from the same country often form their own "social clusters" and developed team spirit within the clique naturally. Very low individualism and strong collectivism is not necessarily good because it may give rise to group think (Janis, 1972). Table 3 shows that project managers significantly encourage feedbacks from all groups of workers (R7). This may help to discourage group think by providing avenues for workers to be heard. The presence of groupthink is also indicated by Ogunlana and Chang (1998). They found that good relationships with workmates are more important to workers than gaining recognition and being "distinguished from the flock".

The results show that project managers do not hold staff meetings to discuss work related problems (R5). One interviewee explained that:

> "Asian workers come from collectivist societies that exhibit more cooperative behavior. If we hold meetings to discuss work related problems, they may still not voice out their problems as they do not want to be seen as trouble makers. They are afraid their jobs may be jeopardized unnecessarily when they have many mouths to feed back home."

The finding agrees with Ogunlana and Chang (1998) who found that participating in decision making is one of the lowest ranking motivators for workers. Their study showed that "lack of communication" is not a powerful "demotivator" of work.

Masculinity vs femininity

Masculinity stands for society's inclination towards achievement, heroism, assertiveness and material success, while femininity stands for a preference for relationships, modesty, caring for the weak and the quality of life (Hofstede, 1984). China, India, Thailand and Singapore's Masculinity scores are 66, 56, 34 and 48 respectively (Hofstede, 2001). In comparison, the UK and USA's scores are 66 and 62 respectively, indicating that China and India are more similar to these societies in this aspect. The scores suggest that China and India's societies may put more emphasis on work goals and assertiveness, while Thailand and Singapore put more emphasis on personal goals and nurturance.

Table 3 shows that project managers do make significant efforts to try to make Chinese

workers as satisfied as possible with their work (R2). This is important as they have high masculinity index, and the traditional work role model of male achievement, control and power are important to these workers (Ng et al., 2009). When workers are satisfied, their performance would also improve (Ng et al., 2009).

LIMITATIONS

The main limitation of the study is that the responses were based on project managers' ratings on a 5-point Likert scale. Each respondent may apply the management practices to a different extent from another. The second limitation is that while ratings of respondents were amalgamated and a mean rating computed for each nationality of workers, it cannot be generalized that all workers from the same nation should be treated in the same way. Project managers should still treat each worker as a unique individual and find the best way to manage each of them, in accordance with Contingency Leadership theory (Hersey and Blanchard, 1969).

CONCLUSION

With a low participation rate of Singaporeans as construction workers, a typical construction site in Singapore comprises migrant workers from several countries for it to be sustainable. This study investigated the leadership style adopted by project managers in managing migrant workers from China, India and Thailand working in Singapore's construction industry using a survey research design.

Among the 3 nationalities of workers, Chinese workers would generally have the highest masculinity traits and lowest uncertainty avoidance. These suggest that they may be more inclined towards assertive and competitive behaviors, and are comfortable with unstructured situations. The implication is that to manage Chinese construction workers, project managers may need to adopt task-oriented leadership style by: giving assertive instructions (T2) and enforcing rules (T3) to control their high masculinity; and emphasizing punctuality (T6) and getting a lot of work done (T5) in order to "get the message across" effectively.

Indian workers have the highest individualism among the 3 nationalities of workers. This suggests that they are less integrated and cohesive. The implication for project managers is that task-oriented leadership style needs to be adopted and the relevant management practices include: enforcing punctuality (T6) and rules (T3) strictly.

Thai workers have the lowest masculinity and highest uncertainty avoidance scores when compared to Chinese and Indians. The generally modest and caring culture indicates the need for project managers to apply relation based leadership style. With their high uncertainty avoidance, it is recommended that project managers give Thai workers the clearest instructions at work (T2).

The findings suggest that Singapore project managers practice contingency theory leadership to a large extent. Their very low uncertainty avoidance score enables them to practice contingency leadership, by being both task-oriented and relation-oriented at the same time. There is no need for them to rigidly adhere to one style to achieve social sustainability on site. With Singapore's moderately high power distance index, the outcome is project

managers use more task-oriented leadership in the supervision of the workers. Singapore project managers are also deemed to be more feminine than masculine. They are therefore observed to also practice relation-oriented leadership.

SUSTAINABLE TRANSFORMATION OF CITIES: THE CASE OF EINDHOVEN, THE NETHERLANDS

ANTONIO ZUMELZU SCHEEL
Eindhoven University of Technology (TU/e), Department of urbanism
The Netherlands
e.a.zumelzu.scheel@tue.nl; antoniozumelzu.arq@gmail.com

Abstract
The question of sustainable urban development is linked to the issue of urban transformation; the challenge is to make use of ongoing transformation processes to achieve more sustainable urban environments. Hildebrand Frey is the main protagonist of the "urban cell theory" (UCT), focused on the redesign of existing cities, laying down important arguments for neighborhood borders and centers. For decisions to pursue the sustainability path, the pragmatic method will be a practical tool in bringing sustainable considerations in the realm of project decisions. This paper examines the sustainable transformation of cities upon a re-mapping of the existing city to identify the potential urban cells, restructuring of the actual city of districts and neighborhoods; focused on Eindhoven as a case study, specifically the District of Woensel, describing the operationalization of the UCT as a conceptual framework. This work is structured in three parts: 1- a preliminary analysis identifying the existing neighborhoods in the district to analyze how the existing parts of the city meet the criteria of UCT; 2- the description of how to join non-potential and potential sustainable areas of the existing city to create "large units" of the city; 3- The elaboration of results indicates that all the parts of the city are part of potential sustainable areas, obtaining hence a principal layer of the map of the sustainable city. The relevance of this approach is to contribute new insights to the debate of sustainable city borders.

Keywords: Urban form, Sustainable cities, Urban transformation, Pragmatics

INTRODUCTION: REMAPPING OF EXISTING CITY

Focusing on the urban redesign of Woensel area, a post-war district of Eindhoven, the goal of this paper is to make a re-mapping of the existing city to identify the potential urban cells on the study area. To achieve this goal it is necessary first to analyze how the existing units of the city meet the criteria of sustainability –UCT-, classifying them as a potential and non-potential sustainable areas of the existing city under evaluation of the UCT criteria; and second to lay down how to join non-potential with potential sustainable areas of the city to restructure the district by creating large units to optimize sustainability. Finally to remap the city based on this new structure: all the parts of the city should be part of potential sustainable areas, obtaining hence a principal layer of the map of the sustainable city. The contribution will present an example of a pragmatic design strategy to adjust form and structure of an

existing area, a method to implement new directions to achieve the challenges of sustainability.

HISTORICAL-EVOLUTIONARY APPROACH OF THE CITY

Sustainability regarding cities has many definitions and angles, however the re-making and adaptation of existing cities to sustainable objectives is an urgent double priority towards the global push for sustainability (Kenworthy, 2006). To meet the objectives of a sustainable city new methods, strategies and design tools are required as part of a pragmatic-based integrated planning, considering each factor converging in the physical, social and economical necessities of a community, connecting them to the environment (Burnett, 2007; Frey and Yaneske, 2007; Gunder, 2006). In this sense, sustainable development is concerned not only with social, economic and environmental qualities or inefficiencies of the city but also with urban form as it largely exists and the form and structure development should take for the city to become more sustainable.

Pragmatics as a way of thinking

Hence, at present we are generally confronted not with the task of planning and designing new towns and cities but, rather, with re-planning and redesigning existing cities, towns and settlements to make them more sustainable. Therefore the challenge is to redesign existing urban form (Barton, 2000; Breheny, 1992; Frey, 1999; Frey and Yaneske, 2007). This involves a pragmatic way of thinking: the pragmatic method will be an effective tool in bringing sustainable considerations to achieve these objectives. The task, then, is to address the real problem of the cities by a pragmatic thinking (Moore, 2010).

The assumption to achieve a sustainable city is to shape a resilient city, flexible structures of the city: future city is the existing city transformed into the direction of sustainability by the shaping of a flexible structure, able to create a solid community in the core of a healthy and pollution-free environment. Therefore, are there certain urban forms that contribute more than others to sustainability? In literature models and concepts of sustainable city form are identified; as well as there are seven design concepts related with sustainable urban form: compactness, sustainable transport, density, use of mixed land, diversity, passive solar design and greening; and also four types of sustainable urban forms: neo traditional development, urban contention, the compact city and the eco-city (Jabareen, 2006). City models that meet sustainability are distinguished, however existing cities never can be categorized as such in one or another model; cities are always openly developing, and do not necessarily following consequently a certain model. Models have proved to be abstract and theoretical and in the practice quit far away from realities. In this sense, the message is clear: to achieve sustainability requires not only new development to be guided by appropriate urban models and targets but also the review of the forms, structure, land use patterns and socio-economic conditions of existing urban areas (Frey, 1999; Frey and Yaneske, 2007).

This way of thinking -pragmatic vision- is not really completely new in the urban planning and design. In the history, specifically in the post-war period, many authors have made criticism about the post war planning thought in the late 1950s and early 1960s, owing to the

inflexible planning of the cities. In fact, there were two levels of criticism of postwar urban development that emerged in the 1950s: 1- on the quality of the design of the new development; 2-on the emphasis of physical planning. According to these both fundamental disagreements, town planners typically exhibited very little understanding of the cities, because they had been preoccupied with simplistic "utopian visions" instead of trying to understand and address the problems of real-life cities. Indeed, the main criticism was the lack of understanding of real-life cities and preference for a tidy, ordered view of urban structure (Taylor, 1998).

CONNECTION TO FREY: URBAN CELL THEORY (UCT*)*

Hildebrand Frey is the main protagonist of the "urban cell theory" (UCT), a theory that emphasizes pragmatism and focuses on the redesign of the existing cities~~,~~ through the promotion of urban and suburban cores. In short, H. Frey advocates a recalibration of urban components to a higher level of aggregation –urban cells- that~~,~~ might be instrumental for achieving balanced relationship among transport, urban form and environment hence a more sustainable city. Urban Cells are units of urban district level –neighborhoods- that meet certain criteria to achieve sustainability in the city. In addition, these criteria are divided in five key criteria: key planning, social, environmental, design and economic criteria. If a district meets these criteria, then the urban unit –or neighborhood- is sustainable (Frey, 1999).

From cells to modules

Nevertheless, the biological connotation in regard of a city is not really acceptable as a city is not a living thing, only the people that use it are, because the city is not able to repair itself. Also a "cell" is not alive. A cell remains or becomes alive if there are two or three live cells adjacent to it, otherwise it dies. Fewer than two adjacent cells imply the cell dies from insulation; more than three and it dies from overcrowding. Thus, the "cell" as part of a structure is not necessarily the most important element of that structure; much more important may be the links between "cells" or "modules" that generate a complex structure. Indeed, this means that all living organisms could be viewed as systems, for any organism depends on and is therefore related to its environment. For this reason, it would be interesting to represent an image of the city as an active functioning thing: as a system (Batty, 2005; Buchanan, 2002; Frey and Yaneske, 2007).

In our interconnected world there is a practical difficulty in deciding where to draw the boundary of a complex system. Nevertheless, conventional science seeks for simplifying systems to a comprehensible few interactions that still yield useful results. In this sense, this simplicity is termed modularity, which is a strong interaction among elements within a module but only a relatively weak interaction with elements outside (Frey and Yaneske, 2007).

The concept of module is referred to something that has its own structural and functional integrity while being part of a larger system (Frey and Yaneske, 2007). The existing city is

clearly complex and highly ordered (Batty, 2005); in addition, the city, as many natural phenomena, has a hidden structure that develops "unconsciously" (Buchanan, 2002). For this reason the city has to be understood as a modular construction: modules with own structural and functional integrity while being part of a larger system. This modular structure makes the existing city more resilient; having the ability to adapt to changing circumstances, while providing for the basic needs of residents and ensuring quality of life. Plans are developed for a 100 year period to ensure the city and the city region's long term survival as well as integrity, normal functioning, and self reliance (Frey, 1999; Frey and Yaneske, 2007).

Urban cells theory criteria

According to what was mentioned above, the UCT establishes key criteria for each component of sustainability in the city. Below there is a detailed explanation of the UCT criteria (Frey, 1999).

1. Key planning criteria for sustainable neighborhoods; this principle for sustainable neighborhoods includes the following:

Inclusion of open land: by 40% of developable land kept as forest and agriculture; the reason is to achieve preservation of land, local production of food and timber, and to reach a degree of self-sufficiency and local economy.

A threshold population: by a gross population size between 4.000 and 10.000, in average 7.000 inhabitants, with districts around 25,000-35,000 inhabitants; the main reason is to support local services and facilities into the neighborhoods -provided there is sufficient disposable income.

Accessibility in walking distance: Accessibility in walking distance to local services and facilities, including public transport node/stop with distances between 400-800m, says 600m. This generates areas of about 110-120 ha and with a gross population density of 60 per/ha over total land, 100 per/ha or 42 dwellings per ha over developable land; the main reasons are to improve the local access -to local facilities- and district/regional access -to city centre and other provision centers in the conurbation- for those not highly mobile, and to obtain a reduction of car dependent local and regional travel.

Mixed use: by 40% of developable land for non-residential uses, 60% for housing, which results in a net population threshold density of 167 per/ha or 70 dwelling units per ha. The main reasons are to improve access to work places, services and facilities, specifically for those not highly mobile, and give the possibility of the interaction of different uses/users generating "urbanity".

Local facilities: The presence of local facilities into those areas (neighborhoods), such as: local shops/mini-supermarket, bank auto-teller, post office counter, primary school, police station, community facilities and park, access to open green space, play areas, sport areas and workplaces. The reasons are mainly to allow an ease access to local services and facilities, as well as reduced car-dependent mobility, and to have access to city level facilities with public transport.

2. Key environmental criteria for sustainable neighborhoods; this principle for sustainable neighborhoods includes:

Energy conservation: Energy conservation by the use of clean renewable energy such as solar, wind, geothermal, among others. The reasons are mainly focused in the conservation of natural resources and the reduction of pollution through burning of fossil fuels, these could help to reduce energy consumption of a typical dwelling and create more sustainable neighborhoods.

Water conservation/management: Water conservation and management will be achieved through rainwater collection, as well as the reuse of grey water, and recycling of waste water (including sewer) after treatment. The reasons are principally to become a reduction of water waste, the preservation of water resources, and the reduction of the waste of potential fertilizers.

Waste recycling: Waste recycling by separating and reusing waste materials such as paper, glass, plastic, metal, and food products. The reason is mainly to achieve a reduction of waste mountains, as well as land fill sites.

Establish or re-establish biodiversity: Establish biodiversity through maintenance and enhancement of local fauna and flora. The reason is to achieve a symbiotic relationship between city and nature.

3. Key social criteria for sustainable neighborhoods; this principle for sustainable neighborhoods is specified as:

Social inclusion: by social mix to avoid exclusion or marginalization of socio-economically weaker groups of people. The main reasons are principally to obtain a reduction of tension between those that have and those that have not, and economically weaker groups of people benefit from the inclusion of people with disposable income that support local services and facilities.

Safety and security: by the activation of legible public spaces, laying down activated edges, good lighting and design spaces. The reasons are to improve the living quality and to get a reduction of real or perceived fear of crime.

Participation of community: by people involved in local decision making and local democracy. The main reasons are that the community holds ownership of neighborhoods, to obtain more responsibility of local people for their environment, as well as to increase the sense of belongingness, and to reduce vandalism.

4. Key design criteria for sustainable neighborhoods; this principle for sustainable neighborhoods includes:

Legibility and imageability: Legibility and imageability of the built form of the neighborhood, as well as a sense of centralization and belongingness, improved access, and a meaningfully built form. The reason is to reach a better quality of life.

Adaptability: Adaptability of the built fabric and neighborhood layout; say adaptable, expandable housing. The main reasons are to reach the possibility to adapt to changing needs and aspirations and to changing external conditions, as well as to obtain durability of buildings and neighborhood.

5. Key economic criteria for sustainable neighborhoods; this principle for sustainable neighborhoods includes the following:

Affordable housing: To reach affordable housing by a mixture of different tenure and housing types, from villa to semi-detached, terraced tenement, etc. The main reason is to be a support for social and income mix.

Keeping profit in the area/neighborhood: through credit systems in a local economy, by local production and services, both formal and informal. The reason is to reach that profit can be used for improvement to the neighborhood and its facilities rather than disappearing into the pockets of distant international companies.

TRANSFORMATION OF DISTRICTS IN THE CITY OF EINDHOVEN: UCT APPLIED TO WOENSEL

The aim is to demonstrate the existence of potential urban cells on the study area. First, it is necessary to find out which of the existing neighborhoods meet the criteria of UCT. The area selected is Woensel, a district located in the north of the city centre of Eindhoven, the Netherlands (Figure 1).

As a preliminary analysis, the district of Woensel is described as a great postwar expansion area of Eindhoven largely made since 1960 (Figure 2), being an existing environment with a clear transformation phenomenon by dispersion. Woensel is an incomparable area in relation to others in terms of population, with 101,218 inhabitants (M.L.M.G. Boumans, 2005), being the half of the total population of Eindhoven (208,000 inhabitants); in this sense Woensel is one the largest settlements in the region; not only the Eindhoven's largest district concerning population, but also even larger than some settlements of the region, such as the city of Helmond with 86,000 inhabitants, located in the east of Eindhoven.

Woensel is almost entirely a residential area with services and facilities for the community, such as schools, parks, churches, shops, post offices, trade facilities, hospital, among others. The district has its own district center -shopping center Woensel-, providing for the upper district facilities. Woensel offers few places of local interest, being almost entirely a residential area; Eindhoven's main entertainment venues and industry are in other parts of the city.

Figure 1: *Woensel district located in the north of Eindhoven city center.*

Figure 2: *The area of Eindhoven's development in 1950 inside of today's city boundaries (based on Morfologische Atlas Eindhoven, 2005)*

The first part of the analysis was focused on identifying the existing neighborhoods on the district, recognizing around of 27 urban quarters that make up the district of Woensel, divided in two main zones: Woensel-North and Woensel-South (M.L.M.G. Boumans, 2005). Neighborhoods centers are recognizable by the identification of functions: the location of post offices, police stations, primary education schools, trade and other facilities. Generally, four or five neighborhoods are grouped to form a district, four or five districts are grouped together to form towns, and over town centers are located the major transport routes between towns (Frey, 1999). In this case, Woensel district is made up by two "great areas", and each area is set up by around twelve and fifteen neighborhoods respectively. Woensel district centre -shopping center Woensel- is located in one of the main transport routes, allowing a good connection with Eindhoven city center. The connection between Woensel-center with other town centers is poor, because Eindhoven is currently a mono-centric city, the public transport connections are exclusively aimed at Eindhoven center (Figure 3).

With the identification of the existing neighborhoods boundaries, then it is possible to start with the next level of the investigation, related with the analysis of how existing units meet the criteria of sustainability –UCT.

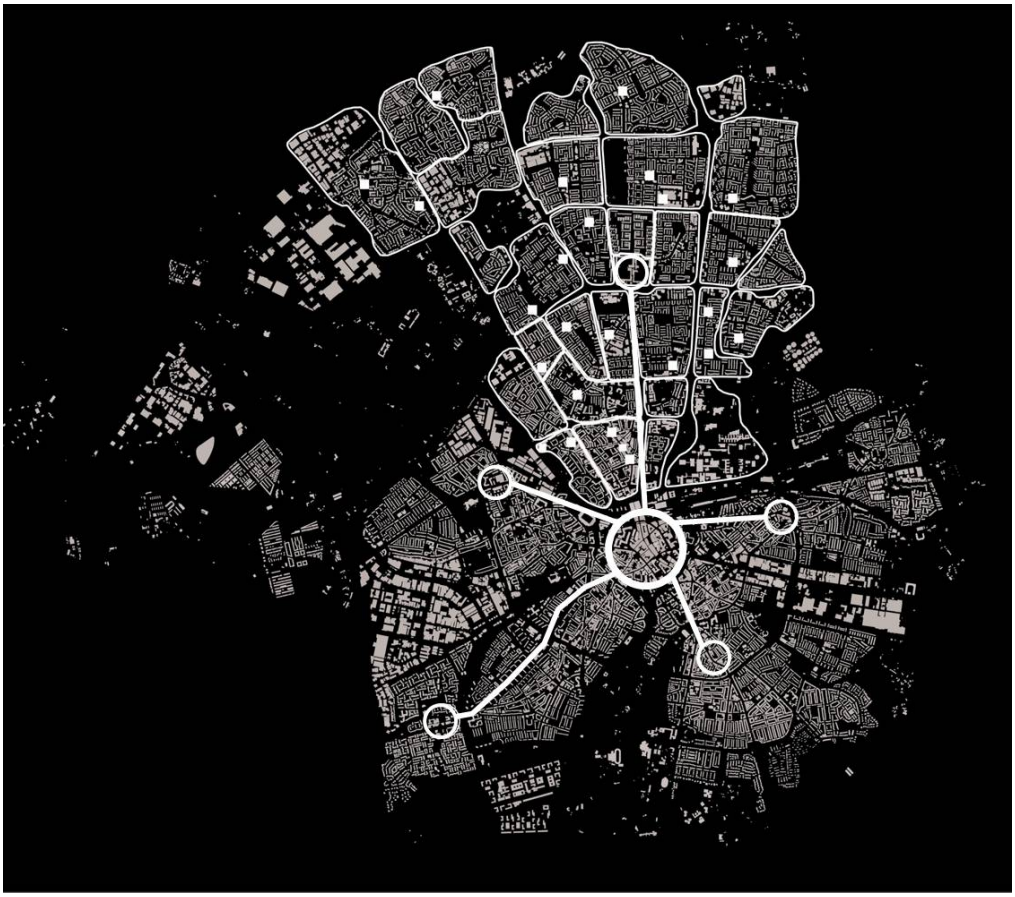

Figure 3: *Location of existing neighborhoods boundaries and centers, and main center district connections.*

Fieldwork and evaluation table

In the next level of the research, the analysis was focused on how the existing neighborhoods of the district meet the criteria of sustainability, to classify them as potential and non-potential sustainable areas according to the UCT-criteria. For the applicability of the UCT on the study area it was necessary to make an evaluation over each identified unit. In this sense, the evaluation consisted on making an analysis on the place by fieldwork and literature review from institutional and academic data by desk research. The analysis was focused on environmental, economic, social, design and planning aspects of each neighborhood of Woensel, according to UCT.

The results of the analysis were placed on an evaluation table. The table consists of assessing the aspects of each neighborhood under the criteria of UCT –social, economic, environment, design, and planning- establishing what areas meet the criteria and what areas do not meet the criteria. Then, we obtained estimated percentages of every neighborhood evaluated under each criteria of the theory, obtaining a total average for each area.

As a result of this analysis an estimative approach was obtained; describing areas that meet above 50 percent of the criteria denominated as “potential areas”, while areas that meet less than 50 percent of the criteria are “non-potential areas”. The graphic below shows a summary of this evaluation (Figure 4).

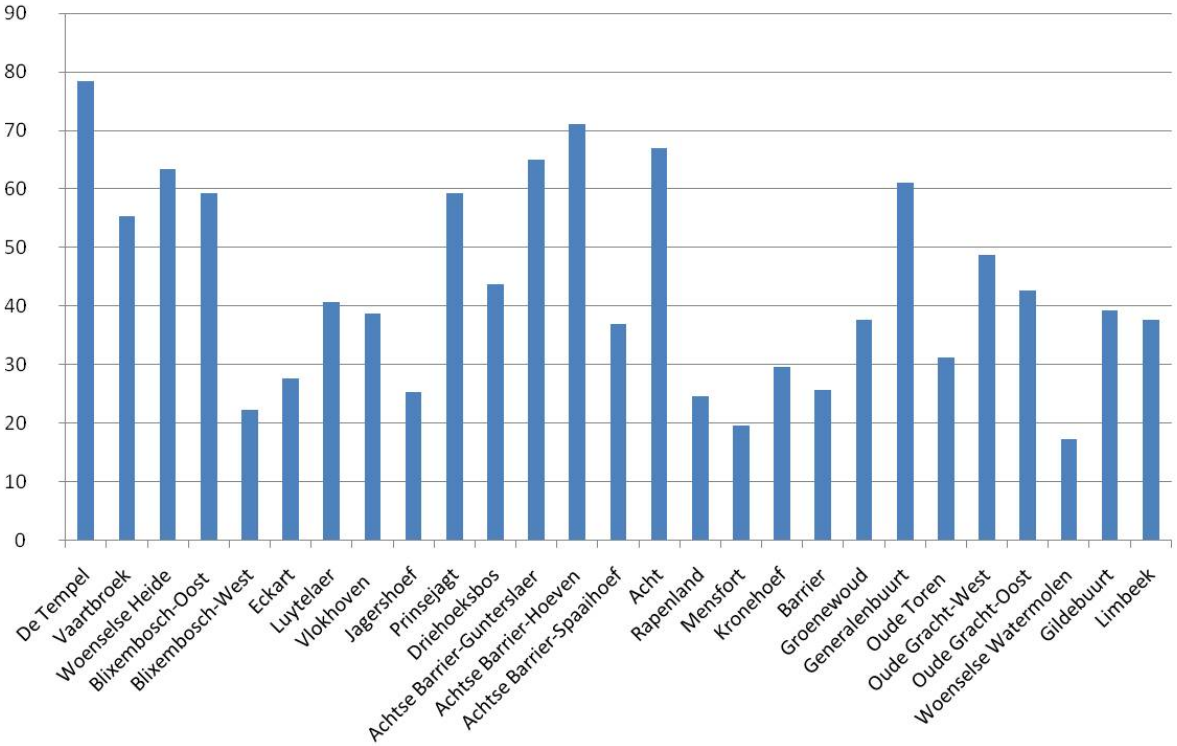

Figure 4: *This graphic shows the evaluation of neighborhoods under UCT criteria.*

Finally, the results of this analysis were translated in an evaluation map (Figure 5). The map describes the potential and non-potential sustainable areas in the district identified by different colors. Dark areas are described as potential, while light ones are non-potential, according UCT-criteria. According to figure 5, as a conclusion of this first level, nine neighborhoods are potential sustainable areas in Woensel. Those areas meet most of the 50 percent of the UCT criteria.

Figure 5: *The evaluation map showing potential and non-potential sustainable areas of Woensel district.*

As an example, the urban quarter called De Temple is potentially one of the most sustainable areas, meeting all the planning criteria; also this area presents a potential concerning green and biodiversity aspect, with the Henry Dunant Park. However concerning design, this area is a typical postwar neighborhood, with monotonous row housing development and public spaces, but with a good proximity to local services and facilities by walking distance. In relation with the UCT of H. Frey, those potential sustainable areas in figure 5 meet around three or four aspects of the planning criteria, regarding good population number, local facilities, mixed-used, good accessibility by walking distance and open land space. For instance, the urban quarter of De Tempel is one of the largest population areas in Woensel with around 5,000 inhabitants; good number to support local services and facilities. In addition, there are eleven areas in Woensel that meet this criteria; most of them have also a community organized in relation to participation in local decisions, good green areas especially in some edges of the district, as well as work places as modest business on the area (Figure 6). However, one of the most important aspects is the “green” condition of Woensel-north. Most of the urban quarters located in Woensel north meet the biodiversity criteria. Indeed, there is a good presence of green areas, such us parks, forests, and sport areas close to the boundaries. Also, green corridors are on the main avenues and streets, connecting neighborhoods.

Nevertheless, the situation in Woensel south is different. In figure 5, this area presents most of the non-potential sustainable areas of the district; mainly characterized to be residential areas, with a poor accessibility and quality of design concerning public spaces and architecture, as well as lack of green and leisure areas, unsafe public spaces, the absence of social mix and less number of inhabitants that could support local services and facilities (Figure 7).

Figures 6 and 7: *Urban quarter De Tempel; and typical neighborhood in Woensel-south*

Therefore, neighborhoods in Woensel are predominantly with residential functions and hardly with mixed-use; with just eleven urban quarters with a good base of population and presence of eligible amenities center. In the second level of the investigation, the analysis was focused in how to join potential with non-potential sustainable areas of the existing city to restructure the district by creating ‘’large units’’, to make a balance of them and to improve non-potential areas to optimize sustainability.

At this level it was necessary first to recognize principles to the process of design, applying to these areas, and thus to restructure Woensel district. These principles are derived from the UCT-framework and pragmatic redesign considerations in relation to the city, specifically to the assumption of the city as a resilient structure: the future city is the already existing city transformed into the direction of sustainability, (Frey, 1999; Frey and Yaneske, 2007; Moore, 2010). In the city, the places are important elements; people define themselves by the place they live in and value the unique characteristics which give continuity with the past and relationship with the present. Every citizen has had long associations with some part of his city, and his image is soaked in memories and meanings. Sustainability is the history of the city (Frey and Yaneske, 2007; Rossi, 1993; Tarvernor, 2007; Tweed and Sutherland, 2007). To preserve and enhance the physical and spatial balance of the existing built environment, redesign can help to promote sustainable development by improving the quality of the existing environment and sense of place.

Following the UCT-framework, strategies were made to restructure Woensel by two steps:

1- According to the UCT criteria, the interaction among urban quarters –or cells-, say four or five of them, form a district with a core which might become the focus for a much larger population of 25,000 – 35,000. The district center would be linked with neighborhood centers by public transport; such districts would have a sufficiently large catchment area to accommodate commerce and other equipment and services (Frey, 1999). In this sense, Woensel north zone has a large size and the presence of facilities is striking. The stores not only provide assistance for all typing on the large amount of housing in this area, but also for the lack of facilities. In Woensel north reside about 70,000 inhabitants. This number could be divided into two districts with potential units and own centers, with a population of 35,000 inhabitants each one. This approach would create enough support above district facilities in the area (Figure 8).

2- From the districts established, we can start to join non-potential with potential areas to create large units of urban quarters. A neighborhood needs to be recognized as an essential building unit of the city (Barton, 2000; Frey, 1999). It is important so as to know which units have relationships with each other, identifying the existing urban structure relationships. The analysis was made by examination of layers, included the existing development patterns, in terms of greening, infrastructure, density, compactness -built-up areas- and local centers of provision, in relation to cluster potential with non-potential areas. The sketch reflected in figure 8 (Figure 8) describes the overlap of both steps, via layer-by-layer the existing city form is recorded and examined; this enables the examination of the relationship of each of these layers with the overall.

A global inventory of equipment and services provides a characterization of the new districts, made up by “new large units” recognized as essential building units of the city. Thus, the lack of facilities, as well as a poor social mix and limited variation in housing types and public spaces presented in Woensel, could be improved by the revitalization and enhancing of some potential places hence transforming them into “hierarchy” centers of each new district established.

Figures 9 and 10: *Commercial Woensel center; and Woenselse markt in Woensel south*

Figure 8: *This sketch shows the overlap of the two steps of the strategy and also the creation of large units~~,~~ by the joining of potential with non-potential urban quarters.*

Three main key zones are described in figure 8, clustering Woensel-north in two districts and enhancing Woensel-south with an own main center. The first district proposed could be defined as “recreational center”: Sport Park Woensel –located in the north-west- is the current area for active recreation within Woensel. If Sport Park Woensel is upgraded with mixed uses, adding trade and culture facilities, then it could be a new center of district. In relation with the second district proposed, the existing Shopping Woensel center is joined with care facilities -Catherina Hospital in Rapeland. Thus it would become, in an improved current, the center of the district defined as “commercial center”. Both districts have own centers and will have less dependence on Eindhoven city center (Figure 9).

Finally, in the third district proposed to Woensel south the objective is to recover this place as a “cultural area”, an important place of reference in the city. In fact, some of the non-potential areas in Woensel south have “cultural potential”; this potential could help to define the character of the place; every citizen has had long associations with some part of his city. Some existing neighborhoods have important cultural value, for example Woenselse-markt. Presently Woenselse markt is located in Gildebuurt, an urban quarter in Woensel south. This area is an important trade corridor with local services and facilities and transformed into a market place some days in the week. On this area there are other neighborhoods with important culture values, such us Oude Toren, with an important historical value from around the 12th Century when Woensel settlement was founded (Boumans 2005). The proposed

district, thus, would have an important cultural character, with trade and facilities as reference into the city (Figure 10).

CONCLUSIONS

Hildebrand Frey established the UCT as a tool for the redesign of existing cities, laying down important principles for neighborhoods and districts structure. The operationalization of the theory is used as method for exploration on Eindhoven, specifically the district of Woensel. The elaboration of results indicates that Woensel could become part of sustainable areas.

The new Woensel is described in the final map (Figure 11), laid down with three different new districts, created by large units set up through the interaction among non-potential with potential sustainable areas. Every new large unit will be a resilient structure, adaptable during the time; this means that to meet better the criteria of UCT, the larger units will have the possibility to adapt to changing needs and aspirations. Also these large units provide local services and facilities within walking distance to the edge, local centers with mixed-uses and public transport stops. Main connections routes have been preserved and upgraded, used as boundaries for the large units extension, and as main links connection with the rest of the city.

The current main routes are upgraded as green corridors, allowing not only good vertical and horizontal connections among the new areas, among large units centers to district centers, but also good access among district centers, and from them to suburban municipalities of Best, Son and Breugel in the Region.

Regarding the borders of Woensel, they have been developed to improve the borders with the countryside. Borders are maintained and enhanced as a conservation green area; hence the districts are limited by natural boundaries. The reasons are:

- To keep some current uses as open land development such us forest, and agriculture.
- The objective is to create dense green areas at the district borders, as roots for the green corridors and main green points into the city.

To establish green spaces as a second structure incorporated to the existing one; to protect large urban units from the noise pollution coming from main routes connections by green corridors, as well as to provide and enhance green existing areas as “key breathing spaces” into the city; creating clear connections among the main green spaces at the larger units.

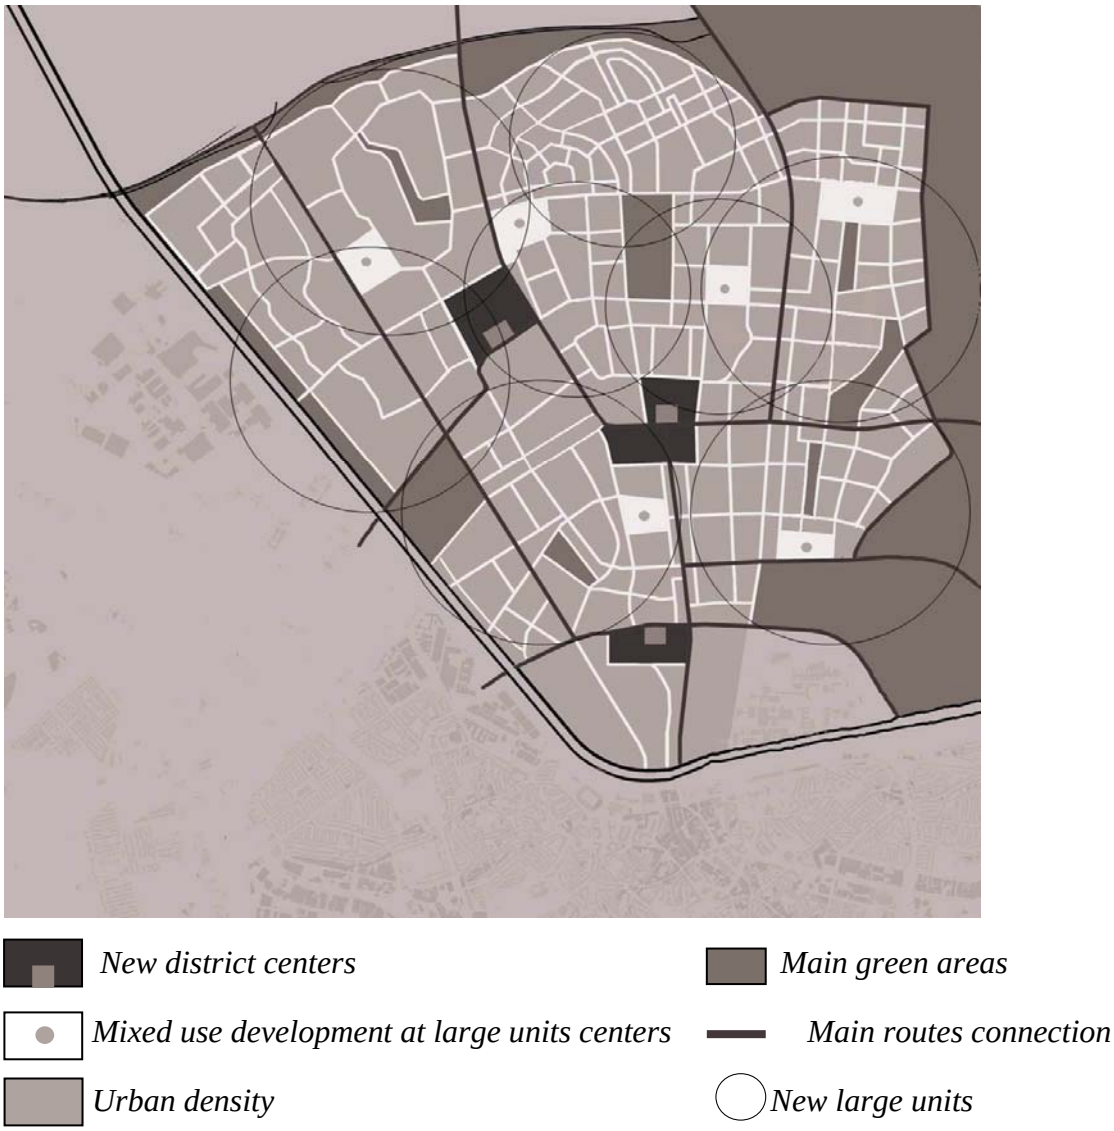

Figure 11: *The principal map of sustainable city borders.*

The design concept for Woensel attempts to generate clear district centers, assigned as mixed used development, which are linked with each other by new central routes. These routes would accommodate the major public transport line, linking the new centers with the city center as well as with the suburban municipalities in the region. Therefore, the new redevelopment structure (Figure 11) shows a clear density development, with peaks at districts centers as well as at the large units centers; which accommodate mixed use, to give each new area an identity and a sense of centrality.

In general, UCT is a useful tool for pragmatic urban sustainable redesign. This tool clearly takes as a starting point that the future sustainable city is the already existing city, establishing operational criteria to each component of sustainability in the city.

Abstract
Major construction sites in Australia have an above average presence of ethnic minorities. These groups and the interfaces between them require effective management in order to meet the social imperatives of sustainable design and construction. A survey of 1155 workers and 204 managers on Sydney construction sites respectively, found a significant level of normalisation of negative forms of cross cultural interaction. Yet it was also found that anti-racism programs are not currently a management priority and that they generally lack sophisticated community relations aspects. This paper presents the results of a desk-top study of leading global companies within and outside the construction sector which have won international awards and recognition for their cultural diversity strategies. A key insight is that the companies profiled see diversity as a key resource and as an opportunity rather than a risk which is best harnessed through long-term and on-going commitment of senior management. These leading companies also recognise that cultural diversity strategies operate at three levels - in terms of its relationship with its own workforce; its relationship with its clients and; its relationships with the communities in which it operates - and if properly managed it can be a source of competitive advantage.

Keywords: Cultural diversity, strategy, best practice, racism, discrimination.

INTRODUCTION

Loosemore and Phua's (2010) review and analysis of corporate social responsibility practices in the construction and engineering sectors found that while the industry had made significant strides in advancing its ecological sustainability performance, its social sustainability performance remained a challenge. There are many dimensions to this issue including occupational health, welfare and safety, policies relating to ageism, gender and disability, community consultation in design and development, philanthropic donations etc. One major aspect of social sustainability in the industry, which has received growing attention in recent years, is the issue of managing its cultural diversity. Major construction sites in many

countries are settings of significant cultural diversity since they have a workforce which has a disproportionately high presence of ethnic minorities. This diversity largely stems from the nature of the work undertaken on these sites, and the structure of the labour force. For example, in Australia, 16 per cent of the Australian labour force is from non-English speaking background (DIAC, 2009) and the Australian construction industry is one of Australia's largest and most culturally diverse, directly employing about 9.2 per cent of the working population (ABS, 2009). It has also been found in previous research that there is some occupational ethnic segmentation on major construction sites with different trades associated with certain ethnic groups (Loosemore and Lee, 2002). For example, steel workers and scaffolders are usually of Maori and Southern Islander decent, concreters are generally of Italian decent, carpenters of Croatian decent, tilers of Korean decent and managers, designers and engineers of Anglo-Saxon decent. As different trades enter and leave sites during the construction phases, there is a rotation of specific ethnic groups. This means that over the life cycle of a project, many of these ethnic groups may have limited interaction with one another. The aims of this paper are to explore how these groups and the interfaces between them are managed and to explore the relevance of recognised best practice strategies used in other industries to the construction context.

BACKGROUND

Construction sites are not popularly perceived as sites of sophisticated cosmopolitanism. In many countries such as Australia, they are commonly seen as places of cultural insensitivity from where for example, gender incivilities emerge (such as wolf whistles to women who pass by etc). Furthermore, these settings would generally be perceived as lacking community relations programs. Indeed, there are emerging empirical evidence that demonstrates the existence of racism and ethnic discrimination on construction sites. For example, Loosemore and Chau (2002) found that 40 per cent of Asian workers had experienced workplace discrimination on Australian construction sites. Despite the high ethnic minority presence, and the labour intensive nature of the work, construction sites are often regarded as places of below average levels of education. Research on attitudes in Australia has demonstrated that those with lower levels of education are more likely to have more intolerant attitudes towards ethnic diversity and to minority groups (Dunn et al., 2004; Forrest and Dunn, 2006, 2010). So for these reasons, we could anticipate that construction sites may be places of heightened cross-cultural wariness and tension (Jupp and Nieuwenhuysen, 2007, Noble, 2009). This makes construction sites very fitting environments for testing the feasibility of anti-racism management interventions (Pedersen et al, 2005).

In response to this broad hypothesis, Loosemore et al (2010) reported a major survey of attitudes towards cultural diversity in the Australian construction industry administered between May and December 2008. The survey aimed to identify the nature and extent of cultural diversity and the boundaries of cultural groupings on construction sites. It also sought to investigate feelings about cultural diversity and other ethnic groups and experiences of intolerance and equality of treatment on construction sites. The survey was administered on twenty-eight construction sites in the Sydney metropolitan area and in the Construction, Forestry, Mining, and Energy Union (CFMEU) office. It resulted in 1155 completed and useable questionnaires and the key findings were that there is a good deal of cross-cultural interaction on construction sites (85 per cent interact with other ethnic groups during social situations and work-based activities). However, there are many perceived barriers to interaction on sites for some workers (31 per cent of respondents reported that they did not

make an effort to talk with workers of different ethnic backgrounds). The majority of respondents (76 per cent) believe their own ethnic group understands them better and 45 per cent of respondents reported that members of their own ethnic group need to stick together to 'survive' on construction sites. This suggests that ethnic groupings have some positive functions such as maintaining positive bonds among group members, group support and providing safe-havens. The vast majority of workers are comfortable with cultural diversity and think that it works well. However, they simultaneously perceive homogeneity to work well. Most respondents (64 per cent) indicated that they would like to see more opportunities to mix with people from other ethnic groups while at work. Communication problems caused by language barriers are one of the major challenges affecting work and social relations between different ethnic groups on sites. A considerable percentage of respondents (32 per cent) think that different ethnic groups should stay away from each other, thus implying that support for cultural diversity is not consistent and depends on the nature of the relationship between workers.

A second follow-up study published in Loosemore et al (in press) presented the findings of a survey of construction site supervisors and managers administered between May and August 2009. The survey aimed to identify managers' perceptions of ethnic diversity on construction sites and to map management strategies for workplace diversity. The survey also sought to compare managers' perceptions with operatives' experiences on sites from stage one of the study. The questionnaires were distributed on 16 construction sites which were mostly large commercial and residential projects in the Sydney metropolitan area. This resulted in 183 usable questionnaires and the key findings were that the majority of respondents indicated that responsibility for managing ethnic diversity belonged to site managers, supervisors and project managers. OHS and EEO policies were perceived to have more importance and be more widely implemented within the industry than affirmative action and managing ethnic diversity policies. There is also a low level of awareness about ethnic diversity policies. Most managers saw ethnic diversity strategies and affirmative action plans as discriminatory and unfair since such strategies may favour some groups over others. Seventy-five per cent of the managers reported that they did not receive any training that aimed to reduce stereotyping and ways of managing ethnic diversity effectively.

Fifty four per cent of the managers reported that they embraced a personal ethnic diversity management strategy to compensate for the lack of centralised policy. The other forty six per cent ignore the issue and rely on others to manage it for them. Thirteen per cent of the managers who did not have a personal strategy reported that having a strategy to manage ethnic diversity was not a priority. More than half of the managers did not identify any problems with ethnic diversity and did not see any need to manage it proactively. The cultural diversity of the industry is taken for granted and it appears as if the problems associated with it are accepted as an inevitable part of daily life on sites.

This paper reports the results of the third and final part of this research. The aim of this research was to explore management strategies which could be used in the construction sector to address the challenges we discovered in stages one and two.

METHOD

Data were collected via a desk-top study of global best practices in managing cultural diversity within the workplace. The desk-top study consisted of a review of a large number of

online and published sources including specialised diversity reports, journal papers, books, company annual reports, company websites and press releases. In total, 156 companies were investigated across 15 industry sectors including hospitality, apparel, pharmaceuticals, entertainment media, information technology, internet services and retailing, megabanks, construction and engineering, health care, aviation, petroleum refining, and fast moving consumer goods.

These companies were sourced from lists of the largest and most successful companies in the U.S. and overseas such as:

- ENR's Top 400 Contractor List 2009;
- Fortune Magazine's World's Most Admired Company List for 2010 (People Management; and Management Quality) ;
- Fortune Magazine's 100 Best Companies to Work For 2009; and
- Human Rights Campaign Foundation's Corporate Equality Index 2009.

A number of companies profiled were also acknowledged in the field as leaders in diversity management and some have won awards and accolades for their commitment and innovative solutions to managing cultural diversity and have been featured on award winning lists such as:

- Diversity Inc.'s Top 50 Companies List 2010;
- Diversity Inc.'s Top 10 Companies for Supplier Diversity List 2010; and
- Reader's Choice Best Diversity Companies 2009

The methodology used to assess the diversity rankings above were also studied, where available, as a guide to determine the effectiveness of diversity actions, assess their applicability for the construction industry and the practicalities of implementation on construction sites. Essentially, we only chose to report strategies that we thought were transferable to the construction sector and which could address the challenges we have discussed above.

It is worth noting that engineering and construction, or the property and developer companies rarely, if any, feature on award lists in terms of their management of cultural diversity.

FINDINGS

The following sections discuss the main findings from our research.

Senior management leadership

Strong leadership and senior management commitment to growing a culturally diverse workforce is central to ensuring the effectiveness and longevity of any cultural diversity initiatives. For example, the appointment of a senior executive to champion and lead diversity initiatives can make a critical difference to how the issue of diversity is perceived in the workplace. Senior management positions such as 'Chief Diversity Officer' or 'Global Chief of Diversity' are often found in leading companies with direct reporting responsibilities to the CEO to ensure diversity remains a strategic priority. For example, Johnson and Johnson's Chief Diversity Officer, has been appointed to champion, communicate, implement and

monitor its diversity policies across all business units, and works in parallel with its CEO to keep diversity and inclusion strategies as a key strategic priority, by for example linking top executive remuneration to their achievement of diversity goals etc (Diversity Inc., 2010). These findings align with the social science on cross cultural contact, and the conditions under which it has a productive effect on community relations.

Offices of diversity

A number of recognised leaders in diversity, such as Johnson and Johnson, and PriceWaterHouseCoopers, have established an office of diversity and inclusion as a separate business unit from human resources to reflect senior management's belief in the strategic importance of diversity initiatives in the workplace (Diversity Inc., 2010; Johnson and Johnson, 2010). Although diversity and inclusion strategies are closely related to traditional human resource management functions of hiring and promotions, they are considered to have wider strategic value that extends beyond a company's internal management to impact on its wider supply chain, the community it serves and external stakeholders. This is a key mechanism for driving institutional-level change, and for engaging with the systemic nature of racism (confronting deeply embedded stereotypes and re-thinking organisational practices that disadvantage minorities).

Measuring diversity management performance

Companies that are committed to diversity initiatives establish measurable KPIs that enables them to monitor the return on investment and effectiveness of diversity initiatives implemented (KPIs may include: number of clients from different minority groups; number of senior managers from minority groups; levels of acceptance and satisfaction among employees; grievances and complaints; workplace conflict and disputes; retention; recruitment; community and public image etc). These companies view diversity initiatives as a valuable investment in the creation of a harmonious, inclusive and productive workplace. They actively seek out, or participate in, specialist rankings as a way to gain recognition or build brand recognition in the marketplace among clients and external stakeholders, and increase their ability to attract and retain new talent. For example, British Airways measures and reports employees' perceptions of the effectiveness of its diversity initiatives through internal employee surveys, the feedback from which influences its diversity strategies (Singh, 2008).

Cultural integration opportunities

Companies are increasingly employing creative ways to promote awareness of the need for cultural diversity in the workplace. For example, Pearson publishing group organises a diversity week where members of different cultural and minority grouping are invited to share their cultural food, drinks, cooking lessons and cultural knowledge. This extends beyond immediate employees to the company's customers, business partners and supply chain, so that fellow employees, their customer base and the wider community can better understand and appreciate the unique features of their cultural background. While one often finds similar initiatives (site BBQs etc) in the construction sector, they are of much smaller scale, voluntary and typically ad-hoc. In contrast, Pearson's diversity week is a highly structured and planned event which is centrally organised and advertised by the company. It is significant in highlighting diversity as the right thing to do, and is also useful in

showcasing how diversity has commercial value and benefits beyond its employees to benefit their wider supplier chain and the communities they serve (Singh, 2008).

Diversity training

A number of best practice diversity companies, such as Colgate-Palmolive go beyond basic compliance and have made diversity training a standard and mandatory feature of their overall training process. These courses are delivered though online tools to facilitate easy access to the training resource that covers a wide range of topics such as the rights and obligations of employees, anti-discrimination legislation and strategies for dealing with workplace discrimination (Diversity at work, 2003). Other companies such as British Airways emphasise more practical day-to-day managerial approaches for dealing with diversity, such as how to overcome negative behaviours, attitudes and stereotypes. On-line diversity training programs, and those equal opportunity principles, are common within large organisations, including Universities.

Community languages

The ability to communicate in a language other than English is a quality that companies increasingly value as a resource to help bridge cultural divides and to allow them to better understand their employees, and service their clients and stakeholders. For example, companies such as Sydney Water, Australia Post and Medibank Private proactively encourage native speakers from culturally and linguistically diverse backgrounds (CALD) to undertake a language competency test so that they can become qualified translators and interpreters. The cost of the test is normally covered by the company who also provide certified CALD speakers who list themselves on a staff translator list with a linguistic allowance to reward them for assisting in communications with internal and external customers.

Cultural holidays

Different cultural and ethnic groups celebrate events and holidays that have specific cultural value and significance to them. In acknowledging this, ebay and IBM Australia for example, has implemented a ‘Floating Cultural Holiday Policy’ that gives employees the option of ‘trading’ official public holidays for a day that is of cultural significance to them (IBM Australia, 2010). For example, employees may wish to 'trade' a gazetted public holiday such as the Queen's Birthday for a day of particular cultural significance, such as Chinese New Year. A key advantage of the policy is that it effectively allows employees to strike a balance between their cultural and work commitments, while according due recognition to an employee’s cultural heritage.

Role modelling

The positive role modelling of successful and inspirational employees from minority groups can have a significant motivational impact in minority groups (Thomas, 2006). These role models are particularly important in breaking down traditional stereotypes and perceived barriers and misconceptions for entry and promotion in certain industries, such as building, engineering and technology, where visible role models are not common. For example, to retain young women employees, Shell has started role modelling successful women in senior positions, particularly those technology business units where female representation has

historically been low. From their stories, young women employees can learn important lessons about the challenges that many women experience in achieving and maintaining senior positions.

Networking

In a culturally diverse workplace, networks play a key role in strengthening diversity by providing important forums through which individuals and groups can meet and exchange ideas, experiences and embrace similarities and differences among people from different cultures and backgrounds. These networks can serve a range of functions, in providing a supportive or facilitative environment, reducing isolation increasing levels of intra- and inter-cultural interaction and providing access to promotional opportunities through mentoring programs and other initiatives (Laroche and Rutherford, 2007).

Mentoring

Mentoring programs are increasingly utilised as a tool to harness cultural diversity within the workplace and provide a valuable vehicle for promising employees from minority backgrounds to access the managerial support and identify pathways and knowledge they need to reach their full potential at work. For example, Johnson and Johnson match new employees with experienced managers through formal or informal mentoring arrangements (Johnson and Johnson, 2010). Similarly, Sodexo's 'Spirit of inclusion' mentoring program matches people from different backgrounds and provides training to mentors to help them manage this process, regularly monitoring mentor and mentee performance in achieving pre-determined diversity and inclusion goals (Sodexo, 2009).

Supplier or subcontractor diversity

Supplier and subcontractor diversity initiatives are an important way in which companies can give back to the communities they serve by reaching out to minority and women-owned businesses and are aimed at helping these businesses develop the capacity to compete on an equal basis in the market place. A number of recognised advantages of increased supplier and subcontractor diversity include improved reputation and marketing opportunities, the promotion of inclusiveness at all levels of business, better access to innovative ideas and vendors who reflect and understand the culturally diverse communities that companies operate in, and increased customer satisfaction, market share and profitability (Diversity Inc., 2010). Commonly used strategies to promote supplier and subcontractor diversity include: Supplier or subcontractor guidelines & codes of practice; Strategic allocation of a portion of contracts; Certification; Supplier Diversity Mentoring Programs; Diversity sponsorship or scholarships and; Evaluation tools.

CONCLUSION

This paper has presented a number of best practice strategies for promoting diversity in the workplace. All are derived from outside the construction sector since this is where the best practice companies appear to reside (at least from publically available information). No construction or engineering companies globally reside in the best diversity companies lists. Future research might usefully focus on why this is the case and to identify the imperatives needed in the industry to integrate such initiatives more comprehensively into firms' business

strategies. However, in a small desktop study like this, it is not possible to identify and classify every type of cultural diversity initiative being implemented. Nevertheless, we can reasonably conclude, given the construction and engineer industry's relatively high level of cultural diversity, compared to other sectors, and the evidence (provided in stages 1 and 2 of this research) that it impacts on workplace relations, productivity and safety, that firms can and should do more to harness the potential benefits of this diversity within the industry in terms of the firms and people who work in it. This will make a significant contribution to a more socially sustainable industry. More research is needed to explore, classify and test the extent of effectiveness of the full variety of diversity strategies that could be employed in the industry to achieve this end.

ACADEMIC/INDUSTRY INNOVATIONS FOR SUSTAINABLE BUILDING DESIGN AND REFURBISHMENT

BRANKA DIMITRIJEVIC
Glasgow Caledonian University
70 Cowcaddens Road, Glasgow G4 0BA, United Kingdom
Branka.Dimitrijevic@gcu.ac.uk

Abstract
Development and efficient dissemination of innovations for sustainable building design and refurbishment are crucial for the competitiveness of companies operating in the construction sector which faces pressure to reduce levels of carbon emissions from existing and new buildings to zero. An overwhelming majority of companies operating in the construction sector in Scotland are small to medium size enterprises (SMEs) who do not have sufficient resources in the current economic downturn to undertake research in building design, products and processes that will make buildings more sustainable. A joint project of seven Scottish universities has been initiated to support collaboration with small to medium sized enterprises in developing and disseminating innovation for sustainable building design and refurbishment. The project concept and methods used for efficient dissemination of the project outputs to SMEs across Scotland are explained. An analysis of the outputs of completed feasibility studies and the provision of academic consultancy through the project indicates the range of problems tackled as well as trends in the development and use of innovations for a more sustainable built environment in Scotland.

Keywords: Construction innovations, academia, SMEs

INTRODUCTION

The importance of the sustainable built environment for sustainable development of Scotland was emphasised in the Scottish Government's strategy for sustainable development *Choosing Our Future* (2005) and *The Government Economic Strategy* (2007). One of the objectives of the *Scottish Construction Industry Plan 2007-2012* (Scottish Construction Forum, 2007) is to increase good practice in sustainability by sharing best practice and innovation. The Scottish Government's *Policy on Architecture for Scotland* (2006) encourages the recognition and adaptive re-use of Scotland's historic buildings rather than their replacement to meet the objectives of sustainable development of the built environment. *Climate Change Adaptation by Design* (Shaw et al, 2007) and *Sustainable Housing Design for Scotland* (Stevenson and Williams, 2007) point out that it is existing stock which can potentially make the most effective contribution to meeting sustainability objectives and reducing carbon.

The Scottish Government aims to reduce carbon emissions in Scotland by 80% by 2050 as outlined in the *Climate Change (Scotland) Act 2009*. *A Low Carbon Building Standards Strategy for Scotland – Sullivan Report 2007* recommends future revisions to the CO_2 target reductions within the Building Regulations as follows: 2010 – CO_2 savings of 30% more than 2007 building standards; 2013 – CO_2 savings of 60% more than 2007 building standards; 2016/17 – net zero carbon buildings (i.e. space/water heating, lighting & ventilation).

The above targets for carbon reduction cannot be achieved without innovations. The challenge is increased by the risk-averse attitudes of building clients, contractors and building control officers towards innovations. The WWF Scotland (2008) report *Carbon Countdown for Homes: How to make Scotland's existing homes low carbon* points out that sufficient numbers of experienced and knowledgeable building control officers and local authority planners are needed to ensure there are no bottlenecks in obtaining permissions for improvements.

The consultations with the industry organised by the Scottish Construction Centre (Scottish Construction Centre, 2008), the conference *Lifting Barriers to the Application of Construction Innovations in Scotland*, held at Glasgow Caledonian University on 25 March 2009 (The Centre for the Built Environment, 2009), and the report on *Developing Scotland's low carbon built environment* undertaken by BRE Scotland on behalf of Scottish Enterprise (Kelly, 2010), highlighted that the affordability of research for SMEs, the lack of tested innovative solutions and guidelines on how to apply them in practice are perceived as barriers to the adoption of innovations. This market failure within the above context of policies for creating a more sustainable built environment has been identified as a focus for the CIC Start Online project.

CIC START ONLINE PROJECT

The aim of the Construction Improvement Club (CIC) Start Online project is to embed innovations for sustainable building design and refurbishment into practice. The objective is to support collaboration between academia and Scottish small to medium size enterprises (SMEs) in developing and testing innovations for sustainable building design and refurbishment. The project is led by Glasgow Caledonian University (GCU) in collaboration with Edinburgh Napier University (ENU), Glasgow School of Art (GSA), Heriot-Watt University (HWU), the Robert Gordon University (RGU), University of Edinburgh (UE) and the University of Strathclyde Glasgow (USG). The project is funded by the European Regional Development Fund and Scottish Government from 1st September 2009 until 31st August 2012.

CIC Start Online runs a quarterly competition for 50 feasibility studies (FS) and 19 academic consultancies (AC) on sustainable building design and refurbishment undertaken for the benefit of Scottish SMEs. The joint academic/industry applications are assessed and approved by an independent assessment panel whose members are representatives of the Buildings Standards Division of the Directorate for the Built Environment of Scottish Government, the Scottish Association of Building Standards Managers and energy efficiency consultants.

The outcomes of academic/industry collaboration are presented at seminars, transmitted online as webinars in real time and then made available as video recordings on demand at the project website www.cicstart.org to the project members. Membership is free and open to everyone.

Three whole-day online thematic conferences are planned. The first one, on *Sustainable Refurbishment*, was delivered on 4th June 2010. The seven webcasts filmed in collaboration with academic partners are available free at the project website following registration. The second conference will deliver the project partners' webcasts on their research and innovation related to the *Resilience of Buildings, Neighbourhoods and Cities*. This conference will take place online

from 14th until 17th June 2011. Each webcast will be followed by an interactive discussion with their authors.

The project publishes a quarterly free online Innovation Review that includes case studies on innovation for sustainable building design, construction and refurbishment applied in practice, information on support for innovation and related research.

Online dissemination of the project outcomes has assisted in attracting membership across Scotland, the United Kingdom, and internationally. By the end of February 2011, the project has over 620 members from over 470 organisations, of which over 320 companies are Scottish SMEs. Online dissemination of the project outcomes reduces carbon emissions of the continuous professional development of the project members.

INNOVATIONS SUPPORTED BY CIC START ONLINE PROJECT

The following section provides an overview of the types of innovations supported through FS or the innovations that have been further refined through AC. The overview is based on the studies completed or initiated until the end of January 2011. The approved applications can be divided into five thematic groups as presented below: Sustainable building design, Sustainable refurbishment, Post occupancy evaluation, Sustainable building materials and components, and Decision making for sustainable building design and refurbishment. The competition is open to additional potential themes for FS or AC that will address other aspects of the application of innovations for sustainable building design and refurbishment in practice.

Sustainable building design

A Hybrid Solar Thermal Mass (HSTM) System Development for the Application to Tenants First Housing Co-operative's Zero-carbon Affordable Homes, GSA, ENU and Tenants First Housing Co-operative, Aberdeen.

The benefits of using the building foundation as the heat store over alternative, more common, wet (or phase change) thermal storage media were demonstrated. The study concluded that using the Ecocirc pump in combination with a 30 Wp PV module, the desired design condition of a relatively constant collector outlet temperature can be achieved in practice. Measurement of irradiance, and collector temperature and flow, has provided an accurate appraisal of the Solartwin collector thermal performance. It indicates that the HSTM system is able to deliver heat to, and store heat within, the thermal mass of the building foundation (Noguchi et al, 2010).

Assessment and Application of Zero Carbon Building in Scotland, HWU and IES Ltd, Glasgow

The study involved investigation of recently published guidelines into the definition of 'Zero carbon' by the government and a comparison with 'true' zero carbon buildings. The study uses the proposed Riccarton Ecovillage on the campus at HWU to provide the sample building used for the detailed analysis and assessment parts of the study. HWU and IES worked together using IES's Virtual Environment software to perform predictions of carbon emissions. The detailed calculations consider a range of currently available building technologies, and systems that could be used either in isolation, or in conjunction with one another. The analyses are intended to demonstrate the differences between current building standards and the improvements that will be needed in future both to meet the published regulatory guidelines and also to provide a

comparison with true zero carbon using representative domestic Scottish buildings as the basis for the analysis. The report aims to show what renewable technologies need to be employed in order to meet Zero Carbon – using both dynamic simulation methods and Building Regulations SAP software meeting the Scottish Technical Standards Section 6 requirements (Roaf and McEwan, 2010).

Tarryholme Sustainable Housing Project, USG and Assist Design, Glasgow
Assist Design is currently engaged in a sustainable housing development project Tarryholme Eco-House in Irvine in collaboration with the Irvine Housing Association and Irvine Bay Regeneration Company. The project aims to attain a higher level of sustainability than those promoted by existing assessment protocols and be reflective of contextual realities in Irvine. The study aims to demonstrate that it is possible to build an affordable, organic Eco dwelling that can optimise the conflicting demands of energy efficiency and good indoor air quality in the context that the UK has the highest prevalence of asthma in 13-14 year olds and that the last 25 years has seen the incidence of asthma episodes increase four-fold in adults and six-fold in children. The study will include the detailed design of a two-bedroom, semi-detached property including drawings, specifications, whole life cost and carbon analysis. Direct comparison with an affordable house designed to the 2010 Scottish Building Standards will also be provided (Howieson and McCafferty, 2010).

Energy Impact of different strategies of integrating PV/Thermal heat transfer, GSA and Robert Ryan Timber Engineering Limited, Saltcoats
Robert Ryan Timber Engineering Limited is developing design ideas and solutions towards the construction of two net ‘zero-energy’ healthy housing prototypes in North Ayrshire which aim to surpass the energy usage profile of zero-carbon counterparts being recognised by the UK Government. Extensive studies have been conducted on the design optimisation of photovoltaic thermal (PV/T). However, the energy impact of a PV/Thermal Heat Recovery unit integrated into housing for space heating is barely conceived or examined in today’s homebuilding industry. The goal of this feasibility study is to assess the most effective strategies of integrating PV/T Heat Recovery (PV/T HR) system in Scottish 'zero-energy' housing in the context of energy, economic and life cycle performance. It will be conducted through scale model experiments to test different installation (PV/T HR architectural integration) scenarios and the performance with aim of applying the PV/T HR system to the two zero-energy demonstration homes (Masau and Noguchi, 2010).

Enkelt Simple LivingGSA and Ballyconnelly Construction Ltd, Wemyss Bay
The purpose of study is to scope out the next stage of improvements to the Enkelt house model developed by Ballyconnelly Construction Ltd. This will include identification of minimum standards as well as improved U-values with increased insulation using a 180mm SIP panel; improved window and door specification balancing the brief to maintain cost level at typical housing construction cost; improved efficiency of the MVHR unit with e.g. integrated ASHP and Hot Water Cylinder, reviewing the potential to remove the heating system; potential for integrated renewable systems such as solar hot water, PV and heat pumps and their impact to reduce future running costs and CO_2 emissions; assessment of the responsible sourcing of materials reviewing any opportunity for improvement; assessment of the Enkelt system against recognised criteria e.g. EcoHomes, Code for Sustainable Homes, and appraisal of potential

improvement against these criteria; and a review of potential for a prefabricated modular version of the Enkelt home to improve construction time and build quality (Sharpe and Stewart, 2010).

Independent verification of a climate based worldwide building energy index, GCU and IES Ltd, Glasgow
IES Ltd has prototyped a set of energy indices that can be used to assess, classify and compare any worldwide climate (weather data or extrapolated climate change data) for the purposes of understanding climate and for the use in sustainable building design. The indices are intended as rapid and interactive holistic design tools applicable to any building type, with any design strategy, in any location worldwide and for the simple quantification of the impact of climate change on building energy progressively over a sustainable building's lifecycle. The basis of the indices is the fact that climate underlies building energy use and it is therefore possible to compare designs relative to climate, visualise where design emphasis needs to be placed and directly and interactively track the effect of design strategies. The index is applicable to both the design and operational phases of buildings and is directly usable by building professionals without the need for specialist energy knowledge i.e. architects, quantity surveyors, students, etc. The SME was in need of an independent peer review and detailed verification to prove the prototyped index performs successfully. With this need in mind the academic partner carried out a review of the Climate Energy Index and the Building Energy Index developed by the SME partner with the aim of verifying their scientific soundness and ease of applicability. The following tasks were performed: a peer review or the physics and implementation of the Index, an extensive series of tests to confirm the validity of the Index, and a series of robustness tests (Kumar and Emmanuel, 2010).

Sustainable refurbishment
Tenement Flat Carbon Reduction Shopping List, USG and Holmes Partnership, Glasgow
The study aimed to provide typical Glasgow sandstone tenement flat dwellers with a guide as to the most suitable carbon reduction measures to apply to their dwelling. In particular, it was intended to provide a cost per tonne of carbon dioxide saved comparison to demonstrate value for money for various retrofit options. A particular tenement flat was selected and surveyed. The dimensions and conditions were passed to ESRU who prepared a dynamic thermal model. Various retrofit options were agreed and applied to the model and the outcomes recorded in terms of tonnes of carbon dioxide emissions saved. Doig and Smith (Cost Consultants) prepared costs for all the retrofit options allowing the cost-per-tonne saved to be calculated (Cockroft et al, 2010).

Upgrade Strategy Development for Garrioch Residents Association, USG and Collective Architecture, Glasgow
The study has defined and demonstrated a process for assessing and communicating the energy upgrade options to a residents association, landlord or housing association. The first process step is a meeting with the client to explain the project and get their inputs on the current issues with the building and the range of upgrades of most interest. Following this consultation process the current building performance is established through a physical survey, air-tightness testing, thermography and smoke analysis in representative dwellings. The appropriate upgrade options and best practice examples for the building type are then researched and a reference database created. The carbon and energy performance of a representative sample of the existing dwellings

is then modelled; and the carbon, cost and energy impact of a range of upgrade options quantified. Based on best practice and modelling results some recommendations are provided. A customised version of the modelling tools is made available to the residents association and training offered to allow them to assess further upgrade options on an ongoing basis. The customised tools are similarly available as the starting point for future similar projects. A report of the outcomes of the work is prepared and presented to the clients allowing them to gain understanding. In this case the process was applied to the quadrangle of traditional red sandstone tenement flats in the west end of Glasgow represented by Garrioch Residents Association. As there are many similar properties in Scotland requiring similar upgrades, work undertaken in this study can be utilised elsewhere. However, the process is not restricted to these similar properties; it can also be applied to other dwelling types (Touhy et al, 2010).

Solar-Wall systems for domestic heating: an affordable solution for fuel poverty, HWU, Changeworks Resources For Life Ltd and Ormandy Ltd, Edinburgh

The aim was to test a number of key variables of a solar wall heating system currently under development, to maximise solar heat collection in the context of Scottish weather and heavy buildings built with solid walls (pre-1919 buildings account for 20% of the housing stock in Scotland). The study quantified the thermal effect of internal solid walls used as thermal storage for solar heat in tenement flats for all-day usage, optimised the device to maximise heat exchange between the wall and hot water from the solar panel, provided a modelling tool to enable a Solar Warm Wall system to be designed to suit individual buildings (either new or retrofit), and estimated costs of system implementation. In addition, this study analysed solar availability, heating demand and domestic water supply for two typical dwellings based on two reliable methods: a) a purposely developed dynamic thermal model, and b) data collected in previous studies carried by Changeworks. The tests were carried out using two methods: Computational Fluid Dynamics (CFD) and laboratory simulation. Developing the CFD model was one of the major objectives of this feasibility study. The lab tests were conducted to collect data to validate the CFD model (Wang and Roaf, 2010).

Synergy of Fabric and Energy conservation in older historic properties, ENU and The Morrison Partnership, Edinburgh

The Morrison Partnership (Architects) have a private client who wishes to convert and extend a 19th century traditional built two storey mansion house in Alyth, Blairgowrie, Scotland. The proposal is to convert the former hospital to a home. An energy efficient heating system for both space and hot water was proposed, which is not only sustainable but respects the behaviour and appearance of the existing historic building fabric. The study will identify appropriate actions in achieving minimal fabric intervention for maximum energy conservation in traditional buildings with specific reference to solid stone/ lath & plaster wall construction typical of the 19th century in Scotland. The project will aim to address: 1. Environmental issues by seeking methods of reducing CO_2 emissions and improving energy conservation and management in older, difficult to heat, stone built properties; 2. Social issues by improving health as a result of improved and balanced indoor air and heating quality; 3. Economic issues by considering whole-life energy costs in large domestic, difficult to heat, buildings in Scotland. The proposal will aim to: 1. Establish a detailed energy assessment process for the building study type that could be used in other similar projects; 2. Identify future research and improvement work in this area to develop and market an energy management process for this building type (Currie and Purdie, 2010).

Post occupancy evaluation

Development of Post Occupancy Evaluation for evaluation of innovative low carbon socialhousing projects, GSA and John Gilbert Architects Ltd, Glasgow

The study includes a monitoring programme over a 2 – 4 week period of time measuring performance in terms of temperature, humidity, air quality, general and specific energy consumption. This is supplemented by interview, questionnaire, observation and spot measurement to determine occupancy regimes, patterns of use and consumption, users understanding of systems and controls. The second stage comprises a limited number of pilot programmes to test the methodology and data capture systems. The long term aim is to enable participating housing associations to understand how the performance of their housing is in comparison to other projects, what changes they may consider making to future projects as well as addressing issues in existing projects. It will also help in the setting of realistic energy targets so that those setting the targets have a real understanding of the consequences and achievability of certain energy targets. The eventual goal is to provide a much more accurate feedback loop on performance, problem detection, remediation and avoidance, and improved design and specification (Sharpe and Gilbert, 2010).

Embedding simplified post occupancy evaluation in design process, USG and Page and Park Architects, Glasgow

The team studied: 1. information relating to existing POE methods; 2. current benchmarks to determine industry best practice and compare appropriate figures against Page & Park attainments; 3. various existing questionnaires in order to devise a simple questionnaire that clients would regard as user-friendly; and 4. the range of formats in which clients/companies receive energy data so that a meaningful POE process could be devised that would cope with a wide range of data. It was decided that the most effective way to deliver a simplified POE process, to complement the existing work practices of Page & Park, was to design and trial a software tool, named POET (for Post Occupancy Evaluation Tool). This tool was developed over the period of the project and underwent a number of revisions to deal with issues relating to compatibility with Page & Park hardware, work practices and application expectations (Clarke et al, 2010).

In-service testing of a prototype dwellings in relation to passive versus active ventilation strategies and assessment of air quality and comfort balance with fuel poverty avoidance, USG and Assist Design, Glasgow

Primary research outcomes will include construction process monitoring and post occupancy evaluation. It is proposed that a dwelling with low energy characteristics can be designed to be significantly faster and easier to construct making both time and skilled labour savings that would considerably impact the potential cost of achieving greater than 60% CO_2 reductions. Construction process monitoring of the prototype low energy house will allow quantifying such savings and making direct comparison with an affordable housing designed and constructed to the 2010 Scottish Building Standards that meets 30% CO_2 reduction commitment. It is further proposed that such a dwelling should address indoor air quality and public health. Post occupancy evaluation research outcomes will be realised within 12-month monitoring period (Howieson and McCafferty, 2010).

9-11 Gilmour's close – comparing the theoretical performance of a suite of sustainable installations in the building against actual performance and user experience, GSA and Assist Architects, Edinburgh

9-11 Gilmour's Close is a low-carbon refurbishment project for Hillcrest Housing Association, located in Edinburgh's World Heritage Site. The project addressed the difficult task of refurbishing an existing listed building to minimize CO_2 emissions and dependency on non-renewable energy sources. The project aims to gather data to compare the theoretical performance with actual performance. The context for this is the increasing need to develop design and technologies for all newly built homes to ensure that they would be carbon-neutral by 2016. Whilst predictions can be made about performance at design stages, there is very little evidence being collected about how these buildings perform in use. This gap in knowledge must be addressed if effective designs and technologies are to meet these rigorous standards (Sharpe and Jack, 2010).

Post Occupancy Evaluation of Municipal Terrace, Dumfries, GSA and Dumfries & Galloway Housing Partnership (DGHP), Dumfries

The Municipal Terrace in Dumfries was built in 1913 to house the "working classes". The block consists of eight one-bedroom workman dwellings that have cavity walls, which is unusual for the built age, with 9" outer leaf, 2"cavity and a 4½" inner leaf. The property had two large rooms and a rear scullery which was built in solid 9" brickwork (area converted into kitchen/bathroom 1962-3). DHGP developed and incorporated ways of improving four of eight homes above existing Building Regulations levels and along the ideas, principals and standards of ecological building design and refurbishment (including Passivhaus). In order to test the effectiveness of these measures, this consultancy will undertake a post occupancy evaluation to examine the performance of the dwellings (Sharpe and Trant, 2010).

Sustainable building materials and components

Developing Homegrown Natural Fibre Insulation Products, GCU and Kraft Architecture, Glasgow

Kraft Architecture has been working on in-house research into the processes and manufacturing of natural fibre products using home-grown & waste fibres. Having identified prototyping facilities, waste material suppliers and carried out market research into demand, they are now at a stage where they wish to prototype the product and have the products undergo testing. This project is focused primarily on the use the climatic chamber facility in GCU's Centre for Research on Indoor Climate and Health to test the thermal performance, vapour diffusion, resistance co-efficient of prototype natural fibre insulation product(s) consisting of various recycled waste textile and cellulose materials (Baker and Newlands, 2010).

Novel Solar Thermal Collector Design, HWU and AES Ltd, Forres

The primary objective was to improve the basic design of the AES solar thermal collector; to make it more efficient, lighter and more robust and generally a more fit for purpose and greener product. The intention is to provide an improved collector to market at a competitive price relative to the current one. Taking into account that the solar gains and heat losses are linked to conditions of operation and design of the collector, it was necessary to focus on analyzing the mechanism of energy gains and losses from the collector, such as type of material cover, material housing, insulation material properties, surface area, weather conditions, inlet temperature water,

ambient temperature, mass flow rate, position of collector, dimensions, gross area to absorber area ratio, absorber material and best thickness, and collector tilt angle. Four sample units were manufactured by AES and supplied to HWU for thermal performance testing (Roaf and MacLennan, 2010).

Decision making for sustainable building design and refurbishment
An Investigation of the Adoption of Low-Carbon Technologies by Scottish Housing Associations, RGU and Anderson, Bell and Christie Architects, Glasgow
A feasibility study was proposed as a means of investigating the decision making of housing associations (HAs) with regard to the adoption of low carbon technologies. The starting point for the study was a consideration of what impact incentivisation schemes (in this case particularly feed-in tariffs) had on the adoption of low carbon technologies. The study developed further, in that it added an objective to assess the feasibility of producing a unified business process (UBP) focused on aiding individual HAs when deciding which low carbon technologies (LCTs) are appropriate to them. The study involved two housing associations that had both considered the adoption of innovative sustainability technologies, but ultimately made different investment (in the form of "purchasing" sustainable technologies) decisions. Within the study, interview and document analysis methods were used to determine both the culture (in terms of propensity to innovate) and any filters that had strong or weak impact on the decision making of the respective housing associations (Moore et al, 2010).

DISCUSSION

The launch of the CIC Start Online project at the seven universities involved in the project in October and November 2009 provided opportunities to advise the industry on funding available to Scottish SMEs for collaboration with academia in developing innovations for sustainable building design and refurbishment. SMEs' requests for assistance are submitted online as a brief description of a problem that they wish to tackle and forwarded to the project partners. Sometimes, the assistance is provided jointly by the academics from different partners' institutions according to the expertise required and available for addressing different aspects of an innovation.

The overview of the studies approved to date indicates that there is an interest in tackling innovations both for existing and new buildings, and for assessing their true impact through post occupancy evaluation. The studies have also enabled SMEs to access laboratories at the participating universities to test innovative building products and technologies. How building clients make decisions in relation to the incentives to reduce the carbon emissions of buildings was the theme of one academic consultancy that will provide an insight not only for the architects who initiated this research, but also for the wider professional audience when the research outcomes are presented at a forthcoming seminar and webinar.

The scope of the approved studies includes not only the environmental impact of buildings such as the reduction of carbon emissions and the use of renewable energy and building resources, but, in many cases, the social and economic impacts by tackling fuel poverty, indoor air quality and whole life costs for building occupants. As only the innovations that simultaneously address environmental, social and economic impact could contribute to a more sustainable built

environment; this was one of the main conditions of the competition. As a consequence, interdisciplinary collaboration of researchers from different departments at the partners' institutions and sometimes with external consultants has been initiated.

Feasibility studies and academic consultancies have developed new knowledge regarding the technologies for generating energy from renewable resources and building materials made of recycled or renewable natural resources. They have also contributed to a better understanding of how new technologies can be integrated in existing and new buildings to reduce carbon emissions and fuel poverty. Other studies have refined some existing software tools for building modelling, or indicated the limitations in some existing assessment tools that should be considered when using them to estimate building performance, or used the tools to indicate improvements required in traditional building types to achieve zero-carbon standards. Most studies focused on real building projects, either recently completed as exemplars of sustainable design or refurbishment that need to be verified through monitoring or to suggest further improvements to achieve zero-carbon standards. Due attention was given to existing building stock by consulting building occupants on how buildings are used, applying innovative methods for assessing building performance, recommending and estimating costs of potential improvements, and providing guidelines to the building owners on how to undertake future assessments and improvements.

As the studies have been initiated by the industry, they indicate the range of issues that the industry faces in its efforts to create a more sustainable built environment, a range which will probably be extended in the future applications for feasibility studies and academic consultancy through the CIC Start Online project. The majority of studies focused on the Scottish environmental, social and economic context regarding the need for more sustainable existing and new built environment, thus assisting in solving local problems. However, some studies have tackled more generic innovations in sustainable building design and refurbishment that can be applied internationally. The results of both approaches assist in increasing the competitiveness of SMEs which have benefited from their collaboration with academia through the CIC Start Online project, and of the project members to whom the outcomes of innovations are disseminated through seminars, webinars, online conferences and an online magazine. The project has been included in the Scottish Green List 2010 as one of the top twenty projects that contribute to a more sustainable development of Scotland.

Webinars are increasingly used for the dissemination of knowledge on sustainable building design and refurbishment across the world, e.g. by U.S. Green Building Council (USGBC Webinars, 2011), American Society of Civil Engineers (ASCE, 2011), ArchDaily (ArchDaily, 2011) and Mechanical Contractors Association of America (MCAA, 2011). In comparison to the webinars provided by the above organisations, other professional associations or a range of consultancies and publishers, the CIC Start Online webinars disseminate the outcomes of academic/industry collaboration in developing and testing innovations for sustainable building design and refurbishment in Scotland's economic, social and environmental context. The collaboration between the seven Scottish universities and local construction sector enterprises accelerates the capacity building and increases the competitiveness of the local industry to apply innovations in practice, which is the project aim.

CONCLUSIONS

As the academic/industry collaboration through the CIC Start Online project has contributed to the development of a range of innovations for sustainable building design and to a better understanding of how they can be applied in practice, the project partners are planning a proposal for a project extension that will eventually include more higher education institutions and link with further education institutions to support the development of skills required for creating and maintaining a sustainable built environment. In addition, stronger links are planned with local construction fora to reach all participants in the construction supply chain.

In the context of recent policies and proposals published by the Scottish Government such as *Energy Efficiency Action Plan for Scotland* (October 2010), *A Low Carbon Economic Strategy for Scotland* (November 2010) and *Low Carbon Scotland: The Draft Report on Proposals and Policies: Scotland – A Low Carbon Society* (November 2010), interdisciplinary collaboration will be further extended to reduce carbon emissions through the research and application of integrated design, refurbishment and management of the built environment that tackles energy conservation and efficiency, sustainable transport, and waste reduction, reuse, recycling and energy recovery.

LUIS RAMON VALVERDE
Universidad Politécnica de Madrid
luisrval@arquinex.es

Abstract
This paper is presented in CIB: Management and Innovation Sustainable Built Environment 2011, as the study and analysis of the residential model of a rural area from the Iberian Peninsula, specifically applied to the case of the province of Cáceres, in the autonomous region of Extremadura, in Spain.
To this end, from a database made up of building projects whose real costs are known, it is intended to establish the links of the different parameters studied through the corresponding functions of statistical analysis. One of the main objectives of this process is constituted by the possibility of establishing those design variables of higher economic importance, so as to keep an economic control of these parameters, generally geometrical and typological, from the very start of the project. And, in general, a higher optimization of resources in the construction of dwellings in the rural environment from their design is intended.

Keywords: Self-development, sustainability, design, costs

AIM

The characterization of a residential building pattern and its repercussions on production costs is one of the tasks which explain the particular features of the economy of the built environment. When this area is immersed within a rural environment with a context of limited economic development, as is the case in the territorial scope of this work, it is essential for the public authorities to articulate policies which encourage and support access to a decent home. Not only for the household economy but also for the public funds which finance the process.
This study takes place within the framework of Management and Innovation for a Sustainable Built Environment CIB International Conference; and its purpose is to determine the repercussions of programmatic, geometric, constructive and technological design parameters on the final cost of a determined constructed object: the owner-developed home. It is with this element that the Public Administration of the European region of Extremadura aims to make use of available land for family units, generally in small rural centres of population.

Thus, the aim is to make an own home more affordable in an environment of limited economic resources, sidestepping the burden of purchasing the land where the building is to be, and providing financial help for the building process. In terms of territorial policy, the end goal is to facilitate the stability of the population in the area and to promote permanent renovation of the built environment. By these means the aim is to achieve sustainable growth of small rural nuclei, in which traditional economic activities, such as farming and cattle raising and their associated small industries, can be integrated naturally and harmoniously.

Along these lines, the purpose of this study is to determine the ideal characteristics, from the point of view of functional and economic efficiency, of a basic residential typology for balanced development of a territorial remit undergoing emigration and depopulation, and which is a factor of social cohesion in rural communities.

THE PHYSICAL SCOPE OF STUDY

Physical and Geographic Framework.

The geographical context for this study is the Province of Cáceres, in the Autonomous Community of Extremadura, a region in the mid-west of Spain, bordering on Portugal.

***Figure 1**: Autonomous Community of Extremadura in Spain*

The climate is continental: high temperatures in summer and low ones in winter. The rainfall is fairly low and concentrated in the months of October and April.

The north of the province flanks a large mountain range and is home to several districts - La Vera, the Jerte Valley, the Ambroz Valley, Las Hurdes… made up of population centres which are close together and the municipal districts are small.
The centre of the province is a broad plain crossed by a large river: the Tagus; this area has very few, widely scattered population centres with large municipal districts. The Monfragüe National Park is to be found here.
The south-east of the province is again of considerable altitude and there are small villages set close together, similar to in the north.

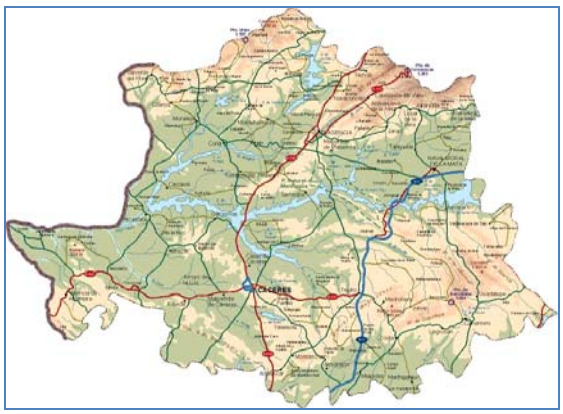

***Figure 2**: Cáceres Province, north of Extremadura*

Socio-economic Framework: Population and Main Activities
Cáceres Province has a population of approximately 400,000, of whom 69% live in population centres of fewer than 15,000. The other 31 % live in two main cities of under 100,000 - Cáceres, the capital, with a population of 94,197, and Plasencia, with 41,447. Therefore, the region can be seen to be dominated demographically by a rural structure, which characterizes the aim of this work.

The main activity of the rural population is agriculture (fruit-growing, olives, tobacco, maize, tomato, asparagus …) and free-range livestock-raising (cattle, pigs, sheep). Manufacturing industries for the farm produce only exist in district-based cooperatives.

The Owner-Developed Home of Extremadura Regional Government

Present State of Affairs: Background to Public Policies of Residential Owner-Development in Other Fields.

In the rest of Spain there is no record of any other type of housing with public subsidies until 2008, with the exception of State-subsidized community housing (VPO) on a nationwide level. In this case, although the land receives a subsidy, until recently there has been no attempt to encourage development on land of which the developer is the owner.

In the unfavourable context of the economical, financial and property crisis of 2008, the State Plan for Housing and Rehabilitation 2009-2012 funds new building work by the owner-developer for the first time.

The only record in Europe of the existence of public policies for owner-developed housing is in Greece, where, according to Maloutas (2003, 2004) they constituted a means of integrating the rural population into urban society. The latter was at a time of rapid expansion: the early post-war, after the devastation of the rural areas caused by the war and economic crises. Thus, cheap housing was made available in the conditions of a poorly developed welfare state. Furthermore, this author points out that the importance of owner-development in the early post-war is intertwined with the reduction in direct state intervention, as opposed to the important public housing schemes that dealt with the demand for housing in northern Europe. Likewise, Golland (1998), Nicol y Golland (2004) y Haartsen, Groote y Huigen (2000) have analyzed the phenomena of residential owner-development in other contexts and latitudes.

Historic Background to Housing Assistance in Extremadura
In those times repopulation schemes were carried out which built villages from scratch. However they were not as successful as hoped, perhaps due to the lack of roots in what was new, perhaps since the farming tasks on the land were so hard compared to the opportunities of the city. This meant that numerous villages were virtually depopulated by the end of the 80s. As a result of this state of affairs, by the 70s Extremadura had become one of the most depressed regions of Spain, and therefore among the least developed regions in Europe.

The coming of democracy to Spain and, later, joining the EU with its subsidy policies marked the turning point and the initiation of a process of growth in the region. In this context, Royal Decree-Law 31/1978, of 31st of October, on low-cost state-subsidized housing (VPO) gave a direct impulse to incomplete regulations which already were pointing the way to social housing subsidies.

The Spanish Constitution of 1978 sets out in Article 47 that all Spanish citizens have to the right to a suitable and decent home. Moreover, it states that public authorities will promote the necessary requirements and will lay down the relevant regulations to bring this right into effect. The Constitution itself indicates that this right is to be transferred to the various Autonomous Communities. Thus, Extremadura Regional Government, as Public Administration of the Autonomous Community, aware of the characteristics of its population, adopted subsidy measures for owner-developed housing in Decree 11/1996, which are still in force today, with slight modifications.

The table below, which records the owner-developed housing interventions in Extremadura from 1996 to 2007, shows the intervention of over 7,800 homes out of a total of 360,000 homes present in the whole region. This means that over 2% of all housing built over this time has been developed with the Administration's help, following the technical requirements of the owner-developed home.

Owner-Developed Housing Subsidy Regulation
Owner-developed housing, in short, possesses the following common features of subsidy and required technical conditions.

A) Maximum usable area is 95m2.
B) The beneficiary must be the owner of the land which is legally apt for building.
C) The average annual income of the developer must not be more than 2.5 times the Guaranteed Minimum Wage.
D) The promoter will receive 18,000 euros, which are non-returnable, in two payments. The first one on presenting the final design and the Municipal Building Permit; and the second on obtaining the First Occupancy Licence and the Certificate of Occupancy of the property.

As differentiating features, the homes analyzed have the following characteristics:

a) No design criteria is imposed as to number of floors, shape, volume, layout nor programme of use, apart from those laid down by the local urban planning regulations.
b) There is no compulsory specific technical or constructive solution, apart from the general ones which are obligatory in the whole of the state or autonomous community.

Regarding the particular effects that this regulation has on the owner-developed homes themselves, it is worth noting that they present differential features in terms of design and

costs, as well as similarities in the dimensions of the intervention. On the other hand, as the developer is also the user of the home, the programme of use is certain to be met, since the regulations allow certain leeway in the design.

As far as the public consequences of this kind of interventions are concerned, it should be pointed out that owner-development subsidy policies are of moderate economic development, insofar as they are applied to owners of land which is of much lower value than that in the cities. Moreover, the family situation of probate facilitates buying land. On the other hand, these public actions constitute a system of backing for the small plot-owner which prevents speculative actions.

As we are dealing with small-scale interventions, they are favoured by a local economy in which the local building contractors and subcontractors are highly competitive in this class of development. Thus, it is possible to keep out the larger building companies. This makes it possible to keep local jobs and guarantee the stability of the population in the area. Moreover the regulation prevents Transfer Tax for ten years, which ensures the stability of the population in the communities.

The Administration allows the owner-developer to choose the technicians who draw up the project and the works supervisors. This strengthens the communication between technicians and owner. Furthermore, in general, the technician is used to working in the area and knows the technical resources available to the builders.

Lastly, the fact that there is a final supervision of what the Administration technicians have done, before granting the economic subsidies, ensures that the planning and technical property regulations are met. The Autonomous Community's supervision makes sure the building takes place on urban land. This reduces the number of illegal, clearly unsustainable interventions. All this directly favours a compact growth of the centre of population: filling in gaps in the urban grid or by taking place in new-growth areas already planned for this purpose.

Moreover, the system of subsidies and assistance requires administrative legal supervision, which means the whole building process must be legalized, as the new building works must be recorded in a notarial instrument and must be publicly registered. This way, the new building is taxed according to Annual Property Tax.

Lastly but not least, it should be pointed out that the Financial Institutions feel safer giving mortgages as there are good guarantees: firstly a safe land value, since the dweller is the land-owner; secondly there are additional guarantees, like the economic help from the administration and the owner's presence as owner and inhabitant of the property for ten years.

CHARACTERISTICS OF THE SAMPLE ANALYZED

According to the information published by Extremadura Administration, during the period 1996/2001 some 5400 homes were built subject to the owner-development regulations, while in 2001/2008 over 2500 homes were developed. Therefore over 8000 administrative files of this type exist, which means that this type of owner-developments affects approximately 10 % of the population of the Autonomous Community of Extremadura. These figures increase accordingly with the promotions carried out between 2008 and 2010.

For the purposes of this study, a sample of owner-developments has been chosen which is delimited both in time and space, according to the following criteria:

- In geographical terms, the province of Cáceres has been chosen, in the north of the Autonomous Community.
- From the point of view of time, a period has been chosen to allow the works selected to be finished. And so the most recent administrative files analyzed date from 2008. Spain's entry in the Euro system in 2001 has been taken as the starting point of the study, so as to avoid any distortion of the market due to the currency change.

The sample analyzed, as a result of these two limitations, is made up of an approximate total of 800 owner-developed housing administrative files, subsidized by Extremadura Regional Government in the Cáceres province between 2001 and 2008.

SCALING OF OWNER-DEVELOPMENT COSTS

State of Affairs

In Europe the earliest applications of scaling cost methods come from the "Centre Scientifique el Technique du Batiment", Paris, with the European revival after the Second World War, when a large demand for housing required of the French government some system with which to quantify public investments.

Since then there have been several systems which have aimed to draw up a forecast of building costs; I. Paricio (1971) is the pioneer in Spain because he developed and adapted the French ARC scaling cost method to the realities of the Spanish building sector.

In the 80s some methods were published using tabulations, diagrams and parameterization which aimed to fix scaled cost systems. The Architects' Association, in turn, began to establish cost/m2 modules, which are brought up to date so as to estimate the Real Execution Budget according to use and typology. This is for setting the minimum fees of the technicians and so as to be able to reference other costs such as Municipal Licenses, Stamp Duty, the bidding terms for tenders and auctions, financial or investment evaluation etc.

The everyday use of the computer over the last decade has facilitated the fast and accurate development of the cost estimation procedures. Not only due to the appearance of very complete and easily available price books, but also because of computer applications which carry out scaled cost analysis easily and reasonably accurately.

Another important factor is that over the last few years, Public Administrations (the Councils and the Departments of Public Works within the Autonomous Community) have been compiling a great deal of information that can now be used as a research database. It has been compiled directly via statistical questionnaires, or indirectly via reception of projects for granting licences. This fact, which may seem insignificant, has had a great effect on the development of this kind of research because, until less than a decade ago, many local authorities did not ask for a final design in their remit. This has now changed considerably with the appearance of Law 15/2001 of December 14th, of Extremadura Land and Regional Development Planning. Since then, there have been a number of registered and recorded homes that permit a rigorous scientific analysis of the present situation.

As for the overview, in previous models and empirical findings on building costs estimation models there are independent variables such as location, construction year, building type, number of floors, quality, and building technology (Kouskoulas and Koehn, 1974); construction year and location, total building area, combined percent area of health center and commons, area per unit, number of floors, and percent area of structured parking (Sonmez, R., 2004), the characteristics of the functional elements (Carvajal, 1992; Yaman and Tas, 2007); risk factors inherent in construction such as underestimation, completion delays, inadequacy of cash flow, poor site investigations, changes in scope of work, defective construction works, non-availability of funds and under-valuation (Odeyinka, H.A., 2007); the cost of building materials, interest rates, property price, foreign exchange rates, labour cost, national disposable income and money supply (Windapo, A.O. and Aiyagba, R.O., 2005); or physical and typological data, such as no. of storeys, no. of columns, no. of rooms or type of foundations (Arafa, M. and Alqedra, M., 2011).

In most of these research studies, the independent variables correspond to the technological and socio-economic characteristics of the geographic area in which the research is to be performed, as well as the features of construction typology analyzed in each case. Likewise, the explanatory variables used in this work have been adapted to the particular characteristics of the rural environment and socio-economic conditions in which self-development takes place in Cáceres. Thus, as has been set out in depth in the following headings, other factors have been introduced, such as the structural characteristics of the local building industry, access to the building site, and pre-existing buildings. To these variables are to be added those which refer to physical aspects of the land, such as topography and resistance of the subsoil, as well as geometric characteristics and built housing programme, which, bearing in mind the local production methods, have a real effect on the final building costs.

Characterization of a Scaled Cost Methodology
There are three ways of predicting building cost:

- Once the final design is complete, using economic measurement and evaluation of every item and unit that compose it. This is not in itself a scaling system.
- A unit cost module estimate reached by using previous experience in real building costs in similar constructions
- Using cost modules set down by Administrative bodies or by professional organizations respected by the Professional Bodies. These are usually below the real level.

The following required characteristics of a scaling method arise from these three scaling approaches:

a) Sufficient agility so as to be able to manage as few as possible basic meaningful variables which affect the final cost. Thus it can be used in the preliminary phases of the design process, in which most of the parameters which are to define the projected building are unknown
b) The method's ability to adapt to the peculiarities of every construction, once the setting, the design variations and the derived technical building considerations have been observed
c) Enough accuracy to ensure the likelihood of getting it right and which makes it possible to detect the scattering produced in each case, as compared to the characteristics of the average building

d) The method must allow for regular updates and even be adaptable to other fields of work or other construction types
e) The method must be simple to calculate so it may be used in a basic way. Thus it will be accessible to any owner-developer or small-scale building contractor.
f) The method must allow preliminary detection of the factors which most affect the final price, in order to aid design decision-taking before starting the design phase
g) The prescaling must be included in some IT supported service. This makes data entry easier, sidestepping complex mathematical operations.

METHOD DEVELOPMENT: FACTORS ANALYZED IN COST SCALING

For the development of this study, an analysis is carried out of the design factors and parameters which determine the final cost, giving a scaling model which combines three factors:

.- One cost module M expressed per unit of buildable area
.- The buildable area S
.- The intrinsic determining factors for each building work C

The cost module M is based on the scaling systems established by the administrative bodies. This indexing allows for permanent up-dating. The buildable area S is, firstly, limited by the regulations themselves for owner-developed housing and, secondly, determined by the convenience or economic and programme limitations of the private developer.

The third factor is a multiple one, as it is conditioned by the correction coefficients set down by the particular typology of home Ci, which increase or decrease module M. This introduces a factor of flexibility into the design process. These variables stem from three differentiating concepts which are intrinsic to the building itself:

A) Circumstances brought about inevitably by the surroundings and the physical environment of the plot CS
B) Circumstances determined by the design parameters CD.
C) Circumstances which arise on account of the implementation of the building, determined by the technical solutions adopted during the building process, which we shall call CT.

Consequently the cost of implementation will be a result of the formula

$$\mathbf{M \times S \times C = M \times S \, (CS + CD + CT)}$$

Determining factors of the plot: CS.

As for intrinsic determining factors of the plot where building is to take place, the following circumstances will be born in mind:

A) Town/village: refers to the type of population centre where the building takes place. The thresholds of the different categories are:
A4: population centres which do not have builders or building suppliers.
A3: population centres which have both builders and building suppliers.
A2: which, as well as builders and suppliers, have carpenters, metalworkers and locksmiths.
A1: which, as well as builders, suppliers and the tradesmen mentioned above, have plumbing and wiring subcontractors and other essential housing fixtures.

B) Accessibility: this refers to the ease or difficulty in bringing the machinery to the building site and for storing the material conveniently. The following thresholds can be designated:
B4: difficulties in access and in material storage onsite.
B3: good access to the site but difficulties in storage of materials.
B2: difficult access to the site but ease of material storage onsite.
B1: good access from the road for supply lorries and ease of material storage onsite.

C) Building already existing: this refers to previous buildings onsite. The following categories have been defined:
C4: residential building, which would also imply the annulment of existing installations, with particular care to be taken with party walls.
C3: farm building, warehouse or similar, with low property appraisal value, whether in ruins or not, with particular care to be taken with party walls, but on the supposition there are no or minimal installations.
C2: Brickwork walls, rough stone wall or similar enclosing the plot.
C1: Plot completely empty and ready for immediate start to building work

D) Terrain: Refers to the mechanical characteristics of the ground the building is to sit on. The following categories are defined:
D1: for those whose bearing capacity is less than 1.00 Kg/cm2; in other words soils classified according to regulation as soft, fluid clay.
D2: for those whose bearing capacity is between 1.00 and 2.50 Kg/cm2; in other words: for hard clay and sand soils according to regulations.
D3: for those whose bearing capacity is greater than 2.50 Kg/cm2; in other words: for coarse sand and gravel.
D4: for those which are rocky in general.

E) Topography: refers to the slope or height difference in the plot.
E4: Height difference greater than 2.20 metres.
E3: Height difference between 1.40 metres and 2.20 metres.
E2: Height difference between 0.60 metres and 1.40 metres.
E1: Height difference less than 0.60 metres.

Design conditions CD

F) Factor of form of the building: in terms of the relationship between the area and the volume of the projected building.
F1: Less than or equal to 0.945, only an exception could be less than 0.85
F2: Value from 0.945 to 1.04 inclusive.
F3: Value from 1.04 to 1.135 inclusive.
F4: Value greater than 1.135, exceptionally greater than 1.23

G) Building annexes: refers to the inclusion of unimproved garage or premises on the ground floor, semi-basement or basement.
G4: Unimproved Garage or Premises in semi-basement or basement.
G3: Unimproved Premises on ground floor of more than 35 m2.
G2: Unimproved Premises of up to 35 m2 or garage, either concept on ground floor.
G1: Without annex, neither an unimproved premises nor garage.

H) Exterior wall openings: refers to the area of the fachade used for enclosed balconies, balconies and windows.
H4: façades with more than 17 m2 of opening.
H3: façades of from 13 to 17 m2 of openings.
H2: façades of from 9 to 13 m2 of openings.
H1: façades of less than 9 m2 of openings.

I) Plumbed room: includes the area of the bathroom, the toilet and kitchen, and the relation of this to the total built area of the home.
I4: Home with more than 20 m2 of plumbed rooms.
I3: Home with from 17 to 20 m2 of plumbed rooms.
I2: Home with from 14 to 17 m2 of plumbed rooms.
I1: Home with less than 14 m2 of plumbed rooms.

J) Transitional areas: these are the areas set aside for access, corridors, halls and landings and the relation of this area to the rest of the building.
J4: area greater than 30 m2 of corridors or shared zones.
J3: area from 20 to 30 m2 of corridors or shared zones.
J2: area from 10 to 20 m2 of corridors or shared zones.
J1: area less than 10 m2 of corridors or shared zones.

Technical specifications CT

K) Foundations
K1: of continuous ditches with lightly reinforced concrete.
K2: of continuous ditches and reinforced concrete footing.
K3: of isolated footing, party wall of reinforced concrete.
K4: of footing and ditches with retaining walls of reinforced concrete.

L) Structural System
L1: using load-bearing walls and perforated brick 1 foot thick.
L2: using load-bearing wall and perforated brick 1 foot thick and some beams or pillars with steel profile (mixed structure).
L3: using reinforced concrete porticos.
L4: using porticos with standardized profiles of rolled steel.

M) Roofing System
M1: 100% of the plot area covered with sloping roof, with no traffic-bearing roof surface
M2: 75% of the plot area covered with sloping roof and 25% with traffic-bearing roof surface.
M3: 50% of the plot area covered with sloping roof and 50% with traffic-bearing roof surface
M4: 100% traffic-bearing roof, including patio area if it exists.

N) Degree of prefabrication in the construction, determined by the existence of:
A) Lintel beams
B) Gutter channels
C) Vents
D) Steps.
E) Partition walls.

F) Eaves, balcony and external façade mouldings.
G) External chimneys and /or their chimney pots.
H) Blinds housing box

N4: low of prefabrication, at most two of the prefabricated elements.
N3: medium-low level of prefabrication, at most four of the prefabricated elements
N2: medium-high of prefabrication, at most six of the prefabricated elements
N1: high level of prefabrication, at least seven of the prefabricated elements

Sample-Taking for Statistics.
A data-gathering template is drawn up with these fourteen variables and their sensitivity levels. This is to be filled in systematically in every owner-developed housing file which is subsidized by Extremadura Regional Government in Cáceres Province. The information is gathered by means of the analysis of the final designs drawn up for application for Municipal Building Licence. They will come from the municipal archives of all the towns and villages in the province.

RESULTS

Results of the First analysis of the Data-Base.
In the initial phase a mathematical model was developed with as many equations as unknown quantities. In this case it gave a number of necessary equations of fourteen conditions with their respective four levels, with a total of 14 x 4 = 56 unknown quantities. Thus, a matrix is obtained in which each row had 56 digits or coefficients of each one of the unknowns. Of the latter, 14 were of equal value to the unit, giving the other forty a null value.

This equation system matrix was associated with a null value determinant. This implies that the proposed determining factors are related to each other, there being some kind of relation in common which joins or links them. If the determining factors are related to one another, it is important to know the degree of relationship, because determining a certain relationship could establish a scaling criterion.

Results of the Second Line of Research.
The statistical analysis has consisted of a rectilinear adjustment following the minimum squares method. In this, the aim is to construct a straight line to join Variable Y – identified with percentage increase in the building cost module of the School of Architects (M)- with each of the X Variables identified with the 14 characteristics or parameters under study. Thus, for every condition there will be a straight line of the type $Y = aX + b$, where “a” and “b” are unknown quantities to be discovered following the method above. This way, a mathematical link is obtained between the various determining factors and the percentage increase which qualifies the scaling based on the modules of the School of Architects.

The resulting equations for each determining factor are the regression lines found by the least squares method of the form $Y = aX + b$, whose values “a” y “b” are reflected in each corresponding statistical chart. After undergoing the selection implied by the real values of the boundary conditions imposed by the reality of the marketplace, once the values of the regression coefficient of each line have been analyzed, and therefore its degree of inter-relation, the resulting equations are:

For Town/ village	Y = 2,39 A
For accessibility	Y = 3,04 B – 3,04
For existing buildings	Y = 4,18 C – 4,18
For topography	Y = 3,68 E – 3,68
For factor of form	Y = 3,47 F
For wall openings	Y = 2,39 H – 2,39
For plumbed room	Y = 2,24 I
For foundations	Y = 2,42 K – 2,42
For structure	Y = 3,59 L – 3,59

Assigning the possible values according to the parameterization proposed for each of the variables - or, to put it other words, attributing the values 1, 2, 3 or 4 to each of the variables – we obtain cost increase percentages for each concept at every one of the levels. These will constitute the values gathered in the final chart which is representative of the scaling method for the various determining factors.

As a consequence of the above statistical analysis of the variables and parameters which affect the construction costs, the following conclusions may be reached:

a) There is an obvious scattering between the existing cost scaling methods and the reality of the marketplace. This can reach a variation of 20% to 55% in the case of official reference prices of the School of Architects, in comparison with the final cost of a building work.
b) The order of influence in building costs in €/m2 is as follows: Existing buildings, Accessibility, Form Factor¸ Structure, Topography, Town/ village, Wall openings, Plumbed rooms and Foundations.
c) There are five determining factors which do not affect the €/m2 of the home: Terrain, Annexes, Level of Prefabrication, Roofing System and Transitional Areas
d) A quick, easy-to-calculate scaling method has been achieved.
e) This is a method linked to official data about local building costs, like that of the School of Architects' Reference Budget. This means it can be permanently up-dated.
f) The method has an average scaling error of 7.70 %. It has been proven that it will never reach ten percent.
g) The error of the method is always positive, so there will be no unpleasant surprises in terms of the developer's investment or the contractor's offer.
h) All that is needed in order to the method is some sketches of the Design, a visit to the plot and very few technical decisions. Moreover, the scaling method makes some initial reflection necessary at the very start of the process which would not normally happen otherwise.

CONCLUSIONS

The owner-developed home in Extremadura constitutes an alternative to the speculative development system. It gives impetus to self-sufficient lifestyles in small rural communities, favouring their stability and sustainable regional development. But it is necessary to adopt efficient measures to achieve economical viability. These measures must optimize the public resources of the Administration, which backs and subsidizes the development process, as well as the private income of the owner-developer. The latter are severely limited in developing economies like that of Extremadura. The building costs scaling tool, which is proposed here, develops a mathematical model by means of statistical analysis. This model allows, in the

preliminary stages of the design, the drafters of the design to determine the characteristics that the designed building requires in order to reach the most efficient solutions.

Abstract
Counterfeiting has been around since ancient times. Counterfeiting in modern times was once widespread and not confined to any geographic region. With the globalization efforts following World War II, counterfeiting became an international problem, much of it emanating from Japan's developing manufacturing-based economy. As Japan's economy matured in the late 1960s, the epicenter of the counterfeiting industry moved to Korea. As Korea's economy improved, the bulk of the problem moved to China, where it resides today. A research project was funded by the Construction Industry Institute in Austin, TX to answer four questions: 1) Has the worldwide counterfeiting problem extended into construction materials, equipment and other products?; If so, how large is the problem?; If so, what countries or regions are the source of the counterfeit goods?; If so, what countries or regions are the destination of the counterfeit goods? Results showed that counterfeiting of construction goods is a problem that the problem is large and dangerous, that, like counterfeiting as a whole, China is the primary source of counterfeit construction goods, and the destination of the counterfeit goods is most often the U.S., but can be any place that the counterfeiter thinks that a profit can be made. The team was also asked to make recommendations to industry to mitigate the problem.

Key Words: Counterfeit, Construction, Materials, Equipment, China

INTRODUCTION

In the mid-1980s, U.S. Customs estimated that counterfeit products comprised nine percent of total world trade in manufactured goods. Even though many countries have signed agreements to protect intellectual property rights, counterfeit products are more available than ever in both world and national markets. According to the World Trade Organization (WTO), world trade increased by 47 percent from 1990 to 1995, but during this same period the trade of counterfeit products increased by 150 percent. Since 1995, the problem has continued to grow. As of 2003, the total value of counterfeit products marketed in the world was estimated to be more than $1 trillion annually; this total includes counterfeit products that are produced and marketed domestically within countries.

A 2009 report by the Anti-Human Trafficking and Emerging Crimes Unit of the United Nations Interregional Crime and Justice Research Institute acknowledged the link between organized crime and counterfeiting. Their research indicates that organized crime benefits from counterfeiting through the use of trade routes that have been previously and successfully exploited for other illegal activities. Moreover, the globalization of markets and the widespread distribution of technologies present new opportunities for expansion of organized criminal activities through international alliances between criminal organizations (UNICRI 2009). The research revealed that the level of profitability in counterfeiting is relatively high while the level of risk is relatively low. The opinion of experts interviewed as part of this research project is that this is due to the fact that law enforcement tends to focus less on these types of crimes and penalties are less severe. While the team did not established a link between organized crime and construction counterfeiting, its research strongly suggests that the industry's global supply chain is vulnerable to infiltration by these increasingly globalized criminal networks.

In a 2009 report, the U.S. Immigration and Customs Enforcement (ICE) agency estimated that each year, counterfeiting costs U.S. industry about 750,000 jobs, with thousands more jobs at risk around the world. ICE and the Customs and Border Protection agency made more than 14,000 seizures of counterfeit goods in 2008, valued at more than $272.7 million, a 38 percent value increase over 2007.

In recent years, as news stories have surfaced on counterfeit retail products such as baby food, dog food, jeans, handbags, DVDs, and other popular items, questions have emerged as to whether counterfeiting was a problem in the construction industry. A single incident in 2006 involving the construction of a U.S. government installation in Europe by a prominent U.S. construction contractor provided the impetus for this research project.

The facility design for this installation included 48 name-brand telecommunication routers that the contractor purchased from a U.S. Fortune 500 authorized distributor of such products. Within the first few months of service, 12 of the devices progressively failed. Upon investigation of what was clearly an epidemic failure rate, all 48 devices were found to be counterfeits of Chinese origin. Not only were they counterfeit, but when the serial numbers were examined, they were all valid. The counterfeiters were so sophisticated that they had applied serial numbers of genuine identical devices that had not been registered by the original purchaser(s).

Following are other examples of counterfeiting documented by the research team:

- In 1987 and 1998, two crane accidents killed two people in the United States. In each case, counterfeit bolts were suspected. In the 1987 case, counterfeit bolts appear to have been tied directly to the death of a worker at the mammoth Saturn automobile factory, then under construction in Spring Hill, Tennessee (DOE 1992). The worker was tightening a bolt when it cracked and caused him to fall to his death. In the second case, counterfeit fasteners were used in the 700-foot-tall hoist that peeled off the scaffold of an office tower under construction in Manhattan. While counterfeit bolts were identified in the boom, investigators could not determine whether the failure of the counterfeit fasteners caused the collapse (Post 1999).
- According to an industry safety alert discovered during the research, a counterfeit steel pipe manufactured in China in 2007, stamped in the United States, and

- An insurance executive interviewed as part of the research stated that in 2007 a counterfeit cement kiln from India ruptured while in operation in Canada, killing two employees.
- In an interview with the National Electrical Manufacturers Association it was learned that in 2006, one million counterfeit Square D circuit breakers entered the United States in one shipment from China.
- The Electric Power Research Institute (EPRI) posted a report on their website of two counterfeit five-inch (5") stop-check valves being found at a Southeastern U.S. nuclear power plant in 2007. One had been installed in a non-safety application, and another was in inventory. This report was confirmed in a later interview by the research team with an executive of the company that owns the power plant referenced. (EPRI 2009)
- The research team was told by two interviewees, one with the National Manufacturers Association and one with the U.S. State Department, of the U.S. Military buying thousands of counterfeit military grade microchips for use in sophisticated weapons systems aboard nuclear submarines and fighter aircraft. The team verified the truth of these reports by discovering a 2008 videotaped investigative report by Bloomberg BusinessWeek magazine that documents this kind of military sourcing of chips (DOJ 2009).

Although there are many areas of concern related to product integrity, the potential impact of counterfeit products to plant performance, plant life cycle, safety, structural and product integrity was the focus of this investigation. While there is much literature on counterfeiting in general, there is almost nothing documented on counterfeiting relative to the construction industry. For example, the counterfeit "industry" does hundreds of billions of dollars of business annually; however, the scope of counterfeiting within construction is unknown. What is known is that counterfeit products have caused significant negative impacts to safety, project schedules, overall costs and quality of construction.

RESEARCH METHODOLOGY

Since the Principal Investigator (PI) and the research sponsor were located in the U.S., it was imperative to document any problem in the U.S. construction industry. With counterfeiting being an international problem, interests outside the U.S. must also be consulted. Canada was immediately chosen as a target for interviews. The decision was then made to assume that countries that were proven to be a source of non-construction counterfeit goods would likely be a source for counterfeit construction goods. Therefore, investigative teams were formed in the five countries reported as the source countries for the most counterfeit goods seized by the U.S. Immigration and Customs Enforcement service (ICE). These countries were China, Hong Kong, Taiwan, Pakistan, and The U.K. Table 1 shows the breakdown of interviews by country.

Table 1. *Breakdown of Interviewees by Country*

Country	No. Interviews	Percent of Interviews
United States	78	40.6
China	70	36.5
Taiwan	16	8.3
Canada	10	5.2
United Kingdom	8	4.2
Pakistan	8	4.2
Hong Kong	2	1.0

The research was carried out using face-to-face interviews almost exclusively. Five telephone interviews were conducted out of the 192 total interviews executed. No surveys were disseminated and all interviews were conducted by PIs and National Coordinators, none by Research Assistants. The interviews were carried out using interview instruments customized for both the culture and the type of organization that employed the interviewee. Interviewees were chosen by type of organization and the level within the organization held by the interviewee. Each participant answered approximately 40 questions, meaning the research ended up with approximately 8000 data points. Only individuals from large organizations were interviewed. The types of organizations asked to participate in the project were construction owners, contractors, suppliers, insurance companies, manufacturers, and government / quasi-government agencies. Table 2 shows the breakdown of interviewees by organization type.
Below are the research results, summarized by country/region. North America was a major thrust. China was a major thrust, since it was by far the number one country on the ICE list. The U.K., Pakistan, Hong Kong, and Taiwan were the subject of more limited analyses due to resource limitations.

SUMMARY OF U.S. / CANADA

Eighty eight interviews were conducted in the United States and Canada. All but four were face-to-face, with four being accomplished via telephone. These interviews consisted of suppliers, manufacturers, distributors, government agencies, insurance providers, and contractors. Seventy-six percent of these respondents identified at least one case of counterfeiting, and collectively described 141 cases of counterfeiting in the construction industry. Some of the most

Table 2. *Breakdown of Interviewees by Organization Type*

Organization Type	No. Interviews	Percent of Interviews
Contractors	66	34.3
Manufacturers	36	18.8
Government/Quasi-Government	36	18.8
Owners	27	14.1
Suppliers / Distributors	20	10.4
Insurers / Re-insurers	7	3.6

common items identified were valves, fasteners, pipe, and steel. The most common detection method was failure of the component (31% of the cases). This was followed by inspection

(26%) and testing (10%). The interviewees were asked to identify where the item entered the supply stream. Forty six percent of the respondents identified the source as the manufacturer, with the remainder listing the source as either the supplier or distributor.

Attitude of Government

Forty three people addressed the question of the local government's attitude towards counterfeiting. In these questions the local government refers to the source country of the counterfeiter. Twenty eight percent of the respondents felt that the local government is aware of counterfeiting, but tolerates it because counterfeiting produces hard currency through exports and creates jobs. Twenty six percent of the respondents stated that the local government is officially against counterfeiting, but rarely takes action to stop it unless the counterfeiting produces bad publicity or results in deaths. Twenty one percent of the respondents stated that the local government realizes the problem of counterfeiting, and actively fights counterfeiting through legislation. Twelve percent stated that the local government is not concerned with the export of counterfeit items and nine percent think that local government is unable to deal with counterfeiting.

Reaction of Counterfeiters

The respondents were asked to describe the reaction of the source of the counterfeit product when confronted with the facts. Forty five of the respondents noted that the supplier or manufacturer responded and took action to fix the problem. However, 43% of the respondents noted that the counterfeiter denied that the item was counterfeit, denied supplying the counterfeit item, or never responded to inquiries. This statistic is important to remember when dealing with an overseas supplier or manufacturer. In this situation there is little recourse for the purchaser, other than blacklisting the organization. Even blacklisting is not extremely effective, since the counterfeiter can simply not respond and then re-brand their company. It is then very difficult for a company in the U.S. or Canada to know that a new company is not the same organization that supplied them with counterfeit items earlier.

SUMMARY OF CHINA

Seventy construction professionals were interviewed in China. Of these, only one was done by telephone with the remainder being face-to-face interviews. These interviews consisted of individuals of the same demographics as the ones interviewed in the U.S. and Canada. Sixty-four percent of the interviewees had either experienced counterfeiting or knew from a reliable source of a case of counterfeiting. The results demonstrate how cultural differences can affect transactions with foreign companies.

Factors Driving Counterfeiting

Cost is one of the driving factors for counterfeiters in China. One interviewee noted that using low grade steel in place of structural steel will cut material costs in half, while another noted that using low-grade material will increase profit by 20 percent. Chinese manufacturers know that their competitive advantage in the global market is cost. This aligns with the results of the U.S. interviews that showed that companies purchase from low-cost sourcing countries to gain a competitive advantage. Even the domestic procurement market within China drives costs to rock

bottom through competitive bidding. One interviewee noted that China is not suited for the competitive bid market because a contractor will win the bid on price and then provide a "jerry-rigged" project full of counterfeit products to meet the budget.

One source of the problem is that wherever a legitimate factory is established, smaller factories producing non-branded knock-offs will soon be established near the legitimate factory. These are often started by former technicians of the legitimate factory. As these smaller factories lack the skills and equipment to produce quality products, the resulting products are substandard. Also, the smaller company cannot compete with the legitimate company unless costs are kept low through using sub-quality materials and non-skilled workers. The Chinese interview results showed that 20% of the cases of counterfeiting described by the interviewees came directly from the manufacturers. The bulk of the cases (80%) were from distributors, or stockists as they are referred to in China. This concurs with the comments in the interviews that counterfeiting is generally the result of a distributor purchasing sub-standard products from these smaller factories and re-branding them as legitimate products. One interviewee noted that the legitimate factories will purchase and re-brand products from these smaller factories when their orders exceed their capacity.

Another source of counterfeiting is a lack of knowledge and understanding of foreign standards on the part of Chinese manufacturers. Although a project may dictate U.S. or E.U. material standards, one interviewee noted that Chinese manufacturers will often continue to use their national standards regardless of whether they meet the project standards. The attitude is that products that meet national standards are good enough. Other interviewees related thoughts, one noting that Chinese manufacturers are used to supplying products according to their standards, not their clients' standards.

Most of the interviewees thought that counterfeiting would be profitable in the short-term. Counterfeit goods cost less and can be used to meet tight project schedules. However, the consensus is that counterfeiting will increase costs in the long term with increased costs of inspections and loss of buyer confidence.

Attitude of Government

The counterfeiters of low-tech products present a difficult challenge for both the government and industry. These companies produce counterfeit products as a means of economic survival. Their guerrilla tactics include frequently changing their company name and address. One government official said that "the government should lead the market and make it grow healthily. Recently, the market has become over expanded. The development of companies' management capabilities is not balanced with product quality requirements. This results in a chaotic market and disorderly competition."

Sixty-three interviewees believe that the Chinese government would like to crack down on the counterfeiting industry, but 15 of them think the government lacks the power to enforce their decisions and 18 interviewees think that government does not have enough knowledge of the counterfeiting market.

Reaction of Counterfeiters

When counterfeiting is detected within China, the most common reaction of the party responsible is to actively respond to the problem with the owner either rejecting the items, the party replacing the items, or the owner adjusting the cost to meet the quality of the item. One interviewee from an EPC firm said, "Services such as to change, recall, reconstruct, or repair

unqualified items is quite common and easy to obtain or perform in China. However, if it occurs on an overseas project, the cost will increase several times." Foreign companies need to inspect goods within China before shipping overseas.

SUMMARY OF HONG KONG, PAKISTAN, TAIWAN, AND THE U.K.

Only two interviews were conducted in Hong Kong. While these are invaluable as aggregate data, the opinions and experiences of only two experts are not sufficient to form any conclusions regarding the Hong Kong construction industry.

United Kingdom

The United Kingdom research team interviewed eight participants to gauge their understanding of counterfeiting. Of the eight, one was determined to be invalid by the U.K. team, leaving seven interviews for analysis. Of these seven, one was from a governmental/quasi-governmental official, two from insurers, and four from contractors.

The primary results of the investigation into counterfeiting in the U.K. are two-fold. First, it was determined that there is not currently a problem of counterfeit products being manufactured in the U.K. Second, the U.K. is used by international counterfeiters to "launder" their illicit goods before shipment to their final destination, most often the U.S.

When it became apparent that the U.K. was not the home of significant counterfeit manufacturing, the question immediately arose – "then why is the U.K. ranked in the Top Five Countries for importing counterfeit goods into the U.S.?" Further research led to the discovery that counterfeiters from low-cost sourcing countries commonly transship counterfeit goods from country to country, usually ending up in a western European country or Canada before shipment to the U.S. In this way, a counterfeit product is laundered and the authorities in the U.S. will be less likely to closely scrutinize the shipment than if it had come directly from a low-cost sourcing country.

Taiwan

The Taiwan team conducted sixteen interviews, fifteen of which were deemed acceptable for further analysis. Eight were an owner, design professional, or contractor. Five were a manufacturer or supplier. The remaining two were an insurer and a governmental or quasi-governmental agency. The results showed that construction customers in Taiwan are aware of counterfeiting and are concerned about this issue during procurement. Clients will choose legitimate products in accordance with the project specifications; however, it was pointed out that the low-price bid rules of procurement encourage counterfeiting.

Most participants think that the local government is officially against counterfeiting but doesn't actively take action to reduce counterfeiting. The government will only conduct an investigation if there are claims, instead of taking proactive measures to thwart counterfeiting. In regards to using third party verification, nine out of 15 participants showed a positive attitude toward using a third party to verify product integrity. Although one interviewee noted that they would exclude China as a source for certain materials, overall the interviewees tend to rely on determining if a particular company can meet national material standards rather than adopting a list of approved or banned source countries.

Fifty-three percent of the interviewees (eight of fifteen) had either experienced counterfeiting, or were affiliated with a project that experienced counterfeiting. In most of the cases where the

participants encountered counterfeit products, the counterfeiting was discovered through testing. Of the eight cases of counterfeiting discussed, two of the counterfeiters refused to take responsibility while five of the remaining cases were dealt with according to contractual terms.
The interviewees recommend that the government issue clear legal and practical standard quality control processes, implement product certification regulations, make information transparent, establish product information networks, and publicize the discovery of counterfeit items once confirmed. For individual companies, respondents advised them that more quality control measures should be put into place. Clients should be aware of counterfeiting and should procure materials from reputable and qualified suppliers. Strengthening self-inspection and quality control is important to the client.

Pakistan
The Pakistan team completed eight interviews that included two government organizations, three contractors, a consultant, and two hybrids whose companies and duties encompass two or more of the entity types. Five of the respondents (63%) had experienced counterfeiting either directly or through another party on a project they were affiliated with. The sources of counterfeit materials were noted as mostly local. Notably the Punjab province was frequently identified. China and the U.A.E. were also mentioned prominently.
The types of counterfeit materials discovered included floor tiles, water supply fixtures, steel bars, electric cable and paint. The Shershah Bridge over the Karachi Northern Bypass was referenced by one respondent. That bridge collapsed 25 days after its inaugural opening, killing five and injuring many others.
Half of the respondents noted that when the counterfeiters were confronted, the offenders behaved badly, in one instance insisting that the counterfeit product was genuine. Others, after interrogation, accepted responsibility and replaced the offending items.

RECOMMENDATIONS

The following list of recommendations were developed by the research team as a means of providing owners, contractors, and suppliers with techniques to minimize the opportunity for counterfeit and suspect goods to enter their supply chains. A second list presents a composite of key indicators of potential counterfeit and/or suspect goods and materials, and offers more comprehensive advice based on the findings of the research. Both will help industry procurement and field personnel identify any counterfeit goods that have entered their supply chains and prevent any further entry. These are presented as guidelines; following these guidelines cannot guarantee the discovery of all counterfeit goods purchased, nor can it prevent all purchases of counterfeit goods.

Training / Education

- Train purchasing personnel about the hazards of counterfeit goods and the most common ways these goods and materials enter the supply chain.
- Educate and train Customs officials and those from other law enforcement agencies regarding construction goods and materials – not just the higher-profile retail products. These agencies are open to helping the industry, but they don't know what to look for.

Supply Chain Issues

- NEVER buy anything from those not on the AVL, unless the subject of any such deviation has been afforded similar evaluation as the products of those companies on the AVL.
- Specify all base metal requirements in P.O. Requisition per project/industry code requirements.
- If possible, use distributors and/or suppliers who have documentation systems and receiving inspection systems that ensure the traceability of their parts / materials to an approved source
- In foreign countries, where there may be *state-owned* suppliers, it is recommended that the qualified source inspector should be from another country to lessen the chances of intimidation of the source inspector when making sensitive calls regarding quality.

Testing and Inspection

- Consider connections (fasteners) such as bolts as pressure equipment and not just as "commodities.''
- The PMI program should include witness and/or monitoring from a quality stand-point.
- In foreign countries it is actually preferable to have a qualified ex-patriot perform the source inspection when possible. Minimally, supervisory visits from a qualified ex-patriot should be made.
- Consult specialists (i.e., Materials and Corrosion Engineers) whenever in doubt about product integrity.
- Material Test Reports (MTR) should be requested for materials. The MTRs should be matched to the heat numbers or heat codes on the materials.
- If the investigation leads you to believe the goods or materials are counterfeit, or alternatively if the integrity of the goods or materials cannot be verified, all members of the project (purchasing, inspection, engineering etc.) should be made aware of the issue and a conscious decision must be made as to the potential risks and the disposition of the goods and/or materials. This evaluation and final determination should be documented and communicated for lessons learned.

General

- Adopt a "zero tolerance" policy regarding counterfeiting. Report all incidences of counterfeiting and NEVER fail to support any law enforcement agency's effort to prosecute.
- Caution is urged when determining that goods and/or materials will be accepted if a discount in the pricing is granted. In some low-cost sourcing countries accepting a discount is tantamount to a tacit agreement that whatever goods are delivered will be deemed suitable for service. Thus, the supplier or manufacturer will feel sufficient justification for stating that the goods provided are not counterfeit.
- Encourage *victims* of confirmed counterfeiting to share the information with others within the industry to raise awareness and to help reduce the chances of that particular counterfeiting effort to continue.
- Recommend establishment of a repository for documented cases of counterfeit goods and materials in construction supply chains. If photographs and other comparisons between real and counterfeit items are available these should be posted. These could be useful

Key Indicators of Potential Counterfeit and/or Suspect Goods and Materials

At the industry level, the corporate level, and project level, there are things that can be done to help ensure product integrity. This is different than ensuring product quality. Product integrity means that the buyer is receiving what the buyer is paying for – not something else of equal quality, but exactly what is paid for. In some situations a counterfeit item may be of equal or greater quality to the real thing. However, a supply chain that can be infiltrated by high-quality counterfeit goods is more likely to be infiltrated by low-quality counterfeit goods than a supply chain that not only checks for quality, but also checks for integrity. To that end, the research team presents the following Key Indicators that an item may be, or a shipment may contain, (a) counterfeit item(s).

Supplier Behaviors

- Supplier too eager to make sale.
- Salesman / Representative doesn't ask questions when you explain a complicated requirement, but repeatedly says "no problem," or words to that affect, when he is told what is needed. A salesman that asks a lot of knowledgeable questions, while not appearing overconfident, is preferred.

Documentation/ Supporting Information

- Generic invoices and documentation received with goods (not normal specific documentation).
- Shipment contains no, or insufficient, paperwork

Appearance

- Product appearance looks "off', something different about appearance. (Sometimes the counterfeited item or its packaging looks "better" than the real thing.)
- Items from a known supplier not packaged as usual.
- Obliteration of, or alterations to, markings or logos.
- Inconsistent dimensions against a known standard.

General

- Goods are offered from a resource outside of the normal supply chain or typical procurement methods, or from a source not known to you or an experienced procurement staff.
- Normal receiving and/or NDE (non-destructive examination) methods reveal deficiencies or other non-conformance in goods or materials.

SUMMARY OF CONCLUSIONS

Counterfeiting, as defined in this research, is a large and growing problem in the industry, and its ramifications are almost unlimited. Besides the United States and Canada, five other nations were scrutinized. The research team retained the services of experts within each of the five countries to carry out research on counterfeiting in the construction industry within the confines of their assigned nation. Each National Coordinator was also assigned the task of determining the perceived impact that the export of counterfeit goods manufactured within their country

might have on the local and international construction industries. The countries chosen were the five countries that had been the import nations for the most counterfeit goods confiscated by the U.S. Immigration and Customs Enforcement Service (ICE). The nations were China, Hong Kong, Taiwan, Pakistan, and The U.K.

China is the epicenter of today's worldwide counterfeiting industry. This is true of non-construction and construction items. Hong Kong, Taiwan, and Pakistan all seem to be places that have an illicit counterfeit manufacturing industry, though most of those interviewed in those countries fear imports from China. The U.K. seems to be a place that counterfeiters from around the world send their products to "launder" them before they are transshipped to the U.S.

The causes of the counterfeiting problem are many, but some insight can be gleaned from the interviews. Several Chinese interviewees suggested that many of the reasons for the proliferation of counterfeit goods in construction supply chains are grounded in differences in the way business is practiced in developing nations and in the developed world. Other reasons revolve around such issues as the West's focus on getting the least expensive materials and equipment to maximize profits. Whatever the root causes are, the problem is massive and the threat is potentially calamitous. However daunting it may be, the industry's best short-term defense is to question its implicit trust in suppliers, manufacturers, and distributors, and to address its ignorance of how sophisticated today's counterfeiters can be.

Ignorance can be cured by training. The research team recommends that the industry make a priority of training its procurement, quality, and field personnel in how to prevent and mitigate the damage from counterfeit items in the supply chain. The industry must also systematically train the people hired to protect the public. The port master of the largest port in the United States urged the research team to impress upon the industry their need for training. He explained that construction items were off the radar of his customs inspectors because [they] don't know what to look for. He emphatically requested assistance in training them to inspect for counterfeit construction materials.

Finally, more research is needed. Although international in scope, this research project has just scratched the surface of the problem. Indeed, many interviewees expressed their concern that this research has only been able to look at the tip of the iceberg and that the world will eventually see a series of disasters attributable to counterfeit goods.

Future research could make another attack on a broad front, as this project has done, using these results to identify and focus on the areas that need the most attention or that show the most potential for progress. Or, future research could choose a limited number of strategic areas to investigate. The areas of focus could be determined by product type, such as steel, piping, or circuit breakers. Areas of future focus could also be determined by lines of defense, such as the following:

- third-party verification
- inspection of materials or of the manufacturing process at the point of origin, during the improvement or development process, at shipping, or at delivery
- inspection of the finished product, including country of origin and country of destination
- investigation into the ways construction goods are imported into and exported out of key countries in which large international construction firms build projects. This would include U.S. Customs inspection.

Other future research should involve the development of training materials for companies to train their procurement, quality, and field personnel in how to prevent and mitigate the damage from counterfeit items in the supply chain. Training materials and courses should also be developed to train those hired to protect workers and the general population (e.g., Inspection and Customs Enforcement (ICE), the FBI, port authority personnel, and customs warehouse personnel).

Abstract
The traditional system of design-bid-build has long been the principal delivery system for horizontal construction; it has been employed by all the transportation departments in the United States for almost a century. The shift toward design-build (DB) as a time saving method has been successful in many ways, but use of the system has exposed some disadvantages in the last decade. Construction-manager-at-risk (CMR) is a delivery system often employed in vertical construction, but transportation agencies have recently begun to use it for horizontal construction. The Departments of Transportation (DOT) of eleven states in the southeastern United States were interviewed in this study. The focus was on each DOT's experience and satisfaction with the DB delivery method, as well as their experiences, knowledge, and legal status of the CMR method. Florida was the only state of the eleven that has used CMR on horizontal projects. CMR has also been used as the delivery system on some municipal and county highway projects in Florida.

Keywords: Construction, Manager, Risk, Highway, Delivery

INTRODUCTION

All construction was once performed using a form of the design-build (DB) delivery system. In the 1920's and 1930's, knowledge of construction materials and methods grew at a rapid pace due to significant research, mostly sponsored by the American Association of State Highway Officials (AASHO). With this new knowledge came specialization and with specialization came the design-bid-build (DBB) project delivery system, which dominated horizontal construction in the U.S. for decades. The monopoly of this traditional system lasted until the Transportation Equity Act was enacted. In 1998, it became much easier to procure federal funding for projects utilizing alternative delivery systems, if the use of those delivery systems was in compliance with the state's own statutes. Due to the success numerous projects have experienced with DB, the states have become increasingly receptive to these new concepts of project delivery. Now, many states allow application of alternative delivery methods to public transportation construction projects, but some states differentiate their processes of authorization for DB and other alternative delivery systems such as construction-manager-at-risk (CMR). The differences in these procurement processes show

the skepticism held by many authorities toward CMR as a reliable delivery system for highway construction.

The Construction Industry Institute has pronounced DBB, DB, and CMR as the primary methods of project delivery (CII 2003). While this might be true in vertical construction, in the transportation field, CMR projects are not common. One of the reasons for this inconsistency within the two sectors of the industry is the difference in the characteristics of the project owners. In vertical construction, the identity of the owner can be any entity or individual that is able and willing to fund the project. In horizontal construction, the type of owner is fairly limited, most being a state's DOT, or some other public transportation agency. This can result in the support of a particular system due to the owners' singularity of nature. As the owners become familiar with a specific method, the fear of change inhibits their ability to explore additional options. Another reason for the hesitation, or lack of interest in experimenting with a different method would be the size of projects. Compared to private ventures, the level of funding allocated for a state's transportation projects is substantially higher. Therefore there are more risks involved in the testing of an unfamiliar method.

LITERATURE REVIEW

The National Cooperative Highway Research Program (NCHRP) has funded many comprehensive studies in regards to horizontal construction. In this field the two most commonly employed methods of delivery are DBB and DB. Scott (2006) pointed out the problem associated with low bid in DB; instead of getting the benefits of cost control, most of the time it will result in a decrease in the quality of the final product. Scott focused on the best value approach; it places the emphasis not only on the price but also on other factors. Investigation of the legislative regulation and the nature of this contracting method were analyzed to help develop the best value procurement method in regards to highway construction. Shr (2004) studied the growing popularity of Incentive/ Disincentive bidding for highway construction. This concept is utilized for its ability to shorten the contract time by making it difficult for the contractor to not accelerate the project. Shr developed a quantified model to establish reasonable incentive or disincentive rates based on construction cost and time. But like the low bid method, incentive/disincentive contracting may cause the quality of the final product to decline.

Molenaar, et al (1999) studied the emergence of DB into the public segment of the industry, replacing the traditional DBB. His work analyzes each parties' responsibility in regard to the delivery system, and also explains the procurement process and the structure of this particular method. Marwa, et al (2006) went more in depth than Molenaar by building on his work. Marwa studied a total of 76 DB projects and identified correlations between the procurement processes and the projects' performance overall. Chan (2002) sought specific project conditions that can help increase project success rates when using DB. Chan points out that current measures of success are defined by three factors: time, cost, and quality; but he believes a more comprehensive metric needs to be established.

Gransberg (1999) conducted a survey aimed at all the Departments of Transportation (DOTs) in the United States. With the fifteen DOTs that employ DB, he reviewed the three main methods of DB, which are low-bid DB, adjusted-score DB, and best-value DB. As concluded, each of the different methods can be utilized with different types of highway construction, depending on the nature of the project at hand. Gransberg (2008) also addressed the issue of quality assurance concerning DB as it relates to transportation projects. One of the disadvantages of DB is the lack of control over the detailed components of construction, which requires the agency to form a more comprehensive method to ensure the quality of the

work. A survey from the report demonstrated the different ways in which state transportation agencies have successfully controlled quality by focusing on all the aspects of the construction phases; but this doesn't seem to be the case for all the agencies. In the same year Gransberg (2008) pinpointed the issue of communicating the quality requirements public agencies have on DB projects. The Study found that some owners tend to rely on the qualification evaluation process rather than being proactive on the issue. There are still many improvements that can help enhance the performance of DB. Many agencies still use the traditional DBB method exclusively, or have not utilized DB to its full advantage.

There has been an extensive amount of research done on the comparison of DBB, DB and, to a lesser extent, CMR - most focusing on the performance of each method in regard to the aspects of cost, time, and quality. Ibbs (2003) used sample case studies to present a result that confirmed one of DB's key advantages. Design-build does in fact perform more efficiently with respect to time than traditional DBB. Doren (2005) discovered valuable statistics regarding CMR. In this study, 35 percent of project owners believed that CMR provided them the "best value", followed by 23 percent for DB. And yet the traditional system of delivery (DBB) is employed most frequently. Doren's research combines data from the areas of vertical construction and horizontal construction. According to him, government agencies that have experience with an alternative method consider CMR and DB as the "best-value alternatives". Doren believes that CMR has the potential to become the leading method of delivery, due to positive experiences reported by so many agencies.

Rojas and Kell (2008) used data collected from states to compare the performance of the DB and CMR regarding the public schools. The result of the study conflicted with many researches that have been done before, by concluding that 75% of the circumstances exceeded the guaranteed maximum price when CMR was used. However these statistics are in regards to vertical projects, which are fundamentally different from horizontal projects. Concerning horizontal construction Touran, et Al (2009) published a paper focusing on providing an evaluation process that is able to help agencies identify the suitable delivery system to use for specific projects. The paper points out 24 key concerns that will narrow down the most ideal delivery system. The paper also includes a beneficial example that demonstrates how the evaluation should be conducted. But before the proper system can be chosen, regulations regarding each system are different amount all the states. Ghavamifar (2006) investigated all the regulations that had been set in place by states' legislations regarding public transportation projects. A list of the states' statutes that address DB, CMR, and public/private partnerships was provided.

Gransberg (2010) conducted extensive research on the topic of CMR project delivery for highway programs. According to his report, Utah's DOT (UDOT) has the most experience with this method. At the time the research was conducted, 13 CMR projects had been completed, and 16 projects were in the planning. UDOT confirms the system's ability to fast-track projects, which can result in the decrease of project cost. States like Alaska, Arizona, Florida, Oregon and Utah all have experience with CMR as the method of delivery on transportation projects. The city of Phoenix has had more than 200 projects completed by CMR (including both vertical and horizontal projects). Local transportation projects in Michigan and Rhode Island also use the CMR delivery system. Florida has used CMR on projects of multiple types and scales, from minor local projects to a 1.3 billion dollar intermodal center. Alaska tends to use CMR on projects that have a significant portion of vertical component build-in. Even though Oregan's DOT has limited experience with this system, an interstate bridge that was completed by CMR has been a successful project. They plan to employ the CMR system on future projects. Gransberg gathered a substantial amount of research that had been done on construction delivery methods. Structured interviews were

set up with the agencies to gather statistics, and clear instructions were established to help any organization with the procedure involved in implementing such a delivery system.

CASE STUDY: The Miami Intermodal Center

The Miami Intermodal Center (MIC), the first CMR project ever funded by the U.S. Federal Highway Administration (FHWA) is a $2.5 billion construction project located just east of Miami-Dade International Airport (MIA). The facility is envisioned as a state-of-the-art Grand Central Station — a transfer center for passengers using the airport, intercity and commuter trains, rapid transit, local and intercity buses, and cruise ships in and out of the Port of Miami. The project was developed by FDOT and the Miami-Dade Aviation Department, in cooperation with the Miami-Dade Expressway Authority, Miami-Dade Transit, Amtrak, and various rental car agencies that serve the airport. The MIC project is made up of a series of construction contracts, including one for a consolidated rental car facility (RCF), another for a people-mover connection to the airport, and others for road access improvements around the airport.

Even with all the emphasis on the project, as well as all the planning and funding for the project, it appeared for a while that this project would be remembered as one of the great mistakes in modern U.S. construction history. For the first four years, the project seemed unable to overcome its unfortunate start, which was caused by the terrorist attacks on 9-11-01, and exacerbated by mistakes typical of an owner using a new delivery system. In some respects, it never has recovered, but in others, it has recovered marvelously

Several things contributed to the early problems that plagued the project. For instance, the 9-11 disaster, delayed decisions, and unwise decisions caused the timing of the MIC project to get seriously out of rhythm. By allowing the design, which had just commenced when the terrorism unfolded, to continue unabated while contemplating future moves, and then allowing it to continue even further while the scope shrunk due to the drastic dropoff in airline traffic, put design so far ahead of construction that the project has never enjoyed two of the major of advantages of the CMR system; namely construction involvement in the design and full fast tracking. Other things that contributed to early problems can be seen in the literature. (Minchin 2009)

Relatively recently, the project has started to resemble what was envisioned in the beginning. Progress is being made at a much faster rate; payouts are much higher, visible progress is exponentially greater, and the project is shedding its negative image.

Phase I of the project is broken into sub-phases of work called GMPs. GMP stands for Guaranteed Maximum Price, which is the way the CM bids on each sub-phase. The CM on the project must submit a GMP for each sub-phase GMP. If the GMP for any GMP is higher than the owner can stand, negotiations commence and can be very short, or very lengthy. The owner reserves the right to terminate negotiations and either begin negotiations with another CM, or declare that the GMP for which a cost cannot be agreed upon will be let using another delivery system.

Phase I of the MIC construction project is broken up into seven GMPs. To date, three of the GMPs have been completed. GMPs completed to date were finished within contract time, but all were delayed in their commencement. As for costs, the work in GMP No. 1 was completed for 3.9% under budget and GMP No. 2 was completed for 8.4% under budget; The CM exceeded contract duration on both GMPs — by 40.7% on GMP No. 1 and 72.2% on GMP No. 2. There was a significant scope reduction on GMP No. 3, which renders that data useless for comparative purposes. The project is now progressing well, after a fitful four years that saw an almost total personnel turnover for the owner

and the project management firm retained by the owner to oversee the CM. Construction on the Rental Car Facility and bridge, known as GMP No. 4a, has turned the project around. The project suffered for four years from a lack of respect and credibility in the marketplace. GMP 4a has cured that, but many lessons have been learned. For more details, please see the literature. (Minchin 2009)

METHOD OF RESEARCH

Eleven states from the southeastern part of the United States were chosen to be part of the study. A list of state construction personnel was gathered from the American Association of State Highway and Transportation Officials (AASHTO). These served as potential interviewees. Next, Interview instruments were generated to obtain the main objective of the analysis: each DOT's experiences with DB and CMR. Then the list of interviewees was contacted by telephone. Often some redirection led to the most appropriate authority, but most of those interviewed were the State Construction Engineer for their respective DOT.

Level One Interview

The goals for level one of the interviews was to determine the level of experience that each state has with the DB delivery system. Then the interviewees were asked to identify any dissatisfaction they have experienced with DB in the years that it has been employed. The interviewees were then asked if they, or their agency was aware of the CMR delivery system, and if any dissatisfactions with DB have potentially led the DOTs to seek out or consider CMR as an alternative delivery system.

Level Two Interview

Level two of the interview is designed for states that are using or have completed highway construction using CMR as the delivery system. The objective is to study the process the DOT has established for CMR, and learn about their experiences with CMR in comparison to DBB, or DB. The final goal is to identify any advantages and disadvantages the agency may have already noticed regarding CMR.

DEPARTMENT'S EXPERIENCE WITH DESIGN/BUILD

The data collected during the level one interviews clearly illustrate the widespread nature of DB in the area of highway and transportation programs. It has become the most popular method of alternative delivery system to employ. There are many advantages that proponents of DB claim that it can contribute to a project. The main attractions are: the single point of contact for the project's design and construction and allowing the project to start before construction documents are finished (fast-track). Both of these benefits are designed to compensate for the shortcomings of the traditional DBB delivery system. But data shows only two out of the eleven states that participated in the research have no problem with DB. All the other states either dislike some components of the system or have specific concerns regarding the system.

Design-build was first introduced to highway construction as a major delivery system option in the mid-1990s; it has been employed for approximately fifteen years. But one of the biggest issues, reported by more than 36 percent of the participants, was the learning curve for this delivery system. Virginia's DOT believes they "don't have enough resources to support it". Georgia's DOT reported several issues with DB. First, the system doesn't always fit the normal process designated for DB. For example, the process of acquiring right-of-way

(ROW) can take more than a year, and during this time, construction documents will be finished, therefore not saving any time. Another is the lack of understanding of the system. Finally it's been hard for the DOT to give up control after so many years of carefully governing the design and construction processes.

Louisiana's DOT currently has five DB projects under construction. One of the criticisms they have regarding this system is somewhat opposite of Georgia's DOT; they believe they have too much control, and thus risk, in regard to the project. They believe that a main contributor to this is their state's legislation, which keeps them from utilizing a true DB delivery system. Florida's DOT points out the dissatisfaction they have with not being able to link a CEI contract to the DB method. Florida officials also expressed dissatisfaction at the lack of control afforded the owner over the design process by DB, due to the lack of direct contractual relationship between the owner and the designer.

Tennessee's and Kentucky's DOTs both are not in favor of the selection process for which projects are designated for DB contracts in their states. For Kentucky, the project must be hand picked by the state's legislature for it to be eligible for DB. Large numbers of personnel are still foreign to the idea of not paying for change orders, which is supposed to be one of the advantages to DB, and the adoption process is fairly slow. Tennessee has only been allowing the use of DB for three years, a relatively short length of time compared to the other states. The legislative limitations on the types of project that can employ the system are relatively restrictive. Any project involving ROW, utilities, and environmental issues are not eligible to be considered. This greatly limits their selection pool of potential candidates. The DOT for Mississippi has a different issue of concern, cost. Many research projects that have studied DB have pointed out cost as one of the disadvantages to this delivery system (Gransberg, 2009). In most cases the increase in cost is due to the lack of concern regarding the constructability aspect of the construction documents, or the inexperienced nature of the DB firm. Another aspect of DB that creates anxiety for some DOTs is the lack of a clear set of plans, and working with only specifications for a large part of the project is sometimes difficult.

There are two states in this study that overwhelmingly support DB and had no concerns with the system. South Carolina stated that their experiences with the system have been "positive", and Maryland, an old client of the system also likes the method of delivery a lot. Table 1 shows each DOT's experiences with DB and CMR.

Table 1. *Each State DOT's Experiences with DB and CMR*:

States	Employment of DB	Number of Years (or projects) DB has been in use	Aware of the CMR delivery system	Employment of CMR	Statutorily free to use CMR
Alabama	No	n/a	Yes	No	No
Florida	Yes	15 years	Yes	Yes	Extra approval required
Georgia	Yes	10 years	Yes	No	No
Kentucky	Yes	10 projects	Yes	No	No
Louisiana	Yes	4 years	Yes	No	No
Maryland	Yes	13 years	Yes	No	Yes
Mississippi	Yes	5 years	Yes	No	Don't know
North Carolina	Yes	Don't know	Yes	No	No
South Carolina	Yes	Don't know	Yes	No	Don't know
Tennessee	Yes	3 years	Yes	No	No
Virginia	Yes	7 years	Yes	No	Don't know

DEPARTMENTS' EXPERIENCES AND LEGAL RESTRICTIONS ON CMR

Even though all the interviewees expressed awareness of the existence of the CMR delivery system, only Florida has hands-on experience with it as a tool for highway construction. In fact, CMR has been authorized in many states to help offer a possibility other than DB as the alternative delivery method. It's designed to help decrease the amount of oversight that normally takes place on construction projects. It reduces the amount of performance risk for the owner and transfers it to the construction manager (CM). A constructability review by the CM becomes part of the design phase of the projects. This, and a direct contractual relationship between the owner and the designer allow the agency to remain in control of the design process. Of course, his method still offers the advantage of fast tracking the project.
Since Florida is the only state in the study to utilize CMR for highway construction, FDOT was the only DOT to participate in a Level Two Interview. Ten FDOT projects have been done using CMR. In addition to the list of projects and the state's statute, the interviewees were able to provide more in-depth assessment of CMR by submitting to the Level Two interview. The Level Two interview is mainly composed of three components, one being the process the DOT has established for CMR; second is the experience with CMR; finally to note any overall advantages and disadvantages the agency may have noticed with the system in comparison to DBB and DB. Table 2 shows how FDOT views the risk/ responsibilities distribution for DB and CMR.

Table 2. *FDOT's Risk/Responsibilities Distribution for DB and CMR:*

Risk/ Responsibility	Design/Build Project		Construction manager at risk project		
	Owner	Design/Builder	Owner	C.M.	Designer
Final Alignment Geometry		✓		✓	
Geotechnical Data		Depends		✓	
Environmental Permits	✓		✓		
Design Criteria	✓		✓		
Design Defects		✓		✓	✓
Constructability of Design	✓			✓	
Obtaining ROW	✓		✓		
Coordinating with utilities/ railroads		Depends		✓	
Quality Control		✓		✓	
Quality Assurance	✓		✓		
Acceptance		✓		✓	

As part of the Level Two Interview, FDOT provided Florida's statute enabling FDOT to use CMR. The statute is shown here in its entirety:

> "337.025 Innovative highway projects; department to establish program.
> (1) The department is authorized to establish a program for highway projects demonstrating innovative techniques of highway construction, maintenance, and finance which have the intended effect of controlling time and cost increases on construction projects. Such techniques may include, but are not limited to, state-of-the-art technology for pavement, safety, and other aspects of highway construction and maintenance; innovative bidding and financing techniques; accelerated construction procedures; and those techniques that have the potential to reduce project life cycle costs. To the maximum extent practical, the department must use the existing process to award and administer construction and maintenance contracts. When specific innovative techniques are to be used, the department is not required to adhere to those provisions of law that would prevent, preclude, or in any way prohibit the department from using the innovative technique. However, prior to using an innovative technique that is inconsistent with another provision of law, the department must document in writing the need for the exception and identify what benefits the traveling public and the affected community are anticipated to receive. The department may enter into no more than $120 million in contracts annually for the purposes authorized by this section.
> (2) The annual cap on contracts provided in subsection (1) shall not apply to:
> (a) Turnpike enterprise projects, and turnpike enterprise projects shall not be counted toward the department's annual cap.
> (b) Transportation projects funded by the American Recovery and Reinvestment Act of 2009."

FDOT'S EXPERIENCE WITH CMR

The main reason FDOT decided to employ CMR was the system's ability to shift risk and fast track, while allowing the department to retain control of the design process, which was not possible with DBB or DB. They plan to continue using CMR on horizontal projects because of this unique characteristic. But not all projects are suitable for CMR. Here are some of the project traits that FDOT believes can help identify the appropriate project for CMR (FDOT 2011):

- Building type projects where construction methods and specifications vary between professional groups (i.e., engineer/architect and construction trades).
- Innovative funding scenarios, where multiple owners may dictate final project criteria.
- Projects where limiting (limited) budgets (budget) threaten (threatens) the delivery of the project and where the CM alternative can help maintain costs.
- Other projects where construction input is required during the early phases of design.

Table 3 shows the projects chosen to date by FDOT for CMR.

Table 3. *FDOT CMR Projects, Project Identity and Type:*

Project Description	Work Description	System Description	Program Description
I-75 Ramp Renovation at AG Station	Miscellaneous Construction	Intrastate Interstate	Roadway

I-75 Pasco (SB) Rest Area Rehabilitation by CM@RISK Contingent	Rest Area	Intrastate Interstate	Roadway

Once the project has been selected for CMR, FDOT has their own set of contracts and specifications. They have experience with both in-house and outsourced design staff. This process of selection for the design staff or any pre-construction service is sometimes project specific, but overall the more traditional way is to use the qualification method. One of the issues that have most DOTs concerned is the amount of agency administrative time they think this system will require. According to FDOT, CMR consumes less time than the traditional DBB, and about the same time in comparison to DB. In regard to the three delivery systems, small businesses in the state tend to be more involved with DBB than with CMR and DB, with DB being the least preferred of the three. Table 4 shows the performance of the CMR projects build by FDOT to date. Note that some projects are ongoing at the time of publication.

Table 4. *Cost and Duration Variations of CMR Projects Conducted by FDOT.*

Project Description	Cost			Duration	
	Original (Engineers) Cost Estimate ($)	Low Bid or Awarded Bid Amount ($)	Final Cost ($)	Original Contract Duration (days)	Final Contract Duration (days)
I-75 Ramp Renovation at AG Station	3,769,137.94	3,294,096.00	TBD	270	TBD
I-75 @ MP 26.861 Welcome Station	8,170,189.86	13,240,420.00	13,101,578.00	509	519

I-75 Pasco (SB) Rest Area Rehabilitation by CM@RISK Contingent	12,102,611.74	25,137,883.11	TBD	477	TBD

FDOT uses the method of reimbursable basis to a guaranteed maximum price (GMP) to compensate the CM for both pre-construction and construction services. In addition, FDOT requires open book accounting for the CM's pay applications during construction for all subcontractors and vendors. The method of negotiation has been employed to help handle

general conditions, contingency and allowances. Normally when it comes to the issue of unused contingency, there are two types of solutions. One approach allows the owner and CM to split the unused funds, while the other lets the owner claim sole ownership. In Florida, the CM is allowed to self-perform part of the work, but it must not exceed 50 percent of the entire workload. And to get the work, it must bid the work against the interested qualified subcontractors, and be the low bidder. FDOT's process of procuring subcontractors and suppliers requires competitive bid; this is the only way to receive federal funding for any project. To this point, FDOT has not identified any specific aspect of the CMR program that has worked best or has fallen short of its intended purpose. Figures 1 and 2 illustrate the performance of two FDOT CMR projects. Note that in each case the engineer's estimate was inaccurate in predicting the low-bid amount. In one case the estimate was high and in the other the estimate was low. Note also that in each case the actual final cost was below the originally submitted GMP.

CONCLUSIONS

Construction manager-at-risk is a construction delivery system that has been tried and found effective for years in the vertical construction industry. Its relatively recent introduction into the world of highway and bridge construction has been a slow process. Though the first CMR projects were let just after the turn of the 21st century, year 12 of that century yields a scenario that shows only two states have really used the system as a regular course of business. Some others have dabbled in it, but only Florida and Utah have used it extensively. To gain information on CMR, the team thought it important to compare the performance of CMR to DB, as well as to DBB. It is well known that all DOTs use DBB more than any other delivery system, so no questions were asked regarding DBB except how it compared to CMR in some way. The questions to the DOTs began with inquiries regarding DB. All the DOTs have used DB. Florida, Maryland, and Georgia have used it for 10 years or more (Florida 15, Maryland 13), while Tennessee, Louisiana and Mississippi have used it for five years or less (Louisiana 4, Tennessee 3). Since FDOT is the only DOT to use both DB and CMR contracts on horizontal transportation projects, their opinions regarding the two systems are of interest. The Interview Instrument broke the construction project into 11 categories; Final Alignment Geometry, Geotechnical Data, etc. When it comes to responsibility and risk in a DB contract, FDOT believes that majority of the responsibility and risk resides with themselves for five of the 11 categories. They believe that the majority of the responsibility/risk lies with the DB firm for four categories, and for two of the categories, they believe that it depends upon the circumstances of the individual project.

After discussing DB, the interviews discussed CMR. As for the responsibility/risk in a CMR contract, FDOT believes that they bear the majority in three of the 11 categories, the CM bears the majority in seven categories, and the designer bears the majority in one category.
FDOT has used CMR on a variety of projects. The majority of projects could be categorized as "combination" projects due to the fact that they contain substantial work in both the vertical and horizontal construction areas. In fact, six of the projects are of this variety. These six combination projects include an interstate highway Agricultural Station, three interstate Rest Areas, an interstate Welcome Center, and the massive MIC. There are two vertical construction projects - an FDOT office building and a building at an interstate highway Agricultural Station on a different interstate highway than the one mentioned above. Finally, there are two wholly horizontal construction projects, both bascule bridges.
The FDOT CMR projects ranged from $3.2 million to $78 million, based on accepted GMP. The $78 million is the MIC rental car facility, which may grow based on decisions for further GMPs. The entire MIC will not be built using CMR. Of the eight projects that have had an engineer's (preliminary) estimate and an awarded GMP, six have been awarded for GMPs above the engineer's estimate; two for GMPs below the engineer's estimate. Of the three FDOT projects that have reached the Final Estimate stage, two were completed at slightly under the GMP and one at slightly over the GMP. Both underruns and the overrun were less than one percent. All three completed projects went over the original duration, two slightly (less than two percent) and one substantially (almost 44 percent).

ACKNOWLEDGMENT

The research team gratefully acknowledges a grant from Balfour- Beatty Construction, which funded the research reported upon herein.

Abstract
This paper explores the business case for designing more adaptable buildings, an issue that has, for the most part, been overlooked in the literature. It reviews some of the existing literature on adaptability and discusses the drivers for and barriers to designing buildings that are more adaptable. In doing so, it draws upon lessons from the developing market for 'greener' or more sustainable buildings. The costs and benefits of designing more adaptable buildings are explored through a workshop with industry stakeholders and illustrated with evidence from case studies. The findings of this research highlight the circumstances that would need to change, in terms of industry mindsets and market conditions, in order for adaptable buildings to become more widespread.

Keywords: Adaptability; cost-benefit; obsolescence; risk; sustainability.

INTRODUCTION

In recent years there has been growing interest in the issue of adaptability in the built environment. This interest has been stimulated by a number of factors, including increasing rates of technological change and a desire to make the built environment more sustainable by extending the life of our existing building stock. However, most of the academic literature on the subject has tended to focus on *how* to design buildings to be more adaptable, rather than trying to understand the reasons *why* some buildings are designed to accommodate change, while others are not. This paper therefore explores the business case for designing and constructing more adaptable buildings. In doing so, it examines the potential costs, benefits and risks of designing adaptability into buildings and the social, economic, political, legal and

commercial conditions under which greater adaptability would either be a more desirable or less desirable design objective.

This paper begins by discussing what is meant by adaptability in the context of the built environment and by exploring the economic and environmental drivers for more adaptable buildings in the United Kingdom (UK). In doing so, it looks at the reasons why designing buildings for adaptability is not part of mainstream property development and draws parallels with the emerging market for 'greener' or more 'sustainable' buildings. A range of different adaptable design strategies are then introduced, each relating to a particular type of change in the built environment, and the costs and benefits of each strategy are explored through a workshop with industry stakeholders. Case studies are then used to unpack the reasoning behind particular adaptable design solutions and illustrate their implementation. This paper concludes by looking at what would need to change, in terms of current market conditions and industry mindsets, to create a greater demand for adaptable building design solutions.

BACKGROUND

> *"Almost no buildings adapt well. They're designed not to adapt; also budgeted and financed not to, constructed not to, administrated not to, maintained not to, regulated and taxed not to, even remodelled not to..." (Brand, 1994)*

Definitions of what constitutes 'adaptability' in buildings vary widely in the literature, but most tend to imply a capacity to accommodate change (Schmidt III *et al*, 2010). The idea of designing buildings that can accommodate change is by no means new: in the 1960s Weeks (1963 and 1965) talked about 'indeterminate architecture' and in the 1970s Alex Gordon, the then President of the Royal Institute of British Architects, put forward the principle of 'long life, loose fit and low energy' buildings (Anon, 1972; p26). In the last two decades, the terms 'flexible' (e.g. Gann and Barlow, 1996; Slaughter, 2001; Gibson, 2003; Steiner, 2006; Finch, 2009) and 'agile' (e.g. Joroff *et al*, 2003) have become increasingly common in the literature on buildings, perhaps reflecting developments in other business and management disciplines, such as manufacturing, where the capacity to embrace and manage change has become seen as critical strategy for surviving in an increasingly dynamic business environment.

The argument in favour of designing more adaptable buildings has a number of strands. One is that by designing buildings to be more adaptable, designers can help to reduce the whole life costs of owning and using buildings by making them easier to change post-construction (Slaughter, 2001; Arge, 2005). This is particularly important in sectors where occupier needs change frequently and where maladaptive buildings can impose costs on occupiers by constraining their activities (Iselin and Lemer, 1993). More recently, the case for adaptability has been underpinned by concerns about the environmental impact of the built environment, the notion being that buildings that are more adaptable are more sustainable (Kendall, 1999; Graham, 2006). Designing buildings that can be changed with minimal disruption to their existing fabric (Engel and Browing, 2008) could help to mitigate the risk of obsolescence and retain the energy, natural resources and carbon dioxide emissions that were embodied in their structure and fabric during construction.

Nevertheless, despite these compelling arguments, designing buildings for adaptability is still not common practice in the UK and elsewhere. Parallels can be drawn with the slow adoption of 'green' or 'sustainable' building techniques in the UK. As is the case with adaptability, many of the technical solutions to designing more sustainable buildings have been around for

years but it is only recently that these solutions have begun to be adopted by the property development industry. Some authors have attributed this slow up-take to a 'circle of blame' (Figure 2), whereby constructors do not produce 'greener' buildings because they claim that developers do not want them, who in turn claim that investors will not fund them because there is no demand from occupiers (Keeping, 2000). For years, the lack of a clear business case for more sustainable buildings meant that the property development industry was unable to break out of this circle of blame, a situation that has only recently started to change, for reasons discussed below. However, as yet no comparable business case has been articulated for designing more adaptable buildings.

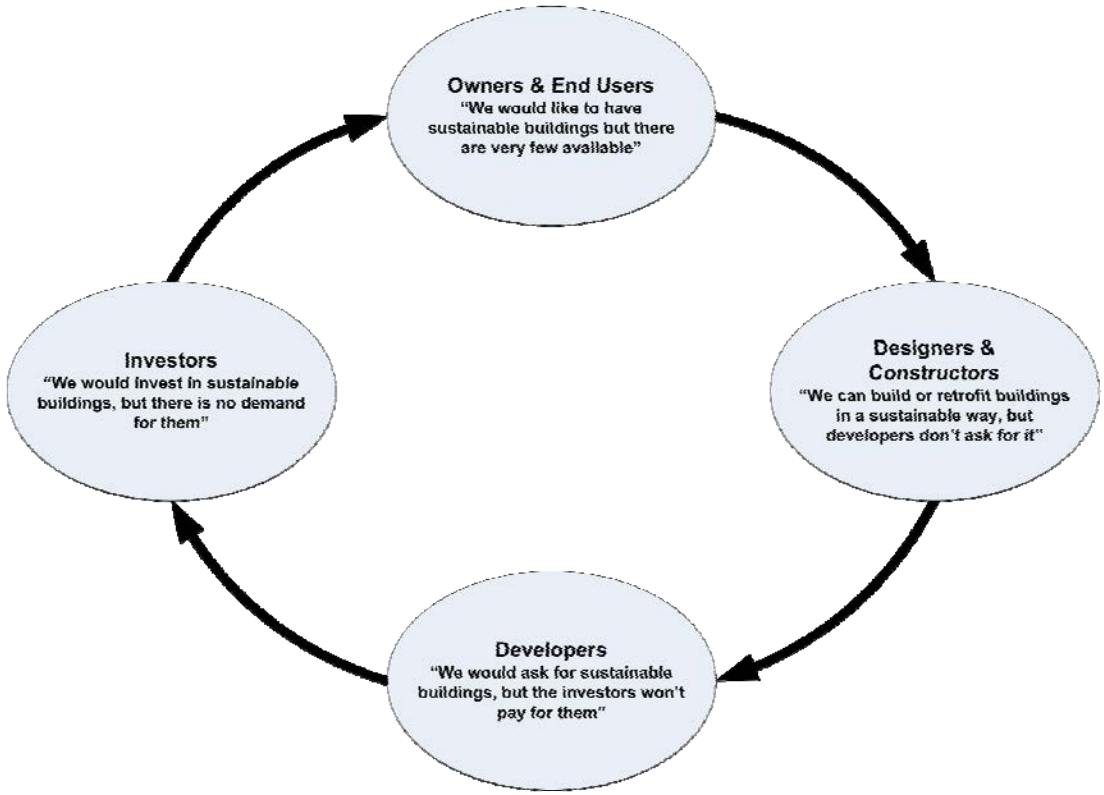

Figure 1: *The circle of blame (from Hartenberger, 2008; p.3)*

As with any other business decision, articulating the case for designing more adaptable buildings requires an analysis of the costs, benefits and risks involved (Gambles, 2009). It is often assumed that adaptability gives rise to higher initial construction costs, an assumption that has been fuelled by previous attempts at 'future-proofing' buildings. For instance, in the UK in the 1980s and 1990s it was common for developers to over-specify the mechanical and electrical services and floor loadings in their office buildings in order to cater for possible future changes in occupier requirements, even though such levels of redundancy were rarely utilised. The costs of such over-specification were ultimately passed on to occupiers through higher rents and service charges (Guy, 1998). In the United States (US), Slaughter (2001) examined the costs of implementing adaptable design strategies in 48 construction projects and found that there was a median increase of one percent in initial construction costs. However, the median cost savings at the first refurbishment cycle were estimated to be two

percent of initial construction costs, although it is not clear whether these costs and savings were discounted and, if so, at what rate.

Some of the potential benefits of designing more adaptable buildings were alluded to earlier in this paper, however understanding who receives the benefits is a key part of developing the business case for adaptability. For owner-occupiers, institutional investors or developers with a long-term interest in buildings, investing in adaptable design strategies can be justified, even if this involves a marginal increase in initial construction costs, because they may recoup the benefits in the future, in the form of lower adaptation costs. However, for developers that construct buildings for sale, the incentives to design for adaptability are less clear, because the cost of changing the building in the future will fall on another party. This thinking was borne out in research undertaken in Norway by Arge (2005), who found that office buildings developed by owner-occupiers incorporated more adaptable design features than those that were developed to let and manage; the office buildings that incorporated the least number of adaptable design features were those that had been developed for sale.

For developers that are procuring buildings to sell, more adaptable buildings will only be worth investing in if they are easier to sell and/or command a premium over less adaptable buildings, which in turn will be dependent on them being more attractive to investors and/or occupiers. Moreover, the attractiveness of adaptability to occupiers and investors would need to be reflected in the calculations of worth used by valuation professionals. Research by Ellison and Sayce (2007) suggested that only a very limited interpretation of adaptability, relating primarily to the flexibility of internal spaces, was currently factored into commercial property valuations. Consequently, valuations fail to reflect other forms of adaptability, such as the ability to accommodate changes of use. Ellison and Sayce (2007, p.298) concluded that:

> *"An appraisal that fails to reflect a property's potential to adapt is likely to be proved erroneous over time by not accurately reflecting the extent to which one property may represent a higher risk in terms of depreciation than another. This is of growing importance to investors as lease lengths shorten, making re-lettability a more critical issue, and as discount rates fall, increasing the significance of cash flow over the lifetime of the asset."*

Again, comparisons can be made with the developing market for more sustainable buildings, where a frequently asked question has been: do more sustainable buildings command a price and rental premium over less sustainable buildings? The ability to answer this question has been facilitated by the development of voluntary 'green' building certification schemes, such as the BRE Environmental Assessment Method (BREEAM), Leadership in Energy and Environmental Design (LEED) and Energy Star, which provide a proxy measure of 'sustainability' in buildings. A recent study by Fuerst and McAllister (2010) examined the sale price and rental differential between buildings in the US that were certified through LEED or Energy Star and buildings that were not. They found that LEED certification resulted in a 5% rental premium and a 25% sale price premium, with Energy Star certified buildings commanding a 4% rental premium and 26% sale price premium. Such premiums will send price signals to funders and developers that it is worth investing in more sustainable buildings.

When considering the costs, benefits and risks of designing more adaptable buildings it is useful to distinguish between the different types of change that occur in the built

environment. Schmidt III *et al* (2010) identified six different types of change, each of which they associate with a particular type of adaptability (Table 1). For instance, the 'stuff' inside a building, such as furniture, fixtures and equipment may be designed to be adjustable in order to facilitate changes in the tasks of users, something that may occur relatively frequently. In contrast, a building may change in size very infrequently; nevertheless the building's space, services, skin and structure may still be designed to be scalable. In some cases, one particular type of adaptability may affect another. For example, many contemporary 'open-plan' offices are designed to be versatile, but the ability to change their spatial layout is often constrained by the inability for users to easily adjust the location and configuration of the furniture and equipment within the space.

Table 1: *Adaptable building design strategies (adapted from Schmidt III et al., 2010; p.7)*

Type of adaptability	**Type of change**	**Building layer(s) affected**	**Frequency of change**
Adjustable	Change of task	Stuff	High
Versatile	Change of space	Stuff, space	High
Refittable	Change of performance	Services, skin	Moderate
Convertible	Change of function	Space, services, skin	Moderate
Scalable	Change of size	Space, services, skin, structure	Moderate/low
Moveable	Change of location	Structure, site	Low

WORKSHOP

In order to explore in more detail the costs and benefits of designing more adaptable buildings, the authors undertook a workshop with a range of stakeholders from the construction and property development industry. Further details about the workshop and the outcomes arising from it are described below.

Approach

The workshop participants were divided into two groups, each consisting of an industry representative from the seven stakeholder categories in Table 2 (e.g. funder, owner, designer etc.), and were presented with a project scenario (Scenario A: private office building; Scenario B: public building) in which to contextualise their ideas. The scenario data included local and national context, briefing notes, procurement information, details of the built solution, highlighting the different systems and components used, and an insight into how the users had appropriated the building over time. Each group was then asked to work through a stakeholder specific sheet of costs and benefits for each of the six types of adaptability, and indicate whether the costs and benefits were relevant to them in their particular scenario.

They were then asked to work through the sheet a second time and rate the significance (high, medium or low) of each cost and benefit, after which the high responses were marked on a large matrix for all stakeholders to see and discuss the advantages and disadvantages of the

six design strategies and the potential alliances and conflicts between stakeholders. Table 2 provides a condensed version of the sheets illustrating the costs and benefits for each stakeholder (in parenthesis, with the costs marked in red) related to higher-level costs and benefits that cut across stakeholders and adaptability types. For example, designing buildings to be scalable has the high-level benefit of extending their life spans, which may ultimately bring future costs for constructors, in the form of less construction work. However, such buildings are likely to be easier and cheaper to adapt, thereby giving rise to benefits for constructors, in the form of more adaptive re-use work and lower levels of risk during such projects.

Outcomes

The workshop exercise served to highlight the motivating factors behind different stakeholders when it comes to the development of new buildings. Funders conveyed a desire for simplicity and the use of traditional construction methods to reduce risk, costs and tenant churn. Owners were driven by a desire to minimise risk and initial capital expenditure, while being able to sell or lease the building was a key motivator for applying any type of adaptability. As shown in Arge's (2005) research, there was also a clear distinction in the motivations between the different development models (develop to sell, manage or occupy), with owner-occupancy driving a greater interest in adaptability. This was complimented by end-user preferences for a versatile and refittable building that provides fewer disruptions, improved service and better quality of space.

From the supply side, designers saw the adaptable design strategies as a means of improving their reputation and as a basis for generating future work opportunities. They were positive about an increased shift away from new build work and viewed scalable buildings as the most likely source of future work opportunities. Contractors saw themselves not as initiators of adaptability, but as a service, only focused on the speed and cost of initial construction. While they did see potential to improve quality and competitiveness in response to client demands it was not a huge motivator in changing practices. Manufacturers felt more removed from the decision-making process, but were interested in balancing the tension between reducing costs and extending component lifecycles. Overall, society was seen to be one of the main beneficiaries of designing buildings that are more adaptable; keeping buildings occupied and reducing waste, resource use and disruption to the community were all seen as positive benefits for society. However, there was a realisation that these benefits would be dependent on strong local activism and/or government regulation.

One of the major outcomes of the workshop was the greater sense of clarity amongst stakeholders, due to an improved understanding of the full spectrum of stakeholder motivations. This helped the dialogue to avoid 'muddy waters' by enabling stakeholders to clarify their own position, even to the extent that it allowed them to be more selfish or focused. In addition, it was agreed that designing for alternative uses should not compromise the initial use: future benefits cannot be applied if it is at the cost of a sub-optimal first use. However, there was also an agreement that many of the costs and benefits are context specific and need to be evaluated on a project-by-project basis. The mapping exercise would therefore be a useful tool for a client when trying to determine the extent to which a building should be designed to be adaptable.

Table 2: *Summary of the costs and benefits of different adaptable building design strategies, by stakeholder group*

Stakeholders	Costs/benefits	Adaptable design strategies					
		Adjustable	**Versatile**	**Refittable**	**Convertible**	**Scalable**	**Moveable**
Constructors	Overdesign buildings for initial use (increase construction costs/revenues)		x	x	x	x	x
	Easier to construct buildings (quicker construction/lower construction risk)			x		x	x
	Easier/cheaper to adapt buildings (more adaptation work/lower project risk)		x	x	x	x	x
	Extend the life of buildings (less new build work)		x	x	x	x	x
Designers	Easier to lease/sell buildings (develop good reputation/generate more business)		x	x	x	x	x
	Overdesign buildings for initial use (develop bad reputation/lose business)				x	x	x
	Easier/cheaper to adapt buildings (more adaptation work/lower fees)		x	x	x	x	x
	Extend the life of buildings (less new build work)		x		x	x	x
	Increased user control over buildings (loss of design control)	x					
Funders	Overdesign buildings for initial use (increase construction costs/capital required)		x	x	x	x	x
	Easier to construct buildings (quicker construction/lower construction risk)			x			x
	Easier/cheaper to adapt buildings for initial use (reduced demand risk)		x	x	x	x	x
	Easier to sell buildings (quicker exit from projects/lower financing costs)		x	x	x	x	x
	Higher sale prices for buildings (increase return on investment)		x	x	x	x	
Manufacturers	Easier to construct buildings (develop good reputation/demand for products)	x		x		x	x
	Easier/cheaper to adapt buildings (more adaptation work/demand for products)	x	x	x	x	x	x
	Extend the life of buildings (less new build work/reduced demand for products)	x	x	x	x	x	x

Stakeholders	Costs/benefits	Adaptable design strategies					
		Adjustable	Versatile	Refittable	Convertible	Scalable	Moveable
Owners	Increased building values (more capital/larger mortgage loan required)		x	x	x	x	x
	Easier/cheaper to adapt buildings to new demands (less demand risk/voids/cost)	x	x	x	x	x	x
	Easier to lease buildings (higher occupancy rates/fewer voids/greater cashflow)		x	x	x	x	x
	Easier to sell buildings (quicker to sell/reinvest capital)		x	x	x	x	
	Higher rents/sales prices for buildings (increased return on investment)		x	x	x	x	
Society	Overdesign buildings for initial use (increase resource use/embodied energy)		x		x	x	x
	Easier to adapt buildings (reduction in resource use/waste/environmental impact)		x	x	x	x	x
	Extend the life of buildings (less demolition waste/maintain embodied energy)		x	x	x	x	x
	Less demand for new buildings (reduction in resource use/environmental impact)		x	x	x	x	x
	Easier to sell/lease buildings (fewer vacancies/less urban decay/more taxes)		x		x	x	x
Users	Overdesign for initial use (higher rental costs/service charges)	x	x	x	x	x	x
	Easier to adapt buildings (buildings stay fit for purpose/less downtime)	x	x	x		x	x
	Cheaper to adapt buildings (lower service charges/churn costs)	x	x	x		x	
	Increased user control over buildings (lower churn costs/better productivity)	x	x				

CASE STUDIES

The issues arising from the workshop have been investigated in further detail through case studies of existing buildings in a range of sectors, including offices, schools and retail. The case studies have involved interviews with developers, designers, owners and other project stakeholders in order to unpack the reasoning behind the use of particular adaptable design strategies. Two such case studies are presented below.

Case study 1

The first case study building is located in the Brianza region of northern Italy. Completed in 2009, the building was designed to be convertible, in that it can be fitted-out for use as an office, warehouse, laboratory or storage space. The three-storey building (Figure 2) has two adjacent wings that are connected by two separate lobby areas, to enable the building to be sub-let more easily. Sub-letting of the building is also facilitated by the fact that the building has four separate service cores, two in each wing of the building. The building's external cladding was designed to be more easily refittable, for example to enable warehouse doors to be retrofitted, and floor loadings are sufficient to accommodate light-industrial activities. However, the desire for a convertible building has involved some compromises. For instance, the building is fitted with a building management system, the performance of which can be affected when occupants open windows, a feature that had to be included because, according to the architect, local planning regulations dictate that buildings used for industrial purposes must have operable windows.

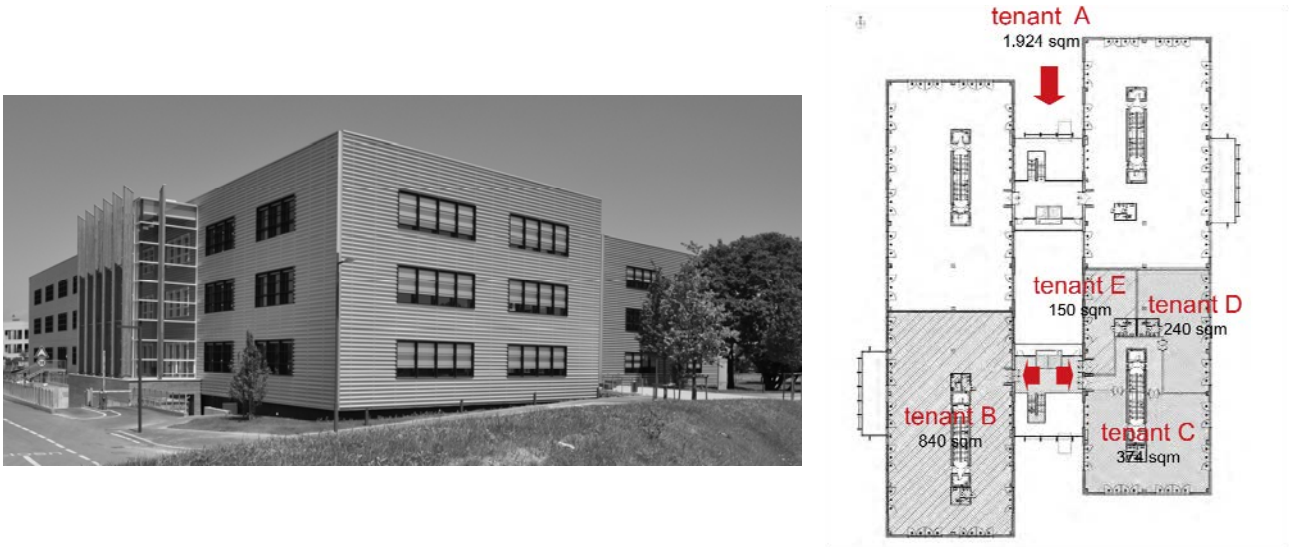

Figure 2: *An external view and floor plan of case study 1*

The construction costs for the building were higher than those for comparable Grade A office buildings that the developer had constructed elsewhere, although some of these costs can be attributed to the fact that the building was designed to achieve LEED certification. However, as an investor-developer with a long-term interest in the buildings that it constructs, the developer views adaptable design as an intrinsic part of its business strategy in response to

changing occupier demands and achieving higher levels of sustainability. By procuring a building that can be converted to different uses more easily, the developer is attempting to mitigate demand risk and reduce its exposure to future adaptation costs. The design of the building also raises a number of interesting questions, not least about whether the building could, in practice, accommodate mixed-uses. For instance, would a corporate office tenant be content to see adjacent spaces being used for light-industrial purposes or would their lease preclude such an arrangement? The interplay between such non-physical factors could therefore potentially limit the adaptability of the building (even though it is technically feasible).

Case study 2

The second case study is a speculatively developed science park building that was constructed on a brownfield site in the East Midlands region of the UK. The building (Figure 3) was completed in 2008 and comprises approximately 3,000 m^2 of floorspace that can be used to accommodate a mix of offices and laboratories. Serviced workspaces range from 90 m^2 to 1,800 m^2 and can be occupied on flexible lease terms by organisations involved in research and development, science and technology industries. The rationale behind the development was to provide 'grow-on' space for such companies. Adaptability was designed into the building through the provision of a central hub, with pods feeding from it, enabling the floorspace to be divided up to meet the needs of different occupiers. Other adaptable design features included raised access flooring, refittable external wall cladding and services that can be adjusted to meet different space layouts. Such design features are common in speculative office developments in the UK.

Figure 3: *An external view of case study 2*

The developer behind the science park building is half owned by the UK government and half by an investment fund that was specifically set up to be a catalyst for regeneration and sustainability. This enabled the developer to take risks that other private developers would

not normally be willing or able to take. Whereas the funding structures of most commercial developers are normally based around short-term returns, the developer of this building had a longer-term outlook (based on a 5-6 year business plan). As the developer confessed, conventional property development models are not good for encouraging innovation and adaptability, as they are all about finding a formula and replicating it as much as possible, in order to mitigate risk. Nevertheless, despite its longer-term business model, it was not the developer's intention to retain ownership of the development and the scheme will eventually be sold to a property investor. Ultimately then, the design of the building needed to conform to the expectations of the mainstream property market, something that might have precluded the use of more innovative adaptable design strategies.

CONCLUDING REMARKS

Despite the fact that adaptability in buildings is considered to be a desirable design characteristic by many in the construction and property industry, it is still not common practice for buildings in the UK to be designed with adaptability in mind. So what would need to change in the industry for adaptability in buildings to become more commonplace? Figure 4 presents an archetypal view of a property and construction industry in which adaptability in buildings is the norm due to an alignment in the interests of different stakeholder groups: developers procure buildings that are more adaptable because they attract higher prices from investors, who in turn find that they are more attractive to occupiers and end-users because they are easier to change. This 'virtuous circle' is reinforced by a series of other influences: valuers factor the benefits of adaptability into their appraisals and industry bodies encourage their members to think about adaptability when procuring, designing or constructing buildings; similarly planners encourage developers to develop more adaptable buildings and banks lend to investors and occupiers at more favourable rates because more adaptable buildings are seen as less risky.

A number of factors could help to bring about such a change in industry mindsets. One would be to develop a better understanding of the costs, benefits and risks of adopting different adaptable design strategies. In the construction and property industry, existing attitudes towards adaptability are, to some extent, epitomised by a comment from the architect of one of the two case study schemes, who suggested that:

> *"I completely concur and I like buildings to last 500 years. I'd like them to change uses ten times. I'd like to be able to dismantle an office façade and put another kind of façade and respond to the climate and all of that. I guess the problem is that the more flexibility you create… the more cost there is"*

Providing more robust evidence as to the real costs and benefits of adaptability and the way in which these play out in practice could enable clients and their advisors to make more informed decisions about which, if any, design strategies to deploy in their buildings. Learning from examples of existing buildings can be a useful way of understanding the costs and benefits of adaptability and the authors of this paper are therefore engaged in ongoing case study research in this area.

There is also a need for a clearer articulation of what constitutes adaptability in buildings, so as to overcome some of the misconceptions that surround the issue. Evidence from the related field of 'sustainable' buildings suggests that being able to certify or label a building as

'green' can help to improve transparency in the property market and help occupiers to make more informed decisions about which buildings to purchase or lease. Moreover, such certification schemes can help valuers and investors to factor the benefits of sustainable design features into their appraisals of worth and send positive price signals to developers. A useful goal for researchers and industry bodies might therefore be to develop a similar scheme for the adaptability potential of buildings or to see how adaptability potential can be factored into existing 'green' building certification schemes, such as BREEAM and LEED. Indeed, there have already been moves in this direction. For instance in the UK, the *Lifetime Homes* standard – a set of design criteria for ensuring that new homes are adaptable for lifetime use – has been incorporated into the *Code for Sustainable Homes* (DCLG, 2006). In the US, the American Institute of Architects has adopted the "long life, loose fit" principle as one of its ten measures of sustainable design in its annual top ten green projects competition, in which entrants are asked to describe, amongst other things, the adaptive re-use potential of their buildings (AIA, 2004).

Government regulation may also play a role in changing industry mindsets towards adaptability in the built environment. One of the key principles of sustainability is that development today should not compromise the ability of future generations to meet their own needs (WCED, 1987). However, buildings that are difficult to adapt pose a problem for future generations, because the buildings either need to be demolished, undergo costly and potential environmentally damaging refurbishment or remain vacant, which itself can have indirect negative social and economic consequences. Rising land fill taxes in the UK and other countries mean that waste from building demolition and refurbishment will be increasingly costly to dispose of in coming years and although the principle of extended producer responsibility is unlikely to be applied to whole buildings, it could potentially be applied to particular building elements and components (Guggemos and Horvath, 2003). Such changes could give rise to greater demand for buildings that are more adaptable, particularly in terms of the ease with which they can be retrofitted, scaled up or down in size, or converted to a new use.

ACKNOWLEDGEMENTS

This paper is based on research undertaken as part of the *Adaptable Futures* project at Loughborough University. The authors would like to acknowledge the financial support of the Engineering and Physical Sciences Research Council and the Innovative Manufacturing and Construction Research Centre at Loughborough University, together with the input and case studies provided by the *Adaptable Futures* project partners. Abstract

Purpose

Globally the development of property, being part of the creation of fixed investment and wealth, is taking place unabated. The development of an universally acknowledge profession, designated to manage and optimise the utilisation of the ever compounding fixed investments in the products of the collective built environment, is observed. However, in South Africa this is still in an early formative stage. The objectives of this research are to contextualize facilities management by defining it, to identify bodies of knowledge/competencies and to establish a suitable educational knowledge framework and to address existing shortcomings. From a sustainability perspective serious shortcomings exist in many parts of the world and particularly so in South Africa and the rest of Africa. The sustainable utilization of buildings and infrastructure is seriously jeopardized due to underdeveloped facilities management.

Design

The problem at hand is to extract, from the present international practice of facilities management, a body of knowledge and secondly to formulate the results in terms of suitable tertiary and continuing education programmes to address shortcomings in South Africa.

Findings

The results of this research found application in the enhancement of an existing short continuing education programme and the introduction of a new three-year tertiary education programme in a school for the built environment.

Value

The value to be realised out of the structuring and presentation of formal educational programmes in facilities management is that a neglected area of the built environment family of disciplines are being addressed and elevated in South Africa, to what is fast becoming the norm elsewhere in the world. Professional facilities management can make a key contribution to create sustainable utilization of the products of the built environment.

Practical implications

By offering formal education in facilities management a meaningful contribution will be made to satisfy the obvious dire needs of the private, and particularly the public sector, to

optimize the utilisation of the products of the built environment through continuous improvement of those facilities in a scientific and sustainable fashion, to the best advantage of all the stakeholders.

Keywords:, Body of knowledge, built environment, facilities management, sustainability, tertiary and continuing education.

INTRODUCTION

Investment in properties, as fixed assets, is growing continuously internationally. These property development activities are served by a multitude of highly skilled professionals such as engineers, architects, quantity surveyors, construction managers, project managers, town planners, land surveyors and others. The development of a universally acknowledged profession of the same standing, designated to manage and optimise the utilisation of the ever compounding fixed investments in the products of the collective built environment (buildings, engineering structures and infrastructure), is necessary. This situation may be explained by the fact that, in the present day accepted vocabulary, facilities management as a managerial concept developed in the United States of America only during the 1970's, when a Facilities Management Institute was founded and the first known formal symposium was held in Washington DC in 1989 (Binder, 1989). Though these events started approximately 30 years ago, the development and spread were slow, and in comparison with the other built environment professions, it is still in its infancy. However, although perhaps lacking some of the prestige associated with other professions, there are reasons to believe that facilities management is one of the fastest growing "new professions" in the built environment. Sustainability in ensuring that buildings and infrastructure are fit for purpose is paramount. Furthermore, it is becoming evident that facilities management is in the process of becoming a driving force, not only of scientific management and optimisation of fixed assets, but as an initiator of development in the built environment.

Perhaps not adequately acknowledged in the past, is that facilities management deals with 57,5% of the life cycle costs of a building. See Figure 1. Although this % is not universal for all facilities, it underscores the importance of facilities management as discipline. Although life cycle costing is often sighted as a knowledge area in facilities management, it could be argued that the extend to which life cycle costing rests with facilities managers may be under estimated and warrants further research.

Although facilities management is a "new" profession, it is observed that comprehensive sources of literature are constantly being developed. Also noteworthy is the associations that have been established globally. Although in its infancy in South Africa, in some countries tertiary education in facilities management is developing rapidly, supported by research activities.

The terms facility (singular) and facilities (plural) will be used synonymously, as will also be evident from referenced sources, although "facilities" will enjoy preference.

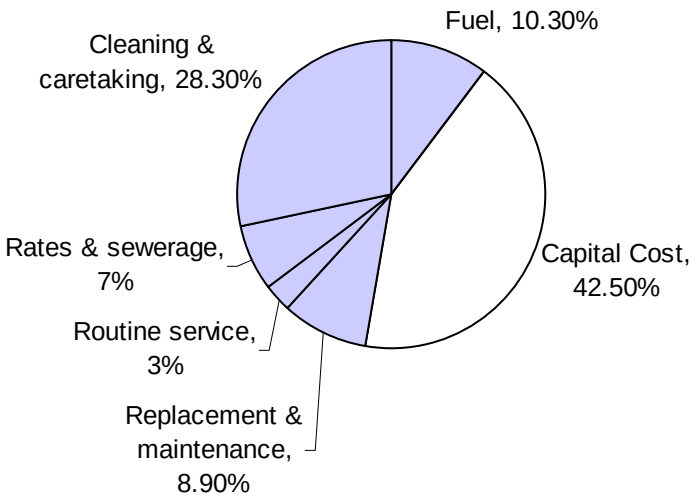

Figure 1: *Local authority school life cycle cost (Cloete, 2001a: 178)*

LITERATURE SURVEY

Literature was selected by undertaking a web search in order to identify and obtain suitable works regard facilities management and by identifying and utilising known local South African works, commonly used by training and education providers. For obvious reasons "all" literature available internationally has not been reviewed. A selection was made of those sources regarded as presenting a fair overview related to this study. The contents of the following literature have thus been analysed in order to establish what appears to be representative of a general knowledge profile in literature: Barret and Baldry (2006), Bender (2002), Best, Langston and de Valence (2003), Cloete (ed) (2001a), Cloete (ed) (2001b), Cloete (ed) (2002a), Cloete (ed) (2002b), Collins and Porras (2000), Cornwell (1973), Cotts and Rondeau (2004), Crocker (1990), Gross (2002), Friday and Cotts (1995), Hauptfleisch (ed) (Volume 1&2) (1999), Hauptfleisch and Sigle (2009), Magee (1988), Means Company (1996), Occupational Health and Safety Act (2003), Owen (1993), Pearce and Robinson (2000), Project Management Institute (2004), Robinson (1999), Rondeau, Brown and Lapides (2006), Seeley (1987), Wang (2010). To this was added those knowledge areas regarded to be of importance in continuing education programmes and in formal academic degree programmes.

Table 1 (placed in later section) provides an analysis flowing from surveying the sources as described above, divided into three categories: Firstly dealing with the "contextualising of the managerial challenge", secondly with the "practice" of facilities management and thirdly with "property maintenance". The topics contained in Table 1 are in main heading format, synthesised from comprehensive subdivisions.

It should be noted that the literature survey covers sources from 1973 to 2010 but that the bulk of it has been published since 2000. For this reason no attempt was made to place the

development of a knowledge profile on a developmental time scale. Figure 2 therefore represents an attempt to provide a contemporary "balance sheet" rather than a "developmental pathway".

METHODOLOGY

The problem at hand is to extract a body of knowledge from the present practice of facilities management, and secondly, to formulate suitable tertiary and continuing education programmes. This was done through literature study, web-searches and by obtaining feedback from facilities management practitioners attending continuing education short courses (in order to create a limited statistical sample), and from non-quantified observations in practice. A qualitative and quantative survey was conducted amongst stakeholders in order to obtain their views regarding a proposed three-year tertiary education programme on under-graduate (degree) level. Figure 2 shows the generally perceived position of facilities management, in context of overall asset management, within an enterprise that holds built environment assets. This diagramme was tested for general correctness by subjecting it to assessment by 12 different groups of facility management practitioners taking part in continuing education short courses over a period of four years.

The general support that it received was taken as indicative of actual facilities management practice in South Africa, offering some guidance in the creation of a primary body of knowledge for education.

From Figure 2 (own diagramme) it is clear that the research done was not hypotheses testing. The intention was to establish current thinking regarding where facilities management could be placed in the bigger context of asset management, thus contributing towards the development of academic programmes, pre-empting the needs of industry, resulting in a structured knowledge profile, validated by a broad group of stakeholders.

DEFINITIONS

Facilities management is defined and analysed in a variety of ways by associations and authors of books. The following selected definitions are based on a survey conducted via internet to provide an overview of "what facilities management" is perceived to be internationally by facilities management associations:

International Facilities Management Association (IFMA)
IFMA is a very comprehensive association, providing comprehensive input and educational opportunities in the discipline. Its head office is based in the United States of America (USA), but it also covers Canada as a North American body. IFMA also has chapters in other regions in the world. The IFMA (2010) web-page contains the following definition:
"Facility management is a profession that encompasses multiple disciplines to ensure functionality of the built environment by integrating people, place, process and technology."

The IFMA (2010) web-page also provides a comprehensive structure, summarized below, of nine competency areas (others may call it knowledge areas, or a body of knowledge):

I Operations and maintenance

a. Oversee acquisitions, installation, operation, maintenance and disposition of building systems

b. Manage the maintenance of building structures and permanent interiors
c. Oversee acquisition, installation, operation, maintenance and disposal of furniture and equipment

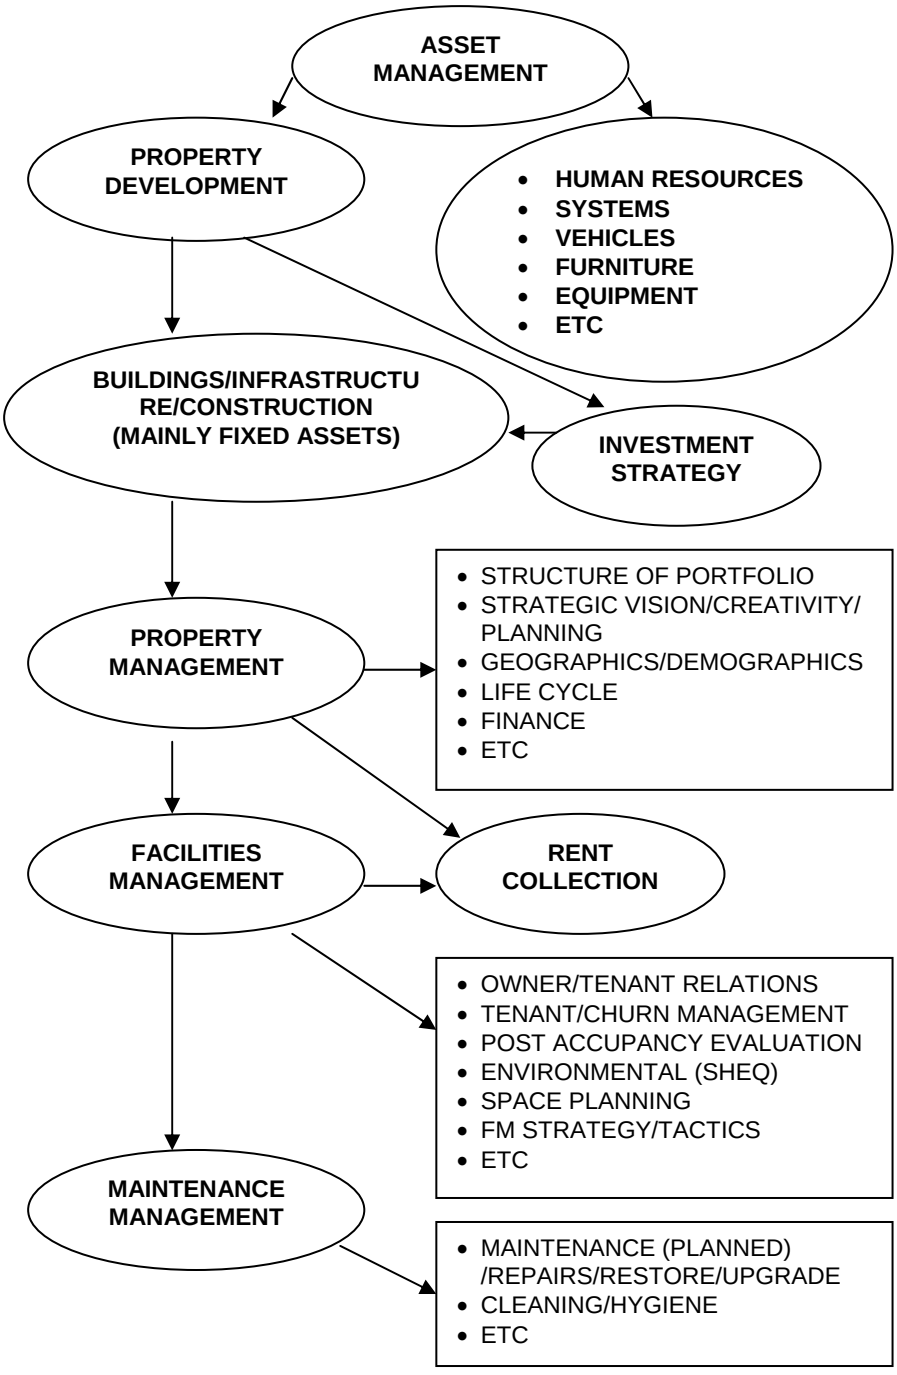

Figure 2: *Facilities Management in Context of Asset Management (own diagramme)*

d. Oversee acquisition, installation, operation, maintenance and disposition of grounds and exterior elements

II *Real estate*

a. Manage and implement the real estate master planning process
b. Manage real estate assets

III *Human and environmental factors*

a. Develop and implement practices that promote and protect health, safety, security, the quality of work life, the environment and organisational effectiveness
b. Develop and manage emergency preparedness procedures

IV *Planning and project management*

a. Develop facility plans
b. Plan and manage all phases of projects
c. Manage programming and design
d. Manage construction and relocations

V *Leadership and management*

a. Plan and organise the facility function
b. Manage personnel assigned to the facility function
c. Administer the facility function
d. Manage the delivery of facility services

VI *Finance*

a. Manage the finances of the facility function

VII *Quality assessment and innovation*

a. Manage the process of assessing the quality of services and the facility's effectiveness
b. Manage the benchmarking process
c. Manage audit activities
d. Manage developmental efforts of facility services to make innovative improvements in facilities and facility services

VIII *Communication*

a. Communicate effectively

IX *Technology*

a. Plan, direct, and manage facility management business and operational technologies
b. Plan, direct, manage and/or support the organisation's technological infrastructure

Facilities Management Association (UK) (FMA)

FMA (2010) information from its web-page is limited, but the following definition is provided:

"Facilities Management is located in the Support Services Sector of the UK economy and is the efficient integration of support activities within the business environment which is essential to the successful performance of any organisation."

British Institute of Facilities Management (BIFM)

BIFM (2010) defines facilities management as follows on its web-page:

“Facilities management is the integration of processes within an organisation to maintain and develop the agreed services which support and improve the effectiveness of its primary activities.”

The BIFM (2010) web-page provides the following 20 “strategic and operational” competencies:

- The Business Organisation
- Management Principles
- Risk Management
- Information and Knowledge Management
- Project Management
- Personal Leadership
- Human Resources Management
- Relationships with Suppliers and Specialists
- Quality Management
- Customer Service
- Management of Property
- Property and Building Services Maintenance
- Space Management
- Support Services Operations
- Sustainability and Environmental Issues
- Energy and Utility Management
- Financial Management
- Procurement, Contracts and Contract Management
- Legislation, Codes, Directives and Regulatory Issues
- Facilities Management – Development and Trends

Facility Management Association of Australia (FMAA)

The FMAA definition of facility management is stated by Best et al (2003:1) as follows:
“Facility management is the practice of integrating the management of people and the business process of an organisation with the physical infrastructure to enhance corporate performance.”

FMAA competencies are categorized as follows by Best et al (2003:3): “The broad categories are:

- Use organisational understanding to manage facilities
- Develop strategic facility response
- Manage risk
- Manage facility portfolio
- Improve facility performance
- Manage the delivery of services
- Manage projects
- Manage financial performance
- Arrange and implement procurement/sourcing
- Facilitate communication
- Manage workplace relationships
- Manage change”

The range of skills and knowledge required of facility managers, if they are to successfully carry out all of these functions, is quite alarming as it includes everything from computer networking and mechanical engineering to human resources management theory, occupational health and safety legislation, contract negotiation, future financial planning (eg budgeting, life costing, discounting), subcontract administration, construction management – the list is endless."

Euro FM

Although no specific definitions or core competencies occur on the EuroFM (2010) web-page, it is noteworthy that it networks 80 organisations based in 15 European countries. These organisations represent professional associations, education and research initiatives and corporate organisations.

Hong Kong Institute of Facility Management (HKIFM)

The HKIFM (2010) web-page defines facility management as follows:

"Facility Management is the process by which an organization integrates its people, work process and physical assets to serve its strategic objectives. As a discipline, facility management is the science and art of managing this integrative process from operational to strategic levels for promoting the competitiveness of organizations."

HKIFM (2010) identifies professional core competencies as per Figure 3.

Figure 3: *HKIFM (2010) Professional core competency*

Japan Facility Management Promotion Association (JFMA)

The JFMA (2010) web-page defines facility management as follows:

"It is a comprehensive management approach for the optimization of the ownership, utilization, operation, and maintenance of the business real properties (land, buildings, structures, equipment, etc.) and maintain them in optimal conditions (minimum costs and

maximum effects), so that they could contribute to the overall management of the business." Core competencies are not provided.

South African Facilities Management Association (SAFMA)
The SAFMA (2010) web-page provides the following definition:
"Facilities management is an enabler of sustainable enterprise performance through the whole life management of productive workplaces and effective business support services."
SAFMA however does not list the required core competencies required by facilities management on its web-page.

Other definitions
As previously noted, a large volume of literature exists and is growing rapidly regarding facilities management. A limited number is reflected below, being indicative of general points of view.

Best et al (2003:12) provide the following descriptive statement:
"Facility management is therefore about empowering people through provision of infrastructure that adds value to the processes that they support. Facility managers are charged with the responsibility of ensuring that the infrastructure is available, operational, strategically aligned, safe and sustainable. Above all, however, facilities must encourage high productivity through a continual search for ways to improve quality, reduce cost and minimize risk."

Atkin and Brooks (2009:3-4) provide the following descriptive statement:
"Facilities management can therefore be summarised as creating an environment that is conducive to carrying out the organisation's primary operations, taking an integrated view of the services infrastructure, and using this to deliver customer satisfaction and best value through support for and enhancement of the core business. We can develop this definition to describe facilities management as something that will:

- Support people in their work and in other activities.
- Enhance individual well-being.
- Enable the organisation to deliver effective and responsive services.
- Sweat the physical assets, that is, make them highly cost-effective.
- Allow for future change in the use of space.
- Provide competitive advantage to the organisation's core business.
- Enhance the organisation's culture and image."

Barret and Baldry (2006:xiii) provide the following definition of facilities management:
"An integrated approach to maintaining, improving and adapting the buildings of an organisation in order to create an environment that strongly supports the primary objectives of that organisation."

Although the *International Council for Research and Innovation in Building and Construction (CIB)* is obviously not a trade association, it is of value to review its position as a contributor to the creation of knowledge. The CIB (2010) web-page does not provide specific definitions, nor does it list core competencies. But, as a highly regarded international research facilitator (the work done, and reported through its work commission: CIB W070), its contribution to the creation and dissemination of best professional practice in education, research and practice is of high standing.

UNDER-EMPHASISED KNOWLEDGE AREAS

The knowledge areas that are perceived as important for practicing facilities managers and the relevant emphasis of each in the surveyed literature are reflected in Table 1. The table therefore represents an "emphasis" evaluation, based on the extent to which various knowledge areas receive attention in literature. This analysis is not substantiated by quantitative and triangulated research procedures, but has value as an attempt to observe general tendencies to emphasise knowledge areas, required in a primary body of knowledge for the development and practice of facilities management. The table was compiled by the authors after scrutinizing what knowledge areas receives more or less (how much) emphasis in the surveyed literature.

ANALYSIS OF CONTINUING EDUCATION SHORT COURSES (5 DAYS) AND TESTING OF THE PROPOSED CONTENTS FOR AN ACADEMIC PROGRAMME (3 YEARS)

The researchers have substantial experience in presenting short courses (5 days) in facilities management. As part of the structuring of a three-year tertiary education programme it is regarded valuable to source the views regarding the introduction of an academic programme from short course delegates. Their evaluation of the short courses was seeked to test their acceptance / rating of the contents. This was further extended to also test their evaluation of the proposed contents of the three-year academic programme. Further enhancement of this was done by surveying two selected organised industry groups in the facilities and property industries. A final ongoing evaluation has been regularly conducted since introduction of the three-year programme by continues surveying of the importance attached to 20 core competencies selected by the authors.

ANALYSIS OF CONTINUING EDUCATION SHORT COURSES EVALUATION

Table 2 is based on the results obtained from a limited quantified 100% covered survey, assessing broad disciplines covered during continuing education short courses, soliciting recommendations regarding course content. Delegates are also prompted to make alternative suggestions. This survey has been conducted six times (from 2004 to 2007) amongst delegates, after they have completed a five-day continuing education short course offered to middle (and top) management practitioners of facilities management. Table 2 contains the results that emanated from the last three courses offered during 2006 and 2007, before

structuring the reported academic programme. These courses are always well subscribed. Delegates that are required to take part in the above survey are also evaluated by way of assignments, in order to support continuous quality improvement. These evaluations have subsequently also been conducted from 2008 to 2010, with no noteworthy different result.

KNOWLEDGE AREAS	ACTUAL LECTURE %	RECOMMENDED LECTURE %
Management (assets, property, facility, general)	35	34.1
Client care	6	7.1
Finance	15	13.9
Legal	18	17.2
Quality	13	12.9
Maintenance	13	14.8
Total	100	100

Table 2: *Recommendations for Continuing Education Programme Content Weighting*

From the results reflected in Table 2 it is concluded that the respondents that have attended continuing education short courses, are satisfied that the course content is on target.

ANALYSIS OF SURVEY REGARDING PROPOSED ACADEMIC PROGRAMME OBJECTIVES AND OUTCOMES

Based on all the data obtained, a three year academic programme has been structured, to be offered in a distance learning format, as follows:

- Year One: Facilities Management Introductory Certificate (NQF Level 6: 80 Credits)
- Year Two: Facilities Management Intermediate Certificate (NQF Level 7: 80 Credits)
- Year Three: Facilities Management Advanced Certificate (NQF Level 7: 80 Credits)

Note: Some of the course contents/subjects may be offered as credits towards obtaining a BSc-degree.

The proposed contents of the above programmes/certificates have been subjected to a quantitative and qualitative survey in order to assess the validity thereof. Three stakeholder groups that could contribute to this process were identified and requested to take part in a survey. The quantitative results are reported in Table 3.

- Group 1: Practitioners that have participated in Continuing Education Short Courses.
- Group 2: The South African Property Owners Association (SAPOA) Facilities and Technical Services Committee members.
- Group 3: The South African Facilities Management Association (SAFMA) management committee requested prominent members to participate.

All participants in the survey were provided with details of the proposed course content, including the objectives and outcomes of each subject.

The focus of the survey was to determine to what extent the curriculum content was regarded as important. This assessment of a primary body of knowledge for a three year educational programme was conducted regarding the following quantitive data:

QUESTIONNAIRE ON PROPOSED THREE YEARS COURSE CONTENT FOR CERTIFICATE PROGRAMMES IN FACILITIES MANAGEMENT

1. Your response (x) should please indicate the importance of each subject as per the attached proposed modules for certificates in facilities management over a three year period.
2. Not important: 1
   Most important: 5

			GRP 1	GRP 2	GRP 3
FIRST YEAR: FACILITIES MANAGEMENT INTRODUCTORY CERTIFICATE (NQF 6:80 credits)					
1.1	DQF 104: 16	Descriptive Quantification	4.12	4.25	3.50
1.2	COE 104:16	Building Economics	4.47	4.00	4.25
1.3	SBE 102:8	Structure of the Built environment	4.41	4.00	4.00
1.4	FAM 100:40	Facilities Management	4.88	4.75	4.75
	AVERAGE		**4.47**	**4.25**	**4.13**
SECOND YEAR: FACILITIES MANAGEMENT INTERMEDIATE CERTIFICATE (NQF 7:80 credits)					
2.1	DQF 204: 16	Descriptive Quantification	3.58	4.00	3.50
2.2	COE 204: 16	Building Economics	4.29	4.00	4.00
2.3	CSC 304:16	Construction Science	4.17	4.25	4.00
2.4	EGS 202: 8	Engineering Science	3.76	3.25	4.00
2.5	FAM 206: 24	Facilities Management	4.88	4.75	5.00
	AVERAGE		**4.14**	**4.05**	**4.10**
THIRD YEAR: FACILITIES MANAGEMENT ADVANCED CERTIFICATE: (NQF 7:80)

3.2	CCM 306: 16	Construction Contracts and Management	4.35	4.00	4.67
3.3	BSC 304:16	Building Science	3.76	4.00	4.25
3.4	PDE 302:8	Property development	4.29	3.25	4.00
3.5	FAM 308: 32	Facilities Management	4.52	5.00	5.00
	AVERAGE		**4.22**	**4.00**	**4.38**

Table 3: *Responses by stakeholder groups*

NOTE:

Group 1: From the 213 questionnaires delivered 19 responses were received (8,9%)
Group 2: From 22 committee members 4 responses were received (18.2%)
Group 3: It is unknown how many questionnaires were circulated, from which 4 responses were received.
Although the response rates are not high, it may be regarded as adequately indicative, coming from prominent interest groups.

RESPONDENTS	VALUE
Group 3: Course Participants	4,28
Group 4: SAPOA Committee members	4.10
Group 5: SAFMA members	4,20

Table 4: *Average arithmetic results from all respondents on a 5-point scale*

From Tables 3 and 4 it can be concluded that the proposed three year courses enjoy comprehensive acceptance and that the courses' contents are on target.

The qualitative data that was obtained is not reported on in detail. It basically constitutes guidelines/suggestions and does not distract from the outcomes of the quantitative surveys.

Following the initial data collection reported above, both the 5-day continuing education programme and the 3-year certificate programme candidates have consistently been surveyed since, in order to strengthen the facilities management knowledge base, core competencies required, and to develop the relevant definitions supporting understanding of this multi-disciplinary profession. Table 5 reflects the outcomes of further surveys conducted amongst the 3-year academic students and the 5-day continuing education delegates during 2009-2010. A limited list of 20 knowledge areas/competencies was drawn-up and surveyed on a 5-point Likert scale. None of the delegates are school leavers, all are in full-time occupations. It is noteworthy that overall the 3-year students (people who have elected a serious study commitment), rate the overall importance of the knowledge areas higher then the 5-day continuing education participants. However, all assessments are higher than the 2,5 midpoint, indicating the general perceived importance. The 3-year students' evaluation produced a mean score of 3,86, whilst the 5-day delegates produced a mean score of 3,20.

NO	KNOWLEDGE AREA	3-year students	Short course delegates
1.	General management	3.72	3.12
2.	Strategic management	4.22	3.42
3.	FM Specific management skills	4.00	3.54
4.	Project management for facilities managers	4.22	3.31
5.	IT Utilization	3.61	2.54
6.	Contract law	3.67	3.19
7.	Construction technology, building & infrastructure services	4.11	3.35
8.	Space planning	3.61	3.12
9.	Energy efficiency and environmental control	4.06	3.50
10.	Support services	3.56	3.08

11.	Maintenance management	4.28		3.96

19.	Enhancement of FM practice	3.89		3.35
20.	Total quality management	3.94		3.77
	Mean	**3.86**		**3.20**

Table 5: *Facilities management generic knowledge areas evaluation of importance in practice*

CONCLUSIONS: DEFINITIONS

From the variety of definitions observed and the various surveys that were made, the notion develops that facilities management comprehensively deals with the creation of fit for purpose working environments, or workplaces. The latter is rapidly expanding to become "places of business/work and centres of experience". People globally preferably interacts in optimally created physical environments, whilst some may "live" only in cyber space, away from the physical workplace. The ability to serve these "customers" in the most efficient and sustainable fashion will be the future norm against which FM "services" will be measured.

A unified international definition nor unified core competencies however exist. From the contents of this paper the following definition has been created as focal point for future research: *Facilities management is the process that creates and continuously optimizes the productive utilization of physical operational spaces, services and infrastructure for its intended purposes*.

It is noteworthy that many formal associations apparently have not identified "core competencies" required to structure a unified body of knowledge. Unlike for instance project management, facilities management internationally has not developed a consensual body of knowledge. This is an important deficiency, placing providers of education in a position where each has to select its own, often in isolation.

The knowledge base of the traditional built environment professions offers an excellent point of departure in order to address the challenges offered by facilities management. Facilities management is a "new profession" in the built environment family of professions. It has however been neglected in this regard in South Africa, thus developing in "isolation".

The knowledge gained from offering continuing education short courses, expanded with the analysis of a literature survey, non-quantified observations of academia and practice, and quantitive and qualitative surveys, this attempt in assessing a proposed primary body of knowledge for facilities management rendered useful information. Being a "new" discipline makes it a moving target that requires continuous evaluation and development, particularly regarding the structuring of tertiary education programmes.

The knowledge gained by the University of the Free State from offering continuing education short courses and a three year tertiary education programme have now lead to the structuring of a BSc-degree programme. This is a work in progress, of which the final curriculum will be developed during 2011, with first enrolments envisaged for 2012 or 2013.

Abstract

Description of the paper

A development corridor is important, particularly regarding its impact on future property development and socio-economic growth. The objectives of this study include the following:

- *A theoretical overview on development corridors;*
- *A literature review on economic wealth creation within a broader region. The South African-Mozambique Development Corridor is used as a case study;*
- *An overview of the planned comprehensive extension of existing corridors and its impact;*
- *The influence that a corridor development could potentially have on property development.*

Application

An entire region must take part in the development process of corridors in pursuance of stated objectives. For a development corridor two primary development centres must be linked by means of an axis, preferably with other secondary development centres in between. There must be mutual dependency between the centres in order to achieve development objectives.

Results, observations and conclusions

Nodal points are important for a corridor in order to provide property development and employment opportunities that stimulate growth and spatial interaction within the corridor. Recommendations could be made regarding the requirements for sustainable development.

Keywords: Development corridor, nodal points, property development, socio-economic development, spatial development initiatives.

INTRODUCTION

In mid-2008 Trans African Concessions (Pty) Ltd (TRAC) requested a multi-disciplinary research team of the University of the Free State and the Council for Scientific and Industrial Research (CSIR), Built Environment Division to initiate a socio-economic impact study on the Maputo Development Corridor (MDC) along the N4 toll road. TRAC is, since 5 May 1997, the Concessionaire of the R3 Billion ($1=R7.50: April 2010) project to build, finance, operate, maintain and expand the 590 km N4 toll road stretching from Pretoria in the Gauteng Province, in South Africa, through the Mpumalanga Province to Maputo in Mozambique (Figure 1 refers). It runs through some of the more industrialised and productive regions in Southern Africa, including mining and agricultural areas and large concentrations of manufacturing, processing, mining and smelting industries, which are located in the cities of Johannesburg and Pretoria on the western end (nodal points) of the corridor (Nathan

Associates Inc: 2008). The other nodal point is the city of Maputo, which also contains the harbour port of Maputo on the east coast of Africa.

The MDC is presented as a case study regarding the probable impact on property and social-economic development.

The vision of the MDC is to rehabilitate the core infrastructure, i.e. road, port and dredging, electricity and the border post within the corridor, through public private partnerships (PPPs), thereby re-establishing key linkages and opening up inherent under and unutilised economic development opportunities. Underlying the vision is the desire to see this initiative contributing to other key policy areas – notably regional economic integration, international competitiveness and a broadening of the ownership base in the economy of the corridor. In order to facilitate the implementation of the project in partnership with the private sector, protocols were signed between the Governments of South Africa and Mozambique (TRAC N4 Toll Road: online).

The Southern African Developing Community (SADC) is interested in the possible positive outcomes of corridor development: "The SADC Secretariat intends to undertake a study to develop the Corridor/SDI program as a development strategy to accelerate regional economic integration and development. The success of this development is dependent on the cooperation and political commitment of member states on the Corridor/SDI Program" (SABC News: Online 05/06/2007).

The objective of the National Physical Development Plan (RSA, 1975:17) was to link existing metropolitan areas with identified or future growth poles by means of development axes. Geyer (1986:163) found that some of these axes were not supported by secondary development centres or were stretching over too long distances to make development realistically viable. The greater the distances between centres, the stronger these secondary centres must be as a propelling force. In some cases these so-called axes were not axes at all but rather finger developments with no equilibrant pole at the other end. The development of a good road network which provides better interaction with the hinterland in many cases led to the decline of economic activities in small towns as the threshold "time" to bigger centres was changed. The Spatial Development Initiatives (SDI's) of the South African Government, conceived in 1995 by the Cabinet was an attempt to improve investment in those areas where the greatest potential for growth exists (Jourdan, 1998:717). The MDC is a typical axis development between two big centres, taking economics into consideration, as Maputo is the closest harbour to Gauteng. In the 1970s 40% of the export from Gauteng went through this port, but this faded away due to socio-political reasons. (Jourdan, 1998:720). However, strong growth has subsequently been experienced, following new political dispensations.

The analysis indicates that areas closer to the N4 corridor (axis) had higher growth than those further removed. This is the case for total output as well as for several sectors. Gross Value Added (GVA) per capita also indicated a similar situation – areas close to the road corridor had a higher growth rate than those further removed.

DELIMITATION OF THE STUDY

Figure 1 provides an indication of the physical extent as geographically defined at the start of the Maputo Corridor Project. The MDC is a major import/export route that connects the

North-East provinces of South Africa with the capital and main port of Mozambique. It serves Gauteng (industrial heartland of South Africa), Swaziland and South-West Mozambique. Reference is also made to the potential of other development corridors in Africa, more particularly Southern Africa. The MDC is used as case study in this paper.

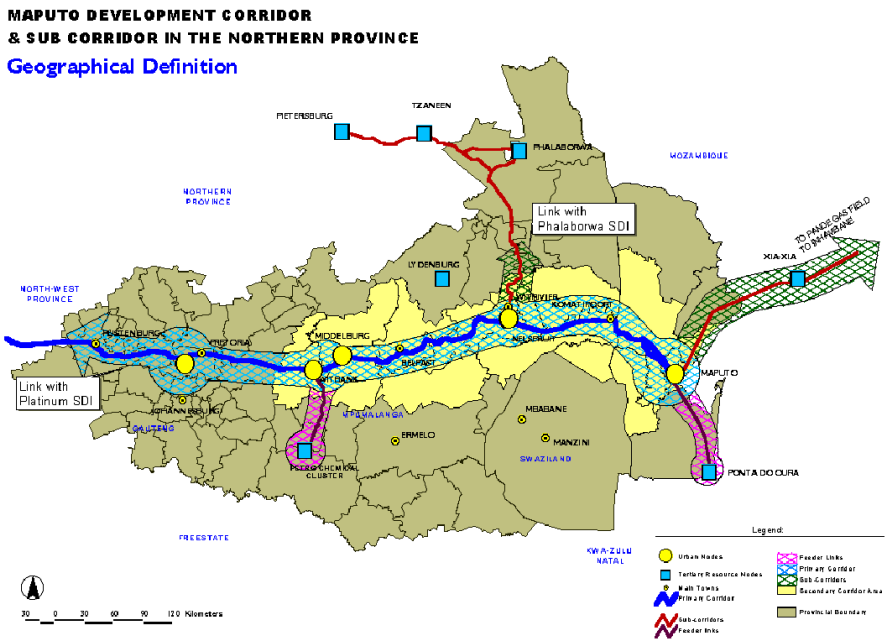

Figure 1: *Geographical definition of the Maputo Development Corridor (MDC) (Source: Technical team to the ICC, 1996)*

RESEARCH METHODOLOGY

This paper revisits concepts related to corridors and their theoretical foundation. Some sectors and components of socio economic development have been included as well as main activities that occurred since the inception of the MDC. Although some studies investigated the impact of the MDC it is clear that subsequent deductions are matters of interpretation. Some changes cannot clearly be related to the MDC. There are clear deficiencies and constraints (example: the coverage of Mozambique and Swaziland) currently. A literature comparison is made regarding the interim perceived unsuccessful outcomes of the corridor, the present positive aspects, areas that may be improved upon, and the viewpoints of a stakeholder forum. The focus of this study is mainly on the road component of the corridor, whilst acknowledging that it is not possible to divorce it completely from for instance the rail linkage.

PROPERTY DEVELOPMENT

Throughout this research it was found the "property development" as an outcome of corridor development is not isolated by researchers and other commentators. Although emphasis is often placed on socio-economic development, the measurable outcomes are likewise poorly quantified in specific terms. This also applies to other industries such as agriculture, mining, etc. There are thus very little available regarding industries specifically. What is however abundantly available is data regarding measurable outcomes in certain nodal/centre developments, such as increases in harbour activities, freight movements through border posts, etc. A quantified data survey was launched, with continuous pressure applied, to obtain specific quantified data regarding property development. The limited results are reported in

this paper. However, though there could be subscribed to the view held by some researchers that "a corridor is a corridor", it is clear from the research reported in this paper that comprehensive "overall" impacts are abundantly visible. This is described elsewhere as "trickle down" effects, acting as catalyst for each other. It appears as if "tools" have not yet been developed to measure specific overall industry outcomes, other than those very directly measurable, as stated above.

THEORETICAL ASPECTS OF DEVELOPMENT CORRIDORS

Development corridors are difficult to define spatially as they are often based on the use of transport infrastructure. Such road or rail connections, though development corridors, cannot be restricted to the narrow band where such infrastructure is located. Its developmental linkages are much broader than the area adjacent to the transport infrastructure. It is clear, from literature that different approaches exist. For the purpose of this study it is important to consider the corridor as originally envisaged and conceptualised. Geyer (1988:123) sees the development corridor or axis as a dynamic phenomenon that evolves in different stages over time, which can be seen as a concept to elevate an area to a certain level of development. Four stages are identified and shown in Figure 2, namely:

- The potential axis (A) or the development finger with the potential for the establishment of a development centre at the other end (B);
- The axis in an infant stage with a well established communication axis between two primary centres (C);
- The mature stage with the corridor or axis having one or more secondary centres in between (D) and
- The axis in its old age or dormant stage where an over-concentration on the axis may lead to the development of agglomeration, diseconomies or polarization reversal (E).

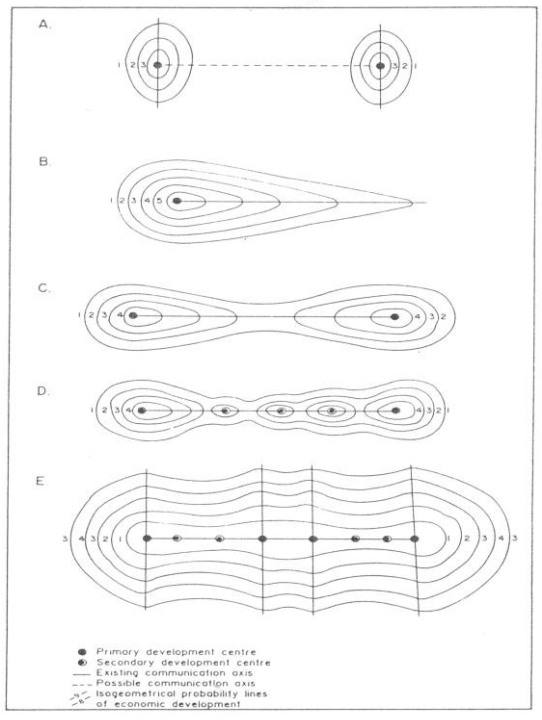

Figure 2: *The evolution of the Development Corridor (Geyer, 1988:123)*

Geyer (1986:163) found that some of these axes were not supported by secondary development centres or were stretching over too long distances to make development realistically viable. The greater the distances between centres, the stronger these secondary centres must be as a propelling force. In some cases these so-called axes were not axes at all but rather a finger development with no equilibrant pole at the other end. The development of a good road network which provides better interaction with the hinterland in many cases led to the decline of economic activities in small towns as the threshold "time" to bigger centres was changed. An understanding of economic forces is vital to any development planning as people and businesses will only locate in areas where it is economical viable. The MDC could presently be rated as a Figure D corridor development.

GOVERNMENT INITIATIVES: SPATIAL DEVELOPMENT INITIATIVES

The regional Spatial Development Initiatives (SDIs) are projects identified on the basis of their inherent unutilised economic potential. Their developmental objective is to create sustainable jobs in these areas by identifying and facilitating new investment. The mechanism by which this is achieved is focused, co-ordinated action at all levels of government and by all relevant line functions within the spatially defined area, in order to remove blockages to investment. SDIs are a key industrial policy committed to foster sustainable industrial development in areas where poverty and unemployment is at its highest. This objective is carried out through the SDI, which focuses high-level support in areas where social-economic conditions require concentrated government assistance and where inherent economic potential exists (South Africa: 2007, online).

Primarily all the major projects in the SDI are based on a partnership between the public and private sectors such as the MDC, and are set to provide opportunities for participation in sectors such as agriculture, mining, tourism, environment, forestry, infrastructure and ports. The MDC was expected to create more than 68 000 new jobs. A key component of this initiative is the move towards international competitiveness, regional co-operation, and a more diversified ownership base (South Africa Information/doing business/economic development: 2007, online).

Certain SDIs are also beyond the confines of the borders of a country where the economic imperatives of the strategy dictate that the SDI includes part of a neighboring country. The MDC between South Africa and Mozambique also affects Swaziland, Zimbabwe and Botswana.

In order to investigate the impacts resulting from a development corridor this report is thus further structured to provide a "mid-term" overview, followed by an African continental perspective, MDC nodal acknowledgement in future planning, and 2010 observations, supported by some empirical data. The research findings are provided under conclusions.

A "MID-TERM" OVERVIEW

Söderbaum and Taylor (2003) compiled, with the aid of seven co-writers, a book, Regionalism and uneven development in Southern Africa, providing an in depth analysis on the topic, concentrating primarily on the MDC. The perspective that they hold provides an important balance sheet, reflecting, albeit negatively, on the impact of the MDC. The following page referenced abstracts, in some instances re-worded and/or abbreviated for this paper, bear relevance:

P6: The MDC is based on four key objectives:

1. To rehabilitate the primary infrastructure network along the corridor, notably road, rail, port and dredging, and border posts, with the participation of the private sector in order to have minimum impact on the fiscus.
2. To maximise investment in both the inherent potential of the corridor area and in the added opportunities which infrastructure rehabilitation will create, including the provision of access to global capital and facilitation of regional economic integration.
3. To maximise social development, employment opportunities and increase the participation of historically disadvantaged communities; and
4. To ensure sustainability by developing policy, strategies and frameworks that ensures a holistic, participatory and environmentally sustainable approach to development.

Concluding remarks by Söderbaum and Taylor (2003) summarize the outcomes as follows:
P107-108: The uneven development impulses reinforced by the MDC and the ineffectiveness of its governance radically undermine the potentiality of the MDC as a "model" SDI for the rest of the Southern African region. We are sceptical that such a spatially focused framework engineered, in the main, by the private sector can stimulate genuine long-term and sustainable development. In a region characterised by a labour surplus (albeit largely unskilled), highly capital intensive and "big-bang" development projects do not seem particularly apposite.
P108: In effect, the prevailing paradigm, which the MDC is founded upon, contains a very strong emphasis on the notion that the state is inefficient and needs to be deregulated and made more competent.
P108: It is this reconfigured posture that confirms that the MDC has seen the state in both Mozambique and South Africa reduced to what can be seen as a transmission belt for capital, neglecting in the main questions pertaining to social and participatory development.
P109: Building on general insights from critical international political economy, many of the chapters in this volume draw attention to the reality that the political purpose behind the state's involvement has not been to promote development and public goods or needs, but has rather been first and foremost to promote an enabling environment for the private sector.
P110: …, it is thus clear that the governance structures and the Public Private Partnership (PPP) operating in the MDC have had a mainly negative effect on governance, democracy, ownership and participation.
P110: As a matter of fact, the political support provided by the "political champions" and the specially designed SDI methodology has not worked satisfactorily. The important thing here is that despite concerns expressed by the private sector to government to take the MDC initiative more seriously, the MDC has increasingly become characterised by a lack of political leadership in South Africa.
P112: For sure, the MDC is officially held to be a development corridor, but in practice it is an investment and "market guidance" initiative with the hope that it will create jobs and somehow lead to "development". In fact, certain leading government officials behind the MDC admit that the MDC is not about development at all: it is to be understood as the Maputo *Investment* Corridor.
P113: In short, just because regional elites proclaim the MDC to be a "development corridor" does not make it so.
P114: The "market" cannot be left to its own devices if development and empowerment within the MDC (and indeed other SDIs) are to be realised.
P114: It is not good enough to predicate the micro-region simply around "growth" and "big-bang" investment, and then simply *hope* that "trickle-down", job creation and empowerment will occur.

P115: It is thus very unclear whether the spatially focused approach, driven by private investment, will be able to trigger genuine "development" in the targeted areas. Indeed, the SDI strategy is a highly capital intensive development strategy that may not be suitable for regional economies whose main endowments are labour and natural raw resources.

The foregoing, overly negative perspective published in 2003, seven years after the launch of the MDC in 1996, fails to acknowledge or fundamentally evaluate the real effect of the "trickle down" impact. In fact, it also fails to recognize or provide guidance as to how the stated objectives 3 and 4 should be practically brought to fruition. Guidance is also not provided regarding how the desired social development and employment resulting from the MDC is measured, or measurable. The positive outcomes regarding key objectives 1 and 2 are evaluated, for thinly disguised reasons, by Söderbaum and Taylor (2003) as negative, probably because 3 and 4 are emphasized as failures.

AFRICAN CONTINENT

Jourdan (2008: 20) reports as follows, further reflected in Figure 3: "An African Development Corridor desk-top study was undertaken by the RSDIP[1] & Mintek (for NEPAD) in 2006 to investigate the potential and status of continent-wide development corridors, examined in a preliminary fashion the potential of DCs across Africa. It makes the case that Africa's physical and social infrastructure needs are so large that they cannot be met in any reasonable timeframe without substantive contributions from the private sector."

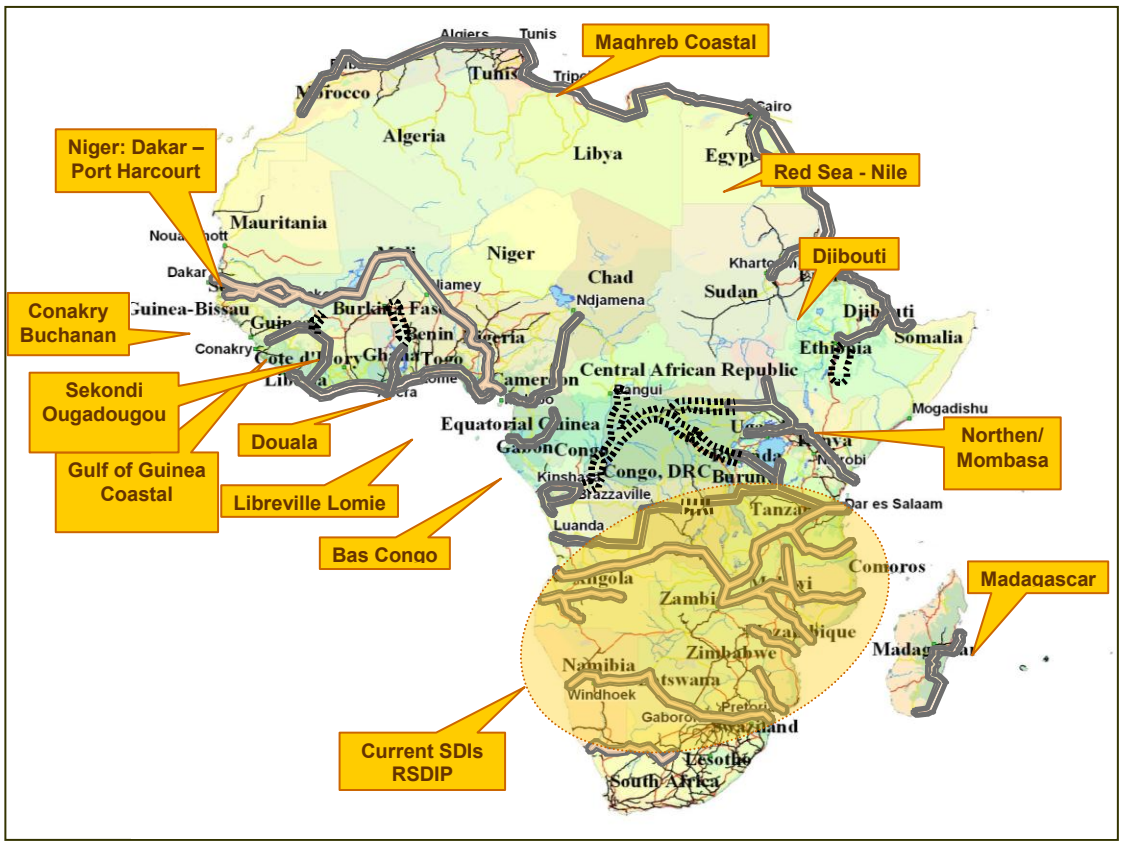

Figure 3: *Potential Resource-based African Sustainable Development Corridors*

[1] RSDIP: Regional SDI Programme of the SA Department of Trade & Industry

The Japan International Cooperation Agency (JICA) (2010:1-276) has prepared a comprehensive study titled: Preparatory Survey for Southern Africa Integrated Regional Transport Programme. This study was conducted to cover the region reportedly with the highest cross-border traffic in Africa, covering the 8 most southern countries. Significant growth has taken place in this region over the last decade, but was also negatively impacted on by the global financial crises of 2008. The study confirms a substantial growth in Direct Foreign Investment (DFI) in the region since 2005. However, to ensure sustained development, the report identifies corridors as a key requirement for growth. JICA (2010: ES-4) states: "The existing 18 corridors in the region connect local mineral and agricultural resources with global markets. The study proposed re-defining the role of regional economic and transport corridors according to growth scenarios (strategies), building on the growth belt concept, which encompasses the integration of resources, value creation, and global markets". Constraints that are identified to achieve these objectives relate strongly to border crossing delays, often for many days, maintenance of infrastructure, poor port performance and taxation regimes. Solutions are offered to address these negative findings. Figure 4 indicates the existing 18 corridors, for which in each case comprehensive trade movement data is available. Some of the corridor positions are (probably) not geographically 100% correct, but the overall presentation is acceptable for the purpose of this paper. From a socio-economic perspective, comprehensive data is available for each of the countries regarding demographics, scale of economic activity, governance and the business environment. From this a corridor development priority programme has been created for Southern Africa. Social conditions were further analysed per country in order to quantify population growth, governance standards, economic activity, trade, investment and regional co-operation and integration.

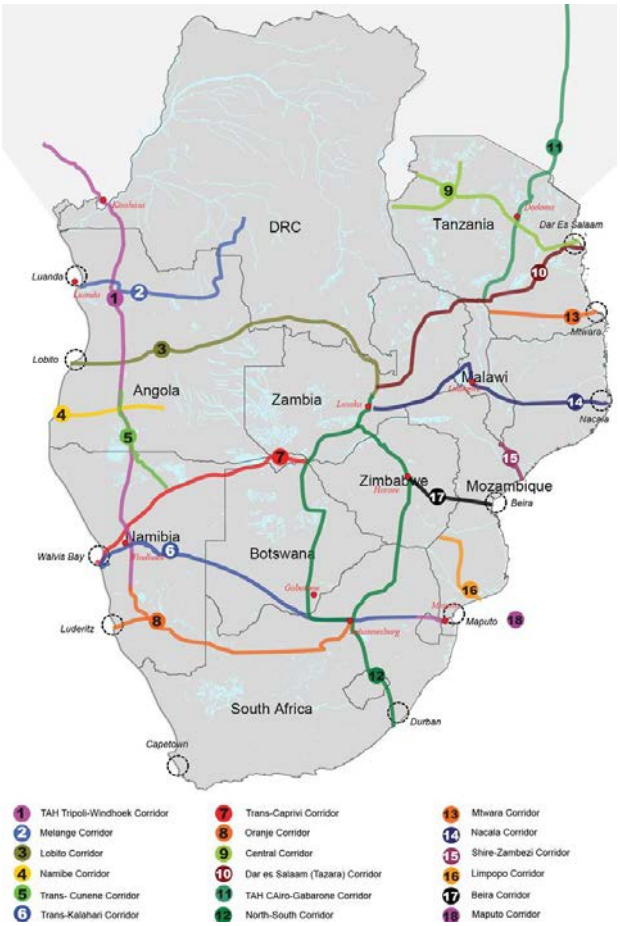

Figure 4: *Southern Africa Transport Corridors and Major Ports (JICA, 2010: 2-22)*

EXTENSION OF MDC: NODAL POINT ACKNOWLEDGEMENT

From The World Bank (Africa Region) Summary Report, the further extension of the MDC is anchored in a "growth poles strategy" that supports the position in this paper that development centres/nodal points/growth poles are key drivers of corridor development. Evidence indicates that "a road is a road" that connects poles. Development tends to take place mostly in the nodes/poles, with the axis benefitting socio-economic development, along the corridor in a catalytic fashion.

The World Bank Summary Report (2010: 4-21) reflects the above position, supporting the principle of a nodes/poles analysis when assessing corridor development. The following page referenced aspects of the report is indicative thereof. Noteworthy is the lack of specific "social upliftment" strategies, silently supporting the view that private economic development is the driver of development in general. "Social engineering" is not mooted in this report and it could therefore be assumed that "social development" is regarded as an automatic "trickle down" beneficiary of private sector-led economic growth initiatives.

P4: The objective of this study is to assist the Government of Mozambique in designing and implementing growth pole strategies in selected subregions, based on current and proposed programs and international experiences. The study focuses on subregions situated on the three main development corridors: Beira, Maputo, and Nacala. These subregions were chosen based on their concentration of private investments, opportunities for private sector-led growth, current development challenges, and ongoing interventions, as well as their potential to demonstrate the benefits of an integrated growth poles approach.

P4: The main goals of an integrated growth poles strategy for Mozambique are to promote private sector-led growth and employment while maximizing the development outcomes for sustainable and equitable growth, especially in underserved provinces. It consists of six pillars: (i) enhancing subnational economic competitiveness through business environment reforms; (ii) nurturing and developing local and indigenous enterprises by fostering linkages with large foreign investments; (iii) strengthening local institutional capacity; (iv) upgrading urban infrastructure; (v) strengthening economic governance; and (vi) improving management of the social and environmental impacts of large investments.

P4: In terms of national development objectives, the growth poles strategy supports the Government's program for shared and equitable growth throughout the country. It addresses critical development challenges at the subnational level and seeks to strengthen the competitiveness of regions within the corridors. It also accelerates the outcomes of ongoing spatial development initiatives (SDIs) through targeted interventions. The proposed growth poles strategy in Mozambique will complement existing initiatives by the Government and its development partners, including the World Bank, at the national and local levels. One of its main objectives is to support local authorities in planning, coordinating, and finding synergies among the government, donor, and private sector interventions in the context of decentralization. Where possible, the growth poles strategy will build on lessons learned from local initiatives, and complement or scale up those that support an overall local development strategy.

P4-5: Over the past decade, economic growth has been driven primarily by a number of large investment projects in agriculture, infrastructure and mining, as well as by large inflows of overseas development assistance (ODA). Megaprojects have helped stimulate economic

growth but account for less than 2 percent of urban private sector employment. The challenge is therefore to enhance job creation and technology transfers associated with large productive investments. In 2007-2009, the total value of investment projects authorized by Mozambique's Investment Promotion Agency (CPI) amounted to $14.9 billion. If a significant proportion of these projects are realized and well managed, they would have the potential to transform the socioeconomic environment in Mozambique and create many thousands of new jobs.

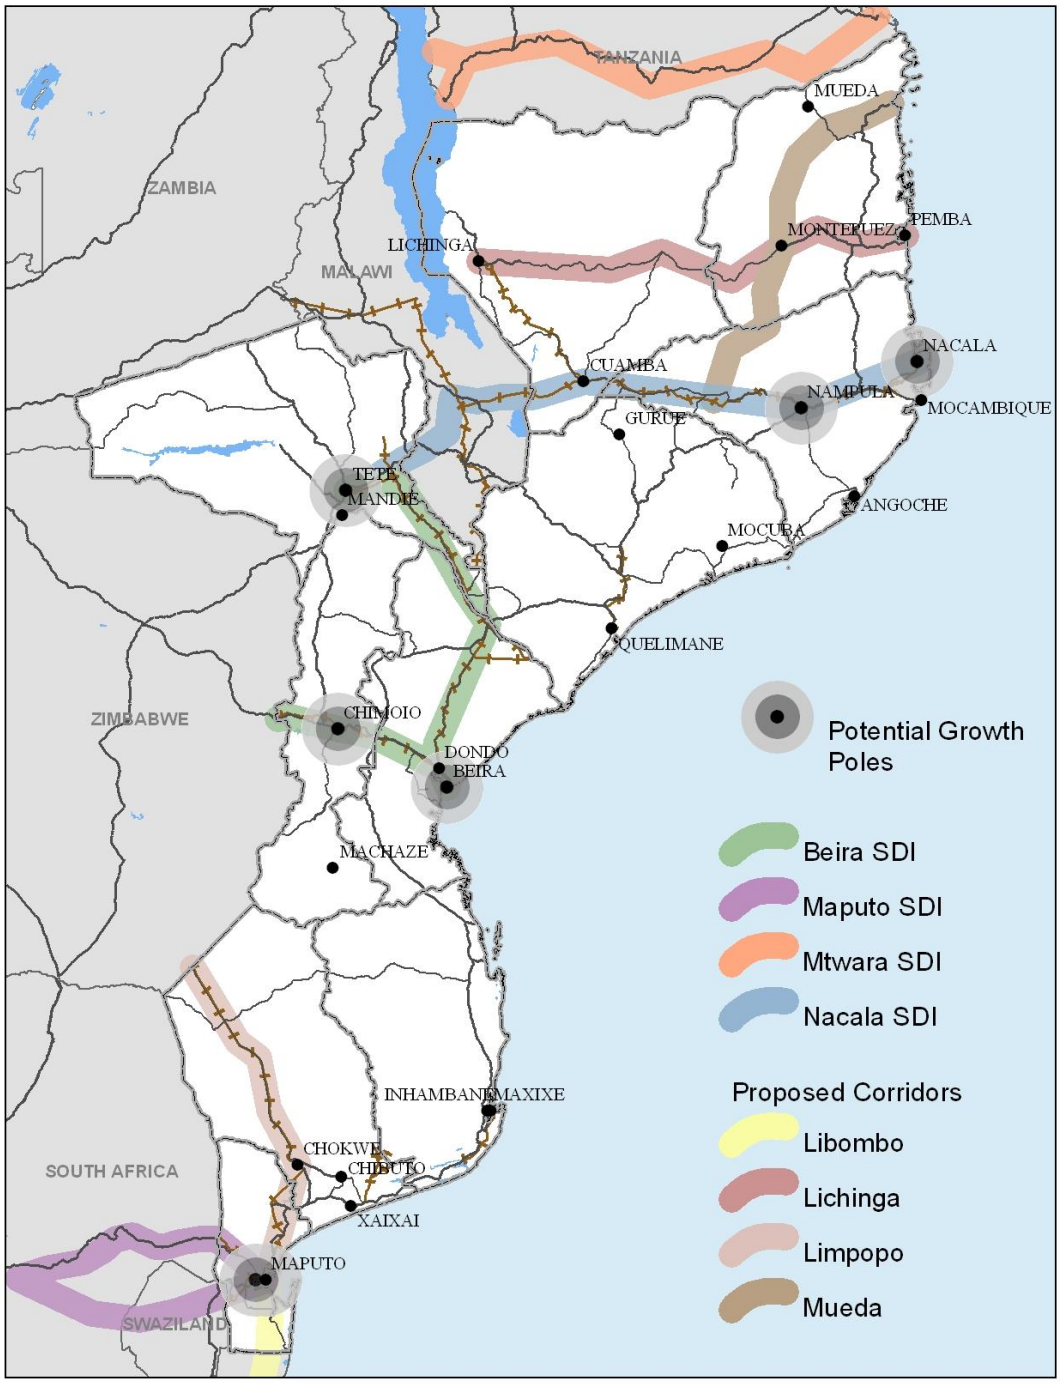

Figure 5: *Development corridors and potential growth poles*

The report emphasizes a variety of growth pole strategies, some specifically related to certain provinces. The following steps are however proposed in regional Mozambique context:
P21: ***Build awareness and stakeholder consensus on a growth poles approach.*** To chart a way forward, it is necessary to discuss the study's preliminary findings and proposals with key stakeholders in the national and provincial governments, the private sector, and the development community. Key issues are to ensure that: (i) the growth poles strategy is integrated into the spatial planning work being undertaken by COCEP; and that (ii) there is consensus among the key stakeholders, including the donor community, on the identification of potential growth poles and the implementation of the strategy.
Provide detailed identification of potential growth poles. A more detailed assessment of the potential for growth pole development is needed.
Ensure Government ownership and leadership. Adoption of a growth poles strategy by the Government of Mozambique will require high-level political commitment and support, possibly at the level of the prime minister or presidency.

OBSERVATIONS 2010

An interview took place with the Chief Executive Officer, Brenda Horne (2010) of the Maputo Corridor Logistics Initiative (MCLI) to obtain a perspective regarding the ensuing years since 2003, thus observing the resultant outcomes up to 2010. The MCLI, a non-profit company was registered to create a body where all stakeholders may contribute to develop the MDC in their collective best interest. MCLI subscribes to the following mission: "To support the development of the Maputo Corridor into a sustainable, highly efficient transportation route, creating an increasingly favourable climate for investment and new opportunities for communities along the length and breadth of the Corridor". Figure 6 indicates the MCLI membership structure.

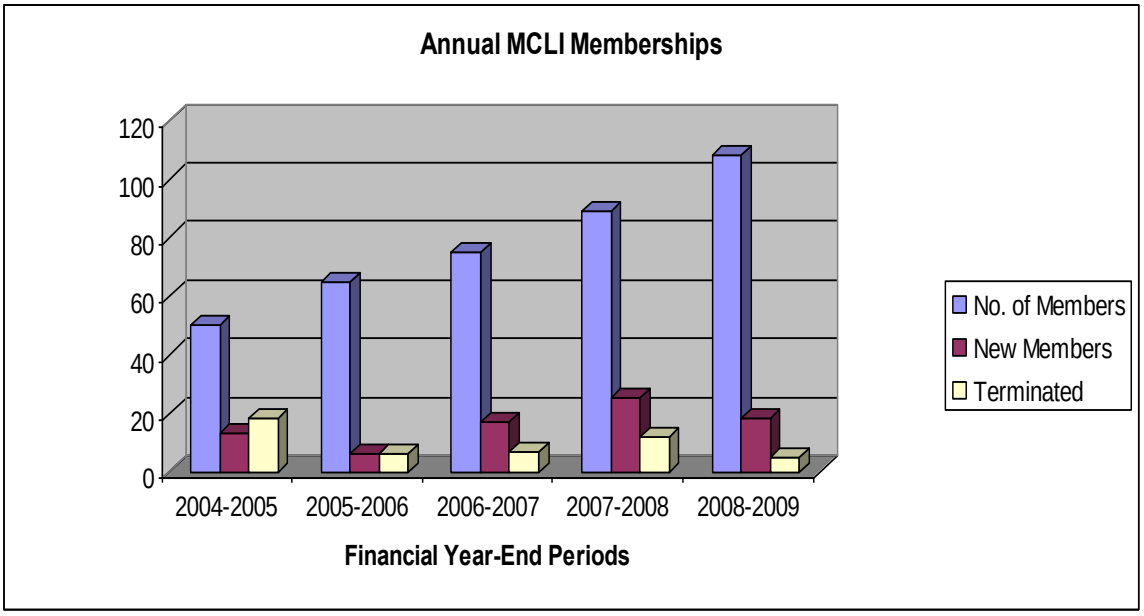

Figure 6: *MCLI International Membership*

In pursuance of the above the following provides an overview of the MDC as perceived by the MCLI presently, as was published as a MCLI Editorial in Export News, February 2009:

- The Port of Maputo is only 590 kms by road from Gauteng and 581 kms by rail and presents the shortest route to a port for South African exporters from the industrial heartland, Gauteng.
- To date, the private sector has committed an estimated figure of well beyond US$5 billion worth of investments in southern Mozambique and Mpumalanga.
- Some US$70m has been invested in the priority works programme at the Port of Maputo since April 2003, including dredging and marine operations, cargo handling, terminal and warehousing functions as well as port planning and development. Before the end of 2004, the port was working 24/7 in full compliance with the highest international security standards, the first African port that is International Ship and Port Facility Security compliant.
- Total tonnage handled through the port in 2008 was 7 591 000 tons; a 13.25% increase on the previous year. The port had been confident of achieving 8 000 000 tons prior to the dramatic slump in throughput in the last quarter of the year.
- Trans Africa Concessions, (TRAC) a founding member of MCLI, has spent US$400m on the rehabilitation and upgrading of the road from Gauteng to Maputo, with at least another US$400m to be spent on the road over the balance of the 30 year concession. The fact that this road has drastically reduced traveling time between the two countries has contributed significantly to the increase of traffic and consequently to trade. TRAC has indicated that traffic volumes have increased by between 5 and 7% per annum, with truck traffic increasing by 10% per annum on this road.
- By 2007 passenger transport between South Africa and Mozambique had increased by 80% since the lifting of visa requirements between the two countries in April 2005. This phenomenal increase has put pressure on the existing infrastructure at the Lebombo/Ressano Garcia border post, which is being addressed in the planning and implementation of a joint 24 hour one-stop border post scheduled for completion during early 2010.
- The World Bank's World Development report for 2007 listed Mozambique as the African country with the highest economic growth levels, with an average of 6% between 1995 and 2005. Real GDP growth was 7% and 6,5% in 2007 and 2008 respectively.

The MCLI has received one of three prestigious awards in 2009: The New Partnership for Africa's Development (NEPAD) Transport Infrastructure Projects of Excellence Awards. MCLI's Mozambican Chairman, Dr Antonio Matos, was delighted with the recognition given to MCLI's work, stating: "The Maputo Corridor has been a catalyst for economic growth in the region through the significant investment in infrastructure on the corridor and it is a great honour for MCLI. We are delighted that the efforts of this public-private sector organisation are being recognised by organisations such as NEPAD, and we believe that MCLI is a model for transport corridor development in Africa and we share this award with all MCLI's corridor partners." The Chief Executive Officer of MDC, Brenda Horne was also honoured for her contributions to develop the MDC, having been nominated as South African (Shoprite Checkers) Business Woman of the Year, 2010.

The impact of the MDC infrastructure improvements during the past twelve years could be summarized as follows:

- More than US$5billion invested in the Maputo Development Corridor
- 24 Hour Joint One Stop Border post (construction) in progress.
- Increased road safety, at 5% pa traffic growth rate. Freight increases at 10% per annum.

- Harbour concessions are in place and successfully managed by the private sector with a further developments and investments underway and increases planned for infrastructure investment during the next 20 years.
- Increased traffic in the Port of Maputo and its terminals (3 million tons in 1996, 8.3 million tons in 2009 and a 20-year port master plan anticipating 48 million tons.
- Increased shipping services and direct calls to the Far East introduced in 2009 have resulted in the container terminal, realizing the highest ever container movement at the terminal of 103 000 TEU's in 2009.
- Increase in tourism & trade (South Africa/Mozambique).
- Further investment in Port & terminals > US$750m.
- Continued investment and trade into Mozambique and substantial economic growth of Cities/Towns along the MDC.
- 2008 TRAC Gross Value Added desktop study declares that areas in close proximately of the transport corridor grew at higher rate than areas further removed.

REAL TIME VIEWS REGARDING PROPERTY DEVELOPMENT

A questionnaire was compiled to evaluate the views of MDC stakeholders in a **Likert 5-point scale** format, during 2010. The questions were designed to address issues dealt with in this paper. The resultant feedback was very disappointing as only six surveys were received by the time of publishing this document. However, what could be construed as indicative from this opinion survey are the following responses to selected questions (relevant to this paper), reflected in Table 1. The respondents were requested to rank their evaluations on the 1 to 5 scale: 1=little, 5=very much.

Question 1:
General economic growth over the last 10 years in your region attributable to the MDC/N4-corridor: 3.67

Question 5:
Will **future upgrading** of the MDC/N4-corridor stimulate new product development for industries? 4.00

Question 6:
Does the MDC/N4-corridor contribute to **wealth creation** in general in your region?
3.83

Question 7:
Does the MDC/N4-corridor contribute to **job creation** in your region?
3.67

Question 10:
To what extent has the MDC/N4-corridor specifically/directly caused **real estate development** (properties, buildings) to take place in the following economic sectors (in order of perceived importance):

1. Parastatals	2.00
2. Forestry	2.17
3. Agriculture	2.17
4. Mining	2.50

5. Education	2.67
6. Governmental	2.67
7. Manufacturing	2.83
8. Health care	3.00
9. Housing	3.17
10. Industrial	3.50
11. Commercial	3.67
12. Tourism	3.83
13. Maputo harbour	3.83

Question 12:
To what extent will the possible **further development of corridors** higher into Africa have on **real estate** development in **your region**?
3.83

Question 13:
To what extent will the possible **further development of corridors** higher into Africa have on **infrastructure development** in **your region**?
4.00

Table 1: *Maputo Development Corridor Stakeholder Survey*

From the data reflected in Table 1 it is clear hat the overall effect of corridor development strongly support socio-economic and property development.

CONCLUSIONS

From the data regarding Africa as continent, and more specifically Southern Africa, it is concluded that the success of corridors as transport routes, and importantly, creators of general socio-economic development, is undisputed. It could in fact be stated that without the successful development, maintenance, border crossing improvement and optimal functioning of ports, socio-economic development and regional trade growth and integration will be seriously compromised for the entire region, and indeed Africa as continent. The MDC results confirm the above.

A noteworthy shortcoming in literature in general is the lack of quantification of benefits per capita. Data tends to provide typical collective perspectives. Though the authors have attempted to collect quantified data per questionnaire, in the mode of an opinion survey, the response to that was marginal.

It is difficult to specifically adjudicate positive developments that emanate from the MDC into detailed socio-economic segments. It is, except for very pronounced projects, also difficult to ascribe property development to the MDC on a project basis, as most projects in the MDC axes are dictated by the general growth resulting from the MDC. Local municipalities (especially those on the N4 corridor) see the MDC as an important component in their planning and marketing. The positive effects of the corridor are clearly there, and in many instances measurable, but very difficult to quantify according to specific growth in specific sectors. It is rather in the style of a mass movement, than individual events. Data could not be found or generated to determine the exact contribution to, for instance, property development. Collectively the data supporting growth resulting from the MDC is undisputed, physical

development is there to observe, particularly pronounced around nodes on the axes, and at terminal nodes. The results from this research outline the positive outcomes emanating from corridor developments. It is clear that regional socio-economic development, particularly in Africa, will benefit extensively from corridor developments. It is difficult to foresee how such developments can take place in a sustainable fashion without it. Southern Africa already displays excellent results in this regard. It is also concluded that the "trickle down" effect of development corridors calls for further research, with particular focus on quantification of the effect thereof on the different economic sectors.

It is noteworthy that The World Bank is in line with the "nodal point" perspectives supported by this paper. It also appears as if they subscribe fully to private sector-led economic development, with employment creation regarded as an automatic beneficiary, rather than the prime focus.

Abstract
The UK has set a target for a reduction in CO_2 emissions by 80% by 2050 compared to 1990 levels. The domestic sector accounts for 25% of UK emissions from the generation of heat and electricity for homes. For this sector to move to a low-carbon path, it will need to transform the environmental performance of housing. The transformation will require system-wide innovation and change comprising new technologies, new markets and new institutional supporting systems. There is an urgent research needed to better understand, and therefore, steer this system innovation. The ongoing research project reported here contributes to this need by addressing the impact of the growing raft of environmental regulations on the UK housing development. The primary focus is on microgeneration technology (MGT) field within this sector. This research recognizes that the challenge of integrating MGTs is not merely a technical one for housing developers; rather, it has significant technical, social and economic implications for housing developers and their supply chains, as well as for home buyers.

Keywords: Innovation, diffusion, sustainability, housing, technology.

INTRODUCTION

The UK housing sector has a significant role to play in the UK Governments legally binding target to reduce CO_2 emissions by 50% by 2050 compared to 1990 levels (DECC, 2008). If the CO_2 emissions generated by new homes built between now and 2050 are not curbed then there is a significant possibility that this could offset any progress made in other sectors. In order to induce the UK house building sector to move onto a more sustainable trajectory the Government introduced the zero carbon homes agenda articulated through the Code for Sustainable Homes (CfSH or the Code). The CfSH is coupled to a series of planned changes to the Building Regulations (in particular, Part L) demanding increasingly higher levels of environmental performance, culminating in zero-carbon (yet to be defined) by 2016. CfSH is not mandatory in terms of it prescribes performance thresholds which new housing must achieve, but a rating for new homes against the six levels of the Code is mandatory. However, the changes contained within it are mirrored by the upcoming changes to Building Regulations which are mandatory. In this paper when we describe the changes required under the CfSH and the changes to the Building Regulation which will mandate that the targets and levels of performance specified in the Code are adopted for all new homes. Further, we discuss the early stages of an ongoing research project investigation microgeneration technology innovation systems in the new house building sector.

THE CODE FOR SUSTAINABLE HOMES

In 2005 the case for developing the CfSH was presented by the Government and, following a consultation period, policy was confirmed from 2008 onwards all new homes were to be rated against the CfSH was made (ODPM, 2005). The Code is based upon six levels of performance and assessed against nine different areas. These areas include improvements in building materials and energy/CO_2 emissions but also address waste production, water management and ecology among others. In order to achieve a CfSH home rating of 4* a 44% reduction in CO_2 emissions, based on 2006 Part L Building Regulations requirements, is needed (CLG, 2006). The precise definition of zero-carbon is still be determined (*** ZCH report reference ***). The expression of emissions target as a percentage reduction has been identified as potentially confusing (Zero Carbon Hub, 2010). In order to make requirements more explicit a carbon compliance measure has been adopted. The carbon compliance measure expresses emissions as a measurement of kilograms of carbon dioxide produced per metre squared of internal floor space per annum ($kgCO_2/m^2$/year). This means that the CfSH home ratings of 4*, 5*, and 6* dwelling described above can be expressed in absolute terms of 20, 14 and 0 $kgCO_2/m^2$/year emissions respectively. A dwelling complying with the 2006 Part L Building Regulations would be expected to emit typically 25 $kgCO_2/m^2$/year. Currently all new homes are required to be 4*. By 2013 this will be increased to 5* and by 2016 further increased to 6*.

The sources of CO_2 emissions from the home are not evenly distributed. Typically 55% of the emission emanate from space and water heating, 28 % from appliances and the remainder from cooking, lighting, pumps and fans (NHBC Foundation 2009a). The challenge of reducing emissions resulting from space and water heating are distinct from those of reducing emissions from the other sources and the strategies for tackling them are correspondingly different (Zero Carbon Hub, 2010). Emissions from heating water and space can be reduced through better specified materials, improved workmanship in the construction of the dwelling and more efficient boilers. They can be further reduced by the use of heat recovery systems and a range of technologies such as air and group source heat pumps, biomass and potentially combined heat and power units. Once emissions from heating have been reduced offsetting the emissions stemming from the other sources, and any remaining emissions from heating, relies on the active generation of energy on- or off-site. The potential for onsite generation at a dwelling level depends on dwelling type. For example, the use of photovoltaic cells to generate electricity, for example, depends significantly on, among other factors, the area of roof space available per unit. This area is much higher in detached houses that it is in high rise apartment blocks. Different solutions may be more appropriate for sites with greater dwelling densities compared to sites with lower densities. Solutions may also be targeted at a community level (for example a biomass fuelled CHP unit) or, alternatively, off-site renewable generation. The use of off-site renewable generation to offset the emission generated on-site is termed an allowable solution within the CfSH. The exact nature and extent of the use of allowable solutions when meeting the emission targets set in the Code have not yet been specified.

To reiterate, the exact specification of a ‘zero carbon’ home is still developing. The definition of the carbon compliance level has helped. However, the lack of clarity surrounding the meaning of zero carbon, coupled with the unknown nature and extent of allowable solutions, creates a very uncertain business environment for house builders at the very time they are being asked to invest significant resources into developing new design and

production approaches. Indeed, the scale and scope of the challenge is such that it will require system-wide innovation in terms of new institutional arrangements, technologies and markets. To further compound this situation a great number of different technologies are competing to penetrate into the housing sector and provide a solution to lowering carbon emissions. The NHBC Foundation review of microgeneration technologies has 11 separate groups of technologies, many with multiple formats within each (NHBC Foundation, 2009b). No single technology will be appropriate for all situations. In combination, the uncertainty generated by the number of new technologies available and the lack of clarity regarding the meaning of zero carbon presents a very real commercial risk to the house building industry. The next section draws upon the technological development literature to provide a theoretical basis for understanding the potential dynamics at work as the new house building sector selects, absorbs and uses new, in this case microgeneration, technologies.

TECHNOLOGICAL DEVELOPMENT – KEY ISSUES FROM THE LITERATURE

Technological development within firms and sectors can follow two principal paths; either, multiple small, incremental improvements in products and processes, or through rapid, disruptive changes. Tushman and Anderson (1986) present a model of technological change where long periods of incremental change are punctuated by technological discontinuities. These punctuations are followed by periods of great uncertainty termed the era of ferment. In this period there is no dominant technology and a greater amount of competitive uncertainty. The emergence of a dominant technology reduces the competitive uncertainty and concludes the era of ferment. We speculate that the UK housing sector has entered into such an era of ferment with regard to microgeneration technologies. House builders are unsure which of the technologies, or group of technologies, are likely to assert themselves as the dominant way of achieving the energy saving and onsite generation required in the CfSH.

Dominant technologies emerge through a combination of both disruptive and incremental changes. The opening of the market through disruptive changes allows the entry of radical new technologies which have the potential of significant performance and/or cost benefits over the existing technologies. These technologies are often not proven and learning has to occur to exploit them – in combination, they create business risks and uncertainty. From the growing number of alternatives one (or perhaps a group) of technologies begin to establish a dominant position within the industry. This technology is then refined over time through a series of smaller, more incremental improvements. Dominant technology evolution is often not based on pure rational choice. A wealth of factors, including political, economic, technical and individual, contribute to the emergence of a dominant technology and its supporting practices.

The construction industry in the UK, particularly the house building sector, is presented as having a low level of internally sourced innovation. A great deal of innovation within the industry is driven by compliance to regulation rather than competition on performance. Using Pavitt's (1984) typology of industries the construction industry would be classified as supplier-dominated. Supply-dominated industries source most of their innovations from outside of their sector and act as carriers for innovations from other sectors. The supply chain of the construction industry is the primary source of product innovations. This is the case with microgeneration technologies. The new technologies will be supplied by companies external to the house building sector. In this environment where supply chains are the primary mechanism of innovation, factors such as marketing, incentivisation and

relationship capital can become even more influential in determining which technology emerges as dominant. Particularly as often the industry is looking to its supply chain to provide a solution to meeting a regulatory requirement and not to differentiate its product through performance.

The challenge of meeting the targets presented in the CfSH has the potential to cause both component and architectural innovations in the standard designs used by the house builders (Henderson and Clark, 1990). Component innovations are changes in individual elements of a design with no changes in the relationships between the components. Architectural innovation is a change in the relationship between the components with no changes in the components themselves. This classification of technologies is useful when considering the affect that microgeneration technologies have on the standard design of a home. Some technologies, such as photovoltaic cells, are 'bolt on' component innovations that demand little change in the standard design. Others, such as ground source heat pumps, may require alternative heating systems within the home, such as under floor heating, which requires different designs and construction processes each with their associates skills, competencies and knowledge.

There is currently no empirical research within the housing sector to support the industry in dealing with the challenge of dominant technology selection. Although it is unlikely that dominant technology selection can be managed in the strictest sense of the word understanding how it can be encouraged and what factors could steer selection would be of immense value. To begin to address this stemming from this work should be a deeper understanding of how dominant technologies emerge with the construction industry, how they gain purchase and traction and breakthrough into the mainstream. The work will provide evidence for the effects of these technologies once they arrive within the industry and how the arrival of these technologies can be better steered and prepared for.

METHODOLOGY

The development and execution of this research has been underpinned and defined by industry and academe working together in an iterative process of coproduction. Throughout this work the research questions, aims and methods have been jointly guided by input from the research staff and from senior representatives with the UK house building sector. For each package of the work discussion papers have been produce and passed between the partners until a consensus has been reached. This method of communicating has been supplemented by regular meetings, phone call and e-mail discussions. The discussion papers have provided the main vehicle for capturing, refining and reaching agreement upon ideas.

The work has been split into two phases and the first phase will inform the development and execution of the second. Phase one focuses on the challenge of identifying and shaping the emergence of the dominant microgeneration technology while phase two seeks to understand more completely how people are accepting, or not, these new technologies into their homes and daily practices.

Phase one approach

Rogers (1995, p.14) developed five criteria which influence the rate at which innovation diffuse, if they do so at all. These criteria are:-

- *Relative advantage* – the degree to which a new innovation is perceived by the housing developer as being better than the previous.
- *Compatibility* – the degree to which an innovation is perceived as consistent with its existing capabilities and the needs of potential users.
- *Complexity* – the degree to which an innovation is perceived as relatively difficult to understand and use.
- *Trialability* – the degree to which an innovation may be experimented with on a limited basis.
- *Observability* – the degree to which the results or the benefits of an innovation are visible to others.

Although it is possible to contest if these criteria are appropriate for the diffusion of process based innovations they do provide a useful framework to analyse the uptake of product based technologies such as microgeneration technologies.

Rogers' criteria were used to inform the development of a web-based questionnaire. The questionnaire contains both open and closed questions to establish both the current use of microgeneration technologies and the trajectory of their use i.e. to establish if the current used technologies are becoming more entrenched within the sector or losing their position to other competing technology. The survey also explores the reasoning behind why one technology is selected in preference to another.

The most difficult aspect of deploying any web-based research tool is control over the sample set. While this remains a challenge several steps were introduced in order to minimise problems generated by inconsistencies in the sample set. Firstly, invitations to participate in the survey were sent by our industrial partners through their contact databases to increase the legitimacy of the work to the participants. Secondly, the first two questions in the survey were used to identify if the respondent was involved in the process of building new homes (from concept through to handover and sales) and if the respondent had previously answered the questionnaire. In the first case those not directly involved in the house building sector were thanked for their time but prevented from answering any further questions. In the second case respondents were directed to a different version of the survey to capture what had changed in their opinions and why since the first time they had completed the survey.

Invitation to participate in the questionnaire was sent to 3,000 individuals involved in the design, construction and sales of new housing. Individuals were selected so as to give an even distribution of participation geographically. Although other criteria could have been used to stratify the sample set this was the most practical and simplest to control across the partners' distribution lists.

In order to maximise response rate the invitation to participate in the survey was sent as part of a wider series of structured communications. One week prior to the survey being released an initial message was sent by the industrial partners through their distribution lists. This message emphasised the importance of a piece of research to raise the legitimacy of the research in the eyes of the respondents. The e-mail clearly indicated the nature of the research, a time line and reinforced the independence of the researchers and autonomy of responses. One week following this initial message the industrial partners sent an invitation to participate in the survey. This message contained the link to the survey and another statement to the importance of the research, an indication of the commitment (i.e. 20 minute web-based questionnaire), a statement relating to informed consent (covering data protection

and research ethics). Following the invitation to participate a reminder message was sent each each following Friday afternoon for 3 weeks. The survey then closed.

Phase two approach

Phase one of the project addresses technology uptake and trajectory. Phase two of the project follows on and engages the same challenge from a different perspective. Meeting the emissions reduction targets set out in the introduction will require individuals to accept and use the new technologies within their homes. This adds another complex dimension to the design of homes. Should designers and engineers design for the optimum technical performance or try to accommodate user's behaviour and practice? Designers and engineers often assume that people use buildings and the technologies in a rational, predictable way that optimises performance. The decision making process of the 'rational user' is driven by logic and reason often rooted in stark performance comparisons and economics. In truth, actual behaviour is often some distance from this 'ideal' decision making and can appear whimsical and difficult to predict. On a daily basis our behaviour is shaped by a plethora of factors including economic, cultural, social and behavioural.

Technologies can and do shape our behaviours and practices. Where we sleep, eat and socialise within the home is often directed by where the kitchen, bedrooms and living spaces are (Shove, 2007). This is not to say that the layout of our homes dictates these practises only that it has a part to play in them. Over time people often change their homes to better accommodate their practices or the practices which they aspire to (for example, put in an extension to accommodate a growing family, reorganise a kitchen to encourage family meals etc.).

This co-evolution of home and practice can be in stark contrast to the challenge laid down by very new, disruptive technologies. In particular, technologies which have specific user behaviour 'scripted' in. These are technologies in which the designers have particular user behaviour in mind and attempts to 'foolproof' against other patterns of use, forcing the user to comply with the technologies intended use. This often leads to the intended benefits of the technology not being realised and its use being 'subverted' or abandoned all together through 'workarounds.'

This phase of the project will deploy an ethnography like approach to study the everyday 'lived in' expereinces of people living in homes encorporating microgeneration technologies. Ethnographic approaches such as interviews, observations and shadowing will be used to build up a detailed understanding of the way in which home occupiers interact with the technologies incorporated within their homes. Detailed study of these interaction will reveal how our sample group affect, and are affected by, these technologies in the context of the environment where the interaction takes place. This approach will provide a narrow but deep, and hence qualitatively rich, understanding of the day to day interactions, both constructive and destructive, which take place with the new technologies entering the home.

The research team will then begin the ethnographic-like study using the following broad plan:-

•Meeting 1 (60 minutes) – establish family/participant background, previous experience of MGTs, dwelling history/background, establish participant's relationship to the 'green agenda' and motivations for living in a low carbon home, brief introduction to the home, capture of 'headline' issues.

•Meeting 2 (60 minutes) – further explorations of benefits and limitations of living in a low carbon home, demonstration of some of the technologies (if possible), identification of supporting or destructive practices (workarounds), identification of modification of behaviours and practices enabled, or not, by MGTs.

•Meeting 3 (60 minutes) – final meeting to expand upon any issues raised in the previous two meetings and to explain to the participants the next steps in the research.

A very important factor for the success of ethnography is access to, and willingness of, the participants to be involved in the project. Access to participants is being provided through the industrial partners on the project. A minimum of three visits to each home will be conducted to build up a relationship between the researcher and participant and to allow trust and confidence to develop. The researcher will aim to be as unobtrusive as possible while guiding the participant to demonstrate and talk about their interaction with the technologies within their home. During this time the researcher will be making observations of the layout, use and interactions with the technologies within the home. Where appropriate the researcher may take images or recordings of these interactions.

The sample set will include up to 20 homes spread across two different locations. The sample set will encompass different home user profiles (families, indivduals, couple etc.), different primary microgeneration technologies and different periods of time living with the new technolgoies.

PHASE ONE UPDATE

A total of six discussion papers, three for each phases, have been written and have been through a series of drafts to reach a consensus on each of the topics covered. The discussion papers have been through 3 to 6 iterations each. This approach had provided a common ground upon which to base conversations and the development of the research methods and strategy.

The broad structure of the survey questionnaire maps onto the theoretical framework set out in Rogers (1995) as detailed in the 'Phase 1 approach' section above. As would be expected, demographic information about the respondent is captured. This information includes details about the individual replying but also the company they work for. We then move on to interrogate which low- and zero-carbon technologies the respondent would consider using in a variety of dwelling and site types (greenfield vs brownfield vs conversion, terrace vs semi-detached vs detached vs apartment). Having established which technologies the respondent would consider using in which situations the respondent's opinions on various factors relating to the low- and zero-carbon technologies are established. These factors broadly map onto the Rogers' criteria and goal will be to investigate which factors are, or are not, important in shaping which technologies are deployed. Up until this point the data collected is set in the present. Having questioned which technologies are used in which sectors, and having looked at which factors appear to have shaped the inclusion of these technologies, the survey then asks about the respondents their opinion of future trajectories. In doing this we hope to identify which technologies are likely to become more entrenched and which less so.

At the time of writing the web-based survey is live and data is being collected. The iterative cycle of co-production deployed in this research has taken time but has led to a robust, industrially relevant research tool. Data collection will be complete by the end of May 2011 and we will report the results in future papers.

The results from this phase of the project should provide a comprehensive picture of the current low- and zero-carbon technology use. The data should illuminate the important factors shaping the selection of which technologies to use and give an indication of which technologies the sector feels are likely to become dominant. This will be of great interest to the house building sector as greater understanding of how dominant technologies emerge within the house building industry provides them with additional information with which to plan and to manage their risks.

CONCLUSION

Although the project it reports on is still very much a work in progress this paper lays out the challenges facing the UK new build housing sector in meeting the requirements of the CfSH. The various levels of the Code and the carbon compliance level are introduced in the context of meeting the Government's carbon reduction obligations. The challenges of both reducing the consumption of energy and of generating energy on-site are outlined framed by the different levels of the Code. Some of the uncertainties in the environment in which the house builders operate, stemming from the lack of absolute definition of zero carbon, the nature and extent of allowable solutions and the number of new to the sector technologies are identified.

The problem facing the industry in correctly identifying which of the different technologies is likely to become dominant is described. This problem represents a very real commercial risk in where to invest in supply chain and skill development, how to design and construct homes which perform reliably and how to market and sell homes which contain microgeneration technology. Phase one of the project, by addressing technological uptake and trajectory, will deepen our understanding of the factors shaping the uptake of technologies in the sector. Phase two of the project will provide a rich, qualitative insight into how microgeneration technologies are accepted into everyday routines and practices.

Phase one of the project will be complete and the data and analysis ready to present at the time of the conference.

Abstract

The purpose of this paper it to explore the concept of adding value by real estate and related performance indicators, and the way it is or could be applied in value-based design and management of buildings. The concept is being illustrated with research findings on hospital buildings, based on a literature review and ten interviews with CEOs and real estate project managers. The research findings show that different hospitals prioritize different added values, depending on their overall mission and vision, its position in the real estate life cycle, and the local context. On average, stimulating innovation, improving satisfaction of customers and employees, and supporting (change of) culture rank high, whereas risk management and opportunities to get the real estate costs financed are much less prioritized. A number of added values have been concretized in real estate interventions that are supposed to cause a positive effect on organizational performance, e.g. with regard to patient satisfaction, labor productivity, flexibility and cost reduction. The conceptual framework and research data can be used to support complex decision making in briefing, design and management of hospital buildings and other health facilities. The explorations of adding value by real estate might be applicable in other sectors as well.

Keywords: added value; stakeholders; strategy; performance; hospital real estate.

ADDING VALUE BY REAL ESTATE

Corporate or Public Real Estate Management is usually defined as the management of the real estate portfolio of a corporation or public authority by aligning the portfolio and services to the needs of the core business, in order to obtain maximum added value for the business and to contribute optimally to the overall performance of the organization (Dewulf et al. 2000). Several authors have tried to operationalize the concept of added value, starting with a definition. With reference to the well-know VAT-rate – focusing on the economic value added (EVA) – Van Wagenberg (2009) defines value added as: "*the difference between the value of the product/services delivered to a client during a period (value of output(s) in period Δ t1 – t2) and the value of the input(s) in the production function - or functions in the case of a supply chain - in the same period Δ t1 – t2.*"

Per Anker Jensen, Professor in Facility Management at the Technical University of Denmark in Copenhagen, defines added value as the ratio between added use value and costs (Jensen 2009). In a follow-up paper (Jensen et al 2010) this formula is extended to:

User value = Quality & Process / Price & Difficulties.

In the field of relationship marketing, Sarshar and Pitt (2009) present a similar definition for customer value or customer value ratio:

$$\textit{Customer value} = \frac{\textit{Results produced for the customer + service process quality}}{\textit{Price to the customer + cost and effort in acquiring the service}}$$

The definitions so far define added value as a ratio between output and input in connection to the difference between the output and input in a certain period of time Δ t1 – t2.

In the field of corporate and public real estate management the concept of added value is usually linked to the numerator and much less to the denominator. For the study presented here we have build on the work of Nourse and Roulac (1993) De Jonge (2002), Lindholm and Levainen (2006), Lindholm (2008), De Vries et al (2008) and Jensen (2010). All authors use different lists of possible added values. Based on similarities between these references, the added value of real estate can be defined as the contribution of real estate to organizational performance by its contribution to nine fields of performance (Table 1).

1. Reduction of real estate costs during the life cycle (investment costs, operational costs) by steering on efficient space use and smart design.
2. Improvement of (labour) productivity, e.g. by supporting logistics of primary processes and short walking distances between related functions.
3. Improvement of user satisfaction by steering on a functional, comfortable and pleasant working environment, taking into account user needs and preferences
4. Improvement of possibilities to get real estate financed by external parties, e.g. by regarding real estate as an asset to improve the overall finance position of the organization or an assessment of the (future) marketability of the building
5. Improvement of flexibility to enable future spatial, technical, organizational or juridical adaptability, e.g. by standardization, simple opportunities to extend the building or easy adaptability to other functions.
6. Support of a positive corporate image, e.g. by a nice overall building appearance and an appropriate building lay-out
7. Stimulation of innovations in order to improve business processes, e.g. by creating formal and informal meeting space to exchange ideas
8. Supporting (change of) corporate culture, e.g. by sharing work spaces to support social interaction
9. Risk management with regard to time, costs, health and safety, and coping with a changing context, e.g. technically by application of strict safety standards or juridical by short term rent contracts

Table 1: *Nine fields of adding value by real estate defined from literature*

Both from an academic point of view and to be applicable in decision making processes in practice, these nine fields of impact of real estate on organizational performance have to be elaborated in connection to available resources and limiting conditions. An ongoing PhD-research into healthcare real estate strategies in a changing context offered an opportunity to further exploring the concept of adding value by real estate in the health sector (Van der Zwart *et al*. 2009).

HOSPITAL REAL ESTATE IN A CHANGING CONTEXT

Due to the changing juridical and financial context of hospital real estate design and management, adding value management by hospital real estate is an interesting research area. In the last decade the government transformed the old budgetary system into a so-called regulated market system. In the former system the proposal for a new hospital building or renovation of an existing building had to be approved by the government to fit with the planning regulations (number of beds per 10,000 inhabitants), space criteria (maximum number of square meters per bed, functional performance requirements per function), and cost regulations (maximum budget for investment costs per square meter). After approval all building related capital costs and running costs were guaranteed by the government and paid by the insurance companies during the life-time of the building, independent of healthcare production. In the so-called February-letter of 8 March 2005, the Dutch Minister of Health, Welfare and Sports announced the replacement of this budget system by a regulated market system.In the new system not the government but the healthcare organizations themselves will be responsible for a sufficient return on real estate investment – by proceeds from health care delivery - and the consequences of real estate decisions on utility value, investment costs and running costs. “Deregulation” gives healthcare organizations more freedom in briefing, design and management of hospital buildings, but makes them more risk-bearing as well. The main objective of replacing the centrally directed real estate budget system - with governmental ex ante testing of building plans and investment proposals - by a performance driven finance system - with governance on the output - is to stimulating competition and reducing healthcare costs.

As a consequence of their new responsibilities, hospital organizations have to consider more carefully the costs and benefits of different real estate choices and how real estate can add value to organizational performance. Benefits such as creating a healing environment, improving employee satisfaction, or supporting labour productivity and image have to be weighted against the impact of real estate decisions on the costs of health care delivery and real estate life cycle costs. Political decisions, demographical and economical developments, innovations in medical technology and a continuously changing market of demand and supply are all part of a dynamic and unpredictable context, whereas healthcare real estate decisions have a long term impact. The constantly changing context with new opportunities and risks and the involvement of a growing number of stakeholders necessitates to changing traditional hospital real estate management into a more businesslike and integrated approach. Although most healthcare organizations are aware of the necessity to change, many of them lack sufficient knowledge and tools to steer on the added value of corporate real estate in connection to organizational performance.

For this reason a study has been conducted to explore answers on three questions: a) (How) do hospital managers e.g. the CEO or project managers take into account adding value by real estate in hospital real estate design and management; b) What are present priorities in value based real estate design and management? c) Which accommodation choices are guided by (perceived) adding value by real estate?

RESEARCH METHODS

Data have been collected by interviewing CEOs and real estate managers of ten hospitals in the Netherlands. In order to select appropriate respondents, first a list was made of hospitals that recently were or currently are building or designing a new hospital (period 2004 – 2012).

This list has been presented to experts in the field and has been updated when the respondents mentioned other hospitals that are initiating a new building process. This resulted in a list of approximately 20 hospitals. Then a selection of cases has been made in search for heterogeneity on three characteristics: 1) general, top clinical and academic hospitals; 2) size in number of beds and turn-over; 3) position in the building process i.e. initiation, briefing, design, construction, or use (Table 2). This makes it possible to explore if the type of hospital, size and phase in the real estate life cycle affects (priorities in) value added management.

	place	code	category	size	beds	m2	phase	respondent

S = small; M = medium; L = large; XL = extra large

Table 2: *Characteristics of the cases*

The selected cases represent approximately 10% of all Dutch hospitals and 50% of all Dutch hospitals that were/are planning or building a new hospital in 2004-2012. The selection includes three general hospitals, five top clinical hospitals and two academic hospitals. With regard to the number of beds, the case selection includes two small size hospitals, three medium size hospitals, three large hospitals, and two extra large academic hospitals due to the integration of research and education facilities in the real estate portfolio. Two hospitals were in the initiation phase and four hospitals were constructing the building at the moment of the interview. Four hospitals concern new buildings-in-use in the exploitation phase. Half of the interviews were conducted with CEOs, and half with the real estate project manager of the hospital. In advance, available information and documents on the internet were studied in order to get a first impression of the hospital, its mission and vision, and main real estate objectives.

The semi structured interviews consisted of two parts: an open interview where respondents were asked which values were or are taken into account in the real estate decision making process, and a structured interview where respondents were asked to prioritize nine added values found in the literature. The values spontaneously mentioned in the first part may be indicators of managers' awareness of possibilities to add value by real estate. In the second part the nine added values derived from literature were presented on little cards in a matrix with 3 rows and 3 columns (see Figure 1). The ranking of added values occurred in three steps. First respondents were asked to prioritize the three added values in each row. Second, respondents were asked to rank the three added values per column on least importance. In these two steps the respondents were made familiar with the added values used in literature in order to be able to prioritize all of them in the third step. After this ranking assignment, the respondents were asked how these added values are visible in the (design of the) hospital building. After the interviews transcripts have been made of the recorded interviews. These transcripts were summarized and sent back to the respondents for feedback.

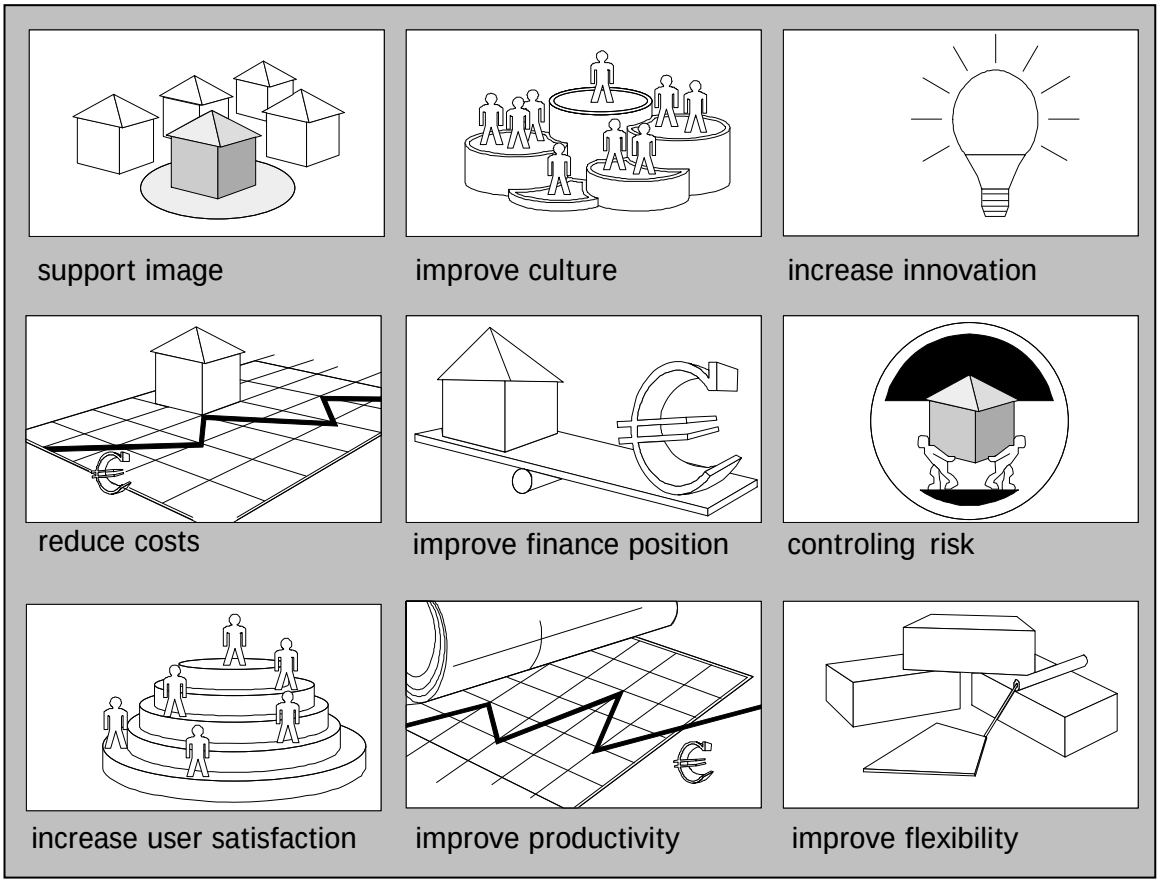

Figure 1: *Nine added values of real estate positioned in a matrix*

RESEARCH FINDINGS

The presentation of the research findings follows the three steps of the interview i.e. a) A summary of the responses to the open question for the main objectives of real estate investment decisions made in the past years, plus textboxes with brief characterizations of specific cases, based on the interviews; b) A cross-case analysis of prioritized values, from 1 (highest) to 9 (lowest); c) Accommodation choices supporting adding value are brought together by decoding the transcripts on the nine previous defined fields of adding value by real estate.

a) Value based hospital real estate management

The first priority of hospitals is to deliver good healthcare in a cost-efficient way. Real estate is secondary but at the same time an important resource to reach the organizational objectives and to optimally facilitate healthcare processes. Being a resource for production, real estate should always be judged upon its contribution to business processes and business economics. Supporting the primary process also means that the building should be comfortable. On the one hand the building should support patient's needs and wellbeing. On the other hand the building should be a pleasant and productive working environment for the healthcare professional.

In most cases, supporting efficient healthcare processes showed to be in the core of real estate design and management on building level. Much attention is being paid to efficient logistics of patients, health care processes and transport of people and goods. In spite of the widely

used motto “the patient is central”, most hospitals focus on efficient healthcare process, because it also benefits the patients if processes are well connected and as such supports both customer satisfaction, labour productivity and employee satisfaction.

Deventer Hospital, Deventer
The building should facilitate the healthcare processes in such a way that the building meets the organization’s objectives on the first day the hospital opens its doors. Besides, the building must be flexible in order to support business processes for a period of 40 years and to be able to cope with changing visions on healthcare delivery. The building concept is based on the vision that healthcare processes include four different patient flows: acute, urgent, elective, and chronicle. This resulted in a process based building with a focus on logical connections between medical healthcare processes.

Furthermore all cases show a connection between the organizational strategy and the real estate strategy. In most cases possibilities of the current real estate portfolio as well as the desired future supply is taken into account in the real estate strategy. Often organizational objectives such as transparency and appropriate healthcare are translated in the architecture of the building. But a strict translation of the organizational mission, vision and ambitions in architecture is also mentioned to be difficult because of the long planning and construction time – often 10 to 15 years - and 40 years of exploitation afterwards. In the mean time the organization will change several times its management structure and style, objectives, vision on optimal organization of healthcare processes etc. Therefore, flexibility is often mentioned as an important criterion of adding value by real estate. Flexibility should enable the hospital building to support the healthcare processes at least 40 years in changing circumstances.

Meander Medical Centre, Amersfoort
First a Long Period Accommodation Plan was made to formulate a real estate strategy. This strategy consisted of a renovation of the existing hospitals to support the use for another 10 to 12 years and in the mean time designing and constructing a new hospital on a central location. All complicated top clinical cure was centralized in the new hospital building. Besides, a regional hospital was renovated and converted into a day care hospital and four policlinics were initiated in the region. The central building is divided into three parts: 1) a hot floor with all high technical functions; 2) nurseries with standard one-person bedrooms, and; 3) multifunctional examination rooms, all with different technical installations and constructions and different access to patients. Flexibility is realized by expandability, adaptability and exchangeability of rooms.

Because of the new financing system that makes payment of investment and running costs dependent of the production in terms of diagnosis-treatment combinations, the usual starting point is very businesslike: no more square meters then necessary and life-cycle-costs as low as possible. The hospitals that initiated a new building after the introduction of the new regulation showed a shift of directing on maximum capacity and quality towards steering on less capital expenses and increasing productivity. These hospitals are designed and constructed on the basis of a business case and pay much attention to create a compact building with a little surplus square meters to enable future production growth, low capital costs and a high level of flexibility. Slim fit buildings are accompanied with extendibility in the future. These extensions are subject of a new business cases to be presented to financiers. The planning and construction period decreased from the usual 10-15 years to 4-5 years.

Gelre Hospital, Zutphen
From the moment of the first initiative, it was known that the building had to be financed on own risk, reimbursed by healthcare production. Therefore, a business plan was presented to financiers. Starting point of this business plan is to steer on as low as possible capital costs in order to gain competitive advantage with regard to the costs of healthcare products and services. This is accomplished with a cheap, functional and lean building with little surplus square meters and a focus on flexibility to anticipate on future alterations. Also typical for this project is the short period of totally 4 years from initiative to design and construction.

Since the introduction of the regulated market system, a growing awareness of the market position of the hospitals becomes visible. Most hospitals are part of a larger network with one central location with all complicated top clinical healthcare combined, and several day care hospitals and policlinics in the region. The peripheral locations demarcate the service area of the hospital and have to ensure that patients chose for this specific hospital and only go to the central hospital if top clinical cure is necessary.

b) Priorities in adding value management

The results of prioritizing nine added values by CEOs and project managers of ten hospitals are presented in figure 2. The horizontal axis is scaled from 1 = highest priority to 9 = lowest priority according to the respondents. The nine added values are presented on the vertical axis of the diagram. Horizontally next to these added values the priority ranks are plotted of all interviewed hospitals with their names abbreviated according to table 2. When two or more added values were given the same priority, these added values received the same average rank. The dashed-lined boxes cluster the most given answers, usually showing a maximum of three exceptional ranks per added value. The vertical lines show the average ranking per added value. The bold abbreviations show the hospitals with a median ranking for that particular added value. The added values on the vertical axis are ordered from the highest median rank (above) till the lowest median rank (below).If two added values share the same median, the average was used to choose the priority rank.

Figure 2 shows that on average supporting innovation, increasing user satisfaction and improving the organization's culture are given highest priority. Cost reduction is highly prioritized by four respondents, but ranked as not that important by five other hospitals. Because of this variety, the average rank is not very representative to express the different thoughts. Increasing productivity, optimizing flexibility and supporting corporate image are prioritized in the middle. Risk control and increasing financing possibilities are usually given low priority.

One hospital (GD) ranked the priorities of the nine added values almost opposite to (clusters of) most other answers. This hospital is currently planning a new hospital according to the so-called living building concept (LBC), a new form of Public Private Initiative.

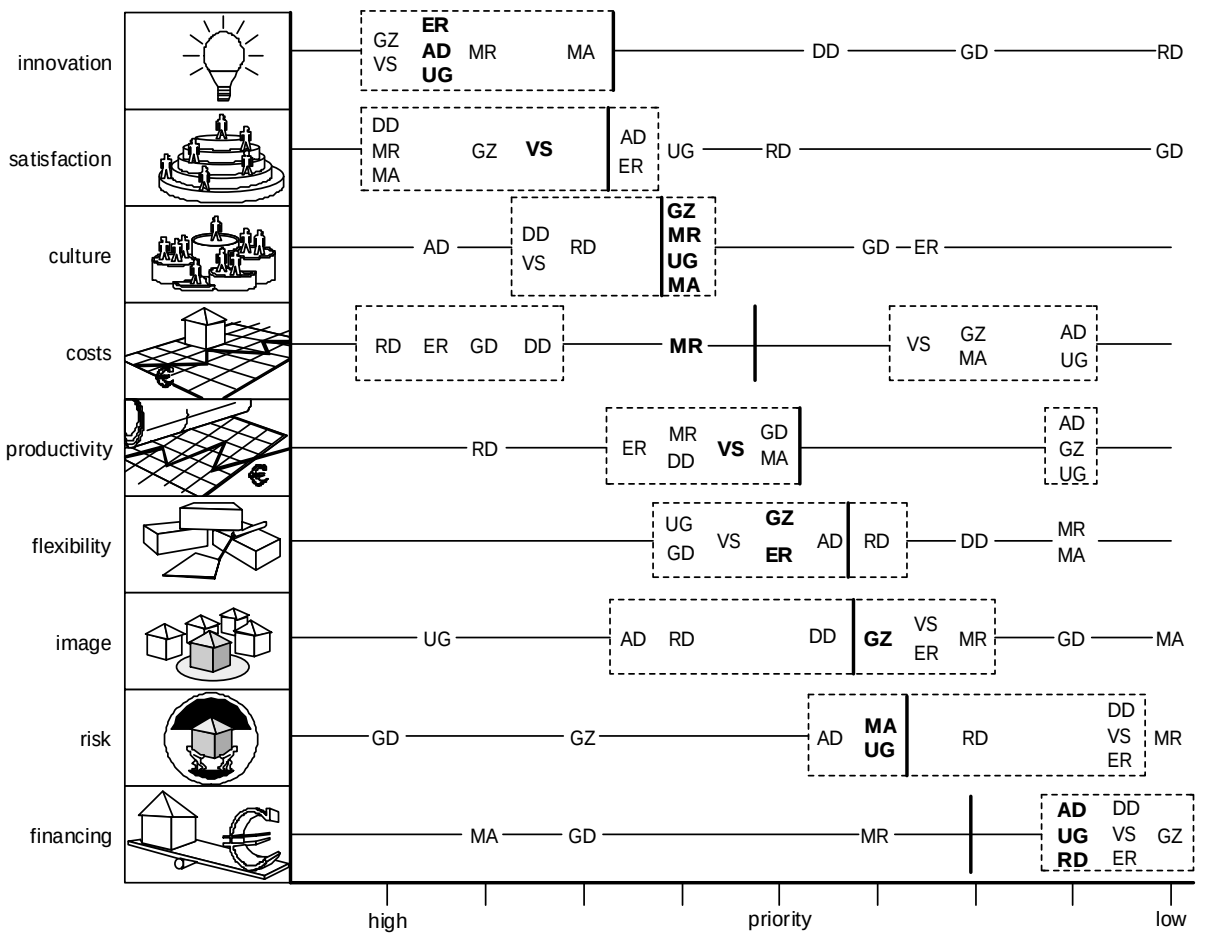

Figure 2: *Plot diagram of ranking prioritized real estate added values*

c) Accommodation choices supporting adding value by real estate

When hospital managers are asked to elaborate on the connections between real estate characteristics and organizational performance, different answers come up. But the responses have also much in common. The overall picture can be summarized as follows.

1. Cost reduction

Due to an ever growing demand for (expensive) health care and a shortage of financial resources, policy makers and hospital managers pay much attention to cost effectiveness and opportunities to reduce real estate costs. Since the introduction of the regulated market system directing on the reduction of life cycle costs and total costs of ownership has become more and more important. Elaborating a business case to make costs and benefits transparent both in the short and long run has become normal practice now. Real estate measures to stimulate cost reduction include co-operation in building, design and management of hospital real estate with other care organizations and commercial parties, new ways of contracting such as Design and Build, or DBFMO (Design-Build-Finance-Maintain-Operate), strict space budgeting, space reduction by shared workplaces and extension of opening hours, and sustainability measures in order to reduce energy consumption. Quite often extra investments are needed to reduce the life cycle costs of the building (e.g. investing in flexibility) or staff costs (e.g. extra lifts to reduce walking distances).

2. Increasing productivity
This added value is usually interpreted as production (output) and less as a ratio between output and input. Real estate choices to support production included:

- Optimally facilitating of medical care processes and supporting activities, e.g. by spatial clustering of top-clinical care processes, urgent care, patients with acute diseases and patients with chronic illnesses, or a thematic clustering of heart diseases and vascular diseases, oncology, mother and child.
- Well considered location of operation theatres.
- Location of units with a high flow rate near the entrance to avoid unnecessary patients flows within the building.
- Sound logistics of transport (beds, bedclothes, food, medical facilities) by a separation of transport of goods and patient flows, use of advanced transport systems, and well considered distribution points.
- Easy and place and time independent access to (digital) data.
- Extension of opening hours and operating time.
- An attractive indoor climate and indoor air quality in order to avoid absence by building related sickness ("sick building syndrome").

The impact of one bed rooms on labour productivity is a little ambivalent. On the one hand one bed rooms evoke fewer infections and speed up the healing process that might shorten the average stay in hospital. It also avoids problems of empty beds due to difficulties in mixing people with different cultural backgrounds or different gender. On the other hand a high percentage of one bed rooms can be counterproductive because of nurses have less overview and because of longer walking distances.

3. User satisfaction
This added value may be split up in satisfaction of consumers (potential customers of the hospital), customers (people that come to the hospital to visit a patient) and patients on one side and staff on the other side. Most respondents emphasize that good staff people with excellent medical skills and a customer-friendly attitude and behaviour are of utmost importance. But well considered real estate decisions can be supportive as well, e.g. by:

- Creating an attractive and functional "healing" environment where people feel at home: easily accessible, with a clear structure so that people can find their way easily, much daylight, a nice outside view, an attractive indoor climate, being able to make use of a one bed room (preferred by most patients but not all of them), and a high quality of semi-public spaces such as entrance halls, waiting areas and patios.
- Optimally facilitating medical care processes by steering on a lay-out that fits with the way cure and care are being organized and short walking distances between related functions.
- ICT-facilities (flat screens for watching TV/ information, internet) and catering services.
- Well organized communication and user participation in decision making processes.

4. Increasing opportunities to get the capital costs and operating costs financed
This added value is being stimulated by the involvement of external parties that rent space in the building or on a so-called health care boulevard or health park, leading to a sound business case. Other options are private public partnerships in owning the building, and steering on future value of the building by adaptability and marketability. Academic hospitals seem to have fewer problems in financing their real estate because they still get a separate budget for real estate investments and they can borrow money at a quite low interest rate.

5. Optimization of flexibility and adaptability
Flexibility is a key issue in hospital design for decades. All respondents include flexibility in their real estate policy and real estate management. Standardization, multifunctional use of space, a clear separation between the supporting structure and fill-in because of their different life cycles, extra power of load-bearing walls and floors in order to cope with future functions, easy-to-adapt bed rooms (from a two bed room in two one bed rooms and vice versa), facilities that make an enlargement of the building easily possible, all kind of measurements are more or less common sense nowadays. A more recent concept is the functional zoning plan. By spatial separation of the hot floor (high tech facilities such as the operation theatres), the fabric (labs), the hotel function (bedrooms) and office activities, hospitals aim to make part of their buildings more courant and as such easier marketable when the hospital want to shrink or to move to another place. One of the hospitals built the hot floor in a special zone and left the adjacent space vacant, so that in case of the hot floor becomes outdated a new one can be added easily while the present keeps going during construction. However, thinking in scenarios in search for spatial and financial implications of future developments is not very common yet.

6. Supporting a positive image
Marketing by real estate is merely managed by steering on a nice and easy to access location in a lively and safe environment, a nice overall appearance, an attractive "healing" environment with a high percentage of one bed rooms, nice colours and materials, light and transparent, and nice facilities, in order to improve patient satisfaction and as a consequence to improve competitive advantage. Attractive and professional staff facilities may help to attract and retain staff people. Quite often semi-public spaces are open for use by people from outside, to reduce the image of an inner directed medical environment. Some respondents emphasize that a hospital should primarily focus on its patients by creating an environment "where it is allowed to be a patient" and not feeling awkward when walking in pyjama wit a drip at hand.

7. Stimulation of innovation
This added value needs a similar real estate policy. Innovation requires individual creativity and team creativity. Creative thinking can be facilitated by opportunities to relax and to concentrate and places that support exchange of knowledge and stimulate new ideas. Most hospitals create meeting places such as a knowledge centre, study centre, or skills lab. Another real estate intervention to stimulate innovations is the spatial integration of different types of cure and care, but the present financing system could with separate money streams is mentioned to be an obstacle here. ICT is also used as a tool to innovating processes, e.g. by the use of information devices or application of a digital system to reduce waiting times. Medical-technical innovations may affect real estate as well, for instance by changing space requirements due to remote care, E-consults and new medical equipment.

8. Supporting (changing) organizational culture
Though culture is merely a matter of shared values and behavioural rules focusing on high quality care, reliability and customer-friendly behaviour, (changing) culture can also be supported by real estate. Most often hospital managers try to do so by creating more openness and informal meeting facilities, facility sharing and hot desking, in order to stimulate communication and to make different ways of behaviour or different attitudes a subject of open discussion. Another option is to create a front-back office with a different atmosphere.

9. *Risk control*
This added value is least discussed and also mainly managed by real estate choices improving flexibility and marketability, a well elaborated business case, outsourcing of maintenance for a long period, and reduction of risks of infections by smart hygiene measures and more one bed rooms.

DISCUSSION

The qualitative approach of this research – using semi-structured interviews with open questions – delivered much information on how real estate added values are perceived by hospital managers and how they are prioritized in hospital real estate decision making. The results contribute to a better understanding of adding value by real estate and the values mentioned in literature, in general and specifically for the healthcare sector. Although quantitative concepts have been used to summarize and interpret the research findings - modus, mean, average, a plot-box - these results should be regarded as qualitative data as well. As the priority diagram (figure 2) is a representation of only ten separate configurations, this diagram is not more then a first exploration of (clusters of) priorities. The validity of the results can be improved by conducting more interviews and organizing expert meetings to discuss and compare individual rankings. The same methods could be applied in other sectors like office organizations or higher education in order to explore similarities and dissimilarities in different fields.

Though hospital real estate is being regarded now more and more as a resource for production, a remarkable difference shows up between the answers on the open question and the prioritizing assignment of added values in the more structured part of the interview. In response to the open question to mention values that are steered on in design and management of hospital real estate, most respondents mentioned facilitating the primary processes and supporting productivity as the main objectives. Confronted with added values of real estate mentioned in the literature, the main real estate objective seems to shift from process oriented priorities towards the contribution of real estate to organizational strategic objectives such as stimulating innovation, improving culture and increasing user satisfaction. Whereas in the open interview flexibility is often mentioned as an important added value, in the ranking assignment this issue is never given a high priority, probably because it is already a common issue in real estate management for decades. Cost reduction shows to split the interviewees in two groups. Part of the respondents ranked cost reduction in the top of highly prioritized values, whereas others give this issue low priority. Although in the open interview most hospital managers call cost reduction a basic issue in most real estate decisions, in particular since the new healthcare real estate regulations, cost reduction gets median priority, just like productivity and flexibility.

The configuration of cards ranked by the CEO of hospital VS (figure 3) represents more or less the average ranking of all respondents. This hospital has been built under the former hospital real estate regulation and is now in the exploitation phase of the building process. This ranking shows stimulating innovation as top priority of adding value. Two other values - improving user satisfaction and improving organizational culture - are ranked second highest priority. Then two columns are recognizable (and also described as such by the CEO while sorting the cards). The three added values at the left were connected to the process: increasing productivity; decreasing real estate costs as a means to decrease the prize of healthcare products and services, and controlling real estate risks related to the production process. The three added values at the right side are more building related values: optimizing flexibility;

supporting corporate image, and increasing finance possibilities. According to this CEO these values were captured in the building design, and as a consequence adding value management with regard to these issues is less possible in the exploitation phase.

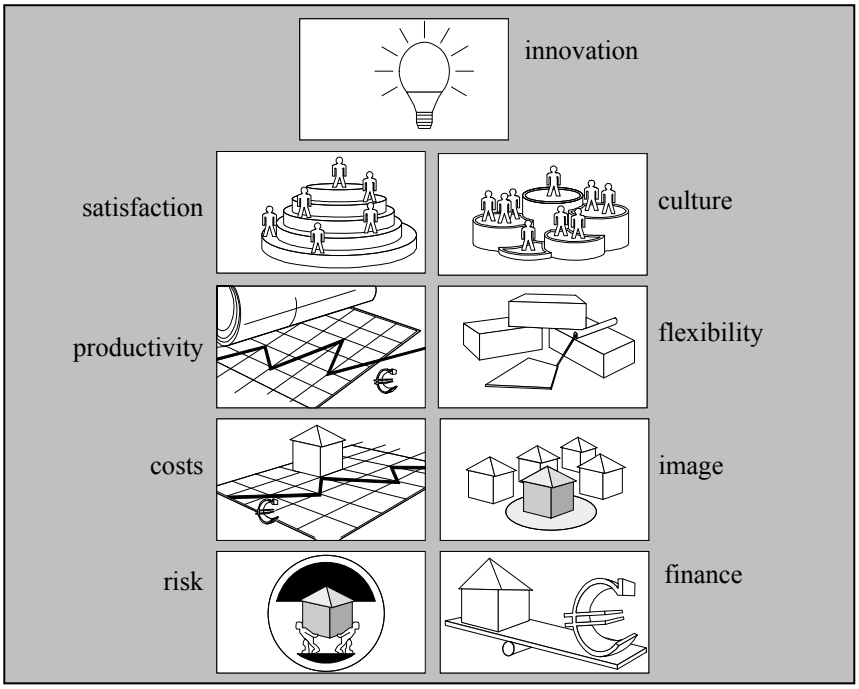

Figure 3: *The most 'representative' result of the ranking assignment*

Both the overall results of the priority ranking assignment (figure 2) and the "representative" configuration (figure 3) show some clusters of prioritized added values that seems to be connected to the widely used triplet of people-process-place (Duffy, 1992). The top three of prioritized added values by the respondents are stimulating innovation, increase user satisfaction and improving corporate culture. These three added values of real estate contribute to organizational performance with regard to '*people working together, in a smart way organizing things efficiently*' as one CEO mentioned in the interview. The second cluster of added values includes cost reduction, increasing productivity and optimizing flexibility. These three added values all contribute to the (production) process of healthcare services and the prizes of these products and services. A flexible hospital building makes it possible to adjust real estate to improve productivity and capital cost reduction reduces prizes of health care products and services. As one CEO mentioned: *'Maybe it is not that surprisingly that improving productivity is in the middle of this configuration, some added values are enablers and contribute to a higher productivity, others are more the result of an increasing productivity (ablers).'* The third cluster of added values - contributing to corporate image, controlling real estate related risks and improving finance possibilities - are more directly related to the real estate portfolio, as it appears in the concept of place. As one CEO mentioned in the interview: '*Contribute to corporate image or finance possibilities are strongly related to the location and appearance of the hospital building. I can imagine that it becomes important that a hospital is located in the city centre, but otherwise it is less important as a real estate objective.*'

In the interviews some other added values of real estate came up, in particular its contribution to a sustainable and healing environment. Usually sustainability is not perceived as a main objective of health care organizations, but as a necessity to cope with societal needs, now and in the future, and as a means to show corporate social responsibility. Most respondents admit that sustainability measures are applied only when the extra costs have a reimbursement period of less than 5-10 years. Of course steering on a healing environment is of utmost importance in health care and cure. Though not explicitly presented as one of the nine added values, it is implicitly included in improving satisfaction and supporting productivity. It seems to be more appropriate to add this value to the list as healthcare specific real estate added value. By adding sustainability as a particular value, as Den Heijer (2011) did in her dissertation on Managing the University campus, rankings in the health care sector may be better comparable with ranking in other fields.

CONCLUDING REMARKS

This research is a first exploration of adding value by real estate in the field of health care. Additional research is needed to improve our understanding of a) which real estate interventions will positively affect organizational performance; b) interrelationships between the performance indicators; c) synergy or conflicts between values; d) clearness and completeness of the list; and e) how does the concept of added value and its different aspects appeal to decision makers. It is well known that managing flexibility and standardization may conflict with other values such as low investment costs and efficient use of space. The need for much daylight may cause high cleaning costs and conflicts with the need for a reduction of CO2 emission. A review of current research in depth with a focus on only one possible added value of real estate - such as labour productivity, employee satisfaction or future marketability – will be one of the next steps. Furthermore the results of interviews will be linked to building assessments in a number of case studies, including floor plan analysis and analysis of documents such as the brief and corporate strategies.

Salford, Greater Manchester, UK
A.opoku@edu.salford.ac.uk

CHRIS FORTUNE
University of Salford, School of Built Environment
Salford, Greater Manchester, UK

Abstract
The construction industry is a very important sector in achieving society's sustainable development goals; however the change towards sustainability is a process that presents a leadership challenge. Construction organizations need leadership that provide the collective vision, strategy and direction towards the common goal of a sustainable future. The aim of this paper is to critically examine the role, drivers and factors affecting leadership in the effective implementation of sustainable practices in construction organizations. A review of relevant literature and preliminary qualitative results from an in-depth interview with eight (8) leaders in United Kingdom construction consultant organizations, including sustainability directors, managers and consultants is presented. The analysis of the collected qualitative data revealed that, the leadership role in promoting sustainability in construction organizations include the development of strategies and the formulation of policies. A major driver for construction organizations to pursue sustainability is to win more business, while increased capital cost for sustainability is still a major challenge to many organizations. This study establishes the basis for further investigation in an on-going doctorial level research on the role of leadership in promoting sustainable construction practices.

Keywords: Construction organization, leadership, leadership style, sustainable practice

INTRODUCTION

Leadership is vital in the construction industry and a key success factor in the drive towards sustainability (Ofori and Toor, 2008). Construction organizations need leadership that provide the collective vision, strategy and direction towards the common goal of a sustainable future. Leaders should embed sustainability in their organizational activities and make sustainable development part of their overall business strategy. It is important that such leaders have both the ability as well as the sustainability knowledge to effectively guide their organizations strategically towards sustainability.

The role of leadership in improving the performance and innovation in the construction industry has been receiving increasing attention in recent times (Bonssink, 2007). However, less attention has been given to the capability of organizational leadership in promoting construction organizations towards the delivery of sustainable construction projects. There is extensive literature on the subject of sustainability and leadership as separate entities; however, little has been written about the link between leadership and sustainability in construction management research. The issue of sustainability is growing ever more importantly and construction has perhaps the greatest impact on it than any other sector. The

construction industry provides benefits to the society as well as causing negative impacts; this makes it a key sector in the fight for sustainable development (Sev, 2009).
The construction industry is a very important sector in achieving society's sustainable development goals; however the change towards sustainability is a process that presents a leadership challenge. Both Egan (1998) and Latham (1994) called on leaders to lead the quest for change in the construction industry. Leaders have an important role in guiding construction organizations toward sustainable practices and it is believed that such leaders require unique leadership styles. Leadership style is all about how people interact with those they seek to lead (Groetsch and Davis, 2006). However, Toor and Ofori (2008) believe that leadership is about authenticity and not style. The construction industry therefore needs authentic leaders (moral and ethical leaders) who can take advantage of the opportunities that sustainability brings, to secure a better future for the construction industry. It is suspected that the ability of organisations, irrespective of their level of maturity, to pursue the sustainable agenda is influenced by the commitment and conviction of their leadership towards sustainability.

This paper critically examines the role of leadership and the promotion of sustainable construction practices in construction organizations in United Kingdom (UK). The first part of the paper reviews literature on sustainable development and construction, leadership and leadership styles, drivers and challenges facing leaders in the effective implementation of sustainable construction practices. The final part of the paper concludes with the findings from preliminary interviews conducted with sustainability leaders in UK construction organizations. The interviews explored their role and identified factors affecting effective implementation of sustainable practices.

LITERATURE REVIEW

Sustainable Development and Construction

Sustainable development that balances social, environmental and economic objectives is now firmly on the agenda for the UK construction industry (Raynsford, 2000). Sustainable development balances environmental resource protection, social progress and economic growth and stability now and for the future. It focuses on improving the quality of life for all without increasing the use of natural resources further than the environment's ability to supply them for the foreseeable future. Sustainable development has been defined in many ways; Parkin (2000) pointed out that there are well over 200 rumoured definitions of sustainable development in circulation, however, the most widely accepted definition is:

"Development that meets the needs of the present without compromising the ability of future generations to meet their own needs"- From 'Our common future' (The Brundtland Report, 1987)

However, Brandon and Lombardi (2011) in their book "Evaluating sustainable development in the built environment" define sustainable development as:

"A process that aims to provide a physical, social and psychological environment in which the behaviour of human beings is harmoniously adjusted to address the integration with, and dependency on nature in order to improve, and not to impact adversely, on present or future generation".

Sustainable development means delivering built environment that sustains and improves the quality of life for human beings; removes the environmental and social damage from the past. Sustainable development also improves the sustainability of the wider environment, ecosystems and development of individuals and society's quality of life (Bennett and Crudgington, 2003). When setting out the UK's government role in sustainable construction, Raynsford (2000), the then UK Minister for Housing, Planning and Construction described sustainable construction as the set of processes though which a profitable and competitive industry delivers built assets (buildings, structures, supporting infrastructure and their immediate surroundings) that enhance quality of life, is flexible for future user changes, supports desirable natural and social environments to take full advantage of the efficient use of resources. Sustainable development is now understood as being a combination of three dimensions or 'Pillars' including economic, environmental and social dimensions; popularly referred to as the 'Triple bottom line' in business circles (Lehtonen, 2004; Hall and Purchase, 2006).
Sustainable development involves minimising the negative impacts of our activities to improve the environment and enhance a better quality of life for present and future generations. It is all about balancing economic growth and progress while protecting natural resources and promoting social equality (Leiper *et al*., 2003). The environmental dimension of sustainability is about reducing ecological impacts today in order to preserve the environment for future generations while the economic dimension involves providing for positive economic growth. Finally, the social dimension involves responsibility of corporations to conduct business ethically (Jones *et al*., 2010). However, Beheiry *et al*. (2006) believe that sustainability efforts in construction projects are biased towards the environment in comparison to the social and the economical dimensions.

The quest for sustainability has put enormous pressure on the construction industry from the government and the general public to improve on its currently unsustainable pattern of project delivery (Adetunji *et al*, 2003). There is now a wide recognition that the construction industry has a vital contribution to make towards sustainable development. However, Leiper *et al*, (2003) comment that, the construction industry is also slow in adopting sustainable approaches in its construction project practices. The construction industry has a significant social responsibility to minimise the damage its projects do to the social environment. Sev (2009) also add that both existing built environment and the process of adding to it have several environmental, social and economical impacts. The UK government in 2000 introduced a construction-specific strategy, "Building a Better Quality of Life" which highlighted key themes for action by the construction industry, namely;

- Design for minimum waste,
- Lean construction and minimise waste,
- Preserve and enhance biodiversity,
- Do not pollute,
- Conserve water resources,
- Respect people and local environment,
- Monitor and report (Department of the Environment, Transport and the Region(DETR), 2000)

Sustainable construction is the application of sustainable development principles in the construction industry. Parkin (2000), describes sustainable construction as a construction process that incorporates the basic themes of sustainable development. Sustainable construction aims at reducing the environmental impact of a building over its entire lifespan, providing safety and comfort to its occupants and at the same time enhancing its economic

viability (Addis and Talbot, 2001). Sustainable construction is conceptualized as having three broad dimensions; social equity, environmental protection, and economic growth as a reflection of those issues in relation to sustainable development. Social sustainability deals with legal, moral and ethical obligations of construction organizations to their stakeholders. Environmental sustainability on the other hand addresses the impact of construction activities on the environment by minimising waste, using natural resources and energy efficiently. Economic sustainability, however involves improved project delivery resulting in high productivity to maintain a high and stable level of economic growth (Parkin *et al.*, 2003).

Sustainability at the organizational level refers to meeting social and environmental needs in addition to the firm's profitability (Porter, 2008). Sustainability makes good business sense because it is of increasing importance to the efficient, effective and responsible operation of business. Some of the primary drivers towards the adoption of more sustainable business practices in construction organizations in UK is government policy or legislation, reputation and competitive advantage (Bennett and Crudgington, 2003; Woodall *et al.*, 2004; Holton *et al.*, 2008). In a qualitative study by Williams and Dair (2007) involving five (5) case studies of completed developments in England, they identified a number of barriers to sustainable construction practices, including; lack of consideration of sustainability measures by stakeholders, sustainability not being required by clients, real and perceived costs and inadequate expertise and powers. To add to the above Boston Consulting group(BCG) and MIT Sloan Management Review carried a mixed method research involving interview with fifty(50) leaders in sustainability and thousand five hundred and sixty (1,560)survey response from business leaders. This work identified the root cause of difficulties facing organizations pursuing sustainability as being a lack of the right information upon which to base decision, companies struggle to define business case for sustainability and flawed execution of sustainability by companies who deliver sustainable projects (Berns *et al*., 2009).

Leadership

Leadership is believed to be an important factor in achieving business success in any organization. Despite the extensive research carried out on leadership, Giritli and Oraz (2004), in their survey of leadership styles of construction professionals in Turkey, argued that, leadership is one of the least-understood concepts in business. Jing and Avery (2008) added that, despite the prevalent appreciation of the importance and value of leadership, the concept of leadership still lacks lucidity and agreement in leadership literature. In Odusami *et al.* (2003) quantitative research of sixty (60) questionnaire surveys to determine the relationship between project leadership and construction project performance, it was pointed out that not much work has been done on leadership in the construction industry.

Leadership has a very significant influence on organizational activities including sustainability yet leadership has not been a focus of research in the field of sustainability. The study and the understanding of leadership and its relationship to sustainability is still in its early stages (Egri and Herman, 2000; Quinn and Dalton, 2009). Little or no research has been done linking leadership and sustainability in the construction industry in particular. Even though, the field of leadership is well researched, Chan and Cooper (2007) conducted research through in-depth interviews with fifteen (15) leaders of the UK construction industry revealed that, the understanding of construction leadership is to some extent primitive, compared with the rather mature developments of mainstream leadership theories. The interest and the significance of organizational leadership is increasing rapidly as a result of the need for organisations to innovate continuously to meet the current changing business environment.

Despite the wealth of knowledge built around the concept of leadership, there is no single definition of leadership; however, a view of leadership according to Doh (2002) is that it is an executive position in an organization and a process of influence. Leadership is concerned with the ability to influence the behaviour of others to deal with the desires of the leader (Fellows *et al*., 2003). Ferdig (2007) describe leaders as those who inspire a shared vision, build consensus, provide direction, and foster changes in beliefs and actions among followers needed to achieve the goals of an organization. Northouse (2010) however define leadership as:

> *"A process whereby an individual influences a group of individuals to achieve a common goal"*

Leaders are essential at all levels (Munshi *et al.,* 2005) and can emerge at different levels of an organisation (Newton, 2009). Ferdig (2007 add that leadership is extended to any one who seeks sustainable change regardless of the role or position, and such leaders can connect with others using different assumptions about how people work together to create meaningful change. From the definition of leadership above, anyone in an organisation could potentially be a leader at some point in time if they are involved in a process of influence that involves encouraging sustainable practices (Taylor, 2008). The construction industry in general and the UK construction industry in particular, is in an era of a difficult socio-economic, cultural, political, and business environment. There is an urgent need to promote a positive culture in the construction industry and these require leaders with positive values and good levels of moral and ethical behaviour to change the conservative paradigm of management in the industry Toor and Ofori, 2008). Leadership theories identified by Munshi *et al*. (2005) include traits and styles; contingency; transformational/transactional; distributed and structuralist leadership theories.

Leadership Styles

Leaders have an important role in guiding construction organizations toward sustainable practices and it is believed that such leaders require unique leadership styles. Leadership style is all about how people interact with those they seek to lead (Groetsch and Davis, 2006). However, Toor and Ofori (2006) describe leadership style as a combined outcome of the leader's self-related cognitive information, personality traits, the primary motives, and thoughts on operating situational variables. Style is an important part of leadership but no single leadership style is best for all situations. There has not been any evidence to show that one particular leadership style is the best (Vecchio, 2002; Giritli and Oraz, 2004). There are different types of leadership styles, each proving effective depending on the given circumstances, attitude, beliefs, preferences and values of the people involved.

Many styles of leadership have been proposed for organizational leaders including; transactional, transformational, charismatic, democratic, servant, autocratic, consultative, laissez faire, joint decision making, authoritative, participative, tyrant, task oriented, relationship oriented, production-oriented, employee-oriented, delegating, authority-compliance, impoverished management, team management (Toor and Ofori, 2006). According to Bossink (2007), charismatic, instrumental, strategic, and interactive leadership styles influence an organization's innovativeness towards sustainability. The charismatic leadership style communicates vision, energizes others, and accelerates innovation processes such as sustainability. An instrumental leadership style structures and controls the sustainability improvement processes, while a strategic leadership style uses hierarchical power to innovate.

Finally, it is suspected that the interactive leadership style empowers employees to innovate sustainably and to become sustainable leaders themselves (Bossink, 2007). Transactional leadership helps organizations achieve their current objectives more efficiently while Visionary leaders (transformational, charismatic) create a strategic vision of some future to achieve high levels of cohesion, commitment, trust, motivation, and hence performance in the new organizational environments (Zhu *et al.*, 2005). Avery (2004) describe visionary leadership as leaders who employ a collaborative style for making decisions, share problems with their followers and seek consensus before the leaders make the final decision.

Leadership for Sustainable Construction

Sustainability requires organizational leadership to take bold steps to move beyond efficiency, compliance or just being green, to a higher level of performance. Sustainability is now viewed by organizations as being part of a strategy for long-term business survival and success (McCann and Holt, 2010). Leadership is vital in the construction industry and a key success factor in the drive towards sustainability. Leaders should embed sustainability in their organizational activities and make sustainable development part of their overall business strategy (Ofori and Toor, 2008). Parkin (2010) emphasises the link between leadership and sustainable practices when she asserts,

> *"Leadership is a vital ingredient for achieving sustainability. Without it sustainability will never make it in government, business or anywhere"* (Parkin, 2010).

Organizations are now required to fundamentally change the way they operate from focussing on the short-term maximization of shareholders value to now pay attention to the economic, social and environmental effects of their operations (Quinn and Baltes, 2007) The construction industry is therefore one of the key sectors required to lead the drive due to the significant negative impacts construction activities can cause. Both Egan (1998) and Latham (1994) called on industry leaders to lead the quest for change in the construction industry. It is believed that any effective change process requires committed leadership. Leaders have a significant role to play in the construction industry as the industry undertakes its critical role in the efforts to attain sustainable development (Ofori and Toor, 2008). It is suspected that the ability of organisations, irrespective of their level of maturity, to pursue the sustainable agenda is influenced by the commitment and conviction of their leadership approach towards sustainability. Leaders should communicate the importance of sustainability and establish a culture of integrating sustainability into day-to-day management decisions (Avery, 2005).

A qualitative study by Quinn and Dalton (2009) using structured interviews, sampled leaders from organizations that formally adopted sustainability practices and found that sustainability requires the integration of social, economic and environmental issues fully into the vision, values and operations of all organizations. This requires leaders to reform redesign and restructure their organizations to incorporate sustainability values into the fabric of the organization to minimize their negative impacts. In contrast, Ofori and Toor (2008) believe that leadership is the key factor of success in the drive towards sustainability. They argue that, the solution lies in leadership that is self-aware, committed and able to earn the support, and direct the actions, of all stakeholders towards the pursuit of a common project related goal of sustainability. This was the result from a study involving interviews with 32 prominent leaders in the Singapore construction industry.

A study by Szekely and Knirsch (2005) **identified** the best available methods and criteria that companies have been using to measure their sustainable performance as a result of implementing sustainable development initiatives. This work examined the way twenty major

German companies measured and reported their sustainability performance. They identified leadership as the most critical success factor that an organization needs to promote and achieve sustainability. Leaders have the opportunity to use the influence to help shift their organisations towards sustainability. This study acknowledges that it was important that such leaders have both leadership abilities as well as sustainability knowledge, to guide their organization effectively (Quinn and Dalton, 2009). In a survey to assess students' personal commitment to sustainability, sustainability knowledge, and interest in the topic of sustainability, it was found by Middlebrooks, *et al*. (2009) that as organizations and governments continue to underline a shift towards sustainable values and vision, then effective sustainability leadership will become increasingly important. Therefore the next generation of leaders must learn how to integrate their conceptualization of sustainability with the ability to facilitate others in pursuit of that vision.

However, Doppelt (2003) asserted that, organizations are not fully embracing sustainability because most organizational leaders do not fully understand the issues and do not know how to develop strategies required for the adoption of more sustainable practices. Even though Redekop (2007) comment that, the characteristics of a sustainability leader have not been systematically researched, Middlebrooks, *et al*. (2009) have identified the characteristics of sustainability leadership as; the ability to *see* organizational culture through the informed lens of the triple bottom line of sustainability, knowledge and understanding of the different balances and interconnections between bottom lines in the pursuit of sustainable ends, a desire to make a positive difference in the long-term, the ability to influence others in a socially just manner, and the ability to manage behavioural and systems change. Success with sustainability requires clear leadership at the organisational level, to identify, understand and manage efficiently ground-breaking solutions which address the critical social, environmental, and economic challenges faced by the world today as illustrated in figure 1 below.

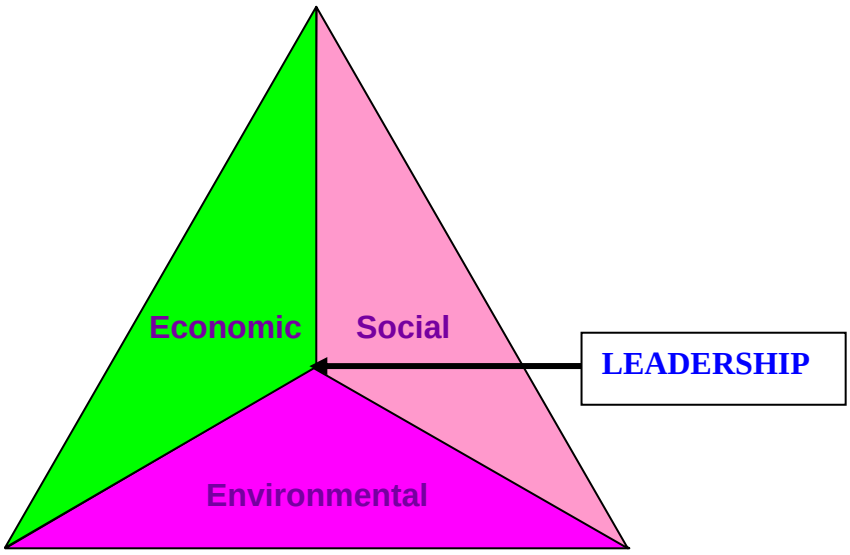

Fig.1 *Leadership at the centre of Sustainability*

When implementing a business strategy that commercially incorporates sustainability, leaders must be able to understand the motivation of different stakeholders, and engage and partner with mangers to weave sustainability into the fabric of the organizations. Leaders must also posses the ability to understand and overcome the challenges or barriers to adopting

sustainability (Lueneburger and Goleman, 2010). Sustainability leaders should not just give directions but should also develop and implement actions in collaboration with others, adapting to unforeseen changes in the environment overtime through modification as when needed (Ferdig, 2007). Sustainability leaders must display result delivery and commercial orientation competence as well as the ability to translate a vision of sustainability into a comprehensive programme of targeted initiatives (Lueneburger and Goleman, 2010).

RESEARCH METHODOLOGY

The primarily aim of this research is to critically examine the factors affecting the effective implementation of sustainable construction practices in UK construction organizations. It also investigates whether there is a difference in the leadership styles of sustainability leaders in construction. The research process commenced with a critical review of the literature, followed by a series of semi-structured interviews with sustainability leaders in construction organizations. A semi-structured interview involves the implementation of a number of predetermined questions. Interviewees are asked open-ended questions in a systematic and consistent order (Berg, 2001; Fellow and Liu, 2003). The interviewer prepares some questions or a frame for the interview and is also free to probe when necessary. Burns (2000) adds that, semi-structured interview allow greater flexibility than the closed-ended type and permit a more valid response from the participant's perception of reality.

To examine how leaders in UK construction organizations are promoting sustainable construction practices, in-depth semi- structured interviews were carried out with eight (8) sustainability leaders from construction consulting organizations in UK. Formal letters were sent to these leaders as an invitation to participate in the study. These were then followed with telephone calls and a total of 8 leaders agreed to take part and the profile of the interviewees is presented in Table 1 below. The interviews were conducted in a slightly loose manner lasting 30-40 minutes. It was also important to contact leaders from construction organizations currently pursuing sustainable construction practices. Despite the above, the data collected and the analysis presented here still yields some interesting preliminary findings related to the exploration of factors affecting the implementation of sustainable practices in construction organizations.

Interviewee	Job Title	Type of Construction organization
A	Sustainable Construction Manager	Consultant organization
B	Head of Sustainability	Consultant organization
C	Senior Sustainability Consultant	Consultant organization
D	Corporate Sustainability Manger	Consultant organization
E	Principal Sustainability Engineer	Consultant organization
F	Associate Head of sustainability	Consultant organization
G	Associate: Sustainability Manager	Consultant organization
H	Sustainability Consultant	Consultant organization

***Table 1**: Profile of Eight UK Sustainability Leaders Interviewed*

Naoum, (2002) indicates that this approach is best used when the research problem to be investigated is at its preliminary stage. Questions asked during the interviews addressed issues such as: what drives construction organizations to pursue sustainable practices; the role of leader in promoting sustainable construction practices; factors affecting leaders in the effective implementation of sustainable practices in construction and leadership style of sustainability leaders.

FINDINGS AND DISCUSSIONS

This section presents a discussion of the findings extracted from the analysis of the interviews. With most of the companies interviewed, the focus on sustainability started with a clear desire to introduce sustainability on the part of the leadership. Figure 2 provides a framework of the summary of each of the above issues considered in turn,

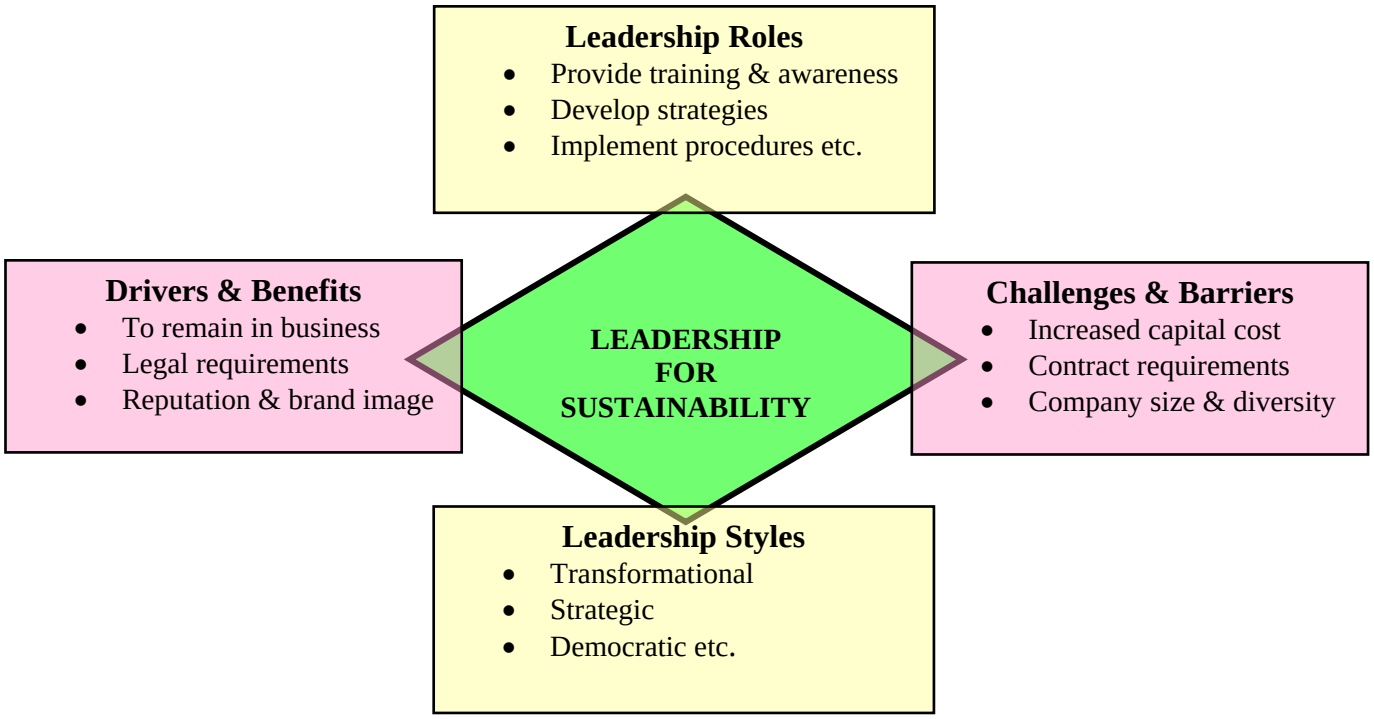

Fig.2 *Framework for analysis and discussion of findings*

Drivers

Sustainability leaders were asked about what drives their organizations to pursue sustainable practices and the results were very interesting. Some of the drivers include: company reputation or brand image; win more contracts to remain in business; position in the market place or competitive advantage; legislation or legal requirement; clients demand, improve economic performance; as a core value in corporate social responsibility. For example interviewee 'D' responded by saying:

"There are a plethora of business sustainability drivers that generate sustainable practices for us as a business and indeed for our clients, including: legislation and legal requirements, cost efficiencies, energy prices, water costs, waste issues, higher building profile, proximity to clients/competitors, proximity to public transport, social issues, ethics, stakeholder influence,

retention of key staff, competitiveness, green agenda, polluter pays, floods, environmental revenue, taxation, resource depletion, higher quality environment etc. These drivers are underpinned by a moral obligation to act with integrity and do the right thing".

Furthermore, many of the interviewees pointed out that, having a green reputation will help their organisations to win more business in periods of economic recession, interviewee 'B' noted:

"What drives this company to pursue sustainability is for corporate identity or brand to remain in business especially in this current economic climate"

Role

It was found that sustainability takes place in an organization better when there is an active leader within the company to champion the sustainability approach. Sustainability leaders have a role in helping to promote sustainable construction through: training staff on sustainability; produce guidance notes and policies; ensure that sustainability is embedded in the business; sustainability monitoring and appraisal etc. Interviewee 'F' highlighted that:

"I am the main author of our sustainability guide and responsible for the integration of our strategy internally within the company and the strategy promotion externally. I also sit on our group sustainability committee which drives the strategy throughout the company"

Several of the interviewees pointed out that the training of employees on sustainable issues was also a part of their roles. For instance interviewee 'E' said:

"I serve as catalyst in raising awareness on sustainability by training staff on sustainable construction practices".

Challenges

Sustainability leaders face many challenges in attempting to persuade their organisations to adopt sustainable construction practices. When leaders were asked about factors affecting them in the effective implementation of sustainable construction practices in their organization the following issues were raised, namely, one major challenge to organizational leaders is the lack of full understanding of what sustainability truly means to their company due to key fundamental information gaps. Following the analysis of the collected qualitative data, the following factors were identified as other challenges; lack of client awareness; lack of business case understanding; lack of client demand; large company size and diversity. In her view interviewee 'D' reflected that:

"Whilst sustainability involves achieving a balance of the social, economic and environmental factors, the current financial climate can influence perception that the economic considerations negate the social and environmental ones. The size and diversity of our company also proves a challenge in ensuring communications reach all stakeholders".

Furthermore, interviewee 'C' added that:

Managing competing and conflicting targets with other departments of the company to the understanding of a common sustainability goal is always difficult".

Senior management of company boards have other high priorities and sustainability is at the bottom of most company boards' priority list. A sustainability consultant; Interviewee 'H' explained that:

"Top management or company board lack the awareness and knowledge to make decision on sustainability"

Style

A significant part of the study was to identify leadership style of sustainability leaders. Leadership style was found to be an important part of leadership but no single leadership style was found to be best for all situations. Style of leadership was identified among the eight leaders interviewed as being; strategic, democratic, charismatic, transformational/ visionary and instrumental. Strategic leadership style was the most commonly identified style among the sustainability leaders. Most leaders described themselves as strategic and influential in the development of sustainability strategies. As interviewee 'A' observed:

"I am in a strategic role, active in the development of our sustainability strategy. I continue to influence the direction of the company in relation to sustainability and to help drive the ethos within the company through various mediums including engagement with stakeholders"

CONCLUSIONS

Sustainability is quickly becoming an essential market force ignited through customer, shareholder and stakeholder demands. Currently a business purely driven by profit without consideration for its environmental impact and no recognition of the social value of products and services will not prosper in a sustainable future. Construction organizations have critical roles to play in the efforts to attain sustainable development. Leadership is a vital factor for achieving sustainability. The role of the leader in guiding construction organizations toward sustainable practices is complex and vast, and it has been alleged that it requires an exceptional array of leadership skills, competencies and ethical commitment for it to be successful.

The desire of construction organizations to pursue sustainability is driven by a number of factors including: company reputation or brand image; the need to win more contracts to remain in business; positioning in the market place or competitive advantage; legislation or legal requirement; and the improvement of economic performance. However, there are number of factors affecting the effective implementation of sustainable construction practices such as: lack of the right information upon which to base decisions; companies struggle to define the business case for sustainability; a lack of consideration of sustainability measures by stakeholders; not required by clients; real and perceived costs. Leadership style is also an important part of leadership. It was found that a strategic leadership style is the most commonly identified style among the sustainability leaders involved in the study. Most sustainability leaders interviewed described themselves as strategic and influential in the development of sustainability strategies.

However, there were some differences in the opinion of leaders interviewed and that of reviewed literature. Sustainable leaders interviewed have a passion and fully understand the business case for sustainable construction, contrary to what was asserted in the literature. However the interviewees and the literature reviewed agreed that the importance of clients in

the pursuit of sustainability. The interviewees confirmed that the importance of client demand was a driver or a barrier to sustainable construction since the industry is client driven. The pursuit of sustainable construction practices is both a challenge and an opportunity. It is therefore important that organizational leaders turn such challenges into opportunities. Sustainable leaders have a role in helping to promote sustainable construction by training staff on sustainability; producing guidance notes and policies; ensuring that sustainability is embedded in the business, as well as the assessment and monitoring of sustainable practices. This therefore establishes the need to further investigate the role of leadership in promoting sustainable construction in the on-going PhD research study.

CONTRACTOR ABILITIES TO DEVELOP COLLABORATIVE PRACTICES IN AUSTERITY TO MEET ENVIRONMENTAL SUSTAINABILITY AGENDAS

HEDLEY SMYTH
The Bartlett School of Construction and Project Management, UCL
h.smyth@ucl.ac.uk

Abstract *The boom era was characterised as continuous improvement in construction. Collaborative practices and a focus upon differentiation were primary features. The current market is austere with a primary focus upon cost. Survival is a dominant contractor strategy. Yet, certain contractors are retaining collaborative practices as a means to secure work, lever value and deliver effectively. Some have embedded collaborative practices as core competencies and dynamic capabilities that lever value in supply chains and networks. Environmental sustainability agendas are long-term and are likely to increasingly drive factors affecting construction in the future. Collaborative practices will be necessary to lever value to meet sustainability agendas early in the project lifecycle. Firms pursuing this path are likely to be the minority yet will be more successful by growing market share in the long run compared to the competition.*

Keywords: Collaboration, Competencies/Capabilities, Investment, Marketing, Survival

INTRODUCTION

How is the construction sector shaping and changing itself in the emergent economic era of austerity? To what extent will the resultant changes equip or constrain the construction sector to meet "sustainability" agendas over the coming years? The *aim* is to conceptually scope the ability to respond to future needs given recent and current responses during austerity. One *objective* is to evaluate the extent to which collaborative and partnership practices of the last 10-15 years provide a means to meet service and sustainability requirements in the future. A second *objective* is to evaluate the potential consequences for main contractors of low levels of investment motivated by survival during austerity.

Austerity is defined in terms of the consequences of economic downturn. It is evidenced as low levels of demand in the construction sector due cutbacks in investment from the public and private sectors. Most construction firms are primarily focused upon survival (El-Higzi, 2002; Skitmore et al, 2006; Skitmore and Smyth 2008). They keep their investment and overheads low; they keep capacity building and developing capabilities low. This is to maximise ability to respond to the "lumpiness" of demand at any time and the amplitude between the booms and slumps in the market (e.g. Smyth, 1985; Linder, 1994; Hillebrandt et al, 1995).

"Sustainability" is defined in environmental terms. Whilst definitions abound, this is conceived around current understanding as presented to industry, for example by the recent Morrell Report to the UK government (Morrell, 2010a). Collaboration is defined along two dimensions. The first dimension is the type of practices conceived in construction around so-called continuous improvement drivers, such as partnering the supply chain (Egan, 1998). In theoretical terms this is underpinned by relational contracting (Macneil, 1980; Williamson, 1985). The second dimension is the type of practices that emanate from investment within the

firms. The theoretical basis is core competencies (e.g. Hamel and Prahalad, 1996) and dynamic capabilities (Teece et al, 1997), which are embedded processes and abilities that go beyond the skills, expertise and professional disciplines that are essential to conduct a business. Examples of core competencies and dynamic capabilities might be organisational learning and knowledge management or the formal and informal routines established to conduct activities more efficiently and effectively. Collaboration can be a dynamic capability in itself to lever value from within mainstream operations, but can also act to lever value from another capability or core competency.

Main contractors tend to subcontract work. Leverage will typically be within a supply chain or industrial network (Håkansson, 1982; Håkansson and Snehota, 1995; Christopher et al, 1996; Skaates and Tikkanen 2003). Levering value is therefore largely a function of service provision rather than technology and production capability. This is why collaboration is important and requires capacity. There are two conceptual tensions. The first is between theoretically transitioning from relational contracting as a basis for collaboration, that is, responding to market and procurement drivers, to relationship management competencies and capabilities that are embedded in the firm. The lessons learnt from relational contracting may have become embedded as capabilities, but not automatically. This needs investment.

This paper explores the extent to which the demands ahead, especially around sustainability agendas, can be met in conditions austerity. Are collaborative capabilities being lost that may prove necessary in the future? The boom era was characterised by continuous improvement initiatives in construction, of which alliances, partnering, integrated teams were advocated as a major component of facilitating improvement (e.g. Egan, 1998). This type of collaboration was a move away from adversarial markets. There was a focus upon service differentiation (cf. Porter, 1985). In practice, initiatives largely fell short of original expectations. Improvements were generally project specific, but nonetheless improvements were made (Smyth, 2010a).

The current market is austere. It has shifted from being focused upon differentiation to one focused upon cost (cf. Porter, 1985). Cost savings and driving prices down are the primary client concerns (e.g. Morrell, 2010b; Smyth, 2010b). But that does not mean the capabilities for levering value across networks, especially through collaboration are lost? This needs exploration. At this point the conceptual case has to be explored in the light of limited available information beyond the anecdotal.

The paper undertakes this exploration by briefly reviewing the boom era of continuous improvement in construction. It considers the period of transition induced by the austerity of the slump market. It then considers the tension and balance between collaboration and low investment to conceptually gauge where the sector may be positioned for meeting sustainability agendas in the future.

THE ERA OF CONTINUOUS IMPROVEMENT

The era of continuous improvement was ushered into being within construction during boom times. It was conceived conceptually and in policy terms during the previous austerity period. Theories had been developed, such as lean production, and concepts were being applied in practice, such as supply chain management and partnering in other industries (e.g. Womack et al, 1990; Womack and Jones, 1996). Discontent, particularly amongst clients that had come to

expect added value when procuring other services and products, had been growing in construction during the early 1990s, as failure to meet minimal time-cost-scope/quality was common occurrence. Initiatives were emerging, for example through the Lean Construction Institute in the US, influenced by the work of Ballard and Howell (1988) in efforts to reduce waste and improve efficiency, and in the UK from the Latham (1994) and Egan (1998) Reports. Parallel influences in the UK were, for example, the work of Bennett and Jayes (1995; 1998).

A series of institutional arrangements were put in place in many countries, for example in the UK the Egan Report led to the Movement for Innovation (M4i) and Constructing Excellence as a successor to encourage and transfer „best practice". Collaborative practices were being advocated through client leadership, partnering the supply chain to improve innovation and performance.

There were early criticisms of collaborative approaches (e.g. Bresnen and Marshall, 2000; Green, 1999). Theoretical rigor was one; questioning how transferrable the measures were into asset specific supply was another; further criticism concerned the extent to which main contractors were committing investment or adopting the rhetoric to secure work and squeeze suppliers, and how penetrating successes were (e.g. Bresnen, 2007; Green 2006; Mason, 2008). A recent UK study considered 150 out of a total of 525 demonstration projects designed as exemplars of transferrable knowledge. Covering a 10-year period it was shown that more project benefits had accrued than strident critics suggested, yet have fallen a long way short of expectations, concluding:

> *…explicit knowledge has not been transferred beyond largely general descriptions of improvements. Although these descriptions may have stimulated other parties to try similar initiatives, there is insufficient description of what has been done and how it has been done in demonstration project write-ups to facilitate direct comprehensive knowledge transfer.* (Smyth, 2010a: 269)

Not only were lessons not being transferred between organisations, they largely remained project-specific in contracting organisations, that is, not being transferred through corporate investment to be embedded as core competencies and dynamic capabilities that go beyond the essential operational skills and expertise, nor embedded into contractor programme management. Furthermore, sustainability was a low priority in the early years of continuous improvement. Whilst it was coming to the fore in the mid-to-late-2000s, specialist consultants and subcontractors were the primary players rather than main contractors (Smyth, 2010a). Therefore, the role of main contractors was to lever value from the industrial network and supply chains. Value leverage is aided by collaboration (e.g. Beach et al, 2005; Kumaraswamy and Rahman, 2006; Anvuur and Kumaraswamy, 2008; Smyth, 2010a).

New tailored services could form the basis for developing core competencies and dynamic capabilities beyond the essential skills and expertise for operations. This could occur through teasing out generic skills and knowledge to be captured for widespread and repeated application. Some contractors took tentative steps, for example an increased strategic systems orientation in certain North American contractors (Zoiopoulos, 2011) and improved marketing capabilities to add service value (Chambers et al, 2009). The effectiveness of embedding such collaborative practices largely depends upon establishing new ways of doing things. This can be practically characterised as establishing formal and informal routines (cf. Nelson and Winter, 1982) that (a) improve the efficiency and effectiveness of mainstream

operations through collaboration by reducing transaction costs (cf. Williamson, 1985), and (b) lever added value through supply chains.

A PERIOD OF TRANSITION

The 2008 "credit crunch" changed a great deal. It ushered in austerity. The level of demand dropped and procurement drivers changed. Demand has shrunk. Where construction clients continue to buy, many have switched from demanding for service differentiation to a cost focus (cf. Porter, 1985). Some of the advocates of continuous improvement have made dramatic shifts, for example the UK supermarket chain Tesco has demanded a 30% price cut from all suppliers including consultants and contractors. The UK Government advisor on construction has also demonstrated how prices have risen (Morrell, 2010b), although an analysis of the extent to which the price rises have accrued as premium profits and/or added value is absent.

Cost drivers are likely to remain dominant short- and medium-term. However, there are two significant underlying trends. Some contractors are minded to retain collaborative practices. They have witnessed a shift in the culture, absorbed as informal and formal routines (e.g. Chambers et al, 2009; Smyth and Fitch, 2009). They perceive benefit in such capabilities for securing work from existing clients under conditions of intensified competition. This links to the second trend: sustainability. Its various dimensions are likely to increasingly drive factors affecting construction in and beyond the current era of austerity (e.g. Edkins et al, 2009; Morrell, 2010a).

Collaboration is an important part of main contractors meeting the sustainability agendas, yet UK projects where effective collaboration is sufficiently penetrating *"are still very much in the minority"* (Morrell, 2010a: 54). The UK case is not thought to be exceptional. What does vary between construction companies and national cultures is the degree to which strategic planning is applied. Madsen (1989) has shown that hands-on strategic planning and investment is necessary to be successful for business development and execution, especially in domestic and adjacent markets, for example the national and EU market for UK or Dutch contractors. UK contractors were less strategic than European counterparts and divested during the last recession, losing market share to European competitors (Stockerl, 1997; Stockerl and Smyth, 1998). Initial indications are towards a similar pattern emerging (Smyth, 2010b). The evidence overall points towards contactors that strategically plan and invest in capacity and capabilities are likely to be most successful in the long-term. This is in line with the resource-based view of the firm (Penrose, 1959; Wernerfelt, 1984), and in line with the theoretical subsets of core competency and dynamic capability theory (e.g. Hamel and Prahalad, 1996; Teece et al, 1997). Collaboration is part of this theoretical line of thinking and builds capacity for the future. In contracting the necessary investment to embed collaborative practices requires investment, which needs to be sufficient whilst not taking risks that threaten survival (El-Higzi, 2002; Skitmore et al, 2006).

What sort of collaboration is in evidence and what is needed to meet sustainability agendas in the future? Collaboration during the boom era was characterised by contracting firms leaving it to individual responsibility (Smyth and Edkins, 2007). Those firms that have embedded collaborative practices have established formal routines through systems and procedures, which guide individuals towards collaboration, around which new norms and informal routines are established that have a reinforcing role (e.g. Pryke and Smyth, 2006; Smyth and

Fitch, 2009; Gustafsson et al, 2010; Zoiopoulos, 2011). However, most main contractors have not made the transition from relational contracting to investment in core competencies and dynamic capabilities.

TOWARDS COLLABORATION OR UNDERINVESTMENT DURING AUSTERITY

As main have not invested in new developing capabilities, collaborative practices are largely residual. They are in evidence through individual behaviour or through informal routines that emerged during the era of continuous improvement. The residual routines of collaborative practices have the capability to help secure work for firms and meet sustainability as it affects construction internally, through supply chains and across industrial networks, as well as in relationships with clients to secure and execute projects. These may prove fragile because of reliance upon individuals and their behaviour. Effective collaborative practices will be those that are most effective for leveraging value, for example to meet sustainability agendas. They will systematically involve project managers, directors and business development managers that can identify needs and lever the value to develop win-strategies prior to and during the bidding process. Collaborative practices during execution will maintain the integrity of the win-strategy and deliver added value benefits to clients and other stakeholders. This may challenge some pre-conceptions that value is primarily levered during execution.

This value leverage is part of marketing, specifically relationship marketing and management (e.g. Grönroos, 2000; Christopher et al, 2006). Relationship marketing has become established amongst some contractors (Smyth and Fitch, 2009). This is part of the strategic project front-end (Morris, 1994). The front-end strategy for projects therefore enables commitments to be made through relationship marketing that adds value to the client and yields improved strike rates, especially for repeat business clients, for the contractor. Commitments are not merely about getting close to a client or suppliers in a business sense but about relationships that lever value. They become part of social capital that is transferred to the client asset (cf. Gustafsson et al, 2010). Commitments of internal resources and with alliance partners in the industrial network are thus made to create capacity and resources necessary to configure the project content and service. This is also the basis for making commitments to the client, which are subsequently embedded into the project in contractual terms and service promises. In this way added value of technical and service content is levered. The result would constitute a shift towards a greater service orientation, in line with what Vargo and Lusch (2004) call the service-dominant logic.

Whilst there is a strong theoretical base to support the argument, mapping out what this looks like on the ground is difficult for two reasons. First, core competencies and dynamic capabilities, such as collaborative practices, are configured in many forms. The different forms are ideally aligned to market segments and individual clients in ways to position a contractor from its competition. Second, sustainability agendas differ as will the substantive content of requirements.

However, there are strong drivers of survival in construction that result in minimising investment as noted (Hillebrandt et al, 1995; El-Higzi, 2002; Skitmore et al, 2006). To develop the point, there are three main problems from underinvestment experienced at the level of the firm:

1. Threats in the market from rivals that do secure a competitive edge through

investment (e.g. Stockerl, 1998; Smyth, 2010b).

2. Low investment carries a series of consequences:
    i. Constrained ability to carry risks, such as in public-private partnerships (e.g. Stiglitz and Wallsten, 1999);
    ii. Clients remain dissatisfied as provision fails to meet expectations and requirements because intensified competition exacerbates low investment (e.g. Stiglitz 1981);
    iii. Opportunism can lead to underinvestment in relationship-specific activities, such as collaborative relationships, and other social or human capital (e.g. Edlin and Stiglitz, 1995).
3. Inability to respond to fast changing environments (Morden, 1997; cf. Micklethwait and Wooldridge, 1996).

Therefore, whilst survival may be secured in the short-run, long-term growth is secured by contractors that invest for growth, particularly in the downturn and on the upturn. Such growth is typically characterised by growth in market share rather than profitability (Smyth, 2010b). The implications of growth is that firms that invest expand at the expense of those that underinvest, so short-term survival may lead to long-term decline or takeover.

CONCLUSION AND RECOMMENDATIONS

It has been argued that long-term success is derived from investment, a type of investment being dynamic capabilities or core competencies shaped as collaborative practices to lever value.

It has further been argued that sustainability agendas are likely to require investment and project specific commitments by contractors to secure work and satisfy clients. Whilst there may be several ways to achieve this, an obvious path is to switch from reacting to procurement drivers to proactive investment, particularly in service provision around relationship building and value leverage. However, there are strong drivers for survival amongst contracting firms that militate against this. Yet, evidence from the last recession shows that those that both invest and survive tend to be more robust and grow market share in the long-term. Sustainability agendas are likely to create similar opportunities in the market on the upturn from austerity.

It is probable that few firms are likely to pursue the path of investment in capability development and collaborative practices. This is likely to be due partly to the perceived risk and partly due to habit and cultural norms. The majority of main contractors may continue to set the primary goal as survival. Whilst this may work in the short-term, it weakens firms in the long-term in the face of competition from firms that invest. Moreover, low levels of investment render it difficult to respond to competitors that do invest and survive. They will grow market share. The implications for clients and society is that construction firms developing capacity will be best placed to provide a high quality service and meet the range of sustainability agendas in the future.

Abstract
Construction is one of the industries of strategic economic importance. Governments using their national institutions are involved in the collection of economic statistics, which indicate the state of their economy in an annual time series. However the completeness and accuracy of these statistics are always questionable by the stakeholders within the sector. Therefore there is an increasing need of accurate, manageable and reliable statistics for the sound analysis of the construction sector. The main purpose of this research is to review construction statistics in North Cyprus. The objectives of the review are to 1) engage with users to ascertain their views on the statistics and to identify their needs, and 2) investigate whether the statistics in their present form continue to meet user needs, and identify options for change. As part of the review, a user consultation exercise aimed to identify whether there are needs that justify continuing the statistics, as well as to ascertain users' views on European Statistical System (ESS) key dimensions of the quality of the statistics. This review of construction statistics will provide a conceptual framework of statistical information to be presented in a more comprehensive content, sufficient portrait, highly reliable in terms of quality, and responsive to dynamic changes of the sector (inflation, structural adjustment policies etc.). Additionally, it is aimed to detect and minimize the uncollected information and thus make contribution for prevention of unregistered activities within the sector.

Keywords: Construction Statistics, construction industry, North Cyprus.

INTRODUCTION

Governments all over the world are involved in the collection of economic statistics, which among other things indicate the state of their economy in an annual time series. These indicators are commonly known as official statistics. Construction is one of the industries of strategic economic importance and governments are obliged to take the industry‟s statistics seriously (K'Akumu, 2007). Construction as a sector of society is characterized by the economic activity of building and civil engineering works (Wells, 1986; Bon and Crosthwaite, 2000; K'Akumu, 2007). It is a sector of strategic economic importance especially for developing economies. This is because of its macroeconomic contributions to gross domestic product (GDP), gross fixed capital formation, employment and inter-sector linkages (United Nations Centre for Human Settlements, 1984). The United Nations defines construction as comprising „economic activity directed to the creation, renovation, repair or extension of fixed assets in the form of buildings, land improvements of an engineering nature, and other such engineering constructions as roads, bridges, dams and so forth‟ (United Nations, 2001). Construction activity represents a significant share of the economies of most countries in terms of its contribution to GDP and total employment and it is also an important market for materials and products produced by other sectors of the economy. Pearce (2003) considered construction both in its narrow sense (on-site construction activity) with its contribution to GDP at around 5% and in a broader definition (including quarrying of construction raw materials, manufacture of building materials, sales of construction products and various associated professional services) making a contribution of about 10% of GDP (Ruddock, 2007a). In addition to the Pearce Report, the case for a new approach to the valuation of construction activity has come from two other areas. Firstly, the „International Council for Research and Innovation in Building and Construction‟ (CIB) Revaluing Construction agenda focuses on improving the value of the final construction output and requires that the totality of activities involved in the production of the built environment is reviewed (Ruddock, 2007b). Secondly, Carassus (2004) proposes a framework system approach for understanding the construction sector. The rationale for this approach is based on the view that the role of the construction sector should be viewed in a wider context than that of the narrowly-defined „International Standard Industrial Classification‟ (ISIC) definition of the industry.

There are some impressive reviews of construction statistics in certain developed and developing countries conducted with a view to improving them. The available literature confirms that the key concerns of construction statistics reviews are mainly with their adequacy (K'Akumu, 2007). The question of adequacy can be split into two: (i) scope; and (ii) quality that can engender reliability. Apart from these, construction economists readily single out the uniqueness of linkages between construction and the economy (Briscoe, 1988; Hillebrandt, 2000). The portrait of the role of construction in the economy is therefore a significant responsibility of construction statistics upon which they can be evaluated. The responsiveness of construction statistics in the light of transforming economic conditions is another important attribute of construction statistics that may be used to evaluate them. As time changes, construction statistics may change with time to maintain relevance (K'Akumu, 2007).

The Annan Plan has had a major impact on the construction industry and its sub-sectors with increasing production, import and sale volumes compared to previous records in North Cyprus. Between the years of 2003 and 2009, many building and civil engineering projects like hotels, residents, dormitories, and highways were constructed by the private sector

initiatives such as owners, investors, developers, and contracting firms. Additionally, many infrastructure projects were constructed under the Grant Program of United Nations Development Programme (UNDP) and the European Union. On the other hand, campus construction of some state universities of Turkey and local private universities are ongoing. Despite these economic developments, a national authority on statistics i.e State Statistics Institute has not been established yet. This creates a great lack of reaching and accessing updated statistic information needed within the construction sector as in other sectors. Department of Statistics and Research (DSR) under the State Planning Organization (SPO), Union of the Chambers of Cyprus Turkish Engineers and Architects (UCCTEA) and Association of Cyprus Turkish Building Contractors (ACTBC) are the current public and non-governmental organizations which provide statistical information to the sector. But the statistical reports prepared by these institutions are not timely and not equipped with sufficient information for the needs of the sector. Therefore all the stakeholders (investors, contractors, architects, engineers, consultants, material suppliers etc.) face difficulties in timely access to the information they need and therefore they cannot make sound decisions.

There is a widespread recognition by uses of statistics that managers in North Cyprus construction industry are poorly served by existing data in the formulation of policies and strategies. Considering DSR‟s current circumstances, lack of departmental investment in organizational structure, qualified staff and also in hard-and software has prevented the introduction of up-to-date systems to analyze relevant data. Although the construction industry has undergone considerably change over the past decade, this has not in any way been adequately reflected in available official data. The statistical requirements of the Government differ considerably from those which should and could make a positive contribution to decision-making within the construction industry. There are criticisms in the area of dissemination and feedback. Dissemination refers to both timeliness in the release of the data and in the detail in which the data are made available. The DSR was aware of the whole panoply of changes affecting the industry in the past decade, but failed to ensure that the statistical resources were available to monitor and track some of those changes.

The main purpose of this research is to review construction statistics in North Cyprus. The objectives of the review are to 1) engage with users to ascertain their views on the statistics and to identify their needs, and 2) investigate whether the statistics in their present form continue to meet user needs, and identify options for change. As part of the review, a user consultation exercise aimed to identify whether there are needs that justify continuing the statistics, as well as to ascertain users‟ views on European Statistical System (ESS) key dimensions of the quality of the statistics.

CONSTRUCTING CONSTRUCTION STATISTICS

Statistics are the cornerstone of most decisions business people take and, indeed, the cornerstone of most government policy. The gathering of data by the Government is seen purely from the point of providing evidence for the ultimate management of the economy rather than statistics which should be helpful to the industry itself. In an industry as large and complex as construction, statistics play a very crucial role, in terms of monitoring both the external and internal factors which influence its structure, its performance and its behavior. To have statistics in adequate detail is a problem both quality and quantity. The quantity and quality of the range of statistics available to the industry is therefore of concern to all those who operate within construction or whose roles call for a sound knowledge of the industry and the factors which affect it. Quality includes definitions, coverage, reliability, consistency

and integrity. These are essentially the concerns of the statisticians who gather and process data. Quality, however, goes beyond this set of factors. It also means accuracy, relevance and timeliness, to which users attach great importance. In terms of coverage, there is no general agreement about what the definition of the construction industry ought to be. Coverage of what is meant by the construction industry is therefore one of the issues which has to be considered in the wake of various endeavors under way to revise the current range of statistics produced by the Statistical Services (Cannon, 1994). Coverage of the industry in terms of obtaining sufficient correct information from firms is an issue with which official statisticians grapple as a matter of course. It is, however, an ongoing problem in an industry where entry and exit are extremely easy and where self-employment has become the major form of labor supply in the past decade or so. This is aggravated by the existence of a large black economy sector. The problem of unregistered labor in the construction industry is international, to the point that in some European countries the official measures of construction output include an estimate for "black economy work".

Construction statistics refer to a collection of selected numerical facts that seek to portray certain conditions or attributes of the construction industry (K'Akumu, 2007). The primary source of data for construction statistics is current and annual reporting. Reports are submitted to agencies of the Central Statistical Board of the countries by builders (including private builders) and by construction and designing and surveying organizations. In addition to reports, construction statistics carries out censuses and one-time inventories and surveys (for example, statistics of construction machinery, uncompleted construction work, stocks of materials and equipment at construction sites). Statistical agencies submit material to State Planning Committees and to ministries and departments for the preparation of future plans for capital construction. They also investigate specific problems, summarize statistical practices, and refine the methodology used for indexes.

To improve the quality of international (and national) data provision generally, Lievesley (2001) indicated that, although the term „quality", when applied to official statistics, is difficult to define, the following components should apply: (1) validity, (2) reliability, (3) currency, (4) clarity and transparency with respect to known limitations, and (5) comparability through adherence to internationally agreed standards. In the context of a truly global market for construction, an international strategy is required to ensure that national and international statistical systems are able to provide accurate and valid information. In many parts of the world the collection of reliable national information on construction activity is not an easy task, and the measurement of comparable, cross-national data can be problematic. Ruddock (2002) considered possible strategies for the improvement of data collection systems in the context of user needs.

Coverage of Construction Statistics in North Cyprus

Data required for producing the statistical outputs is collected from a variety of sources (Ministry of Public Works, municipalities, association of building contractors, etc.), and then is processed using different methods. The data sources used in the report are mainly annual sample surveys and censuses, monthly inquiries and administrative records. Data on public and semi-public construction activity are derived from government records such as the budget, departmental reports and financial statements. For the private sector, the data are obtained through special questionnaires that are filled in by enumerators of the Statistical Service. In the case of data on building permits, these are compiled through a copy of the actual permit issued by the appropriate authorities (municipalities and district administration offices) and forwarded to the Statistical Service.

DSR‟s Yearly Construction Statistics in North Cyprus comprises the following statistical outputs:

- Main indicators of the construction industry
- Output of new construction by category
- New construction by type of project
- Construction costs per square meter
- Dwellings completed by sector, district and type
- Indices of costs in the construction sector
- Cost Analysis by construction activity
- Price index of construction materials
- Building permits authorized
- Employment in construction

REVIEW OF CONSTRUCTION STATISTICS

Construction statistics would give vital insight into the contribution of construction to economic development. In spite of the importance of construction, its statistics are usually of questionable quality even in developed countries (K'Akumu, 2007). In the United States of America (USA), the review of construction statistics has been taking place for a long time. Gill (1933) carried out a review of the construction statistics of the USA. He felt that there was "lack of specific and accurate information available in USA on the subjects of construction and employment in construction" (Gill, 1933). Gill‟s argument about inadequate data and need for adequate data lays the foundation for any reviews of construction statistics. The USA President underscored the fact that statistical shortcomings had handicapped the development of effective policies to combat construction inflation and to meet future construction needs (Swerdloff, 1971), and therefore asked the Cabinet Committee on Construction for recommendations on improving the statistical information on construction. The US recognizes that the construction industry continually undergoes change and that it is important for the national statistical agency to provide users of construction statistics a forum to discuss statistical programmes vis-a`-vis their needs (K'Akumu, 2007). Fleming (1986) had pointed out the shortcomings of the UK‟s construction statistics. There has been a long debate on the inadequacy of construction statistics between UK government agencies in charge of statistics, i.e. the Department of Environment (DoE) and the National Economic Development Office (NEDO) on the one hand, and users of construction statistics on the other (Cannon, 1994). Bon (1990) and Cannon (1994) consider the usability aspects of existing public and private data and the failure of such data to meet the needs of its users. Cannon (1994) point out that many industry users may be unaware of the availability of some information because the originating institution may not recognize the usefulness of disseminating the data to a wider audience. Meikle and Grilli (1999), in their study of the measurement of construction output in European countries, point out that construction output data are not consistent in content and there is no generally accepted standard international definition. Lopes (1998) referred to the inadequacy and rudimentary nature of data on the construction industry in developing countries and pointed out the lack of input–output data in such construction sectors. The uncoordinated collection of data via several agencies leads to unnecessary processing problems, which could be eradicated by the setting-up of a central national agency. Ofori (2000) proposed the notion of a „central data bank for construction‟ and took this notion further, advocating the development of regional construction databases for groups of countries. Pearce (2003) considered measures of the construction industry in the UK and raised the problem of definition conceived in terms of „broad‟ and „narrow‟ classifications.

Briscoe (2006) examined the broader statistical issues in greater depth to identify shortcomings that could cause some of the findings presented by Pearce, and similar studies, to need qualification and possible revision. K'Akumu (2007) evaluated construction statistics of a developing country, Kenya, in order to ascertain their adequacy in terms of scope, portrait, reliability and responsiveness in their coverage of the construction industry.

SURVEY OF USERS AND CONSTRUCTION STATISTICS USED IN NORTH CYPRUS

The review of construction statistics includes data collection and compilation methodologies used to produce the statistics. User needs and requirements for the statistics were identified and their views on quality of the statistics were ascertained in line with the European Statistical System (ESS) dimensions of quality.

Sampling and Data collection

The study was focused on the public and private organizations actively taking part in the construction industry. The lists of all registered private organizations were obtained from the concerned chambers (i.e Union of Chambers of Cyprus Turkish Engineers and Architects; Turkish Cypriot Chamber of Commerce), and associations (i.e Association of Cyprus Turkish Building Contractors). Particular departments of some ministries (i.e Department of City Planning; Department of Planning and Construction; Water Works Department), academic institutions (i.e Universities), and municipalities are also included in the survey. For the study of wide range of organizations using the statistics, the following criteria were used in the selection of respondents taken randomly in the organizations. All respondents were

- either engineers or architects, and
- either from the top management or senior management in their respective departments.

The criteria for selection of sampling companies were homogeneously distributed throughout the country in order to ensure a complete view of the sector; and most of the companies were involved in construction work and design activities. With regard to the stages within the construction process in which the respondent companies were involved, most worked in at least two of them.

The profile of the respondents reflected the selection criteria used for the participant companies. Respondents were homogeneously distributed throughout the country. Selection of respondents for the interview was based on those who are involved in managing and working the day-to-day construction activities of North Cyprus. A collection of opinions from different organization members is assembled instead of a single respondent from each firm. Respondents were purposively selected to provide a representative sample in terms of the definition of the North Cyprus construction industry, i.e., consultancy, contractor, material suppliers and design offices.

The survey was distributed to construction professionals working in different organizations ranged from Material Suppliers, Design Offices and contracting firms in private sector and public organizations. Having considered that statistics were identified through continuous collaboration among members, respondents from different professional backgrounds, which include architects, engineers, project managers, and project coordinators were approached. As a result, 175 prospective respondents were enlisted and to whom the survey was sent. 134 completed questionnaires were returned. The overall response rate is 76 %.

Regarding the respondents‟ background, the results reported in Table 1 indicate that the respondents are playing different roles in firms ranged from engineers to project coordinators. Thus, it is considered that opinions of members working in different construction organizations have been obtained.

Table 1: Surveys received and the respondents‟ background matrix

Respondents‟ background	Material Suppliers	Trade Associations	Design Offices	Consultancy	Contractors	Government	Academic Institutions	Municipalities	Number of questionnaire received
Engineer	8	8	4	3	3	2	1	1	30
Architect	6	6	3	3	2	2	1	1	24
Project Managers	10	9	8	7	4	3	2	1	44
Project Coordinators	9	8	6	5	3	3	1	1	36
TOTAL	33	31	21	18	12	10	5	4	134

User Consultation Methodology

Understanding users of the statistics is fundamental to engaging with them effectively so as to improve the public value derived from the data. As part of the review, a consultation was conducted to ascertain users‟ views on the quality of the statistics, to understand how they make use of the data and to identify their needs. The user consultation was conducted through a user survey and carried out via e-mail and postal surveys using a questionnaire involve a wide range of users from various backgrounds.

The questionnaire was designed to elicit core user needs and their views on key dimensions of statistical quality. It was reviewed by key stakeholders (contractors, engineers, architects, consultants, material suppliers etc.) to ensure correct interpretation and a logical order of questions. Responses received from the e-mail and postal surveys produced both qualitative and quantitative data which were processed and analyzed using the SPSS software.

The questionnaire covers mainly types of respondent, purposes for using the construction statistics, frequency of uses of the construction statistics, and views on the quality of the statistics (timeliness, accuracy, relevance, accessibility and clarity, comparability with other data). The questionnaire also includes structured open questions covering the main use of the statistics, the usefulness of the statistics, user requirements in terms of details, coverage and types of statistics, problems encountered when using the statistics, and impact of discontinuation of the statistics.

Survey Results

A total of 134 responses were received, including postal responses.

Types of Respondent

Respondents to the survey came from a wide range of organizations, reflecting a diversity of users of the construction statistics. Figure 1. provides an overview of the organizations where respondents work or study. Respondents from Material suppliers (25%) and Trade Associations (23%) firms make up the two largest groups, accounting for nearly half of total respondents.

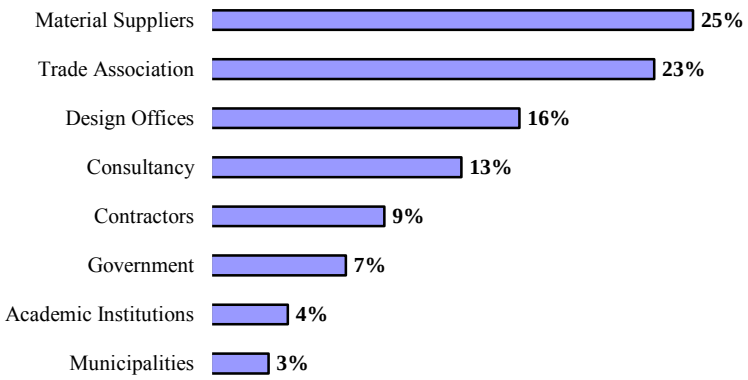

Figure 1: Breakdown of types of respondent

Uses of the Statistics

In terms of types of statistics used, both statistics of main indicators of the industry and statistics of output of new construction by category were used by the largest proportion of respondents (62%) followed by new construction by type of project (58%) and construction costs per square meter (57%). In comparison, only 10% respondents use the statistics of employment in construction, as indicated in Figure 2.

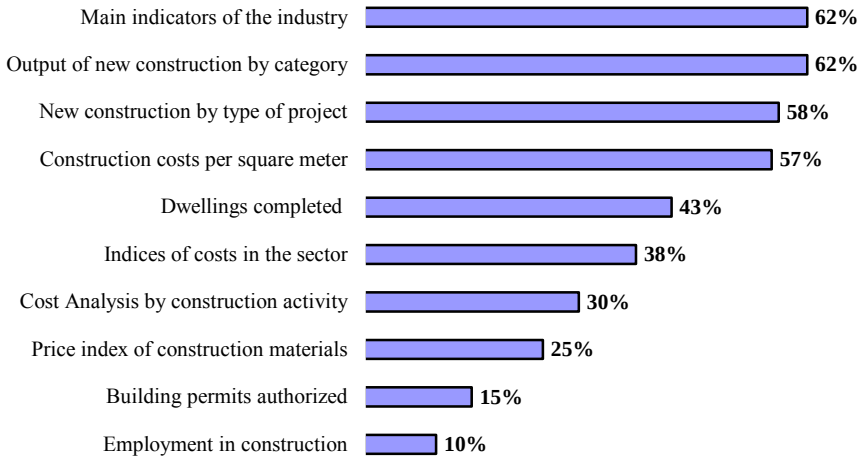

Figure 2: Type of statistics used

To discern respondents‟ principal interests in the various statistics, the uses of the statistics by types of respondent were analyzed as displayed in Table 2. The table indicates that Material Suppliers showed most interest in Main indicators of the construction industry and were least interested in employment in construction data, whereas users of employment in construction are mainly from Academic Institutions and Consultancy firms.

Table 2: Statistics used by types of respondent

	Contractors	Consultancy	Government	Material Supplier	Trade Association	Academic Institution	Design Offices	Total Use
Main indicators of the construction industry	3	7	3	11	6	5	4	39
Output of new construction by category	3	6	3	10	3	4	6	35
New construction by type of project	5	6	2	8	4	4	3	32
Construction costs per square meter	5	5	2	7	4	4	4	31
Dwellings completed by sector, district and type	6	6	3	2	4	5	4	30
Indices of costs in the construction sector	5	5	6	2	4	5	2	29
Cost Analysis by construction activity	6	4	2	6	3	3	4	28
Price index of construction materials	5	5	3	3	4	2	2	24
Building permits authorized	2	5	3	2	2	6	2	22
Employment in construction	2	4	3	2	2	5	2	20

Figure 3. displays the results concerning respondents‟ purposes for using the construction statistics. The largest proportion of respondents (67%) use the statistics for monitoring industry information, followed by assessing industry trends (55%). The statistics on construction are the only key source for assessing the economic environment for property market, for instance, monitoring the impact of the recession on residential real estates. Moreover, the price data of property market are useful for stakeholders to monitor and assess the variations in prices of particular real estates and the impact of recession and inflation on the prices.

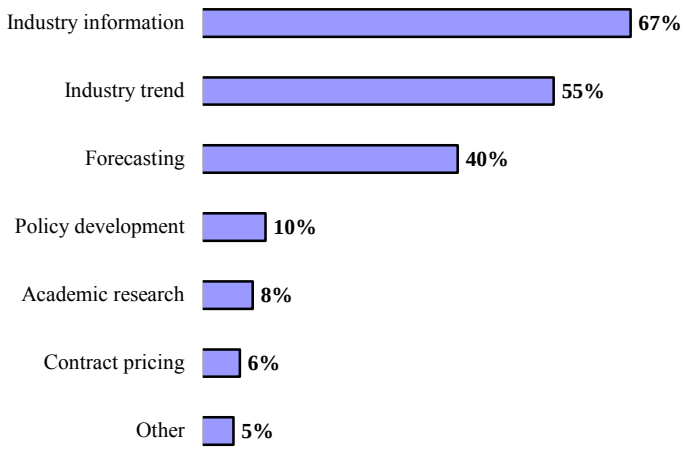

Figure 3: Purposes for using the construction statistics

Regarding the frequency of uses of the statistics, Figure 4. illustrates how often respondents use the construction statistics. It indicates that most respondents use the statistics yearly, which is also the frequency that the statistics are published.

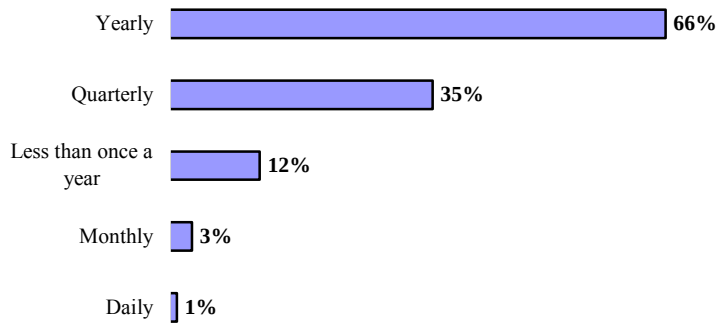

Figure 4: Frequency of uses of the construction statistics

Impact of Discontinuing the Statistics

Table 3. indicates how respondents‟ work would not be affected if the statistics were discontinued. The effect of discontinuing the statistics on respondents varies according to the types of statistics, but in the main, a majority of respondents felt that discontinuing the statistics would not cause major or significant disruptions on their work.

Table 3: Impact of discontinuing the statistics

	Major Disruption	Significant Disruption	Some Disruption	No effect
Main indicators of the construction industry	9%	15%	23%	53%
Output of new construction by category	8%	14%	21%	57%
New construction by type of project	8%	13%	20%	59%
Construction costs per square meter	8%	12%	20%	60%
Dwellings completed by sector, district and type	7%	12%	19%	62%
Indices of costs in the construction sector	7%	11%	19%	61%
Cost Analysis by construction activity	8%	12%	20%	60%
Price index of construction materials	6%	11%	19%	64%
Building permits authorized	5%	10%	18%	67%
Employment in construction	4%	9%	16%	71%

Respondent Views on the Quality of the Statistics

In the survey, the extent of respondents‟ satisfaction with the quality of the construction statistical outputs was ascertained in line with the following European Statistical System (ESS) dimensions of quality; *timeliness*, *accuracy*, *relevance*, *accessibility* and *clarity*, *coherence* (comparability with other data). In addition respondents‟ views were also asked on information available for how data is collected and level of details in the statistics.

The Likert scaling technique was adopted and applied to a majority of questions for ease and uniformity of response. Its application implied for the most part that analysis of data was based on a scoring system. Respondents were asked to state the extent to which they agreed with each statement by using a 5-point Likert type scale.

As illustrated in the Tables 4., 5., and 6. below, a large proportion of respondents were unsatisfied with the quality of each type of statistics in terms of relevance, accuracy and timeliness due to the lack of information on data collection methods and data quality.

Table 4: I am satisfied with the relevance of the statistics to my work.

	Strongly Agree	Agree	Neither Agree nor Disagree	Disagree	Strongly Disagree
Main indicators of the construction industry	10%	11%	3%	44%	32%
Output of new construction by category	10%	12%	2%	42%	34%
New construction by type of project	11%	13%	2%	41%	33%
Construction costs per square meter	11%	14%	3%	41%	31%
Dwellings completed by sector, district and type	12%	15%	2%	43%	28%
Indices of costs in the construction sector	12%	14%	2%	42%	30%
Cost Analysis by construction activity	11%	15%	3%	42%	29%
Price index of construction materials	12%	15%	3%	44%	26%
Building permits authorized	10%	11%	3%	43%	33%
Employment in construction	9%	11%	3%	44%	33%

Table 5: I am satisfied with the accuracy of the statistics

	Strongly Agree	Agree	Neither Agree nor Disagree	Disagree	Strongly Disagree
Main indicators of the construction industry	18%	17%	3%	42%	20%
Output of new construction by category	17%	15%	2%	40%	26%
New construction by type of project	17%	16%	3%	39%	25%
Construction costs per square meter	18%	17%	3%	41%	21%
Dwellings completed by sector, district and type	16%	16%	3%	40%	25%
Indices of costs in the construction sector	15%	15%	2%	41%	27%
Cost Analysis by construction activity	14%	15%	3%	40%	28%
Price index of construction materials	14%	16%	3%	42%	25%
Building permits authorized	14%	15%	3%	40%	28%
Employment in construction	13%	13%	3%	43%	28%

Table 6: I am satisfied with how up-to-date the statistics are

	Strongly Agree	Agree	Neither Agree nor Disagree	Disagree	Strongly Disagree
Main indicators of the construction industry	8%	10%	3%	44%	35%
Output of new construction by category	9%	12%	3%	42%	34%
New construction by type of project	10%	11%	2%	41%	36%
Construction costs per square meter	11%	14%	3%	38%	34%
Dwellings completed by sector, district and type	12%	15%	2%	37%	34%
Indices of costs in the construction sector	12%	14%	3%	39%	32%
Cost Analysis by construction activity	11%	14%	3%	38%	34%
Price index of construction materials	10%	13%	3%	40%	34%
Building permits authorized	10%	12%	3%	42%	35%
Employment in construction	9%	10%	3%	45%	33%

Table 7. indicates how unsatisfied respondents were with other key quality attributes of the statistics as a whole. More than 65% of respondents conveyed their dissatisfaction with all of the quality attributes. “Information available for how data is collected” gained a high disapproving rate, both with 70% of respondents feeling very dissatisfied or dissatisfied.

Table 7: Respondents satisfaction on the following aspects of the statistics

	Very satisfied	Satisfied	Undecided	Dissatisfied	Very dissatisfied
Clarity of presentation	12	18	2	41	27
Ease of access	14	19	2	36	29
Comparability with other data	13	17	2	40	28
Level of detail	14	18	2	40	26
Information available for how data is collected	11	16	3	42	28

CONCEPTUAL FRAMEWORK OF CONSTRUCTION STATISTICS PROGRAM FOR NORTH CYPRUS

Figure 5. shows the conceptual framework of construction statistics program. The flowchart illustrates how data in surveys are collected and employed in providing direct estimates or as input to construction statistics programs. Information on building permits issued for new private residential construction is collected from permit-issuing jurisdictions on number of housing unit permits issued and their permit valuation. These statistics are a leading economic indicator. Data are to be collected monthly from a sample of permit issuing places and annually from the remaining permit issuing places. Monthly, quarterly and annual estimates of housing units authorized by building permits can be available on the Internet. The survey of output for construction collects and publishes information on residential units started, sold, and completed each month. Information is collected directly from construction firms by field representatives. Firms should report business receipts, payroll, assets, and other economic information as well as types of construction they are engaged in during the year of the census. Included in the reports are values of work by type of construction, statistics by size classes, assets data, etc. The system achieves a more rapid collection of data, fewer late reports, and better quality of data since questionable responses are to be verified immediately. All data

collected in the field are to be transmitted directly to headquarters for review and tabulation. Monthly estimates of starts, sales, and completions are made at the national level and for regions, and starts and completions estimates are made for selected regions for type of buildings. The quarterly or annual estimates will include units started, units sold, units completed, and a wide range of characteristics of housing such as sales price, square footage of house, presence of garage, etc. Starts and completions estimates are to be published as preliminary, first, and second revisions. Since sales estimates are subject to greater numbers of late reports than starts and completions, they may have a third revision.

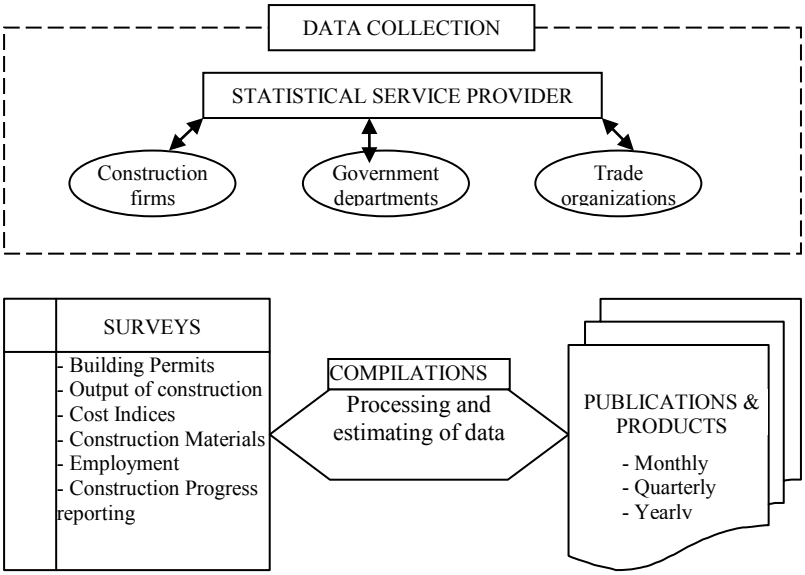

Figure 5: Conceptual Framework of Construction Statistics Program

CONCLUSIONS AND RECOMMENDATIONS

The review of construction statistics documented and examined data collection and compilation methodologies used to produce the statistics. It identified user needs and requirements for the statistics and ascertained their views on quality of the statistics through user consultation. The production of the statistics draws on a multitude of data sources and requires coordinated efforts from SPO-DSR, UCCTEA and ACTCC. The findings of the review indicate that the current data collection methodologies need improving to address various quality issues such as the coverage and accuracy of data inquiry panels.

The statistics have users from various backgrounds with a variety of purposes. Main uses include monitoring market information and assessing industry trends. Material supplier firms and trade associations account for more than half of respondents. The majority of respondents from the construction industry consider the statistics essential and helpful. Respondents‟ views on the quality of the statistics are mainly negative, because they are unsatisfied with the information available on how data is collected, indicating improvement needed in this area. Respondents from the industry have a stronger need for continuing the statistics than those from the government. The review also identified several user requirements for both existing statistics and new data.

This review of construction statistics also provides a conceptual framework of statistical information to be presented in a more comprehensive content, sufficient portrait, highly

reliable in terms of quality, and responsive to dynamic changes of the sector (inflation, structural adjustment policies etc.). Additionally, it is aimed to detect and minimize the uncollected information and thus make contribution for prevention of unregistered activities within the sector.

Recommendations

The main recommendations of the review are for improving the methodologies used to compile the statistics, for user consultation, for user requirements, and compliance with the statistical code:

- The coverage and accuracy of the sample panels used in the data inquiries should be regularly monitored and checked against other sampling frames and with relevant trade associations to ensure the representativeness of the data.
- DSR should consider options for improving response rates
- Methodologies used to process survey results should be improved.
- Sharing the responsibility of collecting and publishing the statistics with others should be considered.
- Wide and regular user consultation should be maintained continually through various ways such as meetings of Consultative Committee on Construction Industry Statistics and periodic on-line consultations.
- DSR should look into publishing more data alongside the existing statistics as requested.
- DSR should investigate how to modify the coverage of the statistics, maintaining their relevance to users and affordability.
- DSR should publish supporting commentary
- DSR should publish a revisions policy, and explain the nature and extent of revisions when revised statistics are released.
- DSR should set out a quality improvement plan to address quality issues identified during this review.
- DSR should ensure the staffs who deal with confidential data sign declarations covering their obligations

Abstract
Responsible sourcing (RS) provides a means to manage and ensure the attainment of sustainability objectives by procuring materials with a certified provenance. It is demonstrated typically through an organisation"s procurement policy, via its purchasing decisions and practices, and addresses a range of environmental, economic and social considerations. In the UK, the government requires that 25% of construction products shall be from RS schemes by 2012 and major contractors are considering raising this target even further for major commodities like aggregates, metals, steel, concrete, bricks and glass.Results from an industry survey and company case studies show that major materials industries are instrumental to provision of RS goods; architects, clients and major contractors will drive change in the supply-chain; scope for enhanced reputation and market differentiation are encouraging many companies to seek certification. RS has the potential to transform the construction supply-chain into a transparent and sustainable enterprise; market forces and the notion of „doing the right thing" may determine its more widespread adoption.

Keywords: Construction materials and products; Procurement; Projects; R&D; Sustainability.

INTRODUCTION

The construction industry is subject to growing stakeholder expectations about the accountability, transparency and legitimacy of its operations. This arises from concerns about:

- environmental impacts
- global supply chains
- labour and welfare conditions
- bribery and corruption

It is time to act on these concerns and ensure that the UK construction industry is responsibly sourcing its materials and products. Although there is no one single definition for responsible sourcing (RS) of construction products, it refers to the management of sustainability issues associated with materials in the construction supply-chain, often from an ethical perspective. Responsible sourcing of construction products offers a novel way to improve the implementation and traceability of sustainability objectives throughout the project supply-chain. The emergence of RS as a means to manage and ensure the attainment of sustainability objectives by procuring materials with a certified provenance, offers potential for improved sustainable procurement practices and higher scores in established sustainability assessment tools (Glass, 2011 forthcoming). Government initiatives for RS have changed the way that the construction materials supply chain is judged and a fast-increasing number of products are becoming certificated to new framework standards on responsible sourcing. This paper reports new results on the current state of RS practices in the UK construction industry. The key objectives of a survey and interview programme, with specifiers, contractors and manufacturers, were to understand:

1. the current scope and definitions of RS
2. drivers and benefits
3. who takes responsibility for RS on projects
4. the current state of RS assessment and certification

The outcomes from this work will help to define future directions for research on RS within the construction sector.

ABOUT RESPONSIBLE SOURCING

Use of the term „responsible sourcing" (RS) is relatively new due to the recent governmental sustainability strategy: Strategy for Sustainable Construction (HM Government, 2008), which encourages the construction industry to select responsibly sourced products. It stated that, by 2012, 25% of products used in construction shall be from schemes recognised for responsible sourcing and asked for framework standards to be developed, which it described as „*a documented set of criteria setting out the obligations of an organisation in managing the supply of construction products in accordance with a set of agreed principles of sustainability*" (HM Government, 2008). RS schemes therefore are expected to be more comprehensive than „chains of custody" such as Forest Stewardship Council (FSC) and managerial systems such as International Organization for Standards (ISO).

Responsible sourcing is demonstrated typically through an organisation"s procurement policy, via its purchasing decisions and practices, and addresses a range of environmental, economic and social considerations. It can be perceived as taking an ethical approach throughout the supply chain, but does not pertain only to social issues. Such attitudes are now enshrined in standards, for example, BS ISO 26000 (2010) urges equal consideration of ecological, economic and social development goals, together with broader scale adoption of principles of social responsibility.

Use of the term „responsible sourcing" has appeared only relatively recently in the context of the construction industry, namely in response to government strategy, which will be discussed late. Taylor (2008) suggests that responsible sourcing demonstrates that an organisation or industry „*accepts a broader responsibility for its licence to operate, beyond profit-maximising activities*", thereby seeking to „*avoid damage to bottom line economic performance by improving procurement policy, labour practices and management of environmental impacts*". His interpretation underpinned the development of the first framework standard for responsible sourcing, BES 6001 (2009), which is also discussed later, but importantly now defines the responsible sourcing of construction products as: *„a holistic approach to managing a product from the point at which a material is mined or harvested in its raw state through manufacture and processing, through use, re-use and recycling, until its final disposal as waste with no further value".*

This will affect procurement policy, supply chain management, product manufacture and specification practices, but will necessarily improve both accountability and traceability in the supply-chain. New (2004:271) asserts that „*...the notion of supply chain ethics cannot be swept away... buyers in particular will share some responsibility for the actions of suppliers".* Indeed, in other sectors like fashion, food and mining, companies and industry partnerships have already reacted to concerns about environmental degradation, child labour, unsafe practices, bribery and corruption by setting up ethical or voluntary codes of conduct. Specific examples include well-known voluntary, ethical trading initiatives such as Fair Trade and Rainforest Alliance for various consumer goods, plus certification schemes for materials such as the Forestry Stewardship Council (FSC). There are also supplier data exchange and auditing schemes, such as Sedex (www.sedex.org.uk) and StringTogether (https://stringtogether.com), used by companies in the clothing industry to handle detailed information on the provenance of materials, products and services, and new reporting mechanisms, such as FTSE4Good, the Global Reporting Initiative, and SA8000 from Social Accountability International, www.sa-intl.org), to report, audit and compare performance.

THE UK CONSTRUCTION INDUSTRY APPROACH

To encourage construction industry specifiers and clients to select responsibly-sourced products, the „*Strategy* for *Sustainable Construction"* (HM Government, 2008) sought to move away from the criteria set out in „chain of custody" schemes like FSC and management systems such as ISO 14001 (2004). It stated that, by 2012, 25% of products used in construction shall be from schemes recognised for responsible sourcing and asked for framework standards to be developed to evidence the management of: „*...the supply of construction products in accordance with a set of agreed principles of sustainability*". Two such documents now exist:

- BES 6001 *Framework standard for the responsible sourcing of construction products v2* (BRE Global) details a series of organisational management, supply chain

management and, environmental and social requirements; it covers legal compliance, management systems, traceability and more specific aspects such as waste management, transport impacts and life-cycle assessment. For each item, it sets out specific criteria against which achievement can be scored; there is a threshold level of achievement which acts as a barrier to entry and four levels of performance (see http://www.greenbooklive.com/page.jsp?id=169 for a list of certified products).

- BS 8902 *Responsible sourcing sector certification schemes for construction products – Specification* (BSI, 2009), sought to create a „standard for standards", defining responsible sourcing as „management of sustainable development in the provision or procurement of a material or product". This is a more straightforward document and contains a useful list of headings or issues that should be addressed in any responsible sourcing scheme. However, it was designed to be applied at sector-level, rather than specific products, so is not considered here in quite as much detail as BES 6001.

A responsible sourcing scheme enables individual manufacturers to gain accreditation for their products to a „standard framework" for a particular product/material group (i.e. concrete, timber etc). The manufacturer is then able to promote specific products as „responsibly sourced", based on its achievement on the rating system used (e.g. „Good", „Very Good" etc). This score can be used in established sustainability assessment tools, e.g. the Building Research Establishment Environmental Assessment Method (BREEAM, see www.breeam.org) and the Code for Sustainable Homes (see www.communities.gov.uk/planningandbuilding/buildingregulations/legislation/codesustainable/). CEEQUAL, the civil engineering environmental quality scheme, also makes specific reference to materials from responsible sourcing schemes in version 4 (section 8.3) (see www.ceequal.co.uk).

Furthermore, RS offers a neat link between the „triple bottom line" aspects of sustainability and management of corporate responsibility. For this reason, a link is commonly made between responsible sourcing and sustainable procurement, a term which carries significant weight in the construction industry, particularly following publication of the „*Sustainable Procurement Action Plan*" (DEFRA, 2007) which called for change in how the government estate, roads and the supply-chain are procured to better address issues of low-carbon, water, waste and other sustainable development goals. Walker and Brammer (2009) define sustainable procurement as „*procurement that is consistent with the principles of sustainable development, such as ensuring a strong, healthy and just society, living within environmental limits, and promoting good governance*". Although the notion of abiding by a set of principles clearly connects this with responsible sourcing, the terms are not interchangeable; rather, the responsible sourcing of construction products nests within an overall ethos of sustainable procurement. This is evidenced in BS 8903 *Principles and framework for procuring sustainably – Guide* (BSI, 2010), which cites responsible sourcing as an example of good practice in leadership and governance.

However, there is a complete absence of a research agenda on RS and a lack of evidence about its current status in the construction industry. Although certification schemes exist, there is no indication of current levels of knowledge and uptake. The research reported in this paper has collected new data from industry respondents and identified some critical new research directions. The data and conclusions also form an important stepping off point for two related research projects:

- **APRES network on responsible sourcing:** Loughborough University is leading an Engineering and Physical Sciences Research Council funded academic-industry network (Action programme on responsible sourcing, APRES) to develop a coordinated response on responsible sourcing (see http://apres.lboro.ac.uk). The overarching aim is to react to the challenges of delivering responsible sourcing, by creating a community „centre" for knowledge-sharing of responsible sourcing practices, forging new research ideas and relationships. It provides an open and impartial discussion forum for industry and its customers, academics, government, professional bodies, trade associations and standard-setting bodies. A core group of companies and leading universities has already signed up to the APRES network (Bovis Lend Lease, Building Research Establishment, Responsible Solutions, URS Scott Wilson, University of Bath, University of Nottingham, University of Warwick), together with over 40 Associate Members.
- **Ready for responsible sourcing – SME training package:** The aim of this research project was to develop a new suite of training resources on the responsible sourcing of construction products; see www.responsible-sourcing.co.uk. It targetted both demand-side specifiers (i.e. architects, engineers and contractors) and supply-side manufacturing enterprises. It was funded by Sustainable Construction innovation Network (iNet), which is funded by East Midlands Development Agency (*emda*) and the European Regional Development Fund (ERDF); the project partners were Loughborough University, the University of Nottingham and Responsible Solutions.

RESEARCH APPROACH

This research study used qualitative and quantitative research methods. An online questionnaire survey was developed and circulated to a variety of stakeholders, including: materials manufacturers, contractors, specifiers – including architects and engineers, sustainable construction experts and advisory bodies, trade associations, regional bodies with a construction and/or sustainability remit; small and medium enterprise (SME) networks and peer/industry networks. A total of 51 organisations responded to the survey, which was then complemented by 15 interviews with key specifiers (contractors and designers) and manufacturers to discuss issues in more detail; their roles are shown in Table 1. The majority of informants were senior level staff; over 20 were from contracting companies, 15 were based in material/product manufacturers and 12 were from specifiers.

Table 1: *Respondents" roles within their organisations.*

Based on the objectives, the project team brainstormed a list of possible topics that the industry survey and interview instruments might include. These included: *"Company profile", "Corporate sustainability and RS", "Manufacturing and specifying for RS"*. From this list, draft questionnaires were developed and piloted with ten industry experts and experienced researchers. The answer formatting options to forms were further examined for fitness-for-purpose; clarity and variety.

The main benefits of using an online survey tool are its ability to present questions in a neat and uniform way, offer a gateway for data collection and perform basic analyses on the received data. This enabled the data analysis to be fairly straightforward and descriptive, although a cross-tab was used to examine and differentiate answers. An interview protocol for asking questions and recording information during the qualitative interviews was designed. This protocol comprised a heading, instructions to the interviewer, key research questions; probes to support key questions; space for recording the interviewer"s comments; and space for the researcher records reflective notes, in addition to audio recording of the interviews. The data were transcribed, prepared for analysis and organised categorically and chronologically, reviewed repeatedly and continually coded. The transcribed data were then sorted and categorised into a number of themes under headings, as per Miles and Huberman (1994). In all cases, a comparison was made between survey and interview responses; the results section which follows attempts to draw together some of the key descriptive statistics and major themes; it is followed by a discussion which relates our study to relevant literature.

RESULTS

Understanding the scope of RS

The survey and case study interviews showed a range of understanding and awareness levels of RS in the UK construction industry, despite the freshness of the subject. Respondents understood RS to be part of sustainability, ethics, standards, quality and supply chain management, as shown in Table 2.

Table 2: *Respondents"comments on the scope of RS.*

Theme		Respondents' statements
Sustainability	Environment	Renewable sources; Sustainable products; Low transportation CO_2; Depleting natural resources; Production/transportation; Manner that minimises impact on the environment; Least impact on the environment; Environmental dimensions; Respect the proper definition of sustainability ; Waste recycling; Use and re-use until final disposal; Responsibility for sourcing materials and products; Recycled and recyclable materials; Balanced societal/environmental impacts.
	Society	Local sources; Locally sourced; Provide work for local community; Maximise return for the people involved; Exploited individuals/resources; Enhance the social conditions of the supplying community; Ensure that people have not been exploited; Social dimension; Exploiting vulnerable people; Positive impact on life.
	Economics	Commercial dynamics; Price competitive; No limited categories of expenditure; Economical dimension; Economically and financially sound.
Ethics		Transparency; Fair trade; Responsible manner; Suppliers are treated ethically and with respect; Fair pay for workers; Ethical suppliers; Wages and working conditions; Ethos of supply chain management; Assurance;

	Principles; Guarantee; Being sustainable and ethical; Ethical, sustainable approach to procurement; Responsible manufacturer; Ethical and fair price; Ethically resourced; Products manufactured in an ethically sound way.
Standards	Sustainable policies and standards; Aspiration laid down in the Code for Sustainable Homes; Labour standards; Meeting legislation.
Quality	Standardisation and certification by 3rd party; Fully legally compliant, transparent fair and third party certified; Health and Safety.
Supply chain management	Approach an organisation takes to manage procurement activities; Ordering only what you need; Procuring materials and products; Process of supply chain management; Point of origin and method of production; Understanding whole supply chain; Product stewardship; Holistic approach to managing the social, environmental and economic impacts; Supply chain; Business requirements; Stage of the supply chain; Effective management; Appropriate environmental, legal, ethical quantity controls in place; Vetted and analysed products and services.

One interviewee stated that RS meant: "*the product and user business are performing at high ethical, quality and safety standards for both business and supply chain*", whereas others linked this with compliance, i.e.: "*sourcing the product and materials to meet with national and international standards... we look at environmental, social, ethical, health and safety issues related to manufacture and supply*". Of the 36 survey respondents who opted to provide a definition, 18 cited sustainability and 11 mentioned supply-chain management; several gave definitions which centred on procurement, for example: *"purchasing from a supplier that can demonstrate its products are manufactured ethically"*.

Examining the drivers and benefits

More than two-thirds of the interviewees stated that RS was highly important to their business. It was the manufacturers that used phrases such as "*extremely important*" and "*very important*", whereas specifiers (i.e. contractors and designers) described RS as "*important*" or "*customer-led*". More than half (54%) of the survey respondents believed that RS would be *"Of utmost importance"* in the next five years and 70% that RS was going to be beneficial to their core business activities. Manufacturers felt that "*having BES 6001 has made it easier to sell more even in a very difficult year*"; it had also enhanced their reputation and confidence. Of the 51 survey respondents, 29 described the benefits of RS; for example, being at the forefront of the market, gaining competitive advantage, showing evidence of duty/CSR and helping towards continuous improvement. One respondent captured the benefits by saying: *"(RS) can improve the rigour of procurement processes, prompt a fuller consideration of whole-life costs, provide a basis for joint improvement activity with suppliers and build reputational capital."* One of the interviewed manufacturers explained the background to this: "*If you take the main drivers of responsible sourcing, some of these came out from BRE documentation in terms of things like BREEAM, the Government"s Code for Sustainable Homes... (for which) you get credits for choosing products coming from RS schemes for the key elements of the building."* Hence, the manufacturer gains a better corporate reputation and more sales from having certified products and the client/building owner attains a higher score in BREEAM, CSH and CEEQUAL assessment schemes by selecting such products. For example, one manufacturer had sought accreditation specifically to gain recognition for products in the Code for Sustainable Homes and increase sales, he said: *"We are very focused on having green credentials. Knowing that we had such a high percentage of recycled material we decided to try for the next level. Also we have a management team that is ready... if you don"t have that it wouldn"t have worked; it has to come from the top*".

Taking responsibility for RS on a project

According to the survey respondents and interviewees, clients and specifiers shared responsibility for the selection of RS products on a project. Many felt that everyone had a role to play, e.g. one manufacturer said: "*everybody in the supply chain has a degree of responsibility... the client has responsibility in procurement because (and) the specifier's responsibility is in specifying the right material.*" 53% of the survey respondents thought clients should take the lead, followed by 12% citing architects and 6% selecting contractors. Indeed, by probing such answers, most interviewees tended to converge on specifiers and/or clients as particularly important. There was a clear sense that some clients were more likely to take a leading role (as „early adopters"), whereas others would latterly be driven by cost, legislation or market forces. Contractors believed that architects and clients were driving the process, but were not always convinced that these parties fully understood what RS meant and in any case, their specification was unlikely to go much further beyond a basic product specification; it would often fall to the contractor to actually select a particular manufacturer and product line. One contractor explained: "*the Client or specifier has the most power to drive RS. We, as a main contractor, do influence that products used are responsibly sourced if we think they (client/designer) are not using products as they should be – we try to influence our clients to source responsibly where we can*". This shows that some major contractors are very proactive on RS and are trying to create stretch goals for their clients.

The current state of assessment and certification for RS

The survey respondents were asked about their awareness of RS credits within the three assessment schemes mentioned previously; 67% were aware of RS credits in BREEAM, 50% CSH and 33% CEEQUAL (although the latter could be due to a bias towards building contractors rather than civil engineering contractors in the sample). This indicates an important gap in specifiers" knowledge of RS and points towards a key barrier to RS becoming more mainstreamed. Furthermore, the product certification standard (BES 6001) was launched in 2008, but less than half of the survey respondents (44%) had heard of it and only eight had actually specified materials with a BES 6001 certificate. That said, more than half of them were actually aware that aggregates, cement, concrete products and steel reinforcement were available through RS schemes; one even thought that there should be a responsibly sourced option for all product types. Seven manufacturers with certification to BES 6001 were included in the interview programme to ensure a balanced response. They considered certification to be an important addition to the construction industry, but raised concerns about the cost and process of attaining the certificate and the fact that RS accounts for only a small percentage of credits available in schemes like BREEAM, CSH and CEEQUAL. That said, the interviewed manufacturers perceived BES 6001 as vital in „setting the bar" at an appropriate level to ensure differentiation, saying that the standard has to remain meaningful. The interview findings also showed that, apart from „point scoring", there are a broader range of driving forces for manufacturers to seek RS accreditation, some of which are internal and the remaining are external (see Table 3); these include corporate reputation, competitors, stakeholder and customer pressure.

Table 3: *Drivers for seeking responsible sourcing accreditation.*

Driver themes		Respondents' statements
Internal	***Main drivers:*** Self confidence Ambition Improve Marketing Recognise strategies	To show what we can do; to be seen as leader in the market; ambition to be No. 1; to identify how to get better; framework for managing our procurement in certain aspects that is better for the business; our intention to increase sales; recognition of Code for Sustainable Homes; we are very focused on having green credentials; we have a management team that is ready to drive that... it has to come from the top.
External	***Main drivers:*** Commercial advantages Enhance strategies Market pressure Competitiveness	Marketing and commercial advantages; to meet with strategies and standards; UK Strategy for Sustainable Construction; we hold standard certifications we decided to go for another one that gathers them all to answer all questions; market place pressure; stakeholder pressure; drive to remain competitive.

There is clearly an increasing demand for RS-certified products in the marketplace: during the time of the research, the number of BES 6001 certificates issued rose from 10 to 43 by early 2011. Although many had been attained by large, multi-national materials companies, the most recent additions to the BES 6001 list (perhaps the start of the „early majority") include small businesses and specialist contractors, indicating a broadening of the adoption of the scheme. Several interviewees have also predicted that the shape of the construction materials supply-chain will be fundamentally changed by RS within the next few years, suggesting that product companies without certification will be at risk of losing market share.

DISCUSSION – CRITICAL RESEARCH DIRECTIONS

The results from the industry survey and interviews now enable us to identify a number of important areas that warrant further consideration and research effort, a few of which are outlined here.

There was concern that the construction sector is yet to alight on a precise definition of what it means by RS; descriptions oscillate around sustainability, supply-chain management and ethics, with some informants making a clear link to corporate social responsibility (CSR). For example, one interviewee suggested that: "*From my point of view about the responsible sourcing is a sort of moral issue. It is about doing the right thing, having the visibility of issues that you have in your supply chain and actually how you manage those*". This confirms Loosemore and Phua"s (2011) view that the construction industry commonly holds a duty-based (deontological) view towards its responsibilities. Indeed, one of the survey respondents said RS was all about: *"showing how responsible we are... it is our duty to give something back and be advocates for the correct procurement of materials".* The emerging literature on ethics and CR, such as Murray and Dainty (2009), Fewings (2009) and Loosemore and Phua (2011), demonstrates a real growth in this research area and it is clear that RS in the construction products supply chain can make an interesting contribution to the debate. For instance, our research confirms that a „compliance" approach towards business ethics is still prevalent in construction and that companies are a long way off from Loosemore and Phua"s (2011:99) integrity-based approach, with its „*long-term changes to espoused and enacted values".*

Certainly the „early adopters" of RS consisted in the main of large companies with integrated management systems and certification for quality, environmental and health and safety management already in place (e.g. ISO 14001, 2004); these features made the BES 6001 assessment process somewhat easier for them because they already had the right systems in place. The importance of management systems is echoed by Holton et al (2010) in their recent study of sustainability management in material manufacturing companies; these systems act as a vital stepping stone towards better engagement with the subject, improved capabilities and market reputation. It is pertinent that Jones et al"s (2010) concern about a lack of focus on the social aspects of sustainability in construction companies (in the US) could be allayed, at least in part, by a greater recognition that RS includes a robust examination of social and moral issues.

Some of our respondents believed that transparency on performance was the common requirement for a product to be described as responsibly sourced. Interestingly, the notion that business should be more transparent and accountable is now firmly embedded in international practice. Commentators like GRI (2010:43) and Lueneberger and Goleman (2010:7) go further, respectively foreseeing „integrated storytelling" and „radical transparency" in years to come, which only serve to reinforce the potential future role for RS as an important mechanism for construction product businesses. We can envisage greater and greater pressure on companies and projects to disclose information on environmental and social indicators in a live and interactive way; this opens up opportunities for IT support tools to help companies communicate their RS performance with stakeholders.

Finally, McKinsey"s (2010) recent survey of 1,946 global business leaders (from a range of countries and sectors including construction and engineering) confirms that companies for which sustainability is a top-three priority are much more likely to actively seek opportunities and embed sustainability into business practices. While this is a truism, some of our interviewees demonstrated a lack of knowledge and understanding in some key areas of sustainable construction, which indicates an important gap between corporate values and operational expertise on the ground. In Accenture"s CEO study and strategy to „create the conditions for a new era of sustainability", Lacy et al (2010:48) call for new concepts of value and performance to be embedded at organisation and individual levels, which suggests that any disparity in understanding could prove to be a major pitfall for RS.

CONCLUSIONS AND RECOMMENDATIONS

Responsible sourcing is an effective means of ensuring that all three aspects of sustainability are managed in the construction supply chain, with particular respect to the procurement of materials. It is already embedded in commonly used sustainability assessment tools and the list of responsibly sourced materials is growing steadily:
(see http://www.greenbooklive.com for a list of certified products) . RS is part of sustainable procurement and helps supply chains to audit and improve transparency and traceability. This is an important development for the construction industry, because it rewards those who take their roles in the ethical supply-chain seriously and represents a major step towards better inclusion of sustainability parameters in decision-making on materials.

RS is a complex issue composed of social, ethical and moral, and economical factors which requires the involvement of manufacturers, clients, contractors and designers. However, there is an imbalance in the supply-chain at present with larger manufacturers being well-informed

and pro-active, but very few small companies participating in RS certification. While our findings suggest that many people have heard of „responsible sourcing" of construction products, there was a lack of awareness of certified products and inconsistent awareness of credits for responsible sourcing in BREEAM, the Code for Sustainable Homes and CEEQUAL. It was clear that people did not fully appreciate which materials are available through certified schemes. Findings demonstrated that currently there is no one party that should be solely responsible for implementing RS, as everyone is involved in the process. However, it is the clients and specifiers (i.e. contractors and designers) who are thought to have the most influence, due to their critical involvement in selecting construction products. It is ironic then that these groups do appear, at least on the face of it, to have a lesser understanding of RS schemes than manufacturers do at present.

These findings form an important early part of the evidence base on RS in construction; the study certainly sits within the realm of sustainability, CSR and ethics research, but specific concerns around definitions, scope, roles, SME participation, procurement, management systems and transparency are specific and need to be addressed if responsible sourcing is to make an important contribution to reducing the impacts of the construction supply-chain.

ACKNOWLEDGEMENTS

The authors would like to thank the project funders, network partners, and the survey and interview participants. Their time and input has been very much appreciated and valued.

Abstract
Firms need various resources and capabilities in order to compete with each other effectively. These resources and capabilities can be acquired, developed internally, or obtained via an ongoing cooperative relationship with another firm through the use of a strategic alliance. The use of strategic alliances in construction industry has increased sharply over the last decade and they are particularly effective in helping a firm maintain a superior competitive position in dynamic environments. Alliances reportedly improve the competitiveness of the construction firms by providing access to external resources, by providing synergies and by fostering rapid learning and change. The purpose of this research is to identify the success factors and key components of the development process of strategic alliances, and propose a process model of strategic alliances performances based on alliance conditions in international construction industry. The research involves a questionnaire survey conducted to the Turkish contracting firms operating internationally. Different types of projects constructed by Turkish contractors in Commonwealth of Independent States, Middle East Countries, African Countries, and other regions of the world between 2002 and 2009, were analyzed and used in the developments made in this study. The results indicate that shared risk, trust between parties, and equity are found to be the most important determinants of strategic alliance success. The research findings support the contracting firms enhancing their productive capacities and acquiring competitive advantages that enable them to increase alliance performances. The study also commences on how the identified factors enhance the effectiveness of the participating firms' competitive strategies by providing for mutual resource exchanges (technologies, skills, or products).

Keywords: Strategic alliances, international construction, success factors, Turkish contracting firms

INTRODUCTION

The globalization of the construction industry is rendering the familiar model of a single firm doing all things in-house outdated. The technological, sharing sources (workmanship, machinery, equipment, etc.), political, financial and competitive capabilities that are required to operate in the global construction market means that firms need to establish alliances with other participants in order to survive. Alliances are defined as voluntary arrangements between firms involving exchange, sharing or co-development of products, technologies or services (Gulati, 1998; Ngowi, 2007). In the construction industry, alliance organizations are

employed when parties that are involved in similar activities, such as contractors joining forces to leverage their complimentary capabilities to carry out work. This occurs in situations where risks are too high for subcontracting to be viable. The cooperative aspect arises from the fact that each firm needs access to the other firm's know-how and that the firms can collectively use their knowledge to produce something that is beneficial to them all (common benefits). The competitive aspect is a consequence of each firm's attempt to also use its partner's know-how for private gains, and of the possibility that significantly greater benefits might accrue to the firm that finishes learning from its partner before the latter can do the same (Khanna et al., 1998). Interfirm collaborations, such as strategic alliances, have become important business management instruments to improve the competitiveness of firms, especially in complex and turbulent environments. Alliances help to bridge the gap between the firm's present resources and its expected future requirements (Eisenhardt and Schoonhoven, 1996). In this time of globalization and radical technological change, alliances have become important strategic manoeuvres in construction industry.

As is the case for many other export-oriented economic activities in Turkey, the unique geographical location of Turkey at the crossroads of three continents -Europe-Asia-Africa- contributes a great deal to the global competitiveness of Turkish construction products and services abroad. However, Turkeys location is only one contributing factor to this competitiveness of the sector, as the country can also boast cost effective service at international standards, high client satisfaction, credibility in partnerships, extensive knowledge and experience gained in a wide variety of projects, familiarity with the business environments in the nearby regions, qualified manpower and a calculated risk-based approach to business. The Turkish construction sector comprises a group of businessmen at the crossroads of three continents that are active in each country in the Eurasian market of 580 million people, covering an area of 26 million km^2. Turkish contracting firms are open to international partnerships, not only in the field of contracting but also in construction industry investments, ranging from the manufacturing of construction materials to infrastructure, housing, industry and tourism. Extensive know-how and experience gained through working abroad for nearly four decades in all kinds of challenging engineering projects and in all forms of business environment are among their distinctive strengths.

There is a significant change in the pattern of Turkish overseas contracting firms portfolios. Turkish contracting firms are now exploring the significant needs of the products and services of the countries in which they are operating or intending to operate. They are catering to those needs with whole package offers consisting of basic or process engineering, feasibility studies, equipment selection and extension of credit. So far, the total value of projects undertaken by the Turkish contractors has reached $33 billion US (the projects still under progress amount to $15 billion US). The present share of the Turkish construction sector in the international market is about 10% and today, Turkish contractors play a major role in the international arena and are active in more than 25 countries. The experience gained in the Middle East and Common-Wealth Independent States (CIS) carried the Turkish Contractors to an outstanding position in comparison with their competitors some additional advantages such as geographical proximity, low labor cost and high quality technical personnel make Turkish contractors noteworthy. Within the six year period between 2002 and 2009, the annual volume of business undertaken abroad increased from 1.7 billion USD in 2002; to 23.6 billion USD in 2008. In 2009, because of the affects of the global crisis, this figure decreased to 18.8 billion USD. The internal and external forces and factors that have contributed to this rapid development can be grouped under the following three categories: the attractiveness of business opportunities abroad; reduced business opportunities in Turkey;

and the increasing competitiveness of Turkish contracting firms. Further market diversification and specialization in certain types of projects were the major trends in this period. The number of countries in which Turkish contracting firms was working increased considerably, causing the percentage of work in each country to decrease relatively. Nevertheless, the Russian Federation maintained the first rank (18.90%), followed by Libya (10.73%) and Kazakhstan (8.07%). In this period, the United Arab Emirates (7.05%), Qatar (6.57%), S. Arabia (6.06%), Azerbaijan (4.12%), Romania (3.86%), Turkmenistan (3.84%), Iraq (3.33%), Oman (2.93%), Afghanistan (2.79%), Algeria (2.69%), Jordan (2.47%), Bulgaria (1.99%), Ukraine (1.85%), Morocco (1.83%) and Ireland (1.46%) emerged as new markets. In the aftermath of the interventions in Afghanistan and Iraq, the rebuilding activities in these countries were closely followed by Turkish contracting firms. The types of work undertaken during this period and their relative shares in the total business volume were as follows: road/bridge/tunnel works (15.28%), commercial centers (12.80%), housing (9.41%), industrial plants (7.56%), pipelines (7.47%), social and cultural facilities (7.39%), airports (6.98%), power plants (5.38%) and petrochemical plants (4.13%). In this period, significant progress was made in terms of the scope and size of projects being undertaken. Market, product and business diversification continued further, while several companies started to specialize in certain project types, such as international airports, railways and urban subway systems.

Firms need various resources and capabilities in order to compete with each other effectively. These resources and capabilities can be acquired, developed internally, or obtained via an ongoing cooperative relationship with another firm through the use of a strategic alliance. The use of strategic alliances in construction industry has increased sharply over the last decade and they are particularly effective in helping a firm maintain a superior competitive position in dynamic environments. Alliances reportedly improve the competitiveness of the construction firms by providing access to external resources, by providing synergies and by fostering rapid learning and change. The research focus is to 1) explore the key elements of the strategic alliance process 2) identify the potential success factors in strategic alliances, and 3) develop a conceptual framework of strategic alliance that would reflect more about the real practices of alliancing in international construction industry..

STRATEGIC ALLIANCES IN CONSTRUCTION INDUSTRY

The ensuing globalization of the construction industry as well as the highly fragmented and divisive nature of the industry are among the forces that are influencing it to seek management approaches such as strategic alliances that could leverage the capabilities of the various participants (Ngowi, 2007). Strategically, organisations may enter into alliances (a form of partnership) in order to innovate, access new markets, overcome local market restrictions, raise entry barriers and share risk for mutual benefit (Stanek, 2004).

A strategic alliance is a cooperation with a duration longer than a project, which has the intention to change the product market competence combinations of the participating partners. These partners share the rewards and risks. They conscientiously create a level of mutual dependence and exclusivity, without losing their independency. Implicit rules of trust and equality apply to the mutual interaction and attitude (Snijders and Geraedts, 2007). Alliancing is generally assumed to be a long-term business strategy linking together client, contractor and supply chain (Rowlinson and Cheung, 2004). Alliance partners are brought together for a specific outcome or project, where risks and rewards are jointly shared and there is goal alignment between parties. Alliance between firms that are engaged in similar

activities has both cooperative and competitive aspects. While the former enables the firms to leverage their complementary capabilities for common benefits, the latter tend to push the allied firms to engage in competitive racing in learning the capability of the partner(s) for private benefits (Ngowi, 2007; Khanna et al., 1998)

Research has documented numerous benefits that strategic alliances hold out for small firms, including the ability to tap into new markets, access scale economies, obtain complementary resources in under-developed value chain activities, respond to environmental uncertainties, and receive endorsements from reputable incumbents, among others (Arino et al., 2008; Deeds and Hill, 1996; Dickson and Weaver, 1997; D'Souza and McDougall, 1989; Eisenhardt and Schoonhoven, 1996; Gomes-Casseres, 1997; Hara and Kanai, 1994; Larson, 1991; Shan, 1990; Stuart et al., 1999).

Process of Strategic Alliancing

Strategic alliancing is typically characterised by a number of phases ranging from the selection of contract participants through to the completion of the correction period. There is a common premise in the management perspective of strategic alliance that the process should be composed of three stages (i.e., formation, implementation, and evaluation) (Buono 1997; Das and Teng, 1999).

In this study, the process of strategic alliance is composed of four stages unlike the past studies. These stages are Alliance Planning, Alliance Formation, Alliance Implementation, and Alliance Completion. Alliance Planning refers to strategy development and partner assessment. Strategy development involves studying the alliance's feasibility, objectives and rationale, focusing on the major issues and challenges and development of resource strategies for production, technology, and people. Partner assessment involves analyzing a potential partner's strengths and weaknesses, creating strategies for accommodating all partners' management styles, preparing appropriate partner selection criteria, understanding a partner's motives for joining the alliance and addressing resource capability gaps that may exist for a partner. Alliance Formation refers to an agreement, implicitly or explicitly, made by all key construction parties to establish an informal relationship for the purpose of accomplishing mutually agreed upon goals and objectives. During this stage, involved parties should prepare to diagnose their current practices and to address their concerns about what partnering can help them to fill the performance gap. They may be required to unfreeze their mind to accept the needs for change when they accept the concept of partnering. Alliance Implementation refers to the execution of the informal relationship to accomplish the mutually agreed goals and objectives in line with the construction project. At this stage, alliancing is operating to exert its influence on the construction projects. It is a process to learn and experience the newly adopted concepts and practices derived from alliancing. Alliance Completion refers to the intention of the construction parties to rerun an informal relationship with the same group of firms for a new project after the completion of the current project. Most often, if construction parties aim at implementing alliancing for a single project, the alliancing team will be resolved after the project is completed.

Determinants of Strategic Alliance Performance

Multiple factors determine the performance outcome of strategic alliances, ranging from the nature of the industry and institutional environment, within which the alliance operates, to the quality and commitment of the alliance management. Successful alliancing requires creativity, trust, commitment, interdependence, cooperation, open communication, goal alignment and joint problem solving (Peters et al., 2001; Howarth et al., 1995; Hampson and

Kwok 1997; Rowlinson and Cheung, 2004). Alliance structure is also a highly relevant factor in alliance performance. Parkhe (1993) reports that appropriate alliance structure curbs opportunistic behavior and leads to better alliance performance. Alliance structure serves the purpose of control in alliances, which is critical because of the shared nature of alliance governance (Das and Teng, 1999).

Collaboration between alliance partners is essential for a successful alliance project. During collaborations, alliance partners are able to share resources including professional expertise; this initiates a higher frequency of ideas flow – after all, two heads are better than one. Alliancing will not succeed without continuous flow of information and communication. Through open and honest communication, foreseeable risks are exposed and parties have a better understanding of each other's needs. Trust, continuous open communication and knowledge sharing are the keys to successful alliancing (Rowlinson and Cheung, 2004). During the life of alliances, the internal and external circumstances may change, often in unexpected ways (in the construction industry circumstances continuously change). How partners adapt to these changing circumstances determines whether an alliance prospers or flounders (Kraar, 1989; Ngowi, 2007). Successful adaptation of these changes calls for a delicate balance between the twin virtues of reliability and flexibility. Flexibility is necessary for partners to have a viable relationship in the face of changing circumstances, yet unlimited flexibility affords companies the opportunity and incentive to cheat, reducing the reliance partners can place on each other (Heide and Milner, 1992; Ngowi, 2007). Black et al. (2000) indicated that partnering experience is a critical factor toward partnering success. Firms learn and experience the newly adopted concepts and practices derived from partnering application. Wu et al. (2009) report that previous alliance experiences is a significant criteria of strategic partner selection process. Firms with experience in international strategic alliance activities may place more value on a partner with potential for development of new technology/knowledge and learning (Nielsen, 2003).

A number of researchers gathered lists of factors that are considered to be influential upon the success of strategic alliances. Table 1. summarises the literature of key success factors for strategic alliances.

Table 1. List of Alliance Success Factors and Sources

No	Factors	Source
1	Mutual goals & objectives	Green and Lenard (1999); Haque et al. (2004); Jefferies et al. (2006)
2	Tight alliance outline	Elliot (1998); Abrahams and Cullen (1998)
3	Alliance structure	Abrahams and Cullen (1998); Haque et al. (2004)
4	Commercial incentives	Abrahams and Cullen (1998); Haque et al. (2004); Jefferies et al. (2006)
5	Stretch targets	Green and Lenard (1999); Haque et al. (2004); Jefferies et al. (2006)
6	Partnering experience	Cheng and Li (2002), Black et al. (2000); Wu et al. (2009); Nielsen (2003)
7	Open communication	Haque, Green and Keogh (2004); Cheng and Li (2002)
8	Trust Between Parties	Elliot (1998); Green and Lenard (1999); Haque et al. (2004)
9	Flexibility & adaptability	Elliot (1998); Jefferies et al. (2006)
10	Shared risk	Bennett and Jayes (1995)
11	Adequate resources	Cheng and Li (2002)
12	Equity	Green and Lenard (1999); Haque et al. (2004)
13	Cooperative spirit	Elliot (1998); Abrahams and Cullen (1998); Haque et al. (2004)
14	Facilitation	Abrahams and Cullen (1998); Haque et al. (2004); Jefferies et al. (2006)
15	Sound relationship	Elliot (1998); Abrahams and Cullen (1998)
16	Best people for project	Abrahams and Cullen (1998); Haque et al. (2004)
17	Strong Commitment by senior management	Elliot (1998); Green and Lenard (1999); Abrahams and Cullen (1998); Haque et al. (2004); Jefferies et al. (2006)

18	Good cultural fit	Black, Akintoye, and Fitzgerald (2000)
19	Joint process evaluation	Green and Lenard (1999); Abrahams and Cullen (1998)
20	Shared knowledge	Abrahams and Cullen (1998); Haque et al. (2004)
21	Dispute resolution process	Green and Lenard (1999)
22	Continuous improvement	Larson (1991)

RESEARCH METHOD

Sampling

A list of contracting firms within the construction sector operating internationally was obtained from the Turkish Contractors Association (TCA). The list consisted of 185 member organizations. The sample includes relatively medium to large companies. Company size is determined by the number of professional staff, number of construction projects per year, and the size of a typical project in US dollars. A company with more than 750-1000 employees is defined as large – 75 percent were large size companies. The numbers of international projects per year ranged from 5 to 20 projects, 60 percent were involved 5 to 10 projects. Project size ranged $1.5 million to $50 million (80 percent) and to over $100 million (20 percent). Distribution of international projects by type of work is shared by building construction (32%), transportation (36%), energy (12%), hydraulic works (7%), infrastructure (6%), industrial plant (5%) and other (2%). Major regions for projects undertaken by Turkish contractors abroad were Commonwealth of Independent States, Middle East Countries and African Countries. In this study, small size companies were not taken into consideration and kept out of the survey as they are not included in the TCA main list.

Data Collection

The empirical data was collected through a questionnaire survey, which was administered to the firms registered to the TCA. During the survey, all these firms operating internationally (185 member organizations) were contacted and asked to participate in the study. They were then fully informed of the research objectives, that the research was a strictly scientific and confidential and that their anonymity was assured. A total of 135 completed questionnaires were received, giving a high response rate of 73 per cent indicating that the sampling procedure was effective and that the respondents perceived the research to be relevant and worthwhile. The respondents were asked to rate the extent to of agreement with each statement based on a five point Likert scale of 0 (No effect) to 4 (Maximum effect). Contact personnel in the companies for the questionnaire survey were either the top management or senior management in their respective departments, therefore their level of knowledge expected to provide responses was acceptable for the purpose of validity of the survey results.

The questionnaire survey consisted of 22 statements. The questionnaire covers general information about the initiatives (owners, developers, contracting firms), alliance conditions and alliance development, partnering criterion and key success factors, partnering experiences, and the nature of the benefits accrued.

FINDINGS

The participating contracting firms provided numerical scoring expressing their opinions on the significance of each factor. The weighted average for each factor was calculated and then it was divided by the upper scale of the measurements in what is referred to as “importance index” therefore the level of important of the factors categorized into four processes of strategic alliance development were calculated using the formula (Kish, 1965):

Level of Importance (Index) = [Σ(aX). 100] / 4
a= the score given to the factor by each organization (varying from 0-4)
X= n/N
n= Frequency of organizations
N= Total number of participant organizations

Table 2. shows a matrix of variations in level of important indices of the factors for determining the success factors and key components of the development process of strategic alliances. The X-axis of the matrix indicates the processes of strategic alliance classified into four categories as *Planning, Formation, Implementation*, and *Completion*. The Alliance Success factors were listed in the Y-axis of the matrix with their index values. The matrix also includes the calculated mean of importance indices and the rank orders of all the processes of strategic alliance listed at the bottom of X-axis with their index values. Studying the matrix the factors carrying the highest level of importance are mostly from the process *Planning*. These factors are "Shared Risk", "Trust between parties", and "Equity". In observing the highest ranked process, *Planning* carries the highest level of importance.

Table 2. Matrix showing the Variations in the level of Importance Indices of the factors

			Processes			
Rank	MIP	Factors	Planning	Formation	Implementation	Completion
6	3,07	Adequate resources	57,00	57,00	42,75	57,00
11	1,75	Tight alliance outline	28,50	28,50	28,50	28,50
4	3,73	Alliance structure	71,25	57,00	57,00	57,00
7	2,85	Commercial incentives	57,00	42,75	42,75	42,75
15	0,88	Stretch targets	14,25	14,25	14,25	14,25
4	3,73	Partnering experience	71,25	57,00	57,00	57,00
10	1,97	Open communication	42,75	28,50	28,50	28,50
2	4,17	Trust Between Parties	71,25	71,25	71,25	57,00

Mean Importance Index (MIP)			13,59	12,5	11,84	11,4
Rank			1	2	3	4

Discussion of the Survey

The factor "Shared risk" is ranked #1 and is perceived by respondents to have influence on all the alliance processes with a value of importance index 71,25. The interviews and observations highlighted that alliance partners are brought together for a specific outcome or project, where risks and rewards are jointly shared. The findings are in congruence with the literature (Walker and Hampson, 2003, Peters et al., 2001). Through open and honest communication, foreseeable risks are exposed and parties have a better understanding of each other's needs. Under the alliance, all parties should take collective ownership of all risks associated with delivery of the project, with equitable sharing of risks using a risk/reward mechanism (Rowlinson and Cheung, 2005). The risk/reward mechanism are to be adopted in the alliance project which will create financial incentives and equitable risk sharing between the alliance parties. By adopting a risk/reward mechanism, there are motivation incentives for all parties which encourage them to work towards "best for project" solutions.

The factor "Trust between parties" is ranked #2 and is perceived by respondents to have influence on the alliance processes *Planning, Formation, Implementation* with a value of importance index 71,25, and on the alliance process *Completion* with a value of importance index 57,00. The interviews and observations highlighted that trust between alliance partners creates an opportunity and willingness for further alignment (such as future job opportunities), reduces the need for continuous cross monitoring of one's behavior, reduces the need for formal controls and reduces the tensions created by short-term inequities. It allows the partners to focus on their long-term business development as well as cutting down cost and time outlays. The findings are consistent with the literature (Rowlinson and Cheung, 2005). Without trust, there would not be sharing of resources and knowledge; without trust, there would be hidden agendas and closed communication.

The factor "Equity" is ranked #3 and is perceived by respondents to have influence on the alliance processes *Planning*, and *Formation*, with a value of importance index 71,25, and on the alliance processses *Implementation*, and *Completion*, with a value of importance index 57,00. The interviews and observations highlighted that firms try to design alliances that are efficient and equitable at the time of the alliance's establishment. Alliances enhance the value of equity ownership ties between firms. Equity is an important ingredient in developing win-win thinking among parties. The findings reinforce the literature (Allen and Phillips, 2000; Chan et al., 2004; CII, 1991; Husted and Folger, 2004). The development of an equitable relationship between the stakeholders has been found to be necessary as equity promotes mutual motivation when "win–win" solutions were sought rather than the "win–lose" solutions of traditional relationships.

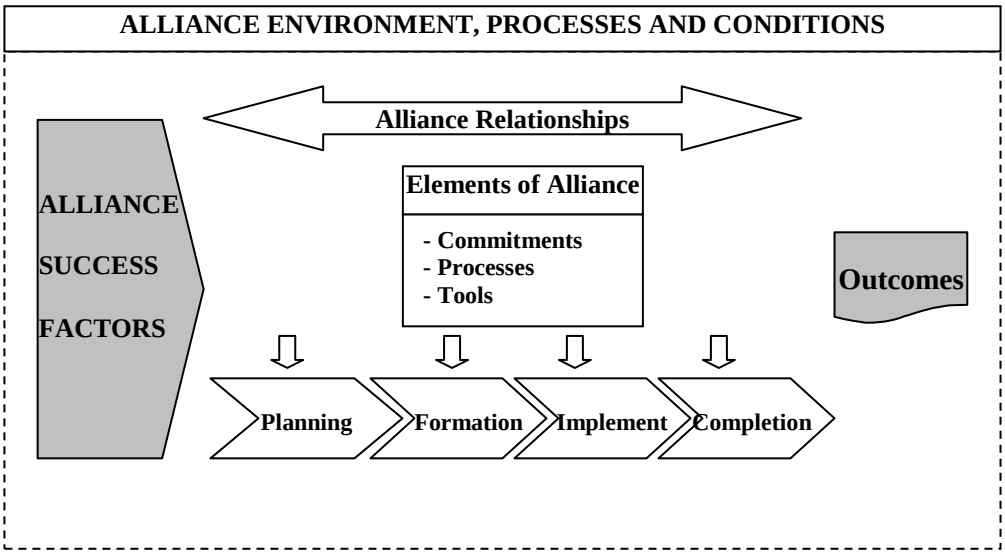

Figure 1. Model Framework of Strategic Alliance

As it is shown in Figure 1., the conceptual framework uses a four-stage process—planning, formation, application, and completion—which forms the basis for considering what factors lead to the success of each stage. In the proposed conceptual framework, it can be seen that the commitment, processes and tools criteria are considered to have the greatest bearing on the establishment and development of the alliance relationship. Successful outcomes of individual projects involving the use of strategic alliance are likely to generate shared rewards and benefits and create an opportunity for the organizations to share risk, develop and build trust and equity between parties, maintain alliance structure, good cultural fit, and achieve joint learning from the experiences. These outcomes act as feedback to the process further strengthening the role of each element and benefit the relationship development process overall. The research findings support the contracting firms enhancing their productive capacities and acquiring competitive advantages that enable them to increase alliance performances. Shared resource exchanges (technologies, skills, or products) between the parties enhance the effectiveness of the participating firms' competitive strategies. In strategic alliances, having a common strategic direction helps firms to have a better understanding of their mutual goals and expectations. Alliance structures should include a learning framework enabling open reflection of partners' knowledge whilst retaining visions and individualism. This allows all parties to benefit from shared knowledge.

CONCLUSION AND RECOMMENDATIONS

This paper presents a survey study for determining the strategic alliances' performances of Turkish contracting firms operating internationally. The success factors and key components of the development process of strategic alliances were identified and a process model of strategic alliances performances based on alliance conditions in international construction industry was proposed. It was found that "Shared risk", "Trust between parties", and "Equity" are found to be the most important determinants of strategic alliance success and *Planning* and *Formation* are the two processes which the interviewees believed would highly be influenced by the success factors mentioned above.

Managers of contracting firms can reduce the risk of alliance failure and can generate more value from their alliances by studying the detailed critical success factors. Process and content issues are equally important for alliance success. Alliance competence, i.e. knowledge of how to forge and manage alliances, could provide contracting firms with the capability to protect their independence while surviving in a tide of globalisation and rapid technological change.

Successful alliance operations require enormous inputs of physical and intangible resources: management skills, production technologies, employee motivation, adaptiveness, innovativeness, and the partners' capacities to set aside direct pursuit of their individual business interests while sharing both the benefits and risks of collaboration. The shared interests of the partners in the alliance create goal alignment which minimizes opportunism, and there is a mutual hostage situation as both partners have made substantial investments and are dependent on each other's performance. These features assist in managing relational risk. As cooperation and competition coexist between alliance partners, cooperative relationship evolves over time as partners learn more about each other's motives, capabilities and attitudes toward control, conflict, cooperation and competition. During this period, and the entire life of the alliance the partners are vulnerable in the various ways. Thus, in successful alliances, trust is often touted as a prerequisite, a necessity, an absolute must.

The challenge for the strategic alliances is minimizing the polarization of construction industry in a global environment. Furthermore, this kind of organizations provide a trigger effect for the contribution of mutual strategy between the developed and developing construction industries through the world.

Abstract
Many studies on policy implementation have emphasized the difficulties of putting policies into practice. The paper presents several ways in which Dutch non-profit housing providers incorporate their energy saving policies in their 'regular' housing management regarding the existing stock, such as planned preventive maintenance, renovations and other physical improvements. Several housing associations were selected that have formulated an energy saving policy and that have at least some experience in implementing these policies. Interviews were held with managers of asset and maintenance management and with policy staff of housing associations. It is investigated to which extent the policy ambitions, both at the portfolio level and at the project level, are carried out, and in which way these ambitions are embedded in the organisations' regular working processes. In addition, the main stimuli and barriers for the implementation of the energy saving policies are identified. Special attention has been paid to the feasibility of combinations of energy saving measures with other physical improvements in the housing stock. Results show that the implementation of energy saving policies in annual improvement and maintenance plans is in most cases not problematic, and that the most significant problems arise during the preparation of individual investment projects.

Keywords: energy saving, implementation, social housing, the Netherlands

INTRODUCTION

As in many other countries, energy efficiency has gained priority on the agendas of governments, housing providers and the building sector in the Netherlands. This paper deals with the implementation of energy efficiency policies of non-profit housing providers (in the Netherlands almost always housing associations), in particular with the way in which these housing associations materialise their own energy policies in their housing management practices.

Dutch energy policy has three major goals: security of supply, environmental quality and economic efficiency. Over the longer term the government aims to achieve a sustainable energy system. Current energy and climate policy focuses on cost-effective measures to carbon-reductions, on energy conservation and sustainable electricity (Kern and Smith, 2008). The official Dutch goals set in reaction to global climate change are ambitious. The Dutch goal states that in 2020 CO_2 emission must be reduced by 30 per cent compared to 1990. In line with EU policy, the Dutch government also aims that 20 per cent of the energy used will be produced sustainably in 2020.
In line with these governmental ambitions, *Aedes*, the umbrella organisation of Dutch housing associations, declared in 2008 that the sector will reduce the natural gas consumption level with 20 per cent in ten years. It also agreed with the Ministry of Housing and *Woonbond*, the national body of tenant organisations, a reduction of energy consumption in new building with 25 per cent in 2011 and with 50 per cent in 2015.

There is a lot of literature on energy saving and other forms of energy efficiency in housing. Among them, many publications deal with energy saving measures and techniques and their application, in individual dwellings (e.g. the use of solar panels, types of insulation, high efficiency boilers), a building block (e.g. heat and cold storage) or at the neighbourhood level (e.g. district heating). A lot of attention is also paid to governmental energy regulations, including taxes and subsidies, subjects on which several internationally comparative studies have appeared (e.g. Beerepoot, 2007; Itard and Meijer, 2008; Sunikka, 2006; Horne, 2008; Engelund Thomsen, Wittchen *et al*., 2008; Schüle *et al.*, 2009; Hamilton *et al*., 2010). In addition, there is growing literature on tools for assessing the sustainability or, reversely, the environmental impact of buildings, for example Life Cycle Assessment (e.g. Fay, Treloar and Iyer-Raniga, 2000; Forsberg and Von Malmborg, 2004; Meijer, 2006). However, the embedding of energy efficiency in the management of individual housing organisations is not often explored, although this subject is important for two reasons.
First, numerous studies show that there can be a wide gap between the policy ambitions and the implementation of these objectives in concrete measures. Many planning studies show a poor implementation of policies due to conflicting interests, miscommunication, misinterpretation and lack of anticipation on possible side effects. In most cases, these implementation studies concern large governmental institutions or large companies, but recent research (Nieboer, 2009) has found similar outcomes for Dutch housing associations, which organisations are considerably smaller (think of a few hundreds of employees). In addition, his research dealt with policies trying to influence *internal* decisions, which are different from most government policies in the sense that these are usually directed towards *external* parties. In his research in the Dutch building sector, Hoppe (2009) found similar results.
Regarding energy efficiency more specifically, there are also many indications for wide gaps between policy ambitions and implementation (e.g. Jaffe and Stavins, 1994; Brown, 2001; Zilahy, 2004; Sorrell *et al.*, 2004; Hoppe, 2009). What is more, many studies regarding the implementation of energy efficiency programmes indicate that progress is often less than what could be expected on the basis of rational models, which assume a smooth translation of

policy into action. Already some decades ago, for instance De Man (1983) and Coltrane, Archer and Aronson (1986) pointed out the importance of social-psychological factors such as personal attitudes in adopting energy conservation programmes. As for housing portfolio management in non-profit housing sectors, recent studies (e.g. Gruis and Nieboer, 2004; Gruis, Tsenkova and Nieboer, 2009) indicate that housing portfolio management is in an early stage of development, despite initial expectations of rapid policy development as a consequence of neoliberal policies and, related to that, reduced government support. Although (particularly in the Netherlands, Australia and the United Kingdom), some studies have focused on transferring approaches from business planning to housing portfolio management (e.g. Van den Broeke, 1998; Larkin, 2000), these planning approaches are not often applied in practice (e.g. Gruis and Nieboer, 2004; Nieboer, 2009a and b).
Second, the implementation of energy efficiency policies at housing management organisations takes place in a political context that was, in the last two decades, dominated by policies that entailed a shift of responsibilities from government to market (Clarke and Newman, 1997; Peck and Tickell, 2002). This has led to a different relationship between government on the one hand and non-profit and other private institutions on the other hand, with government taking a more enabling and a less providing role. This development was particularly visible in the non-profit housing sector (see e.g. Whitehead and Scanlon, 2007; Boelhouwer, 1997 and 1999; Priemus, Dieleman and Clapham, 1999; Priemus and Dieleman, 2002), where government influence is, almost by definition, larger than in the commercial housing sector. The shift away from government control and towards market forces was often coupled with reduced levels of government support, a growth of the owner-occupied sector, and greater independence of housing associations from the government. The shift from government to market has entailed a more dominant role and responsibility for non-profit housing providers to achieve social objectives, for instance in the field of energy saving.
In this paper we focus on the non-profit or social housing sector. The focus on the non-profit sector is particularly important in this context, as evidence from advance performers indicate that it is this that is taking the lead in terms of implementation of energy efficiency policies, not just in individual buildings where the types of measures are selective, but also on a neighbourhood basis.

As has been stated earlier, literature is generally rather sceptic about what to expect as regards the reflection of policies in individual actions. In this light, it is plausible to expect a gap between energy efficiency policies of Dutch housing associations and the realisation of these policies. It is, however, not well known, how wide this gap is and, if there is such a gap, where in the implementation process the main problems occur. As for this process, we distinguish two stages. The first stage is about the embedding of these policies in general steering mechanisms such as the annual investment planning and budgeting. Also the embedding in related policies, such as maintenance policies and rent policies, are addressed. The main focus here is on corporate wide working procedures and related policies. The second stage is about the materialisation of these corporate wide forms of steering in concrete investment projects. The main focus in this stage is at the project level.

The research questions are as follows.
- In which way do Dutch housing associations materialize their policies in their measures regarding maintenance and other investments in their existing housing stock?
- To which extent are planned energy saving measures in investment projects of Dutch housing associations carried out?
- Which stimuli and which barriers do Dutch housing associations encounter when embedding their energy saving policies in maintenance and other investment activities?

The following section goes into the approach of the research. Then, the findings are presented. On the basis of these findings, we draw conclusions and present some recommendations.

RESEARCH APPROACH

The research has been done in two stages. The first stage is about the embedding of the energy saving policies in general steering mechanisms such as the annual investment planning and budgeting. Also the embedding in related policies, such as maintenance policies and rent policies is addressed. The main focus here is on corporate wide working procedures and related policies. The second stage is about the materialization of these corporate wide forms of steering in concrete investment projects.

First stage: energy saving policies

For the first stage, nine housing associations were selected that have formulated an energy saving policy and that have at least some experience in implementing these policies.
The housing associations presented in this paper are anonymously addressed as A, B and so on. Except one housing association with around 4,000 dwellings, all selected housing associations are, to Dutch standards, large organisations. Most of them have approximately 20,000 homes; some of them have more than 50,000 homes.

Interviews were held with managers of asset and maintenance management and with members of the policy staff. In principle interviews were held with people responsible for:

- the asset management and the energy saving policy;
- the maintenance planning and budgeting;
- maintenance projects;
- renovation projects.

Depending on the division of tasks per housing association and knowledge about the subjects, the interviews were held with 2 to 4 persons per housing association. For the interviews a structured checklist was set up. This checklist was tested beforehand by one of the selected housing associations.

Second stage: energy saving projects

The second stage is about the materialisation of these corporate wide forms of steering in concrete investment projects. The main focus in this stage is at the project level. For this research a distinction has been made between 4 types of investment projects:

- void repairs;
- planned preventive maintenance;
- minor improvements;
- major improvements.

For this research void repairs and planned preventive maintenance are considered investment projects. Energy saving measures can be realized simultaneously with void repairs and planned preventive maintenance interventions. Table 1 shows the main characteristics of the investment projects.

	Void repairs	Planned preventive maintenance	Minor improvements	Major improvements
Occasion	Change of tenant	Maintenance planning	Need for quality	Need for quality
Cyclical process	No	Yes	No	No
Realisation per dwelling or housing estate	Dwelling	Housing estate	Housing estate (or dwelling)	Housing estate
Realisation occupied or unoccupied	Unoccupied	Occupied	Occupied	Unoccupied
Service Life extension housing estate	No	No	Possible	Yes

Table 1: *Characteristics of investment projects*

From the nine selected housing associations of the first stage of the research, four were selected for this second stage. The outcome of the interviews at one of the four housing associations gave too little solid information to be included in this paper, so we have included the findings of three housing associations, presented here by the letters A, B, and C. Per housing association projects were selected representing each type of the investment projects. Selection criteria for the projects were:

- significant energy saving measures have been realised that result from the energy saving policy
- the project is typical for the housing association
- the project is (nearly) completed

If possible, per housing association projects were selected with single and multi-family dwellings. Unfortunately, projects representing void repairs were not found at any of the selected housing associations. An additional study is carried out to 'repair' this omission, but the results of this study are not available yet.
The research was done through a document survey and interviews with people of the housing association involved with the projects. For the interviews a structured checklist was used comprising questions about the project management, the results and the process.

FINDINGS

The findings, based on interviews and document study, are divided into the two stages mentioned in the previous section: first the findings about the embedding of the energy saving policies in general steering mechanisms such as the annual investment planning and budgeting are presented. Secondly, the materialization of these corporate wide forms of steering in concrete investment projects is presented.

Policies and goals for energy saving

To make energy saving policies more concrete, ambitions or goals are established. Examples are an ambition for decreasing energy use in terms of percentage, to be reached in a particular year, the number of energy label steps per year, or the removal of the worst energy labels (E, F, or G) within a set period of time.
Mostly, there is a relationship between policies of individual housing associations and the national, local or umbrella organization covenants these individual housing associations follow. A lot of the interviewed housing associations follow the covenant of the Dutch umbrella

organization for social housing associations, which aims to save 2% per year on natural gas, starting in 2008 until 2018.
Table 2 gives an overview of some of the goals per housing association.

Housing association	Goals		
	Total CO_2 reduction	Other	
A	20% in 2018	-	-
B	20% in 2018	Improving/optimizing all dwellings under label D	Striving for label B in renovations
C	20% in 2015	-	-
D	20% in 2018	-	At least a B label when exploitation period exceeds 15 years
E	25% in 2018	-	-
F	2% per year	-	-
G	30% in 2014	No more E/F/G labels in 2014	All renovated homes have at least a B label
H	Unknown	Two label steps if measures are repaid within 20 years	At least a B label when exploitation period exceeds 15 years
I	3% per year	1000 label steps per year	17.000 E/F/G labels improved to B label

Table 2: *Overview of goals per housing association*

Next, the links between energy saving policies and general steering mechanisms such as the annual investment planning, budgeting and the forms maintenance and investments are presented.

Link with budget for maintenance and investments
There are three ways housing associations deal with the embedding of energy saving policies in their (regular) budget. First, there is no special budget for energy saving measures; costs are part of the regular maintenance budget. Secondly, there is a special budget, but this is not necessarily meant for energy saving measures, but can be used for sustainability or environmental measures. Thirdly, a special budget is available only for energy saving measures. Each housing association that was researched is presented in one of these three categories. A special budget meant only for energy saving measures seems to be an advantage but the size of the budget, whether or not earmarked, is much more important.
Some housing association also mentioned another hindrance to incorporate energy saving measures in the regular long-ranged investments plans, because the capacity to invest is under pressure and the future is uncertain. Alterations in tax regulations and the decrease in house sales increase the financial uncertainty. Furthermore, some housing associations did not provide all their stock with an energy label, making it difficult to assess the need for energy saving measures and therefore estimate a budget. Other housing associations are depending partially on the willingness of tenants to agree on an increase in the rent for the financing of energy saving measures.

Link with planned preventive maintenance
For many housing associations in the research, planned preventive maintenance is the most important moment to carry out the energy saving measures, mainly because of scale advantages. In general, a large group of dwellings is grasped and a cluster of measures can be placed per dwelling. Six out of the nine housing associations have standard energy saving measures in its planned preventive maintenance, mostly double glazing and improving or adding insulation of façades, roofs and floors.

The use of the word 'standard' suggests that these six housing associations are executing these measures in all circumstances but some exceptions on this are made. If the particular dwellings have a short life span, measures will not be carried out and investments are restrained. Furthermore, there is some freedom for the department or project managers directly involved in the projects. Sometimes this means parts of the list of requirements are not always followed.
An important condition in general is that the benefits (costs savings and energy saving capacity) are greater than the general costs. Some housing associations use tools such as Gross Initial Return for energy investments or Internal Rate of Return for calculating the return. The table below gives an overview of the standard energy saving measures of the nine housing associations.

Housing association	Standard energy saving measures				Special budget? **
	Double glazing	Façade insulation	Roof insulation	Floor insulation	
A	X	-	-	-	yes
B	X	-	-	-	yes
C	X	X	X	X	yes
D	-	-	-	-	no
E	-	-	-	-	yes
F	X	-	X*	X	no
G	X	-	X	-	nee
H	X	X	X*	-	yes
I	X	X	X	X	yes

*When the roof needs replacement **including special budgets for sustainability or environmental measures

Table 3: *Overview of goals and standard energy saving measures*

Link with void repairs

The housing associations interviewed for this research rarely perform energy saving measures during void repairs. The costs are higher, because of the lack of scale advantages. Sometimes a tenant objects to the planned preventive maintenance or renovations but when this unwilling tenant has moved, void repairs are used to make the dwelling in accordance with the dwellings renovated earlier.
Investments during void repairs can also happen if waiting for planned preventive maintenance is considered irresponsible. An example is the replacement of single glazing by double glazing, when the window frame is ready to be replaced.

Link with renovations and improvements

Most of the researched housing associations have the same requirements on energy saving and use the same conditions for renovations as they use for planned preventive maintenance. This means in general that the same energy saving measures are considered for renovation as for planned preventive maintenance. Higher requirements for renovations do occur, but only if they are required by the Building Code.

As already stated, for the second stage of this research staff members of three housing associations were interviewed. These three housing associations have at least some recent experience in implementing its energy saving policies in maintenance and renovation projects. Below, summaries are presented of the interviews with the staff members of the three housing associations. Subjects covered by the questions were energy saving ambitions, project organisation, project features, the energy saving measures and cooperation of tenants.

Housing association A

To give a practical result to the ambition housing association A has formulated four spearheads: energy saving and CO_2 reduction, health and liveability, sustainable solutions for maintenance and new developments and finally internal environmental care. The energy saving ambition is 20% reduction in 2018 compared to 2008.

A list of requirements housing association A uses has four ambition levels for planned preventive maintenance and renovations. Every ambition level corresponds with the new exploitation period and the strategic label. Once the exploitation period and strategic label for a particular project have been established, a list of energy saving measures is more or less automatically generated. This procedure ensures unambiguous further development by architects and other consultants. The design of projects can also be assessed this way. In its Environmental Policy Plan, housing association A states that they will guarantee tenants that the energy bill will decrease (based on the project as a whole) more than the increase of monthly rent after the renovation.

Three projects of A were selected for this research. The first project was a four storey doorway apartment building, built in 1974. This project can be considered a planned preventive maintenance project. Tendering for this project was done by a private contract, based on a so called 'building team' contract. This means the contractor was already involved from the initial phase of the project. Energy saving measures for this project are replacement of window frames with hard wood window frames with the FSC quality mark, the fitting of highly efficient double glazing, adding of insulation of façades, led-lights in central stairways, removal of geysers, placement of collective hot water supply with heat recovery and adding mechanical ventilation. With these measures, the energy label went from G to B. The placing of solar panels would have made label A possible, but proved to be too expensive.

The second project consisted of four buildings, each with 12 storeys, built in 1960. In total 288 galleried dwellings were refurbished. This project can be considered a planned preventive maintenance project. Energy saving measures carried out in this project were highly efficient double glazing in all window frames, roof insulation, new ventilation registers and closing of cracks, placement of mechanical ventilation, placement of new closed geysers, improvement of collective heating system, placement of thermostatic radiator valves and individual cost indicators, placement of wind turbines on the roof. This last measure was eventually rejected by the municipality, because of objections by dwellers in the neighbourhood. The energy label went from G to B.

The third project, a minor improvement project, consisted of a three-storied doorway housing estate, with a total amount of 226 dwellings, built in 1928. The project was a pilot for 'performance based collaboration', which means the housing association describes the approach through quality and performance requirements. From the design phase, the contractor is involved to consider the measures that ensure technical and financial efficiency on the short and long term. Measures in this project included the placement of highly efficient double glazing, roof insulation, the removal of geysers, the placement of highly efficient boilers and the fitting of mechanical ventilation. Some measures were considered, but not executed. Heat recovery proofed to be technically complicated and not cost-effective and the replacement of inside insulation meant the tenants needed to be temporarily moved from their homes. Furthermore, floor insulation also proofed to be too costly and sound insulation of the floors was not necessary, because the placement of fire resistant ceiling solved this issue. Because of the measures installed, the energy label improved from G/F to C/D.

It seems tenant cooperation was not an issue in executing the measures in the mentioned three projects. The housing association chose not to increase the rents after completion of the projects, only voluntarily when a tenant asked for a specific improvement of their home. A side

effect of not increasing the rent is that tenants could be less aware of energy use and costs, because it is not visible in their living costs.

Housing association B

In September 2009, housing association B specified their Environmental Policy Plan, in which they state to aim for 20 % CO_2 reduction compared to 2008, to be reached in 2018. All dwellings with an EPC lower than D will be optimized, starting with the ones that have the worst performance. Maintenance activities that are part of the planned preventive maintenance program are taken into consideration and adopted for these specific projects. At far-reaching refurbishments, it is policy that at least energy label B is reached. Some measures are considered standard in the Environmental Plan, i.e. placing of double glazing simultaneously with painting of the windows, which is combined with the adding of mechanical ventilation when the tenant alters. Old boilers are always replaced with new highly efficient boilers. Collective boilers are always replaced by environment friendly collective systems, if the system has the capability to individually bill the tenants. This housing association strives to cover 75% of the costs by raising the rent.

Only one project of B was selected for this research, because this was the only recent renovation project that has the Environmental Policy Plan as a framework. The project is a six storied gallery flat, built in 1963, and can be regarded as a minor improvement project. The exploitation period of the building is extended by 25 years.

The project acted as a pilot for 'performance based collaboration'. The contractor involved came up with recommendations for the set of energy saving technologies including installations. The standard set included the fitting of high efficiency double glazing, insulated panels in the façades, placing of mechanical ventilation and the replacement of kitchen geyser for electrical boilers. Additional and more expensive measures the contractor suggested were floor insulation, hollow wall insulation, roof insulation, heat recovery trough mechanical ventilation and solar panels. In the end, the following energy saving measures were considered economically feasible: high efficiency double glazing, insulated façade panels, mechanical ventilation, hollow wall insulation of the brick facades, floor insulation under the first floor, the replacement of geysers by a collective heating and hot water system and finally roof insulation. The increase in rent after the work is finished is calculated based on the expected decrease of the energy bill at the level of the individual home. This will not be guaranteed to tenants, but it might be considered in the future.

The project is going to be evaluated with special attention to investigating if the right measures were applied to the building. The housing association guaranteeing occupants a decreased energy bill is also studied, because this helps to get 70% of tenants to agree on the renovation, which is a legal impediment. Generally, the implementations of far-reaching energy saving measurements are studied per individual project. In this specific project, more energy saving measures were implemented than could be expected from the policies in the Environmental Policy Plan. In conclusion, the success factors in this project are that the building apparently was technically suited for quite a number of measures, and the willingness of tenants to agree with the increase of the rent.

Housing association C

Housing association C laid down its ambitions regarding energy savings for its stock in the document 'Energy project 2009-2015'. The 20% CO_2 emission reduction was to be reached in six years, a period based on the painting cycle. In this period the whole stock was to be updated for a budget of € 90 million. Half of this budget had to be earned back by rent increase. The policy is that every dwelling needs to be equipped with high efficient double glazing, façade insulation and roof insulation, unless the dwelling was already sufficiently equipped.

Ground floor insulation would only be considered if economically feasible. The Energy Project started with a pilot phase, in which homes ready for planned preventive maintenance, were fitted with energy saving measures. The pilot was executed by a project group consisting of a project manager, a communications manager, an engineering project coordinator and a financial consultant.
The initial plan was to start the pilot with six projects, dispersed by type and building year. Four projects were finally included: 40 single family homes built in 1920, a flat built in 1973, 15 dwellings for the elderly built in 1960, and 10 small apartments in a villa, built in 1920 and renovated in 1982. Following the principles of the Energy Project, all homes would be fitted with double glazing, façade insulation, roof insulation (even if the roof doesn't need replacement) and sometimes floor insulation. The actual pilot projects of the Energy Project, however, showed a greater variety in energy saving measures than the policy plan prescribed. This can be explained by technical issues or by the fact that some of the measures had already been taken.
The 40 single family homes built in 1920 were to be fitted with floor insulation, insulated glazing, façade insulation and roof insulation in the extension. Roof insulation in the rest of the dwellings was placed in the 1990s and is still functional. The fitting of double glazing sometimes means replacing the moving parts of the window frame. Tenants only pay for the glazing, not the replacement of the moving parts. Furthermore, the dormers are replaced and these are equipped with double glazing, but tenants don't have to pay an increase in the rent.
The flat built in 1973 is to be fitted with floor insulation for the bottom apartments, insulated glazing in new window frames and the insulation of facades. More specifically, the end wall is insulated on the outside, resulting in a higher insulating value than insulating the hollow walls on the long facades. The roof was already insulated in the 1990s.
The 15 dwellings for seniors, built in 1960 are fitted with floor insulation, roof insulation, the replacement and adding of double glazing and facade insulation of three dwellings. The replacement of the roof was part of planned preventive maintenance for this year. For this reason, the costs of the replacement and insulation are not recalculated in the rent.
The 10 apartments in a villa, built in 1920 and renovated in 1982 are to be fitted with ground floor insulation, insulation of the flat part of the roof and double glazing. 'Wrapping' the building with façade insulation is complicated, due to municipal regulations on altering the appearance of a building. Ground floor insulation is limited to the parts directly under a dwelling, because of the vaulting of the floor. As with the aforementioned project, the replacement of the roof was part of the planned preventive maintenance for this year. For this reason, the costs of the replacement and insulation are not recalculated in the rent. The increased insulation has consequences for the ventilation, but the proposed solution is not popular with tenants.
In the light of the ambitions of the Energy Project, the results of the pilot were rather disappointing. First, the combination with planned preventive maintenance, did not work out well. The preparation of the projects took more time than is actually desired for these type of projects. So, the principle of combining energy investments with planned preventive maintenance projects has been abandoned. Second, the principle to get a 50% payback in the rent for the measures was difficult to realise, for which reason housing association C has abandoned this principle. The most important bottleneck in the progress of the Energy Project was the willingness of tenants to contribute financially to the measures. Further, there were frequent internal discussions about which activities or materials had to be charged in the rent and which not. Ultimately, in most projects of the Energy Project, the costs were not recalculated in the rents. As a consequence, housing association C decided to carry out the energy saving measures with half of the initial budget, which means that it must be much more selective in its selection of investment projects.

An example of a project outside the scope of the Energy Project was a project consisting of 147 particularly small single family dwellings. These dwellings were improved significantly by altering the plans, adding a dormer window and combining 20 small dwellings to make 10 big new dwellings. The roof and floor were insulated and double glazing was put into place. In general, it can be stated that the role of energy saving in the project was limited. First the decision was made to replace parts of the dwellings, then it was decided how to do this as sustainable as possible. Energy saving measures were joined in with other ambitions and options. Because the costs of these measures were only a small part of the total expenses, they were a problem for neither the tenants nor the housing association itself.

DISCUSSION AND CONCLUSION

The interviews from the first stage of implementation (from policy to general steering) seems to suggest that the embedding of energy policies in regular investment activities can take place fairly easy, simply by including energy saving measures into planned preventive maintenance and/or renovations. An important condition is that budget is available for the extra costs of these specific measures, that the financing is independent from third parties and that tenants are willing to accept the resulting rent increase. Especially the financing of energy saving measures is a problem, for several reasons. First, the liquid assets of housing associations have worsened recently, due to decreased sale of dwellings, an increased tax burden and also tight national rent regulations. Second, uncertainty about the future rent regulations and energy prices, which influence payback possibilities, increase the financial risks involved. The embedding of energy policies into the regular work processes seems to be hampered especially by financial constraints and not, as expected beforehand, by internal and organizational factors, such as the lack of coordination between departments.
However, the results about the second stage of implementation (from general steering to projects) give reason to doubt these conclusions. Some interviewees indicated that the official project requirements are not always followed in the preparation of a project, and that energy saving measures agreed upon in the preparation phase of a project is actually not carried out in the execution phase. This research, however, does not give evidence about how often this takes place. Some interviewees have indicated that for those who lead investment projects time and budget are more important than energy saving. In line with Hoppe (2009), interviewees have also stated that the implementation of measures in this area is partly dependent on the motivation of these project leaders.
Another factor in the implementation of energy saving measures is related to the type of investment projects. There is merit in the argument that energy investments must be combined with other investments, because this combination of efforts reduces capital loss and saves money on the long term. The study indicates that energy saving measures can be relatively easily included in renovation projects, because renovation as such entails a range of physical measures and a relatively long preparation period. If combined with planned preventive maintenance projects, however, the story is different. There is a risk that these projects 'explode' in both time and budget, especially if considerable energy measures have to be carried out and if extra communication with the tenants is needed, for instance about a rent increase. This would suggest that improvement projects such as renovations are more suitable moments to carry out energy saving measures, but the problem with these projects is that they do not frequently occur: if we would wait for all such project to be carried out, the energy policy ambitions (as given, for instance, in Table 2) would not be met. So, both planned preventive maintenance projects and (larger) improvement projects are not entirely appropriate to include energy saving measures. A solution to this problem could be a combination with a

long-term investment program to increase the physical quality of the housing stock, a kind of investment scheme that many Dutch housing associations have developed and mostly has duration of 10 to 15 years. Further, it is conceivable to make use of several types of investment projects, for instance to carry out relatively simple measures (e.g. double glazing) in planned preventive maintenance projects and to carry out more complex measures in renovation projects.

SUCCESS AND FAIL FACTORS IN SUSTAINABLE REAL ESTATE RENOVATION PROJECTS

LEENTJE VOLKER PHD

Abstract
Sustainability remains an important issue for the construction industry. Yet, sustainable real estate developments are still considered as highly ambitious projects. To find out how and why sustainable renovation projects actually became sustainable we systematically evaluated 21 leading Dutch real estate renovation projects. In each project we interviewed the client, consultant, architect and contractor. Based on the results it was concluded that it is not necessary to have a pre-defined (sustainability) ambition in order to realize a project that can be considered sustainable in practice. Most of the respondents indicated that the ambition developed throughout the project, mainly because of the potential sustainable reputation or the parties involved in the project. Ambitions were not set as highly as expected: about half of the respondents consider preservation of the building and recycling as sustainable solutions already. The composition, management and collaboration of the construction team were found to be very important during the process. In this sense sustainable projects do not appear to be any different than regular projects, so then the only question is: Why not sustainable?

Keywords: ambition; sustainability; real estate renovation, project management, process management

INTRODUCTION

What we build, maintain and renovate today, has much influence on the achievement of our sustainability objectives for tomorrow. According to the Brundtlandt report (1987) a sustainable development is a development that meets the needs of the present generation without compromising future generations with the potential to jeopardize in their needs. Resulting from the agreements reached in 1997 in Kyoto, the Netherlands needs to reduce the emission of greenhouse gases by 6% in the period 2008-2012. The built environment is responsible for more than 25% of the total use of energy (Jeeninga et al, 2006). In addition, 35% of the national amount of waste is caused by the construction (Hails, 2008). The built environment therefore has a significant impact on the achievement of a sustainable society. Reports of the Ministry of VROM (2002), Atriensis/Vabi (2009) and van Oel et al (2010) show that the biggest potential for CO2-reduction is to be obtained of the attached row houses from before 1975. 3.6 million homes in Netherlands is built before 1976 (of a total of 7 million houses). Of this stock 40% (approximately 1.5 million homes) is weak from architectural and energetic point of view. Offices are of course also important energy users. The total office stock in the Netherlands consists of 46 million m2 usable floor area, of which 27 million m2 (= 61%) in the rental market. 7 million m2 (= 13%) of this stock is permanently vacant, including hidden vacancy this is currently even approximately 25% (DTZ Zadelhoff, 2010). About 20% of all office buildings is in use by national government

and local authorities. The majority of buildings do not currently meet the sustainable purchase agreements of the Government, which is based on a minimum energy label C.
In 2007 the Government (Ministry of VROM, 2007) stated in its working programme "Schoon en Zuinig – nieuwe energie voor het klimaat" (Clean and economical - new energy for climate) three ambitions: 1) to reduce the emission of greenhouse gases, particularly CO2 for 30% by 2020; 2) to double the pace of energy saving in the coming years; and 3) to increase the share of renewable energy of total energy use from around three percent to 20 percent by 2020. From this perspective the Netherlands should therefore strive for 'net zero ' buildings and planning districts which are at the same time as healthy, comfortable and productive as possible and have positive impact on the environment. Energy neutral means in this sense that the total balance of energy consumption for a dwelling or for a district is equal to the energy supply. The three-step strategy of Trias Energetica (reducing consumption, commitment to renewable energy and efficient use of fossil sources) can help to realize this ambition.
For the Dutch construction industry the theme of sustainable is almost inevitable. Yet the Dutch construction sector is unfortunately still mostly project-oriented. Integrated approaches are often lacking, both in thinking and in the process, and knowledge is often not retained and sufficiently deployed in future projects. There is a growing social pressure on the construction sector regarding a contribution to innovation, sustainability and the environment. This means that will also be in the construction industry more and more knowledge sharing needed in order to achieve those goals. At the same time construction projects are a perfect means to achieve objectives in the area of sustainability because they are set up to achieve common goals (Emmitt, 2010; Tryggestad et al., 2010). More and more research is available about sustainable building processes (e.g. Häkkinen & Belloni, 2011; Horman, Lapinski, & Riley, 2005; Pitt, Tucker, Riley, & Longden, 2009; Stenberg, 2006). However, practice still seems to make the same mistakes. Next to that most of the research focused on new building projects instead of renovation. In the Netherlands several buildings and districts have been realized which can be set as exemplary projects in Netherlands, but these examples are (still) not commonplace. The 'Building Brains - Smart Building and District: Energy Neutral' initiative provided an excellent opportunity to make the knowledge about sustainable renovation projects explicit. Building Brains' is a Dutch research programme that has arisen from a series of crisis measures of the Dutch Ministry of Economic Affairs in 2009 to ensure that critical knowledge about construction is maintained for the industry. For the period of one year a diversity of companies from the total supply chain got together under the supervision of a few knowledge institutions to do research on the theme of sustainability in construction. One of the projects from Building Brains research program consisted of an analysis of the construction process of a 21 sustainable renovation projects. The main objective of this analysis was to close of the construction cycle of initiation, design, construction and transfer lessons learnt to future projects. The author of this paper participated as one of the team members in this evaluative research project.

RESEARCH METHODS

Through desk research a long list was generated of sustainable projects that were realized in the Netherlands in the last 2 decades. The list consisted of 80 newly constructed projects and 40 renovation projects in the housing industry, 10 new and 10 renovation projects from the private construction industry and 20 projects from urban developments. In the end 21 projects were chosen to be included in the analysis for this project: 12 housing renovation projects, 5 sustainable commercial buildings and 4 urban area developments. The selection was based on

the criteria of information accessibility (are actors prepared to cooperate and is sufficient information available), use of energy sufficient and sustainable supply measures (e.g. double-glazed windows, solar panels, thermal storage), a fair distribution across sectors (housing, utility buildings), type of projects (cultivation, construction, building and area), types of clients (individuals, housing corporations, private organisations) and approach (innovation, integral approach and representativeness).
We developed a structured interview around a number of predetermined research topics: ambition, actors, measures taken, construction process and context of costs, policies & regulations. By approaching a topic from the perspectives of the various actors involved, it was possible to achieve a thorough way of understanding the success and fail factors in achieving sustainability. For each at least two other members of the project team were interviewed, such as the architect, contractor, sustainability advisor and/or a representative of the municipality. In some projects we also interviewed an external party, such as the energy supplying company or an additional sustainability engineer. In total we collected 73 interviews, which means an average of 3 to 4 interviews per project. Each interview was conducted by two researchers, recorded and written out. The interviews lasted between 45 minutes and three hours. The open answers were then categorized and analyzed with SPSS, together with the answers to the Likert scale questions. This paper discusses the results into the success and fail factors that relate to the cooperation and ambitions of the projects. It is based on the 'Inspiratieboek Duurzame renovatie (Building brains, 2010) in which the results are recorded from the analysis of all 21 projects.

RESULTS

Ambition

Literature (e.g. Van Bueren and de Jong, 2007; de Bruijn et al, 2002) suggests that the ambition of a project plays an important role in successfully realize a project. Our findings indicate that most actors agree on this because it supports the collaboration by developing integral sustainability ambitions, or as stated by one the developers: "Measures that the parties have embraced collectively influence the cohesion of the project positively." Quite a few respondents state that attention and time spend on the provision of a 'SMART' ambition in the initial stage of a project would therefore be beneficial for the further process. In this way, there is a shared frame between the project team members that can be evaluated at regular intervals to show the progress of the project. This is however easier said than done. The results of the interviews show that the concept of sustainability has different meanings among the various actors, but also within the same group of actors (see table 1). Most interviewees indicate that sustainability is about 'long term', 'integral' and 'the conscious use of materials'. Within the actor groups there are differences between the contractors that especially value the use of material (50%) and holistic approach (40%), and the architects who generally think in terms of integral approach and long term thinking (60%) in combination with the use of material (45%). According to the respondents the societal trend of sustainability doesn't necessarily go hand in hand with additional costs; 20% of the actors and 10% of the principals says that in principle there is no additional cost to sustainable construction. To the question of whether additional costs were made in their project, 50% indicated that the high level of sustainable ambition has led to additional construction costs which can be recovered over a longer period of time.

Table 1: Understanding sustainability according to the different actors

	Integral and long term	Holistic approach	Conscious use of materials	Trias energetica	Social sustainability
Client/principal	45%	20%	35%	10%	20%
Architect	60%	30%	45%	15%	15%
Contractor	35%	40%	50%	15%	15%
Sustainability advisor	45%	25%	45%	25%	20%
Municipality	40%	20%	40%	20%	15%

70% of the clients indicated that no clear sustainability ambition was established at the beginning of the project. For 10% of the respondents the ambition was too vague and for nearly 20% of respondents the ambition should have been more specific, measurable, acceptable, realistic and time-bound (SMART). Despite the fact that no real ambition was stated, about 40% of the respondents did indicate that maintenance, upgrading and/or renovation of the buildings was necessary, and almost 50% indicated that energy saving was the main goal of the renovation. Considering the fact that renovation is a sustainable option, sustainability became a central theme in these projects. So in many of these projects the ambition had grown in the course of the design and construction process because the opportunities arose. The respondents also indicated that when a higher ambition had been pursued from the beginning, probably even a higher level of sustainability could have been achieved.

According to the interviewees image and elaboration of the corporate social responsibility were a great motivator for the development of sustainable projects. Almost all the interviewees see that the importance of sustainability quickly increases, and that therefore alone they often consider the issue of sustainability. Many of the projects examined became known, often accidentally, as pilot projects and were considered exemplary for others. We have asked, in line with the Elkington's 3 P's of People Planet Profit, to indicate on a scale of 1 to 5 how much interest they have shown in the social, economical, spatial and ecological impact of construction (1 = no; 5 = very much). The actors gave most priority to the social importance (4.3) and spatial interest (3.8). The ecological interest (3.5) and the economic interest (3.5) have relatively the least importance, but in total all interests are quite important and well balanced. In these results the social pressure on sustainability also speaks. Yet, this outcome could have been influenced by the population chosen in this research because many projects were developed by housing associations, partly to increase the quality of the built environments in certain neighbourhoods.

During an analysis of the ambitions of the various parties, it appears that not one of the 75 respondents indicated to have the same ambitions as the client. Within the projects an overlap above 60% in aims could not be found. This indicates that if a project ambition exists, it is not to say that everyone is aware of this. One of the causes seems to lay in the fact that there is a lack of communication about the desired ambitions. As a result, the various actors act from their own experiences which could sometimes be against the expectations from other team members. If all parties are well aware of everyone's ambitions they could take this into account for further elaboration and realization of the plans.

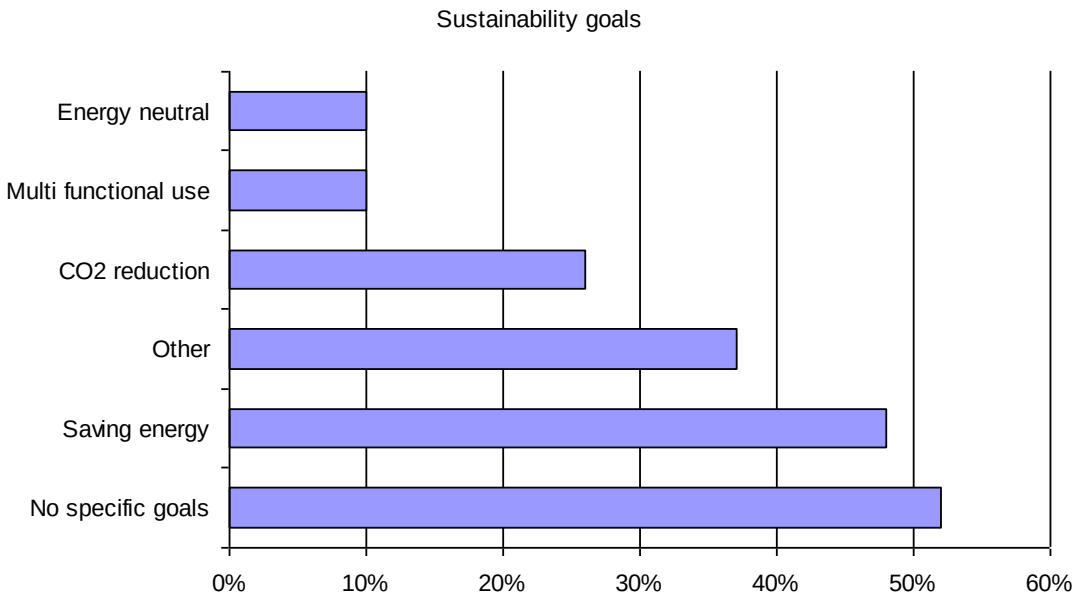

Figure 1: Pre-defined sustainability goals

Both for the projects in which a sustainability ambition existed at the start of the project and for the projects in which the ambition developed throughout the project, in 65% of the cases these ambitions translated that ambition into obtaining a (reduced) EPC standard and/or energy label. Figure 1 shows which goals were set in the context of sustainability. Saving energy and CO2 reduction appear to be the most used goals. However, the majority of the respondents indicated to have no predefined goals.
It seems obvious that if an ambition exists, the development is monitored during the project and evaluated in the end. In 30% of cases the actors however indicated that no monitoring of the goals and/or the ambition had occurred. A little over 30% of the respondents said that the energy meter was monitored after use, while 10% said that 'there were things monitored', but didn't know how and what. Almost 50% percent of respondents indicated not to know who was involved in monitoring of the ambitions, 20% says that it was the energy supplier, 10% indicator the client and 10% the consultant. In line with Häkkinen & Belloni (2011) the lack of monitoring also applied to the costs during the projects. In one of the projects the budget needed to be adjusted halfway because of the high ambitions, and another project proved to be over budget afterwards. One of the respondents recommended implementing a good monitoring of real-time costs throughout the construction process. Then the ensuing effects on the costs on the overall budget can be shown at every change of plan and the ambition can be fine tuned consequently. It is striking that most actors assume that monitoring had taken place, but that they can say little to nothing about the actual results thereof. This seems to be caused by the fact that there is little to no aftercare in the post-delivery and user phase of projects; nobody appears to feel responsible when the final payments have been made. This blocks the learning effect in construction. A good monitoring and feedback of the results to all actors could ensure that the actual impact and usefulness of sustainable measures becomes clear to all actors and experiences are not only based on personal perceptions.

The project team
The results also show that the composition of the project team and the level of enthusiasm are of great importance in realizing sustainable renovation projects. This is in line with the findings of Häkkinen & Belloni (2011) about Finnish sustainable building processes. The client of one the projects stressed that "the success of our project can definitely partly be

attributed to the involvement and collaboration of the team members; all actors have taken their responsibility". Consciously or not, the composition of the team also appeared to have an effect on the achieved sustainable results. If you opt for a sustainable architect or a sustainability consultant, it can be assumed that the level of sustainability of the project will higher. However, it was also indicated that especially the client and the sustainability expert/advisor influence the development of an ambition in the direction of sustainably. 45% of interviewees indicated that their previous experience with the client has played an important role in their involvement in the project. This means that at the moment previous collaborations and familiarity with parties still play an important role in realizing sustainability.

Next to the composition of the team, the functioning of the team members is also important. In virtually all projects it was indicated that a motivated and enthusiastic leader that keeps addressing the sustainability theme is very important. In a number of projects the client took on this role, but in others the architect, consultant, contractor or a supplier was the most enthusiastic actor on the area of sustainability. Personal motivation was usually the main source of this kind of enthusiasm and it was also indicated that this choice was influenced by the fact that the role “wasn’t claimed by others”. This means that in principle any actor could play this part.

Too many personnel changes within the team can be a stumbling block for the project and for the monitoring of a particular ambition. A project manager indicates that "it is very inefficient to constantly figure out how the original setting was. If none of the original setting is involved, the collective memory disappears. It is not known what the objectives and working methods were exactly." Although it a difficult to manage a long-term project from start to finish with the same team, a constant core of actors does seem to have a positive effect on the success of the project because the goals and ambitions are clear and shared. In this respects some of the interviewees mention that it is important that members of the team are selected based on their personality and competences instead of the firms they belong to.

Ang, Groosman & Scholten (2005) emphasised the importance of the project leaders. This was also found in this research. The respondents indicated that the project leader should in any case insist that the ambition is developed on a detailed level and surveyed throughout the process. This usually concerns someone with good decision-making skills. According to an adviser of a housing project many sustainable options should be explored and matched to the ambitions, "but this should not continue for ever and get out of control. At a given moment choices should be made and the package of measures should be finalized." In one of the projects the open mind of the project leader was mentioned as one of the success factors. This openness gave much space in exploring the many possibilities for the package of measures. In the end the indecisiveness however changed into a fail factor: "a success became a failure. If not thought in a single, fixed direction, taking decisions became hard. Always examining everything, we had many sessions and many opinions of experts have been won. This created certain unintelligibility." An open mind should therefore also be accompanied by a pragmatic approach in order to keep things going.

Despite the positive effects of involving a diversity of actors, the respondents indicated the way how parties were involved could have been improved. This does not only have to do with the timing (82% felt they got involved at the right time, 56% was involved from the start) but parties must be concerned with the role they play in the team and should be think along in creating integral solutions. As a principal of a housing project stated: "the installation engineer has the responsibility to apply an integrated design approach and should not from the individual identities." A hotly debated topic in the area of construction management is whether or not to involve a contractor in the initiative stage and/or design phase. The perception still exists (50% of the interviewees) that contractor are mainly involved to built

and that they do not have impact on the ambition level. In 8 projects the contractor was involved from the beginning on during the initial phase and/or design phase. The other actors indicated that they appreciated the early involvement of the contractor and so thought that he was involved on time. "A contractor should be taken in to consider the appropriate project-specific sustainable solutions," said a client of a housing project. A number of contractors also indicated themselves that they wanted to be involved earlier in order to improve the supply chain to deliver an optimal product and minimize failure costs. "The knowledge of contractors is currently too little exploited. We think that collaboration, plan development, and building relationships are more important than a one-time quick job. Long term vision and thinking of the contractor contributes to success".

Another success factor that was indentified in the research is the presence of sufficient knowledge within the project team. Especially for innovations project team members should be aware of the current sustainability options within their field. According to one of the advisors, consultants usually have short lines to keep up with experts and therefore have added value in implementing sustainable measures. In the same line of thinking one of the architects said that "Sustainability is not a layer on a building, but a part of the entire process." According to interviewees sustainability does not only occur in topics such as energy and fossil fuel but also in social and functional value of real estate. "Sustainability is also in the quality of the use: the living comfort and the environment. The building industry should think in values for the consumer/end user" as stated by one of sustainability advisors. Therefore "you first need to examine what these values are exactly." This means that input from the user is desperately needed (see e.g. Rohracher, 2001). In 9 of the 21 projects, the clients indicated to have successfully involved the users in the initiative stage, in one project they became involved slightly later, namely in the design phase. A large number of interviewees (38%) indicated that the end users were of positive influence on the project. Related to that, only 5% thought that users had negatively influenced the project outcomes. In one of the projects a targeted market research was performed because the users were unknown. This led to a good estimation of the living requirements and a smart solution for the diversity of the user needs. Remarkable was that even in projects were the need for the involvement of users was clear, interviewees indicate that the users could have been involved better and earlier. Further analysis showed that in 50% of the projects, communication only went into one direction: the users were only informed about the future changes or the use of the sustainable measures. Most of the time the users were not involved in the choice of options, while they have to deal with the buildings in the end. An important issue that contributes to the positive response of the user's appeared to be the understanding of their energy consumption. Because their energy usage was made transparent and they were able to track their own savings, a greater understanding of the necessary renovation was perceived. The residents got the legitimate feeling that the renovation had a clear advantage for them. In one specific housing project in the North of the country the users were so proud that they decided to change the name of the residential block: before the renovation they called the building a flat and after the renovation a full-fledged apartment complex.

Success factors

After the various components of the research were discussed in detail, we also asked about the general success factors of the project (see Figure 2).

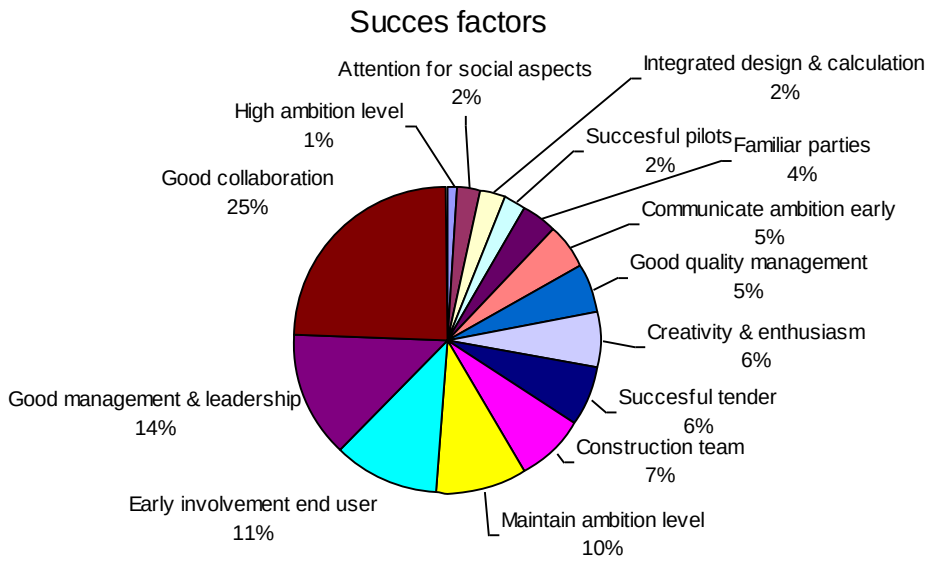

Figure 2: Success factors as indicated by the respondents

These factors can be divided into two themes: collaboration during the process and establishing goals. The collaboration factors related to the organization form and composition of the project team. Most of the projects were realized in construction team. Working in a construction team means that all parties are involved as early as possible. This means that collaboration and knowledge exchange can start from the early start. All team members (contractor, architect, advisor etc) think along from the beginning about the completion of the design and they know from the beginning what they have to each other. This makes it also easier to make adjustments and decision during the process. A successful construction team does require consciously selected partners that can complement each other as well. “It is all about the right people in the right places” according to a sustainability consultant. Several respondents emphasized the importance of good teams moving in perfect synchronicity with each other, and who know and each other. The atmosphere within the team also played a large role in many projects. In cases where the team members were very excited about the project, this enthusiasm turned out to have a positive effect on the commitment and the will to innovate. According to a project developer "an optimal package of measures was developed by this collaborative involvement. The main motivator for the innovation was not our own business interests, but the interest of end users. The team collaboratively sought to find a way to get the best return for the user." The results also indicate that good project and process management and process management are important factors to ensure a good cooperation. The project leader plays an important role in this. Except that he or she is supposed to be able to assess and monitor the goals or ambition, he or she must also be open to the possibilities around sustainable measures. In one project the 'open mind' of the project leader was highly praised. This project leader did not think in a single and fixed direction, but thought it was important to look at all the options available.

Good cooperation is also positively influenced by the presence of a sustainability ambition. As indicated earlier, in many of the projects insufficient attention was given to formulating and adopting the sustainability ambition. It is remarkable that in most of the projects the ambition to create a sustainable project was developed throughout the process; the project eventually grew into their sustainable ambition. Most of the actors consider the determination and monitoring of their ambition an important factor for improvement for future projects. Most of them even preferred a SMART defined one that could be adopted by all members of

the project team. However, it must be realized that recognized methods such as BREAAM, GreenCalc + or other kinds of energy certificates is no guarantee for a sustainable, functional and beloved building. It is the art of a design to apply an integral approach and not just tick of a list of boxes on order to earn points.
Another remarkable success factor is the positive effect of applying for a grant. First of all because of the feeling of victory when obtaining a grant after energy and paper work costly process – this really boosts the project. Secondly because to obtain subsidies clear demands and conditions must be fulfilled. The rules and regulations of these kinds of arrangements ensured that the team members had a clear goal and discussed their preferences before or during the start of the project. Applying for a grant motivated, stimulated, and also increased the will to innovate. This is not to say that all projects have to apply for grants to have a targeted sustainability ambition but it does indicate the effect of having quantifiably and unambiguous directives and measurable ambitions. So even though there is no money allocated a grant still works as a motivator. The other side of the medal is that "whole books and budgets should be submitted. This was so slow and bureaucratic. It is not worth a few thousand Euros".

DISCUSSION AND CONCLUSION

It is very difficult to get a clear perspective on the concept of sustainability that exceeds the level of the standard systems in practice. We found definitions in the range from long term perspective and conscious use of materials to active housing and feeling comfortable. The level of sustainability of the measures however also depends on the situation. In new buildings for example, double glazing or a HR combination boiler is not seen as a specific sustainable intervention because it is considered a default value due to the laws and regulations in Netherlands. In renovation projects these measures are often mentioned as first because characteristics of the existing situation have to be taken into account. As previously noted in literature (e.g. van Bueren and de Jong, 2007; Tryggestad et al, 2010), we found two ways to achieve a sustainable ambition and realize a renovation project in a sustainable manner: establish a shared ambition at the start of a project or develop an ambition during the project. In relation to the realization process of a sustainable renovation project we found four main success factors:

1) elaborating an ambition helps in the beginning helps but you can also develop it on the way;
2) having an enthusiastic leader has a positive effect on the project;
3) a construction team with an active contractor could improve the holistic design approach;
4) use the input from end users by communicating in two directions.

These factors do not seem to be very different from factors that contribute to the success of any building project or sustainable building processes in other countries (e.g. Häkkinen & Belloni, 2011; Horman, et al., 2006; Sodagar & Fieldson, 2008). Media attention is an effect that occurred in almost every project, but that only a very limited number of project members had actually been kept in mind. Some projects received a lot of publicity for the way how they realized their high level ambitions; others received it for the innovative way of working, for example on how they participated with the residents. Because of the media attention these projects are now used as PR resources by the different actors and their firms. This is beneficial for their reputation and is usually an elaboration on their objectives in the field as social responsible corporations. While the findings indicate there is no reason not to develop sustainable projects, these findings also show that sustainable renovation is not yet a habit in the Dutch construction industry. In line with Häkkinen & Belloni (2011) we could conclude

that normative regulations are needed because the voluntary approach did not cause a significant change. However, this is not easy (van Bueren & de Jong, 2007) and comprehends a lot of bureaucracy and public money. We therefore hope that the 21 projects as examined in this project are examples of ambitious renovation projects in which sustainability became a general value instead of a single inspirational action. If that is the case, one question remains: Why not sustainable?

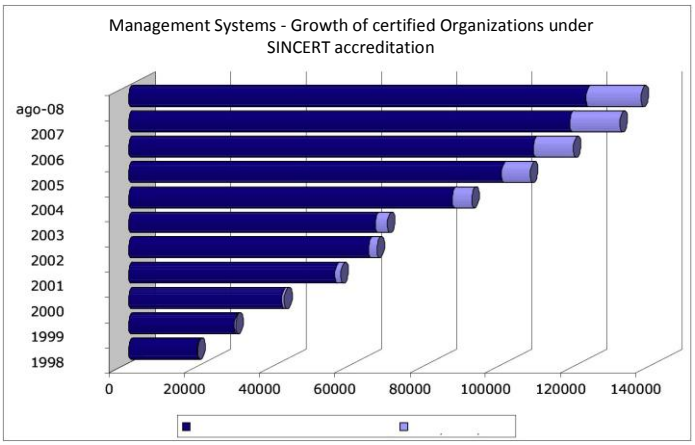
THE INTEGRATED MANAGEMENT SYSTEMS: THE ROLE OF THE MAIN CONTRACTORS



ANGELO CIRIBINI,
DICATA
Università degli Studi di Brescia, Italy

MAURIZIO CONSTANTINI
DICA
Università degli Studi di Trento, Italy

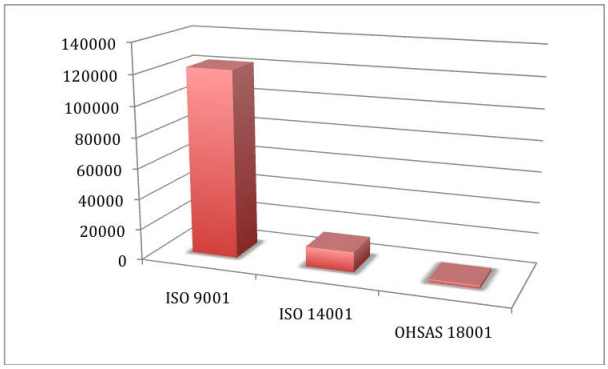
Abstract
The authors examined the concept and qualitatively assessed the effectiveness of integrating different Management Systems (Quality Management System, Environmental Management System, Health & Safety Management System and, in case, Social Accountability Management System) established at Italian Main Contractors in order to improve the Contract Management.
Accordingly to findings gathered by the authors, Quality Management Systems are widespread in Italy and in Southern Europe over the last decade, because of a legal compulsory requirement stemming from the Public Works Acts enforced in 1994 and further developed in 2006 in conformity to European Directives.
Nevertheless, in spite of such a dramatic rise in the amount of certifications conforming to the ISO 9001:2008 Standard, the reliability of Quality Control-related procedures tremendously failed, being the corresponding rules quite often discarded in the field.
Actually, only a small amount of Large Private Clients awarded their own tenders to main Contractors available and wishful to comply with Quality Planning's clauses, while a large majority of public Clients seems uninterested in checking effective application beyond formality of the ISO 9001 standard.

Keywords: OHSAS 18000, SA 8000; Quality Management Systems, Health & Safety Management System;

INTRODUCTION
Very few Italian and Southern European Contractors are certified in conformity to the ISO 14001:2004 Standard and even less complying with the recent BS OHSAS 18001:2007 Standard.

(source: Musa, SINCERT, 2008)

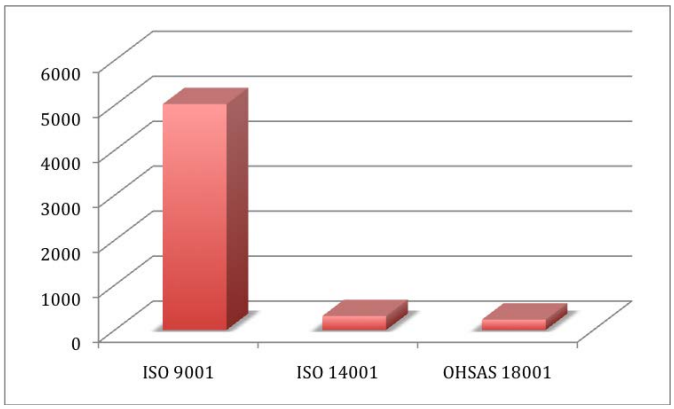
Consequently, it is not surprising that neither Clients nor Contractors have any practical perception of the document PAS 99:2006, a BS specification aimed to bring together the shared requirements and to support the integration of Quality, Environmental and Safety requirements.
Social Accountability Management requirements (with reference to SA 8000) should find also place in such a perspective, if not for ethical reasons, at least to deal with unfair competition.
Whenever constrained to comply with possible requests established by the Clients, the best effort that Contractors display is intended to widen the scope of the basic Quality certification, installing inside the original Quality Management System the other ones.
Through this action, Contractors set up a pseudo-integrated Management System suitable to engender a sort of added value.



Aim, Objectives and Approach

The aim of this paper is to examine, in form of essay, the issues of Integrated Management Systems, and their fall out in Italy, and to report about some findings dealing with such an approach, highlighted in connection with a firm belief of the authors: the efforts made by the Client towards an effectively Integrated Management System could be easily made trivial whenever the Main Contractor is unable or unwilling to reflect the Management System rules into its actual behaviour.
Actually, only a small amount of Large Private Clients awarded their own tenders to main Contractors available and wishful to comply with Quality Planning's clauses, while a large majority of public Clients seems uninterested in checking effective application beyond formality of the ISO 9001 standard.
Moreover, amongst the different existing environmental and energy sustainability certification schemes for buildings, LEED is now at opening stage also in Italy, due to an effort of the Provincia Autonoma di Trento (a Local Authority in the Northern, colder part of Italy, endowed with considerable self-government capacities).
LEED, originally conceived for action in the U.S.A., does not deal just with performances of the buildings, it states specific obligations to the ownership on matter of construction technology and methods, starting from the construction stage.

Integrated Management Systems vs Performance Approach?



The LEED Certification Scheme is the last in order of time in a series of standards (usually non-mandatory standards) aimed to determine higher quality from General Contractors' behaviour. In this case, the certification scheme goes beyond a close scrutiny of the actual performance on duty of the building, and includes whole process aspects: design, components production, on-site building, environmental impact.
This approach involves a soft refusal somehow of the end-user performance approach (do-it-as-you-like, just make it work) in favour of a more holistic, systemic, back-looking approach (check performances, check the whole process and sum up the energy tidbits). In fact the purpose of LEED and LEED-like systems is to avoid high energy performing buildings obtained through unsustainable construction processes.
A more basic, less specific tool, the first as to spread and age, is of course the ISO 9001 standard, today updated to the 2008 release, which in fact evolved year after year from a starting imprinting of quality assurance. Especially, critical productions were the main target for this standard: installations for the military purposes (with specific benefits for European Contractors working on account of the US Army or the Navy), or nuclear power plants.

More recently a conscious attempt was made to implement ISO 9001 more stringently in terms of product quality, i.e. as assurance of adequate global performance of final products, as an attempt to manage and monitor apparently detached processes, like the selling process or the purchase/procurement process.
This perspective, basically non-mandatory, and conceived as a result of free agreement between Contractors and Clients, was made mandatory in Italy within public works procurement procedures: in the Nineties, a new "framework legislation" established the obligation for General Contractors to obtain an ISO 9001 Conformity Certification in order to be qualified to bid to Public Administrations for project of a certain importance (more than 500,000 euros)
Recent global data confirm the effect of a State enforced approach to ISO 9001 in respect of other Management Systems.

Conformity certificates issued today in Italy (source: ACCREDIA, 2009)

One of the many consequences of this is a difficult readability of the effective quality assurance level given by the different contractors: actually, while we can recognize very good and valuable certifications, on the other side some "QMS" can be found not worth the paper they are written on: which means that a Private Client can effectively assess the real quality of its bidders, while the Public Administrations are not allowed to exclude a bidder if it can provide an ISO 9001 certificate together with other non-technical requirements required for qualification.
The last data show even larger divides between Quality Management Systems and Environmental /Safety Management Systems.

Conformity certificates issued from January to September 2010

(source: ACCREDIA, 2010)

In Italy, in front of about 250 certification available schemes, QMS (Quality Management Systems) amount to more than 30 % of issued certificates. The Construction industry deploys at least 80 Certification bodies altogether, and more than 27 thousand ISO 9001 conformity certifications from its beginning: the building sector shows up consequently the most overworked certification block, and also regretfully the lowest technical literacy in the quality business.
We must consider also that the expertise hoarded within the Building sector in the field of the different Management Systems we are dealing with here (ISO 9001, ISO 14001 and BS OHSAS 18001) consists in a unilateral approach, limited to the Contractors via legislative approach, because in any case the same legislation does not require the same behaviour to the other main subjects of the process: Clients, Inspection Authorities, Design Teams, etc. Nevertheless, while Client, Designers and Public Authorithies are rarely "MS conscious", Suppliers are much more sensible to the issue, confronted as they are with more and more stringent requirements from a wider, more private market.
In any case, except for praiseworthy policies of a number of strong professional Clients (Public Clients, like Italferr, Infrastrutture Lombarde and others among them, or Private Clients), the unilateral mandatory approach to MS prevented from establishing a strong community able to share the vision, some practical principles and a common language.
Furthermore, total quality lip-service rhetoric (an empty rhetoric as far as the construction industry is involved today) was spent to cover the simple fact that "non conformity" is a phrase actually unfamiliar, outside strict contract's boundaries, in the dialogue between General Contractors and Clerks of Works.
A non conformity has to be necessarily reported by the contractual counterpart, and in any case Management Representatives and Quality Management Units are too often considered as antagonistic and estranged parts to the Site Managers of their own company.
Lacking in any case a systemic approach by all the subjects of the process, as seen above, this is the reason why the integration of different Models and Management Systems fails to be determinant.

Products or Processes?
The first question to ask deals about the amount of innovation determined in Europe by the mandatory introduction of ISO 9001 Management Systems: QMS standards are doubtless popular because they look easy, or even trivial ("who is not really unable to comply with them?"), and this faulty view never let to obtain full matching complement with product standards. Product standards are indeed more in the custom, even in their performance envelope after the New Approach, but they are much less insubstantial, and much more difficult to cope with: so the way it goes is "product standards are too complicated and too expensive to conform to, while QMS are for us, because we do know how work is to be done".
What mentioned above helps to understand how intimately International Standardised models may stem from a context where cultural appropriation results in technical behaviour sometimes even supported by certification processes. In other places and other contexts, as opposite, a deeper concern for technicalities about the built object leads to consider planning and construction methods themselves as a source of guarantee.
The Italian approach aims to reconcile the two visions analyzed above, offering a medial approach which, on one side countermands the most relevant aspects of both, on the other side delivers well-devised Designers (Architects, Architectural Engineers, Structural Engineers, Designers of Building Services, Landscape Designers, etc) to a job market which is unable to absorb all of them as designers; luck is, but not by chance, that their profile is very flexible; as a consequence, would-be Designers-to-be are instead absorbed by the

construction industry and its ancillary industries: their enrolment discounts the price of lack of knowledge in process management and control, and training starts almost from scratch, with the result of higher costs for the industry, no injection of authoritative contributions, and professional development based more on empirical parroting than over strong research in process innovation.
Leaving the complicated educational issue and going back to Contractors and sites, provocatively we might say this happens as a consequence that the attention given to management standard in Italy in the last 20 years is due more to their bad, widespread deployment, than to effective improvements obtained by the industry in terms of better behaviour towards their Clients and building process practices.
The role of the Management Representative was never pivotal - and it is not today - in company organization charts, neither when the MR was involved "just" in Quality Systems, nor when the MR's competence is widened to cover Integrated Management Systems.
QMS yesterday, IMS today, seem to be always peripherical to the real core of the business, of the financial issues and of the industrial relations between unions and companies.
All this considered, we might even question the choice of keeping today the all-purpose, all-industry scope of ISO 9001. Actually, the mandatory effect given to the standard by Italian Codes determined two opposite perceptions: at first, in the Nineties, the firm opposition due to the publicly declared "impossibility" to implement ISO 9001 according to the Contractors because of their "peculiar field of work"; later, and more and more today, the intrinsic "universal" scope of ISO 9001 is the mitigating circumstance for a trivial, almost lip service, implementation which leads to no significant action.

QMS, IMS and Innovation

In the background, stands the main issue of "innovation" in building site organization: is it a must-have? Furthermore, are Management Standard Schemes actually effective in such a direction? In one perspective, as an example, a comparison between a site of the '70s and a site of the '10s in Italy shows an absolutely significant evolution/innovation in provisional facilities (formworks, scaffoldings, truck mounted decks, glass pane vacuum pad grippers, safety provisions in general), handling machines (more and more performing tower cranes, sophisticated microelectronics controlled truck mounted cranes), road work machines, and not only machines in general, but also in building technologies and processes.
Minor changes we can detect instead (unless cases of more than accurate industrial secret protection) on subject of planning, controlling and monitoring, in spite of interesting and promising innovations proposed as a result of Home and European funded University Research: for instance a technology developed up to the field application stage employs transponders and wi-fi transmission networks to map workforce positions and to report the operating parameters of site machines, making available on the construction site the equivalent of a centralized monitoring and control centre of a "classical" factory.
In our knowledge, a sole exception of implementation of a somehow sophisticated, complementary technology is the usage of microtrasponders to tag and trace concrete specimens for law compliant testing purposes, in a major project in Central Italy.
In any case, process and procedure innovation which allowed the draft and the diffusion of ISO 9001, ISO 14001, BS OHSAS 18001 or other 9001-like standards (as SA 8000 in the field of social accountability) was the consequence of a "good will" approach of Clients who wished to minimize the risk of litigation along the buying-selling process. Such a "good will", solidly based on a possible mutual interest to minimize costs and to reduce processing times, proceeded from the empirical analyses of a great number of "sour cases", through the investigation of the reasons why something went wrong between client ad supplier. The drafting method itself explains why a mandatory approach to quality evaporates whenever

processes are under scrutiny, while it is much more effective if product quality is the involved.
In practical terms, a tools aimed to obtain harmony and concurrence in willing partners' business, is used (in Italy at least) as a certification basis to build up a confidence in Public Clients during the procurement process: in other terms, the chain QMS-certification-certificate leads to the gate of pre-qualification as entry point to the public works market. The reason why almost everybody enters the gate lies in our opinion, following the few data available, in the different attitude of the Public Client in respect of a Private Client.
If it is true that ISO 9001 was conceived under the Clients' initiative, and specifically under the pressure of their Purchasing Divisions, as a way to reduce costs and increase quality, then the success of QMS in the Client's perspective lies on the Client's willingness to implement a systematic effective watch and scrutiny over the execution and fulfilment of the contract: which means that not the mandatory presence of a QMS at the Contractor's office is the key, but - in case - the mandatory effectiveness of the Public Client. With due exceptions of course, a supplier Quality certification in case of an absconded Client may not be worth the paper it is written on.
It is a self-explaining paradox that the pre-qualification procedure regards QMS and its certification as documents to be delivered to the SOA (a private organization conceived to be witness of the fulfilment of pre-qualification requisites), and not to the Client.
This paradox may be explained by the peculiar atmosphere of the Nineties in Italy, in which the law makers of the age felt little confidence in the Public Clients and the awarding Authorities in general, and preferred to set up a guarantee mechanism which is fully external to the straight contract relationship Client-General Contractor.
Consequently, the law established as a fact the otherwise disputable theory that a subject not directly involved in the contract may effectively give guarantee where other internal means failed: such a course gave a job and a responsibility beyond the possibilities of Certification Bodies, authoritative as they may be.
So, the legislative philosophy adopted in the Nineties, beyond a per se non criticizable mutual benefit between Certification Bodies and Contractors, led to consider as insignificant or at least peripheral the contents of Management standards and practices in various fields (Quality MS, Environmental MS, Health & Safety MS, etc). In such a way, many Public Clients widely illiterate about MS contents and methods by themselves imposed do not even receive a conformity certification of their possessions, and above all fail to be real, interested promoters of standardized, even law regulated procurement processes.
The indifference of the Public Client, as a chain effect, induced unreasonable readings of the standards, an absolutely discretionary choice in the selection of building sites to be audited by the Certification Body to start with.

All-business standards and business-related standards

As a result, for instance, the Quality Plan requested by ISO 9001 is correctly understood, drafted and used just by very few Contractors: the Quality Control on site, if present, is the minor substitute of the requested extensive Plan, which is conceived by the standard as a wide-range, general, continuously updated Construction Management Plan, including detailed, specialized, most of all interconnected plans (Supply Plan, Resources, Work & Time Plan, Communication Plan, Work and Performance Control Plan, Logistic Plan, Financial Plan, and whatever plan a wise contractor can think of for the specific site). Even at educational level, due to the scant consideration reserved to management and organizational matters in Architecture and Building Engineering courses, it may not be easy to make

students aware of the difference, as they often reckon the two plans to be inverted (quality plan as a sub set of quality control plan).
The "vision" of ISO 9001, and its foundational process approach, which are suggested as a key to a successful development of a building site and to a profitable completion of a job order, is too in the majority of cases vilified to a few documents containing instructions for quantity and (sometimes) quality survey and (sometimes) to a field survey.
The deep understatement in which is held the role of QPs (Quality Plans) is leading to dire consequences specifically in a public works market in which tools for an efficient and documented job management are few and sparse. This perspective is certified by the effort of the law makers to insert in the process a relatively new character in Italy, the Public Process Manager: he/she is a individual, not an organization, an office or a department, a sort of Project Manager short of means and generally lacking specific experience. Further, the cardinal role of the briefing phase was introduced, but both the set up / execution of a Project Execution Plan, and the creation of a support unit including the project sponsor, were forgotten.
QPs were conceived by the standard maker to adjust the structure of the QMS to the peculiar aspects of different job orders from different Clients: in this role, QPs might have been - whether seriously adopted and not just formally issued - beneficial to lack of method and to the habit of issuing documents neither detailed nor in context.
On the other side, it is undisguised that the preference accorded both by Clients and Contractors to the realm of Quality Control during production points, in the management field, to something very near to the description/prescription approach in product standards field. This leads the companies to underestimate and understate the importance of thinking in terms of processes, possibly because an all-business standard like ISO 9001 cannot avoid to put the matter in ways misinterpreted as vaguely expressed, unspecific when not trivial. From this, a formalistic view follows, centred on "building police" inspections, sanctions and penalties, while the positive, prize oriented cut is not understood and ignored. Furthermore, quality records (simply "records" in the 2008 release), instead of being produced as a "natural" output of construction activities, are routinely postponed, and too often fabricated or misreported: the feeling towards quality records, and their pointless registration, only increases the bad reputation of QMS as formal, bureaucratic constraint.
Finally, the last questions. Are we allowed to conclude that QMSs did determine innovation in the building process? May a crudely simplified implementation of QMSs have obtained their scope, i.e. to trigger actions to remove the sources of uncertainty planted before the construction activity on site began? What meaning may have the continuous improvement concept when it's stuck to the sole Contractor, separate from its Clients and its joint-venture partners? Moreover, what is the perspective of investment in education and training when the bidding is done more and more frequently by temporary ventures of several Contractors with no interest to share procedures, management systems and education and training policies?
We should well keep in mind on this subject that ISO 9001 heavily emphasizes the role of training and education, but it excludes workforce management and union accords from its scope: is a reference to SA 8000, now ISO 28000-2010, enough?
What we have observed shows positive exceptions. Regretfully, lacking a systematic review of a significant amount of cases, it would be partiality or undue favour to report identities and references to specific job orders.
Nevertheless, we can outline undisputed situations in which Public Clients and Private Clients resolved to implement earnestly the QS standard: along the flow of those jobs, the process quality and the final product quality were effectively and positively oriented: which is, combined with the many negative examples above, crystal clear evidence of the miscalculation committed by the law makers when QS standards were limited only to

contractors' pre-qualification and to the decrease of bid bonds or guarantee bonds. At this point, it would be ungenerous to blame Certification Bodies as sole culprits: the limited scopes of the legislative approach themselves prompted the CBs to a slack behaviour as a matter of course, widely contributing to indulge in a trivial view of QMS. As it always happens, cultural shortage determines severe backlash in practical matters.

Beyond ISO 9001

The ISO 14001 Environmental Management System, as long as the LEED requirements, was in high favour at Clients, while it showed much more restricted usage by Contractors, especially in respect of ISO 9001. Yet, ISO 14001 is itself related to law requirements on matter of waste reduction and disposal in industrial activity. Beyond that, the standard is linked to BS OHSAS 18001, because the environmental issues are not disjointed from workers' health, which is of course environment-related.

ISO 14001, a standard ISO 9001-like, so conceived for its integration in QMSs, boasts wider success than its homolog, at least abroad: a well known application was sponsored by the Olympic Delivery Authority, who manages the job orders in view of the Olympic Games, London 2012.

As to BS OHSAS 18001, the running risk is of the same kind of ISO 9001: the British standard was recently recognized, in view of its becoming an European Standard, by the Italian legislation. The approach is too similar to what mentioned above: the certified Safety Management System is due to relieve the responsibility of owners and managers of building companies under criminal and civil law, if those subjects can give evidence that a health & safety management system was established. Absolutely correct in principle, this approach might easily skid towards purely formal documents leaving things worse than they were, with responsibilities ironically flowing in any case towards dead and injured workers. Few implementations are known at the moment, but it is not rash thinking to foresee in the health and safety field the same effects resulted in the quality management field: law constraints favouring widespread implementation might determine no factual application and scepticism as well.

Yet, a doubtless interest and innovation can easily be traced in OHSAS 18001: for instance, the requirement to investigate near misses accidents (keeping records and looking for causations, like aviation authorities investigate missed collisions events), not only actual accidents resulting in death or injury.

This kind of contents, likewise in ISO 9001 implementation, shows success whenever it actually determines a change in managers' thinking, and conversely leads to nothing if no cultural belief is induced. Like old Romans said "leges sine moribus vanae": laws are vane whether not absorbed in habits and custom.

System Integration

ISO 9001 and other mentioned standards were specifically conceived to be integrated. To support the efforts of integration, a "publicly available specification" was published by the British Standard Institution: the PAS 99 "Specification of common management system requirements as a framework for integration".

This pre-standard contains useful guidelines to build up an "Integrated Management System": purview of the PAS 99 is to help in creating a common frame of "general" management requirements, in number of six, as intuition can suggest and as ISO Guide 72 points out:

- Policy
- Planning
- Implementation and operation

• Performance assessment
• Improvement
• Management review

Generally speaking, the Integration of Management Systems is not a solution but an opportunity to go deeper into single subjects and scopes of the standards: actually, integration is worth in the measure it can widen the comprehension of the management about each standard scheme, and it can proceed beyond the sum of each standard scheme implementation.

In the specific field of the construction industry, system integration clashes both with the ineffectual relationship between Contractor/Client, and with the increasing practice of the JVs making the bidding. From this should stem the importance of Quality Plans, and of contributions given by Subcontractors and Suppliers.

Under those points of view, Management System integration stems from the basic asset of a Quality Management System. Which as a consequence shows that the construction industry, starting from non-convincing QMSs, will have even more chances to derail along the system integration process.

CONCLUSION

As a conclusion, the authors point towards two lines of action in the building field, at least for public works procurement and construction in Italy:

- first, give back tenability and authority to ISO 9001 implementation, through cultural and technical growth of Public and Private Clients, and through a thorough investigation about the implementation and certification of the scheme;
- second, innovate the processes active at the Contractors and their Subcontractors/Suppliers, deploying processes of integration among the requirements of richer, more articulate projects/contracts which might be defined under success of the point above.

Outside such a perspective, QMSs and their integration into IMSs would be expedient and beneficial only to commercial purposes of advice / certification markets.

Useful and correct as the standards may be, they would be to no avail effective to change the order of things. The rush to enforce new standards, and even more to enforce them through the law, all the more so as one still sees unaccomplished precedents, strikes as misguided at best. Something is needed "from the heart" here, because we are confronting cultural and educational problems, not simply technical and economical problems. Quality, Environment, Health and Safety, Social Accountability, and other concepts of that kind, are matters of culture and education, and their solution needs a cultural, educational, heartfelt response, oriented to make clear that there are no savings in cutting quality, in being harmful to the environment, in understating and undertreating health and safety, in downsizing social responsibility running Voodoo Economics and importing cheap labour, in short in sparing brainwork and substituting paper to specific, well coordinated efforts to solve the core of the challenges.

Abstract

Several pilot projects have spawned an increasing number of schemes involving individuals in renovation. A well known and awarded (World Habitat Awards 2008) project is the "Wallisblok" also known as "De Dichterlijke Vrijheid". This project involved the sale (for a symbolic amount) of a run down building block to a collective of future homeowners. The building block was in a poor technical condition and the collective owners had to (re)design and renovate the building block according to requirements set by the municipality. These requirements included both the quality of the renovation as well as the minimal investment. This scheme has been exported, copied and repeated due to its success. However, the schemes are different in several aspects, for example the price has never been as low as it was in the first project.

In the evaluations that have been written on the projects and especially on the Wallisblok, several gains are mentioned. Amongst others, neighbourhood improvement, home and street quality improvement, personal control over housing quality, participation amongst owners, strengthening of neighbourhood bonds and collective (neighbourhood) maintenance are mentioned (Sour 2009). Moreover effects that touch on demographic characteristics of the neighbourhood (attracting high income new residents, Van Der Laan 2009), on reaching environmental goals (climate change, Van Hal 2009) and contribute to diminish general socio-economic problems in the neighbourhood.

In this paper an overview of the stated effects and experiences is given and these are compared with the envisioned effects at the initiation of the project. The paper draws upon other (Dutch) evaluations and on literature that addresses similar effects. This paper is limited to a literature review focussing on the description of the project, its aims and effects. For the final conclusion, the effects of the project are put in perspective of scale and the competences of the collective that are necessary to create a successful project. Implementation possibilities of the scheme for use in more generalized housing and regeneration situations are mentioned keeping the limitations in mind. Thus the paper aims to give access to the characteristics of the project and to make an international interpretation of the scheme possible.

Keywords: Wallisblok, klushuizen, commissioning, empowerment, social diversity

INTRODUCTION

The "klushuizen" or DIY-homes (Do It Yourself) project in the municipality Rotterdam was initiated in 2003 by an architect (Ineke Hulshof) and process management agency

Urbannerdam (in person by Frans van Hulten) with the renovation project „Wallisblok". The project scheme that was designed based its approach on two observations. The first was that houses in the area of the Wallisblok were rundown but that their structural rigidity was still suitable to be renovated. The second observation concerned the poor social quality and/or the poor living conditions in the area. As a result of the poor quality in the area the neighbourhood was labelled as a problem neighbourhood by the national government (VROM 2000). Moreover, the area surrounding the Wallisblok was assigned a „hotspot" status by the municipality in 2002 (Rotterdam 2003a). The Rotterdam hotspots are unsafe locations with a problem accumulation, such as a poor physical quality, vacated dwellings, poor inhabitants, nuisance from prostitution and drugs related activities (Rotterdam 2003a). The municipality invited Urbannerdam and Hulshof architects in 2003 to create an approach to change these locations" characteristics in such a way that the hotspot status could be nullified.
The commenced basic idea was to get a collective of new homeowners to buy the complete housing block, make them renovate the houses to a high quality level and to live there for at least two years. In this way both the physical problems and the social problems would be addressed (e.g. VROM 2006). Due to the success of the Wallisblok, the municipality decided for a bigger project with more houses and the DIY-homes project was born and named „169 klushuizen".
Since the first idea in 2003 and the start of the first project, around 450 houses have been delivered in Rotterdam and transformed into nearly 200 bigger homes. The objective of this paper is to give insight in the characteristics of the Rotterdam based DIY-homes scheme. An overview of anticipated effects and effects that are found in several evaluations is given and the contributed effects are discussed. The central question of this paper is: what are the social, physical and financial effects of the collectively sold „Klushuizen". To answer this question the paper distinguishes effects that are aimed for and effects that are claimed to be found in literature. This paper is explorative in describing the goals of DIY-homes, evaluative in comparing results with the goals. The paper draws solely on literature study and project information as obtained from Urbannerdam. The paper concludes with suggesting adjustments for the scheme to make future projects even more successful.

The paper consists of five sections. In this first section first some background for the DIY-homes scheme and some theories that were found applicable are given. The second section consists of a general description of the DIY-homes scheme addressing the conditions for the scheme, the target group and primary goals. The third section illustrates the DIY-homes scheme using the Wallisblok project as a typical example. The physical characters, specific goals, investment scheme, design and renovation process and the results of the Wallisblok project are described. The fourth section presents the effects as found in literature attributed to the Wallisblok project and more in general to DIY-homes schemes. The effects are presented and reviewed. The fifth and final section contains some discussion and addresses the goals, effects and opportunities of the DIY-homes scheme. Finally, it suggests further research to measure the effectiveness of the scheme.

Origination of the DIY-homes scheme

Urbannerdams" office background suggests that the DIY-homes scheme can be traced back to the urge to get inhabitants in neighbourhoods more involved, to restore trust in the government and housing associations and to battle the generic urban restructuring approach (Van Hulten 2004). Van Hulten suggests a different approach for urban restructuring opposing the traditional one. The suggestion to institutional actors, such as the municipality and housing associations, is to rely more on a modest role in urban regeneration. The problem

analysis and the creation of a vision on the future of a neighbourhood are more important in this approach than executing the restructuring. To make this approach successful it is necessary to communicate a vision in an early stage of development. The vision should contain less actual plans to offer opportunity for the inhabitants to identify their contributions in the reaching the envisioned situation. Van Hulten thus suggests a role for the municipality that is to facilitate and initiate, rather than realise. At the same time it offers the opportunity for the municipality to be more susceptible to demands and wishes from the inhabitants. In this approach the interaction between local inhabitants needs to be stimulated and supported and is a mean and a goal at the same time. The approach should lead to an increase in property value, lower turnover rates, improved housing quality, active owners associations, reduction of nuisance complaints and increased social cohesion. This approach shows similarities with so called „area development" and „demand driven housing management" (e.g. Van Overmeeren and Zijlstra 2009) in the respect that the relation and involvement of actual inhabitants (should) prevail. However, for this paper some theoretical backgrounds are found in theories concerning gentrification, rather than management. The following paragraph shortly addresses some relevant backgrounds for the DIY-homes scheme.

Theoretical background for DIY-homes

The selection of the houses in the DIY-homes scheme is based on the neighbourhood, the quality of the building itself and the possible value-gap between them. This approach can be compared to the „rent-gap" theory from Smith (1987). This theory assumes that the factual price of a building, considering the state, location and size, is lower than the current actual price. This so called rent-gap or value-gap (the difference between potential price and present day market value) theory is used to explain gentrification of for example New York neighbourhoods (Smith 1987). Smith elaborates that through the first gentrification effects, the local economy will be influenced as well. Gentrification has, in this respect, effect on both physical and economical climate of the neighbourhood. But the social composition is effected as well. While prices are rising as an effect of gentrification, low income occupants move out, or are forced out, and higher incomes start to occupy the neighbourhood. Accordingly, the gentrification process has effect on three different pillars identified in the introduction: social, physical and economical.

The Wallisblok has been referred to as „gentripuncture" rather than gentrification (Van Eijk 2010, Hoofs 2005, VROM 2007, COS 2007, Crone 2005, De Jong et al 2008). Gentripuncture mainly differentiates itself from urban restructuring in scale and in the approach. Gentripuncture aimes at giving incentives by means of giving opportunities to gentrifiers (De Jong 2008) while restructuring focuses on renovation or demolishment and rebuilding large amounts of estates (Van Eijk 2010;21). Gentripuncture, a contraction of gentrification and acupuncture, could be placed in the state-led gentrification approaches as identified by Uitermark et al (2007). Uitermark et al argue that state-led gentrification is an actively chosen strategy by a coalition of governments and housing market actors to change the social composition of a neighbourhood to restore the social order and structure. Gentrification and Gentripuncture accordingly, can be seen as a global urban strategy (Smith 2002). Gentrification, as defined by Clark (2005;258) is ``a process involving a change in the population of land-users such that the new users are of a higher socio-economic status than the previous users, together with an associated change in the built environment through a reinvestment in fixed capital." Thus by changing the neighbourhood composition the gentrification strategy can fight problems as poor living conditions in neighbourhoods. The definition of gentrification can be recognized in the Dutch urban restructuring strategies as well. The restructuring strategies focus on replacing low rent-price, low-quality houses by homes aided for higher and middle income owner occupiers (Uitermark et al 2007, VROM,

1997; 2000; van Kempen and Priemus, 1999). Rotterdam is no exception and has been aiming to maintain and attract higher incomes to the city (Rotterdam 2003a/b, 2006). However, the success of these strategies are under debate and not yet proven (e.g. Van der Land 2004). The DIY-homes scheme can be placed in the context of "joint private project commissioning" (Collectief Particulier Opdrachtgeverschap (CPO) Blom 2009, NRP 2009) but that has been mostly limited to new construction (Blom 2009, Boelens 2010). For this paper the context is limited to effects related with gentrification.

DESRIPTION OF THE GENERAL DIY-HOMES SCHEME

The DIY-homes scheme can be interpreted in different ways. A building in a very bad shape can be named a DIY-project, which happens often by real estate agents. For this paper DIY-homes are defined as (Urbannerdam):

1) the buyer has a lot of influence on the design and realisation of the renovation and has been given the opportunity to manage and remodel both exterior and interior of the house;
2) the seller demands from the buyer a certain effort by requiring the buyer to:
    a. renovate according to a programme of requirements set by the seller regarding building standards (higher than the usual Buildings Decree) for example in means of energy, comfort and looks. In this way the quality of the renovation is controlled;
    b. live in his DIY-house for a given time (determined by the seller) to prevent the houses from being sold for a higher price and making it less interesting for property traders and to prevent speculation;
    c. to renovate the building block (only if applicable) in a joint effort of all the new buyers.

Requirements/Conditions

Besides the requirements that have to be met in relation to building quality, self-occupation and collective renovation some other requirements are demanded from the future homeowners. The future homeowners have to meet a financial criterion that asks them to be able to finance the purchase plus the estimated renovation costs.
After the completion of the collective renovation all the owners get a determined period to finish the interior of their homes themselves (or have it done by a building contractor). This period ranges from 6 to 12 months in order to keep the project going and to be able to check if the desired minimum renovation level has been lived up to individually as well.
The conditions need supervision and monitoring during the process of renovation and even after completion. The municipality provided the new owner occupiers with experts during the design and renovation process (see next paragraph) and used monitoring tools to check whether the conditions were met.
Over time these conditions changed a bit since their first use in the Wallisblok project and were optimized throughout the other collective projects. The basic three main conditions remained the same.

Target group

The target group of DIY-houses are mainly people who are willing to put a big effort (time and money) in a house, in a dilapidated neighbourhood. They like to realise their own desired living space and by their investment will be involved in the condition of their home and their neighbourhood. Depending on the location, possibilities and conditions, each scheme has it is own more specifically defined target group. Candidates can apply when new houses to be

sold are announced. The only selection criterion the municipality uses is the mentioned financial test. Candidates that prove to have sufficient financial means to pass the test are allowed to enter the drawing of lots to be assigned a place in the project. In advance the desired minimum quality of renovation has to be determined, budgeted and communicated, to minimize surprises (such as failing the test) and unexpected (extra) costs for the new buyers.
In general the features of the DIY-scheme are attractive because:

1) the new homeowner is in full control of the characteristics (quality and costs) of the property;
2) the requirements require both an effort from the homeowners as from the municipality;
3) the requirements guarantee banning of undesired tenures.

Primary goals of DIY-homes scheme

The initiator in the DIY-homes scheme is the municipality of Rotterdam. They own most of the DIY-homes offered in the scheme (eg. the homes in the Wallisblok) as a result of purchasing run down houses. Sometimes the properties are (formerly) owned by housing associations, mostly the properties are purchased from private landlords. The municipality states that the project should contribute to create "bigger, affordable dwellings, to create a more mixed neighbourhood and inhabitants" (Rotterdam, 2006). In the sale agreements the municipality addresses several „considerations". The agreement states that the physical and social living conditions in the area are poor and that the area was assigned a „hotspot". The municipality states to have invested national subsidies to restore the building quality (used on the foundations) and that the obliged renovation has to lead to "bigger, renovated houses that attract and are attractive for other occupants than actually present in the neighbourhood, leading to a more mixed neighbourhood." In these considerations the physical and social goals prevail. Zoethout (2005) signals that the context of lacking tools to control the housing quality and budget cuts at the municipality are a general driver towards the DIY-homes scheme. More in general, the municipality was searching for instruments to get inhabitants and owner occupiers to invest in their own living environment (Zoethout 2005, Blom 2009, Rotterdam 2003a, VROM 2006, Hoogstad 2007). According to Blom (2009) it is a challenge to find solutions for the question "how to attract buyers to a deprived area? How can you change a negative image of an area in such a way that the neighbourhood transforms to a trendy hotspot in a few years time?" Blom thinks that physical renovations, with or without subsidies, are not enough to improve the quality of an area. One of the reasons is that the properties owned by private landlords cater undesired tenancies as (illegal or overcrowded) pensions and sub-letting. Considering the distribution of tenancies in the neighbourhoods (Spangen for example consists for 95% of rental homes and 5% owner occupied homes) stimulating homeownership should be part of the approach. Blom assumes that owner occupiers are more strongly involved in the neighbourhood than rental tenants.
Hoogstad (2007) states that the primary goal of the municipality was to get the building block sold from their portfolio. According to Hoogstad the main question was how to attract potential occupants for the dwellings situated in the "deprived" area (Hoogstad 2007, compare Blom 2009). The privately commissioned collective renovation was the solution the municipality believed in to offer such a "niche" to attract "creative" people (amongst others Hoogstad 2007, Blom 2009).

General goals for the DIY-homes scheme can be summarized in being:

1. improving and guarding housing quality (larger, diversified, renovated);
2. improving and sustaining neighbourhood compositing (different from present neighbourhood composition, higher incomes, creative people);

3. improving economical viability (giving financial incentive to attract and stimulate investments);
4. fighting undesired tenures (sub-letting, illegal pension holding).

Thus leading to an overall improvement in the area and removing a hotspot appointment. The effects can be identified through differentiation in physical housing stock characteristics, raises in average housing values and improving the inhabitants‟ judgements on safety and the quality of the living environment. These goals are enforced by the terms and conditions set by the municipality in the sale agreement and work along several mechanisms such as attracting higher incomes to the neighbourhood and improving the image. Furthermore it is believed that the new homeowners shown a greater commitment to both home and neighbourhood as a result of the investments they have made in time, effort and money. The new homeowners are expected to have higher incomes and different backgrounds than the existing inhabitants in the neighbourhood, thus leading to differentiation and an increase in purchasing power in the neighbourhood. Further living quality improvement could be reached as a result of a role-model effect both socially and physically.

The architect and process manager (Ineke Hulshof and Frans van Hulten) are cited “if a municipality or housing association develops such a project it undoubtedly ends in an unpopular project full of compromises. … people are willing to live in such a project but not when it is situated in a neighbourhood like Spangen, they are only willing to [live there] when they get full control [over the renovation and design].” Ditty Blom is cited “they want a lot of floor surface and space, and most of them have dreamed for years of a home that they can design and model to their own desires.” These quotations illustrate social goals (attracting a different target group, offering a home that can be fully controlled), economical goals (delivering value for money, loosing the building block from the portfolio) and physical goals (a home made to measure and solving poor living conditions in the area starting with the building block). The goal of the project could therefore be captured in terms of state-led Gentripuncture aiming for gentrification of the Spangen neighbourhood (Bosscher 2007).

DESCRIPTION OF WALLISBLOK PROJECT: the first DIY-homes scheme

The Wallisblok also known by the name the „De Dichterlijke Vrijheid‟ (the poetic freedom) is situated in the neighbourhood Spangen in Rotterdam, and the location is assigned a „hotspot‟ status (Rotterdam 2006, VROM 2006). The neighbourhood is referred to as the “drain” of the city, thereby collecting all the dirt and problems of the city (Crone 2005). It is an unpopular area dominated by non-Dutch-native inhabitants (over 75%, ibidem;4). The building block was heavily dilapidated and Spangen as a neighbourhood in general was considered a weak area of Rotterdam. Spangen was well known for its bad reputation. The properties were previously owned by private landlords that neglected the buildings. The municipality bought different poorly maintained properties in the building block since 1998 (Sour 2005) and boarded them up. The municipality has legal tools and had the means to intervene in „dangerous‟ housing situations. The municipality can force a homeowner to improve the housing quality when it becomes dangerous according to the building law. When an owner does not comply, the municipality will commission the renovations themselves and forward the bill to the homeowner or owning landlord. When the homeowner thinks the investment is more expensive to be worthwhile, the municipality can offer to buy their properties from them, renovate the building according to the safety standards and sell them again. This method was used in many cases and is known as the Aankoop-Verbeter-Verkoop concept: buy-improve-sale concept (Blom 2009;35). As a result of the regulations, the

municipality was able to buy the properties relatively cheap. Most of the houses remained boarded up to 2003 and thereby enforced the negative image of the area.

Figure 1: *picture Wallisblok before renovation (2004)*

Physical characteristics

The architect and process management company were invited by the municipality to explore the options of renewal and came to the conclusion that the Wallisblok:

- Was in a poor physical condition and needed a full renovation including the interior, the foundations, roof and the rear facades;
- Represents a high architectural value block since it is constructed in the 1930‟s typical Amsterdam School style;
- Would cost an equal amount to renovate as it would to be demolished and rebuild or redeveloped.

As a result, the advise was to renovate (Blom 2009). Crone (2005) and VROM (2006) emphasize the poor physical quality and stress that the municipality will improve the quality of the building foundation if necessary before the houses are actually sold.

Specific project goals Wallisblok

Renovation is a clear goal and according to the sale agreement, the quality aim is to create not just bigger homes, but to ensure the quality by demanding new-built standards. Improving the physical and structural quality of the homes thereby is important to attract future occupants and preferably is realised before the homes are sold. This is necessary since the image of the area is too bad to attract occupants (Blom 2009).

Joint private project commissioning, mixing (attracting high incomes) and improving the image of an area are goals within urban renewal (Berkelbach 2006). Attracting high incomes and revitalising an area can be part of a gentrification strategy as well.

Agricola and Helleman (2006) place the Wallisblok in the urban renewal background aiming for social cohesion, citizen participation and urban mixing (ibidem;12). According to them especially the link between the social and physical urban regeneration is of importance.

The goal stated in VROM (2006) was to increase owner occupancy in the neighbourhood and to reach dwelling diversification. The follow-up projects have to improve the image of the neighbourhoods and have to contribute to the gentrification of Rotterdam (ibidem;6).

Investment scheme

The investment estimate excluded the costs of purchasing the properties and the costs for improving the foundations. Using subsidies (ISV1 and 2 national subsidies for urban renewal and IPSV national subsidy for innovations in urban renewal, Blom 2009;46) the renovations of the foundations could be paid for by the municipality. Considering the estimated value of the houses before and after renovation, the municipality decided to „give away" the building block to a collective of future owners. In fact the Wallisblok was sold for a single Euro per buyer. In return for a free (in later projects a cheap) home, the future owners had to meet the conditions mentioned.

The price is determined by valuing the renovated property minus the investment costs. This price is (should be) lower than the property"s value in its present state. This method of pricing is necessary to make the project interesting and affordable for future buyers. For the Wallisblok it turned out that the municipality had to sell the houses for a single Euro, later projects were never this cheap since the quality of the properties wasn"t as bad as in the Wallisblok.

It is required for the new homeowners to renovate the building block (if applicable) as a collective. They have to act as one private commissioner. The owners have to come to one general renovation plan. The advantage is that they share the costs of the collective renovation equally (according to purchased floor area in square meters) and thus should be able to get a relatively good price for the works commissioned.

The design and renovation process

After the announcement of the Wallisblok being "given away" in November 2004, there where over 400 interested potential buyers of which 39 decided they wanted to take this challenge and finally formed a collective of homeowners called "De Dichterlijke Vrijheid". The (design) freedom, collective and the price aspects attracted the new homeowners to the project. The costs for a single floor apartment were estimated on €70.000 and € 200.000 for a four storey house (about 160 square meters).

During the process the buyers got assistance from experts. The design and planning process was accompanied by the process manager (Urbannerdam) and architect (Hulshof) and there were municipal permit experts involved, guiding the buyers through the different phases of developing their own homes. The process manager had knowledge of the entire building process and more importantly had knowledge and experience in controlling group dynamics. The architect assisted in designing the wishes and desires of the homeowners and had knowledge about technical and process matters. The future occupants were closely involved by the experts so to become experts themselves on different aspects of the building process.

To get things started, workshops were used to determine housing preferences on which the later parcel layout was based. Groups of buyers were formed which investigated specific terrains. The formed building group of homeowners acted as the private commissioner and formulated the groups" collective wishes. Another group of owners formulated the sustainable investments and another group made a plan for the collective garden.

Result

The Wallisblok project turned 96 dilapidated units into 39 renovated, high quality, inspired and unique homes. As a result the building block was preserved, the architectural value was kept, the facades renovated and the run down image of the street improved (compare figures 1 with figures 2).

Figure 2: *picture Wallisblok after renovation (2008)*

EFFECTS OF FIRST DIY-HOMES PROJECTS

In 2010 a total of up to 450 houses have been offered in the DIY-homes scheme and that has led to improvement of and occupancy of nearly 200 remodelled homes. About 57% of the houses has been offered in some sort of a collective scheme while the other houses became individual homes that were no part of a collective. The DIY-homes are mainly offered in three neighbourhoods of Rotterdam: Delfshaven (Spangen), Feijenoord and Charlois.

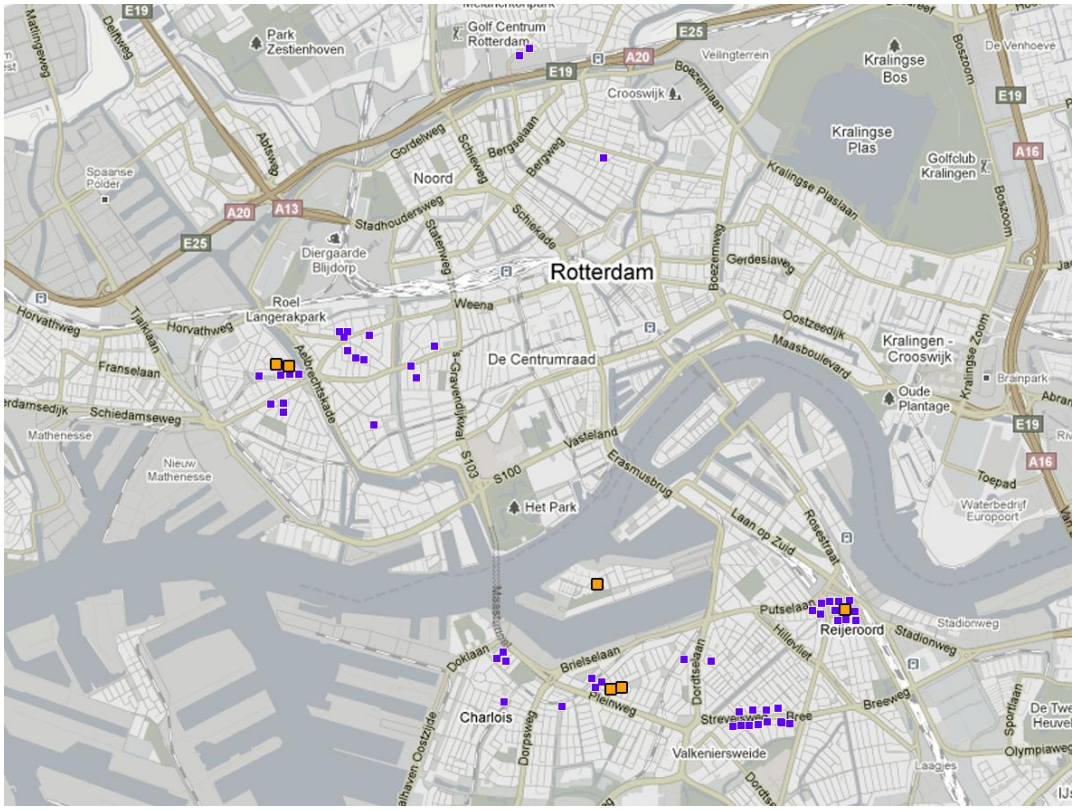

Figure 3: *geographical overview of DIY-projects in Rotterdam. (Orange squares represent collective projects, blue squares represent individual homes)*

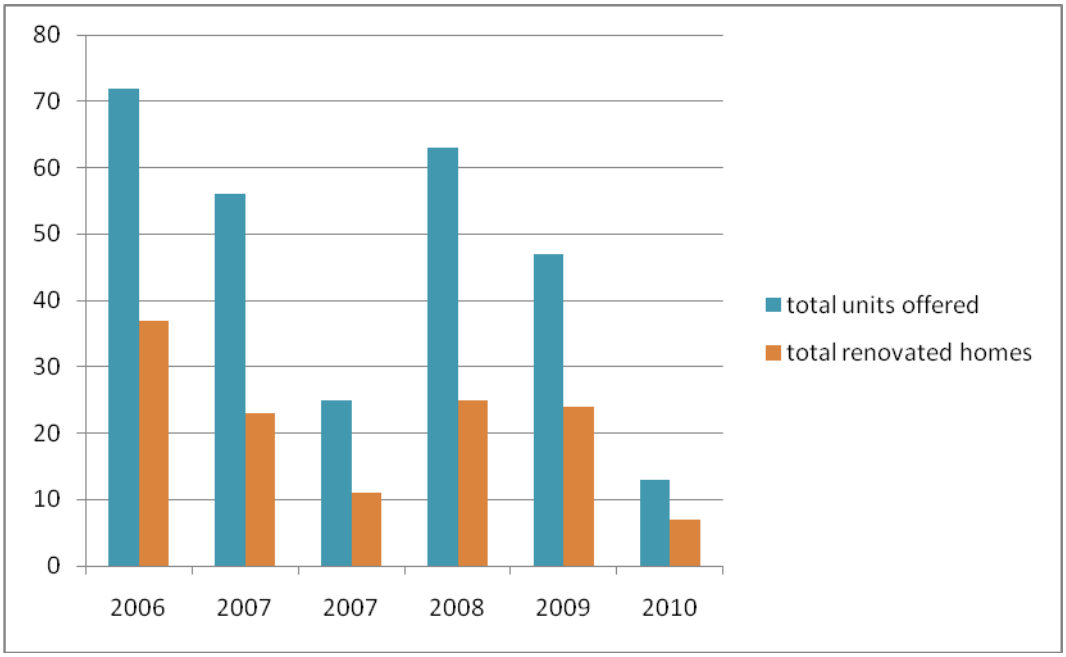

Figure 4: *Timeline and number of homes offered (both collective an individual DIY-homes)*

Selection criteria for homes and neighbourhoods

Selection criteria should be (Zoethout 2005) that the houses are part of a single building block and all houses in the block are included in the scheme. Preferably the area is close to the city centre, the dwellings are cheap or preferably free and worth an expansive renovation. Buildings with ‟30‟s architecture are preferred (ibidem;49).

The houses to be offered are preferably run down since the lower quality will lower the price as illustrated in the investment scheme and calculation of the sales price. The lower price and poorer state offer the future owner more possibilities and at the same time is gives the municipality a justification to demand (more) conditions.

Some warnings are issued by Zoethout as well: the group of new owners cannot be much bigger than 36 to ensure that decisions can be made and meetings will be fruitful. But there is a minimum group size as well, if the group consist of less than about 8 buyers the amount of available time and effort and therefore work being done and knowledge within the group is reduced. Good planning and guidance is essential. Moreover, Zoethout believes the scheme is not applicable in deprived areas, the future inhabitants need to have faith in the future of the area.

Blom (2009) is clear about the economical aspect from the municipality‟s point of view. Other housing investors, such as housing associations, didn‟t manage to envision a financially feasible project in the Wallisblok case, even including subsidies. The buy-improve-sale scheme therefore wasn‟t working and an alternative had to be found. Giving the houses away was left as the only solution (ibidem;39). The scheme was financially backed by a housing association from Rotterdam (if the houses weren‟t sold, however free, the association would do the obliged renovation investment, Blom 2009, De Jong et al 2008). The selection criteria for the possible DIY-homes schemes can thus be supplemented by the need for a value gap and by the availability of subsidies to bridge the negative investment.

Berkelbach (2006) states that inventiveness and a social attitude are needed in the future owners to be willing to join in a (collective) DIY-homes project. To attract the future inhabitants and keep them from withdrawing from the project it is essential to be honest and give an estimation of the costs that is feasible (De Jong et al 2008).

Project name	Period	Area	No. dwellings before-after renovation	Sale price-investment	Remarks
Wallisblok (Dichterlijke vrijheid	2004-2007	Spangen/ Delfshaven	96-36	0/unit 200.000/dwelling	First pilot project
Kleine Kop Vosmaer (Blauwe Vos)	2006-2009	Spangen/ Delfshaven	39-18	10.000/unit 1.400/m2	
Verschoor 2	2008-2011	Tarwewijk/ Charlois	15-5	110.000/dwelling 65.000/dwelling	partly renovated before sale
Beukblok	2007-2010	Hillesluis/ Feijenoord	16-6	0/unit 1.200/m2	Initially non-sold apartments got partly renovated before selling
De Driehoek	2007-2011	Katendrecht/ Charlois	85-36	15.000/unit 1.500/m2	Offered in collaboration with Nieuwe Unie housing association (Woonstad)

Table 1: *Overview of characteristics of the collective projects realised (Urbannerdam 2010).*

Stated effects of the Wallisblok project and DIY-homes

Van der Laan (2009, minister of VROM at that time) concludes that there are three main reasons to stimulate DIY-homes schemes. The first is the positive effluence on the neighbourhood of DIY-homes. He feels the scheme should be used in deprived areas since inhabitants are the first to notice problems and the first to have ideas on solving them. Secondly the scheme gives tenants full control over the housing quality. Third and last he concludes that the bond between occupants created during the renovation will have an effect on the collective maintenance of the homes and of the neighbourhood.

De Jong et al (2008;40) summarizes the effects of the Wallisblok project in 7 "lessons". The DIY-homes "stimulate social cohesion in the area (1); stop the downward spiral of degeneration (2); increases owner occupancy (3); diversifies the housing stock (4); attracts people with higher education levels and incomes (5); comply to individual housing demands leading to diverse and extraordinary homes(6); led to an increased confidence within the municipality in the scheme and its outcomes (7)." De Jong et al don"t state any economical effects but oppose the effects to the investments: between 70.000 and 350.000 Euro per dwelling per individual household. And an additional investment from the municipality of 35.000 Euro per dwelling excluding the additional costs for foundation repairs.

Now an effort is made to distinguish the different effects according to the distinction made between physical, social and economical effects.

Physical

The homes created are extraordinary (De Jong et al 2008) and got published in the (Dutch) Architectural Yearbook (Blom 2009, Van Hulten 2008). Zoethout (2005) states as positive results that "characteristic buildings" are maintained instead of demolished. The dwellings are more diversified (ibidem, De Jong et al 2008), became considerably bigger (Boonstra 2008, De Jong et al 2008, Sour 2009), and contain some very special lay-outs (Van Hulten 2008, Sour 2009). VROM (2006) states that the goals of increasing owner occupancy in the neighbourhood and dwelling diversification has been reached.

The project has been mentioned in relation to sustainability questions such as energy consumption, CO2 reduction and climate change as well (Van Hal 2009). At least they are renovated to high quality standards (Boonstra 2008). The aspects of physical neighbourhood improvement, home and street quality improvement and collective (neighbourhood) maintenance are mentioned, but more in relation to the social effects of the project. The Wallisblok received three awards. The World Habitat Award for the preservation of the valuable buildings, offering affordable homes and triggering local regeneration (World Habitat Awards 2008), the Job Dura Award for the contribution to safety in the area and stimulation of the rehabilitation of the area in the neighbourhood (Job Dura Fonds 2006) and the Innovation Award at the Nationale Renovatiedag in 2009 for innovation in the building process and contributions to social and economical structure of the neighbourhood (NRP 2009).

Social

The Wallisblok attracted 60 new inhabitants to the neighbourhood. The inhabitants have high incomes, which is consistent with the ambitions of the municipality (Zoethout 2005, Boonstra 2008). The inhabitants are a stable group and create a child friendly environment (Van Hulten 2008;45) at least in the inner garden (Van Hulten 2008, De Jong et al 2008). Inhabitants experience the shared responsibilities as pleasant and the inhabitants remain enthusiastic despite the hard work and long hours that had to be invested in the project (De Jong et al 2008).

Blom (2009;41) concludes that the DIY-homes attracted a completely different group of inhabitants to the area. She calls them dynamic urban people and the group is typified as "active with the city and street" and they "actively choose for a neighbourhood". The group is creative: architects, artists, designers and photographers. They are "pioneers" that choose for the control, freedom of choice and good value for money (ibidem). VROM (2007) typifies the group as the "creative middle class" rather than non-Dutch natives. Berkelbach (2006) calls the inhabitants highly educated as well. The inhabitants self-select (VROM 2006) and have the „perfect profile". This profile consists of creative people with high incomes and freelance occupations, that share "ideological motives" and are "empowered" ("weerbaar" VROM 2006). SCP (Gijsberts and Dagevos 2007) states that the owners of the DIY-homes are "frontrunners" and is one of the few successful measures to have a positive effect on social cohesion (Hoogstad 2007). De Jong et al (2008) refer to the Wallisblok effects as social climbing of the tenants. This „climbing" mechanism is referred to as empowerment as well (e.g. VROMraad 2006). In this case the main aspects of the process involve homeownership and control over the dwelling (De Jong et al 2006;42). Van Hulten (2008) refers to the strength of the group and the control they expressed in the project. Without these characteristics the Wallisblok project would not have succeeded in his eyes. It could be explained through motivation and shared opinions (ideology and ambition) of the group. De Jong et al (2008;44) conclude that the new inhabitants are a closely knit community consisting of the creative class (according to Florida).

The DIY-homes have led to cohesion amongst the tenants has been created as a result of intensive collaboration in the renovation and design phase (Zoethout 2005) and shows in the number of groups formed to get things done in the building block and surroundings. The project has contributed to create a more positive image of at least the neighbourhood (Van Hulten 2008;45). A tenant admits to have chosen for the DIY-homes partly out of idealism "we don‟t want to become a white enclave" (Hoogstad 2007). This statement was also found in Sour (2005;45). Some inhabitants themselves claim that the social cohesion within the group is an important factor (De Jong et al 2008). The social cohesion amongst the new inhabitants generates another valuable aspect besides the quality of the house itself (De Jong et al 2008;48). VROMraad (2009) signals that DIY-homes illustrate and generate cohesion and involvement with the living environment.

One of the advantages is that the housing consumer becomes a housing prosumer (after Toffler 1980) and models and thereby creates their own home and living environment. Hoogstad (2007) cites some tenants just after they moved in "we have created our own dreamworld", "an ideal housing situation … where I can settle" (De Jong et al 2008;48).

The effects on the neighbourhood are less simple explained. The safety index has improved (10point scale) from a 4,6 to a 7 at the moment the first homes are inhabited (2007, COS 2007). Major problems in the area have been solved such as related to drugs, homelessness and prostitution (Hoogstad 2007, Blom 2009). De Jong et al (2008) cite an inhabitant that mentions smashed windows and other nuisances in the neighbourhood. But the inhabitant recognises the attractive force of the Wallisblok as well. In its wake all kinds of activities are coming to Spangen and thereby having a positive influence on the image of the neighbourhood.

Urban restructuring could lead to inhabitants protesting against demolishment. Since the houses in Wallisblok were already vacant, it was decided to renovate in stead of demolish and built new houses, the inhabitants of the neighbourhood did not protest the approach. But some uneasy feelings have been expressed (Zoethout 2005;42). And Aussen (2010) concludes that the old inhabitants of Spangen are not really interacting with the new inhabitants of the project. However, the project hasn‟t led to feelings of displacement as could be found in gentrification literature (e.g. Hamnett 2003, Atkinson 2002). The old inhabitants of Spangen view the arrival of the new inhabitants as an achievement they themselves have made possible as a result of all their activities to reduce problems in the area. The different groups rarely meet and when they do some tension can be felt. The old inhabitant agree that the new inhabitants mainly live a different life withdrawn from neighbourhood activities. One of the arguments to support this is their communal (private) garden (compare amongst others De Jong et al 2008). As a result the new inhabitants are regarded as outsiders in the neighbourhood (Aussen 2010).

Economical

As stated among the social effects, the Wallisblok succeeded in attracting high incomes. This could lead to a more entrepreneurship and higher purchasing power (Van Der Laan 2009). Van Hulten (2008;45) sees this economical component as well. He states that the new inhabitants stimulate the local economy as a result of the high purchasing power. But the RMO is less optimistic. RMO (Hokken en Janssen 2005/RMO) concludes that integration won‟t be the case since the new inhabitants will find different schools for their kids, will do shopping in other stores and socialise at other places than the other neighbourhood inhabitants. Colantonio and Dixon (2009) conclude for the Rotterdam South area, but not especially regarding the DIY-homes, that housing mobility has not changed considerably and that social effects, as measured in different monitors, need more time to become visible and might take generations to show (ibidem; 65-69).

The total investment in Wallisblok is over 10 million Euro, of which 6 million by the inhabitants (Berkelbach 2006;186). De Jong et al (2008;44) conclude that the inhabitants got themselves a owner occupied home with new built quality for a price of 200.000 euro per 130 sq meter. Zoethout (2005;34) illustrates the average price per square meter in Wallisblok is 1150, while the average of Rotterdam is 1635 and for the neighbourhood it is 1246 (prices 2004). Close reading reveals some differences in the stated investments. However, the homes can be considered a "good deal" and the inhabitants feel that they got a good deal. The price-quality ratio is stressed by several authors as main point of attraction (Hoogstad 2007, Crone 2005, Zoethout 2005, De Jong et al 2008). However, De Jong rephrases an inhabitant that claims to have high housing expenditures as a result of obliged maintenance reservation and energy costs (2008;48).

Critical review attribution of effects to DIY-homes:

From the previous paragraph it can be concluded that in describing the DIY-homes most attention is put on social effects. These are the most difficult to measure (Deuten and De Kam 2005). The physical improvements can hardly be debated. The economical aspects might be to soon to be measured and might face difficulties as well. Contrary to Van der Laan (2009) who advises to use the DIY-homes more often, Agricola and Helleman (2006) conclude that no generic advice can be given on how to reach successful renewal. The size of the project is debated as well. De Jong et al (2008;42) state that for gentripuncture effects to be found, a minimal amount of 20 (new delivered) dwellings is needed. Van Hulten (2008) states from a process managing point of view that 40 dwellings is the maximum project size. SCP concluded that DIY-homes are one of the few ways of increasing cohesion in neighbourhoods. Sceptics doubt the SCP conclusions. And Blom responds "I still have to find out if the DIY-homes are the magic wand. … talking about integration, this project still has to prove itself" (Hoogstad 2007). Zoethout concludes that the DIY-homes accomplished to attract inhabitants to the neighbourhood that have specifically chosen to invest money, time and creativity in the neighbourhood. However, if this leads to gentrification has still be seen. Note that the scale of the project in the neighbourhood is small and that the effects of mixing are debated (Bolt and Van Kempen 2008, Boonstra 2008). Some sources contradict each other. Zoethout (2005) claims that the scheme is applicable to these deprived areas where people have faith in a prosperous future. Others, as Blom and Van der Laan (2009) praise the scheme to be applicable in deprived areas without making any reservations.

The downside is that the DIY-homes are relatively expensive for the municipality (Zoethout 2005). Blom (2009) gives an estimation of around 100.000 Euro per dwelling in case of the Wallisblok and signals that without available subsidies the project wouldn't have been feasible at all. Blom has the opinion that for housing associations with dilapidated properties in their portfolio, the scheme is much more feasible. But housing associations are reluctant to use the scheme because they approach the sale from a profitable point of view that makes the homes more expensive and thus less attractive (Blom 2009;49). VROM (2006) signals that a similar project (as the Wallisblok but executed by a housing association) has experienced difficulties to be sold. The project offers less modelling options and is situated just a few blocks away from the Wallisblok. The price of the project is considerably higher (opposed to "free") and the marketing used to promote the houses is poor. The media attention for the "free" homes was tremendous and even got on the national evening news. In the Wallisblok case, the municipality intervened actively by buying the properties located in the hotspot and used a more assertive and repressive policy to battle the existing problems in the hotspot areas (Blom 2009). The effects assigned to Wallisblok and DIY-homes might as a result, rather be related to the municipal actions than the result of the new inhabitants moving in (De Jong et al 2008;44).

It is not possible to attribute all the signalled improvements in Spangen to the Wallisblok project since the municipality and housing associations intervened in many different ways (Boonstra 2008, De jong et al 2008, Van Hulten 2008, Hoogstad 2007).

DISCUSSION

There seems to be some shift in the attention for the Wallisblok project. From the outset of the project, aiming to attract high incomes and to solve the hotspot problems, now the focus is more on social goals. The literature used in this paper does focus on the success of the project but lacks a proper evaluation based on the stated goals. The literature doesn‟t seem to be too critical and at the same time the methodologies used are debatable (but is beyond the scope of this paper). In depth analyses are yet to be made, for example an extensive evaluation of the neighbourhood effects has not been conducted. The number of projects will now allow for such an evaluation. The scale and contribution of effects to the scheme will however prove to be difficult.

It is clear that the project succeeded and might have reached more goals than initially aimed for. The goals desired by the municipality, such as getting inhabitants with higher incomes in the DIY-homes, have been reached. Housing diversification has been reached and characteristic buildings have been preserved. The cohesion amongst the inhabitants is good as a result of intensive collaboration and the safety in the neighbourhood has improved but might be a result of the municipal actions.

The owners were willing to invest in the renovation and to choose for the neighbourhood despite the problems. The cohesion within the group might have effect on the neighbourhood; at least the owners are willing to invest the award money in the neighbourhood. This offers an opportunity for additional quality improvement and might lead to more meetings with old inhabitants. However, the bonds between the two different groups are mostly not existent. For social cohesion to be found a different research approach is necessary. The empowerment effects as mentioned by De Jong et al are debated since the attracted group is self sufficient; high educated and has a high income (Elsinga et al 2009). If the selection criteria are to match low incomes, empowerment through ownership might be feasible.

For the project to be successful the value-gap must be present and preferably there are additional subsidies available to finance the renovation. The building has to have some kind of quality; in the location, building or a low price, but preferably in a combination of those three. The DIY-homes have been applied mainly in Rotterdam but other municipalities have shown interest. For example The Hague has already tried a first building block and Arnhem sold DIY-homes both individually and collectively. As long as the value-gap is present the scheme could be applicable. People from Denmark and Great Britain have shown interest in the scheme as well. This paper did not go into international schemes but it should be possible to be exported to other countries. In general this scheme offers a solution for countries where housing quality can be enforced (by governing bodies) and housing market is skewed due to tension on the housing market. However, it demands an investment by municipality to make it possible. For example, in shrinking areas the possibilities to acquire beneath economical value are present, but individuals or commercial entrepreneurs could respond to the opportunities themselves. However, a collective approach, backed by a housing association or municipality, might prove successful in attracting inhabitants. The collective approach guarantees that a building block can be renovated at once and gives a financial advantage over individual renovations. As a result the risk is lower than when a project developer is involved especially in the present difficult housing markets. Maybe the most important factor

is that all the new homeowners are involved from the start of the project, are highly committed and impatient to live in their project.

SUBCONTRACTOR SELECTION BASED ON DATA ENVELOPMENT ANALYSIS

MOHAMMAD S. EL-MASHALEH, Associate Professor
Department of Civil Engineering, The Hashemite University, Jordan
mashaleh@hu.edu.jo

Abstract
In today's construction market, subcontractors execute significant portions of construction work. Subcontractors lessen resource requirements faced by general contractors and provide specialized expertise to construction projects. The reliance of general contractors on subcontractors to execute major portions of construction work makes the success of construction projects highly susceptible to the performance of these subcontracting organizations. As a result, subcontractors' selection decisions are of crucial importance to general contractors bearing in mind that such decisions are exercised by general contractors multiple times in every single project. This paper contributes a Data Envelopment Analysis (DEA) model to guide general contractors in their subcontractor selection decisions.

Keywords
Subcontractor selection; Decision Support system; Performance measurement; Benchmarking; Data envelopment analysis.

INTRODUCTION

For almost the last two decades, subcontracting has been utilized extensively in the construction industry. Several researchers indicate that it is common to subcontract the majority of construction work to subcontractors (Hinze and Tracey, 1994; Kumaraswamy and Matthews, 2000; Shash, 1998; Wang, 2000). It is expected for this trend to continue in the future (Ng et al., 2008 a, 2008 b; Arditi and Chotibhongs, 2005; Wang and Liu, 2005).

Subcontractors help general contractors to overcome problems related to the need for special expertise, shortage in resources, and limitation in finances (Elazouni and Metwally, 2000). The operations of the average general contractor are not sufficiently extensive to afford full-time employment of skilled craftsmen in each of the several trade classifications needed in the field (Arditi and Chotibhongs, 2005). Subcontracting allows general contractors to employ a minimum workforce in construction projects and promotes specialization. It capitalizes on the skills of trade specialists and copes with the fluctuating construction demand (Ng et al., 2003). Arditi and Chotibhongs (2005) advocate that the use of subcontracting has proved to be efficient and economical in the use of available resources. Subcontracting might improve quality and reduce project time and costs (Ng et al., 2003). Qualified subcontractors are usually able to perform their work specialty more quickly and at a lesser cost than can the general contractor (Arditi and Chotibhongs, 2005).

The reliance of general contractors on subcontractors to execute major portions of construction work makes the success of construction projects highly susceptible to the performance of the subcontracting organizations. As a result, researchers emphasize the

importance of selecting appropriate subcontractors (Kumaraswamy and Matthews, 2000; Ng et al., 2008 a&b; Arditi and Chotibhongs, 2005; Arslan et al., 2008; Tserng and Lin, 2002).

Despite this almost two-decade practice of subcontracting significant portions of construction work and the realization of the vital impact of subcontractors' work on overall project success, little research has been conducted to aid general contractors in their selection of subcontractors. Literature review reveals only few models that address this important decision-making issue that is exercised by general contractors multiple times on every single project.

Albino and Gravelli (1998) propose a neural network approach for subcontractor selection. Ko et al. (2007) critique the approach proposed by Albino and Gravelli (1998) because of the difficulties associated with identifying network topology and membership functions. Okoroh and Torrance (1999) develop a knowledge-based expert system using fuzzy logic. Lin and Chen (2004) argue that limitations of the fuzzy logic include the fact that the membership function of natural language expression depends on the managerial perspective of the decision-maker. Lin and Chen (2004) add that another limitation is that the computations of a fuzzy-weighted average is still complicated and not easily appreciated by managers.

Tserng and Lin (2002) propose an Accelerated Subcontracting and Procuring (ASAP) model that is based on eXtensible Markup Language (XML) and portfolio theory in financial management. ASAP helps general contractors to select subcontractors by deciding on an appropriate tradeoff between risk (i.e., cash flow) and profit for different combinations of subcontractors. However, ASAP is based on the assumption that all considered subcontractors are recognized as qualified subcontractors.

Luu and Sher (2006) develop a case based reasoning procurement advisory system for subcontractor selection. In this system, subcontractor selection cases are represented by a set of attributes elicited from experienced construction estimators. Ko et al. (2007) develop Subcontractor Performance Evaluation Model (SPEM) based on an Evolutionary Fuzzy Neural Inference Model (EFNIM). Ko et al. (2007) indicate that a limitation of their model is that both quality and accuracy of training data are crucial to its performance.

Arslan et al. (2008) propose a web-based subcontractor evaluation system called WEBSES. WEBSES determines a weighted average score for considered subcontractors based on 25 evaluation criteria, which are assumed of identical importance. Generally, it is well-accepted that weighted average scores have an inherent weakness due to the biases introduced in the development of the weights and the additive assumptions utilized in the computations of the weighted score average.

Existing models of subcontractor selection are useful in guiding contractors in their selection decisions. However, new methods are still needed as they offer new insights to both researchers and practitioners. Additionally, it is recommended that a general contractor utilizes multiple methods when exercising selection decisions.

This paper contributes a Data Envelopment Analysis (DEA) model to guide general contractors in their subcontractor selection decisions. The proposed DEA model is highly flexible. It can be easily tailored to reflect a general contractor's criteria for subcontractor selection. This flexibility includes number and type of factors considered in the analysis. More importantly, the proposed approach provides a framework for selection decisions at

large. The DEA model is well-suited to guide organizations that are exercising selection decisions.

DATA ENVELOPMENT ANALYSIS MODEL FOR SUBCONTRACTOR SELECTION

This section discusses selection criteria for subcontractors, DEA background, methodology, and mathematical form. The section concludes with an example to illustrate the proposed DEA model for subcontractor selection.

Identifying the selection criteria

In making selection decisions of subcontractors, construction researchers call for an evaluation that is based on a set of criteria. Several researchers have isolated factors that impact the selection decision. Examples on these factors include: number of years in business, highest value of relevant subcontracted work completed in the past, number of relevant projects completed, previous relationship with the contractor, financial capacity, completion of job within time, standard of workmanship, quality of materials used, delay in payment to labor, failure to adhere to subcontract provisions, safety record (incident rate), and non adherence to relevant environmental regulations (Ng and Luu, 2008; Ng et al., 2008a, 2008b; Arslan et al., 2008; Ko et al., 2007).

Table 1 shows variables that are considered in the proposed DEA model for subcontractor selection along with their method of measurement.

Table 1: *Variables that are considered in the DEA model for subcontractor selection*

Variable	Method of measurement	Input/Output
Number of relevant projects completed	Number of projects	O1
Highest value of relevant subcontracted work completed in the past	Dollar amount	O2
Financial capacity	Subjective scale of 1	O3
Completion of job within time	(lowest) to 10 (highest)	O4
Quality of workmanship		O5
Failure to adhere to subcontract provisions		I1
Delay in making payment to labor		I2
Non adherence to relevant environmental regulations		I3
Safety record	Incident rate	I4

Data envelopment analysis (DEA)

DEA was developed by Charnes et al. (1978, 1979, 1981). Nowadays, DEA is well-deployed in other industries with many papers published on its utilization for performance measurement and decision making. DEA deployment in construction is still limited. Examples on construction-DEA research include the work of El-Mashaleh (2003, 2010), El-

Mashaleh et al. (2001, 2005, 2007, 2010), McCabe et al. (2005), Pilateris and McCabe (2003), and Vinter et al. (2006), Cheng et al. (2007), Chiang et al. (2006), and Xue et al. (2008).

DEA is a non-parametric linear programming approach that is designed to compare and evaluate the relative efficiency of a number of Decision Making Units (DMUs) (Charnes et al., 1978). These DMUs can be organizations, business units, universities, etc. For the purposes of this research, DMU refers to a subcontractor.

Thamassoulis (2001) explains that DEA is non-parametric because it allows efficiency to be measured without any assumptions regarding the functional form of the production function or the weights for the different inputs and outputs. Charnes et al. (1978) realize the difficulty in seeking a common set of weights to determine relative efficiency. As a result, DEA allows each DMU to adopt a set of weights to determine its relative efficiency compared to other DMUs. Each DMU is allowed to adopt a set of weights, which shows it in the most favorable light in comparison to the other DMUs. Consequently, McCabe et al. (2005) argue that a DMU that is inefficient with even the most favorable weights cannot argue that the weights are unfair.

DEA is based on an input-output framework, where inputs are minimized and/or outputs are maximized. Cooper et al. (2000) provide the following data selection criteria for inputs and outputs:

- Numerical data are available for each input and output;
- The items (inputs, outputs and choice of DMUs) should reflect an analyst's or a manager's interest in the components that will enter into the relative efficiency evaluations of the DMUs; and
- The measurement units of the different inputs and outputs need not be congruent. Some may involve number of persons, or areas of floor space, money expended, etc.

Bearing in mind the above input/output selection criteria and the fact that inputs are minimized and outputs are maximized, we categorize the first five variables in Table 1 as outputs. To the contrary, the last four variables of Table 1 are classified as inputs.

DEA makes use of linear programming to determine which of the set of DMUs under study form an envelopment surface. This envelopment surface is called the efficient frontier. The efficient frontier is "made up" of efficient DMUs. Figure 1 shows an example of an efficient frontier for a simple one input-one output case with only 5 subcontractors under consideration. The slope of the line connecting each point to the origin corresponds to the output per input. The highest slope is for the line connecting the origin through Sub2. This line is called the efficient frontier. Note that the efficient frontier touches at least one point and all points are therefore on or below this line. The frontier "envelops" all the data points suggesting the name data envelopment analysis.

DEA provides a comprehensive analysis of relative efficiency by evaluating each DMU and measuring its performance relative to the efficient frontier. DMUs that lie below the efficient frontier are considered inefficient compared to the DMUs that "determine" that frontier. As such, Sub1, Sub3, Sub4, and Sub5 in Figure 1 are considered inefficient compared to Sub2.

 ISBN: 9789052693958

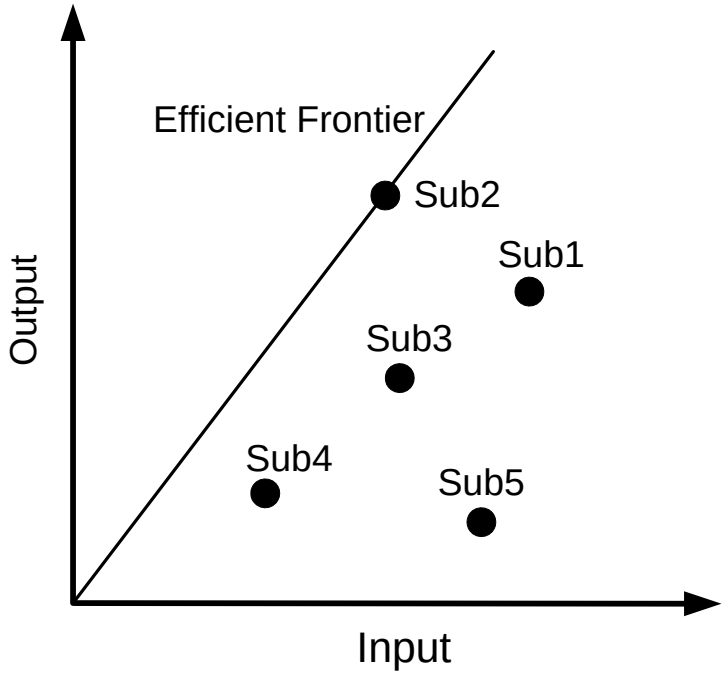

Figure 1: *Efficient frontier*

A limitation of DEA is the fact that its discriminatory power depends on the number of DMUs in comparison to the number of variables (inputs + outputs). A rule of thumb indicates that the minimum number of DMUs should be 3 times the number of variables (Charnes and Cooper, 1990). However, Ellis (2003), Wang (2002), and Cheng et al. (2007) relaxed this requirement by creating an "Ideal" DMU. An Ideal DMU has the lowest values of inputs and the highest values of outputs (Cheng et al., 2007).

The mathematical form of DEA

The mathematical form of DEA is shown below (Equations 1-4). For a detailed discussion, readers are referred to Thamassoulis (2001), Cooper et al. (2000), and Coelli et al. (1998).

Assume that we have n DMUs ($j=1,\ldots, n$) with m input items and s output items. Let the input and output data for DMU_j be ($x_{1j}, x_{2j}, \ldots, x_{mj}$) and ($y_{1j}, y_{2j}, \ldots, y_{sj}$) respectively. Note that we measure the efficiency of each DMU once. As a result, we need n optimizations, one for each DMU_j to be evaluated.

$$\max\ \theta_0 = \frac{\sum_{r=1}^{s} u_r y_{r0}}{\sum_{i=1}^{m} v_i x_{i0}} \qquad (1)$$

$$\text{subject to}\ \frac{\sum_{r=1}^{s} u_r y_{rj}}{\sum_{i=1}^{m} v_i x_{ij}} \leq 1 \qquad (2)$$

$i=1,..., m;\ \ j = 1,..., n;\ \ \ r=1,..., s$ (3)

$u_r , v_i \geq 0$ (4)

Where:
θ_0 = the measure of efficiency for DMU_0 (the DMU under evaluation), which is a member of the set $j = 1, ..., n$ DMUs.
u_r = the output weight, which is determined by the solution.
v_i = the input weight, which is determined by the solution.
y_{r0} = the known amount of the *rth* output of DMU_0.
x_{i0} = the known amount of the *ith* input of DMU_0.
y_{rj} = the known amount of the *rth* output of DMU_j.
x_{ij} = the known amount of the *ith* input of DMU_j.

The objective function is to maximize the efficiency of DMU_0 (the DMU under evaluation). This is done by maximizing the sum of DMU_0's outputs divided by the sum of its inputs (Equation 1). Equation 2 means that the efficiency of all DMUs is ≤1.0. This implies that all DMUs are either on the efficient frontier or below it, and that the efficiency scores range between 0 and 1.0.

Therefore, in DEA terminology, efficient DMUs are given an efficiency score of 1.0. Inefficient DMUs have an efficiency score that falls in the following range: 0≤ efficiency < 1.0.

Illustrative example

To illustrate the proposed DEA model for subcontractor selection, let's consider the data shown in Table 2. Ten subcontractors are considered for selection with 5 outputs (O1-O5) and 4 inputs (I1-I4). Outputs and inputs refer to the ones shown in Table 1. For the sake of demonstration, we limited the number of DMUs to 10 and the number of variables to 9. However, note that DEA can handle tens of variables and thousands of DMUs.

Table 2: *Example data*

Subcontractor	O1	O2 ($)	O3	O4	O5	I1	I2	I3	I4
Sub1	7	279,520	7	5	2	6	9	2	9.4
Sub2	4	267,615	4	2	5	5	8	9	8.3
Sub3	6	225,688	6	5	8	5	8	3	12.0
Sub4	4	199,461	4	6	9	6	7	8	11.1
Sub5	2	232,589	2	9	8	6	9	2	8.8
Sub6	3	287,398	3	2	4	5	2	1	7.4
Sub7	1	213,333	1	4	3	4	1	3	7.3
Sub8	2	241,576	2	6	7	6	7	8	7.6
Sub9	3	143,244	3	5	1	5	4	3	9.0
Sub10	4	215,815	4	6	7	5	2	1	8.2
Ideal Sub	7	287,398	10	10	10	1	1	1	7.3

Given the fact that we have 9 variables, this means that at least 27 DMUs are needed to keep the discriminatory power of DEA. Since we only have 10 DMUs, we need to create an Ideal Sub. As indicated earlier, an Ideal DMU has the most favorable outputs and inputs. Starting with O1, an examination of number of relevant projects that are completed by a subcontractor in Table 2 indicates that Sub 1 completed 7 projects. This is the largest number of projects across all subcontractors. Consequently, O1 for the Ideal Sub equals 7 as shown in Table 2. Similarly, when considering O2, we notice that Sub 6 executed the highest value of relevant subcontracted work for a sum of $287,398. As a result, O2 for Ideal Sub is set at the same dollar amount of Sub 6 as shown in Table 2. For the remaining outputs, the value for every output for the Ideal Sub is 10, since this is the most favorable value. For inputs (I1-I3), the contrary is true. The value of these inputs is 1, since this is the most favorable value. The last input (I4) is calculated based on a formula, where different countries utilize different formulas. OSHA recordable incidence rate which is utilized in the US construction industry is a good example for such formula. It is shown below for demonstration purposes.

Incidence rate = No. of incidents * 200,000 hours / No. of hours worked

It is common knowledge that lower incident rates reflect better safety performance. Table 2 shows that Sub 7 has the lowest incident rate with a value equals 7.3. Consequently, this value is used for the Ideal Sub as shown in Table 2.

The DEA solver software of Cooper et al. (2000) is used to run the DEA model. Table 3 ranks all considered subcontractors (Sub1-Sub10) and shows their efficiency scores. Note that subcontractors (Sub1-Sub10) are rated in comparison to Ideal Sub, which has an efficiency score of 1.0. The rest of subcontractors (Sub1-Sub10) have efficiency scores that are less than 1.0.

Since Sub1 has the highest efficiency score (0.78) among all considered subcontractors, we consider this subcontractor as our first choice in executing relevant construction work.

Table 3: *DEA results*

Rank	DMU	Efficiency Score
1	Ideal Sub	1.0
2	Sub1	0.78
3	Sub5	0.75
4	Sub10	0.70
5	Sub8	0.67
6	Sub4	0.59
7	Sub3	0.51
8	Sub2	0.50
9	Sub6	0.43
10	Sub9	0.41
11	Sub7	0.40

The above example demonstrates how the proposed DEA model is utilized to select one subcontractor out of 10 potential subcontractors. The proposed DEA approach combines 9 criteria to aid in the selection process. The model results in efficiency scores rating every subcontractor in relation to the efficient frontier. The subcontractor with the highest efficiency score is selected to execute the relevant construction work. Consequently and

based on DEA results, general contractors can exercise more informed decisions when considering subcontractors for executing construction work.

For demonstration purposes, the illustrative example is based on 10 subcontractors and 9 variables. However, note that DEA can handle tens of variables and thousands of DMUs.

CONCLUSIONS

Subcontractors' selection decisions are of prime importance to general contractors. These decisions are exercised by general contractors multiple times on every single project. This paper contributes a DEA model for subcontractors' selection. The proposed DEA model is highly flexible. It can be easily tailored to reflect any general contractor's criteria for subcontractor selection. This flexibility includes number of DMUs and number and type of factors that are considered in the analysis. More importantly, the proposed approach provides a framework for selection decisions at large. It is well-suited to guide organizations that are exercising selection decisions.

Abstract
Financial appraisal is an important aspect in adopting techniques that reduce the (fossil) energy use of buildings. When financial appraisal of an energy technique takes place, fixed prices for the form and amount of energy are often used and are multiplied by the estimated amount of energy savings. However, after a certain time period an energy bill for the user of a building only partially shows variable prices depending on the form and amount of energy. Many costs mentioned by a common energy bill are time related or are related to the national political regime. Infrastructural costs depend on the type of connection you have to the grid. These costs form an annual fee. The VAT or additional energy taxes that need to be paid, depends on the political regime and are often expressed in a surcharge in terms of percentage. This paper focus on the differences between marginal and average energy costs and the differences in variable and fixed energy costs. The impact price differences have for the financial appraisal of energy saving techniques for multiple actors is shown by conducting a comparative study on energy bills. It shows that marginal energy costs are significantly lower than average energy costs.

Keywords: investment appraisal, energy costs, consumer, energy bill

INTRODUCTION

Within the European Union (EU) the energy use by the built environment is more than 40% of the total energy consumption (European Council, 2002). Many measures exist and are being developed to reduce the energy use of residents and their houses. Nevertheless, during the last decades Dutch residents seem to be confronted with increasing electric energy use and increasing energy prices. In the time period 1985-2008 the average electricity use of a Dutch household increased by 25.8% (EnergieNed 2010a). According to Statistics Netherlands (2011) the energy prices for natural gas and electric energy more than doubled in the time period 2000-2009. The average natural gas consumption per household was reduced by 34% in 2008 compared to 1985 (EnergieNed 2010a).
Multiple scholars (e.g. Shin, 1985; Hutton et al, 1986; Wilhite & Ling, 1995; Edelstein & Kilian, 2009) paid attention to the relation between energy use and energy prices. On the one hand much research was conducted using the energy bills of households, offering valuable data regarding the annual energy use and energy costs for a household and house with specific characteristics. On the other hand, focusing on the development of energy measures to reduce fossil energy use another group of scholars and practitioners can be distinguished

that uses average energy prices to give insights in the financial savings of the introduced measure. Boonekamp (2007, p. 137) states that the financial *benefits are saved energy times mean price*. The reduction in energy costs by adopting new energy measures is often computed based on energy use and costs in the past as expressed by energy bills of the household where the energy measure is introduced.

In 2002 two Swedish studies focused on the preferences of customers regarding their electricity bills (Sernhed at al, 2003). The study of the Swedish Energy Agency showed that nearly 90% of the responding households wanted to be alerted, when their energy use suddenly increases. Approximately 75% indicated that they want to have a graphical presentation of the actual energy use compared to the energy use in the same month one year earlier. Around 65% wanted to have tips to reduce the energy use and just about 50% indicated that they wanted to have comparative statistical information from a comparable household.

Research of Wilhite & Ling (1995) in Norway already showed that better feedback on energy bills led to a more energy-conscious consumer. In the third year of their experiment the group of consumers receiving a more informative energy bill reduced their energy use by 10% compared to a control group receiving a traditional energy bill. The principle of providing information about the energy use and about energy saving via an energy bill is a form of indirect feedback (Darby, 2006). The immediate information from a meter or monitor showing the current energy flows in a building is considered to be direct feedback.

In order to know what the actual financial benefits of an energy measure are, one needs to know how energy costs can be influenced by residents and energy techniques. Therefore, we wonder 1) what developments there are regarding energy prices and 2) how the constitution of energy bills and the adoption of energy techniques by households are related. This paper presents a research on energy costs in energy bills for Dutch households. More than eighty energy bills were collected addressing the energy use and costs of seven households over multiple years.

The following section addresses the research methodology. Section three describes four categories of costs mentioned in the energy bills for consumers. Section four sets out the general developments regarding energy prices for the different cost categories. In section five the results of the empirical research among seven households are addressed, before closing the paper with a section six stating the conclusions.

RESEARCH METHODOLOGY

To learn about the composition of energy bills and the costs specified in energy bills, multiple energy bills were collected. The energy bills are related to seven cases of Dutch dwellings (see for specifications Tabel 1).

Table 1: Specifications of the case study objects (see for more details Entrop et al, 2010).

	House 1	House 2	House 3	House 4	House 5	House 6	House 7
Year of construction	1925	1939	1948	1964	1972	1982	1992
Building type	Detached	Row	Semi-det.	Row	Row	Row	Semi-det.
Habitants	5	5→2	2	2→1	2	2→4	2
Total floor surface (m^2)	170.95	102.74	145.04	148.74	174.98	100.45	124.17
Surface shell (m^2)	440.2	196.9	262.1	296.2	214.1	158.3	232.5
Energy Index	1.87	1.85	2.46	2.11	1.76	1.41	1.02
Energy Label	D	D	F	E	D	C	A

Due to differences regarding building characteristics and household characteristics these houses also have different energy usages regarding quantity and form. For example cases 6 and 7 do not use natural gas, because they are connected to district heating. Based on building characteristics House 7 can be regarded as the most energy efficient object and House 3 is the least efficient. This is expressed by an Energy Index and Energy Label as is being used all across Europe, since the introduction of the European Energy Performance of Buildings Directive (European Council, 2002).
The households provided more than eighty energy bills from the time period 1987-2010. The energy bills were dispatched by nine different companies, namely Cogas, Elektran (nowadays MainEnergy), Eneco, EnergieDirect, Essent, GreenChoice, MainEnergy, Nuon, and PNEM (nowadays Essent).

Some difficulties exist when you want to compare energy costs of different households:
The format of the energy bills differs per energy company. The sequence of the individual services will for example differ. Some companies directly add Value Added Tax to the costs for individual services mentioned in the energy bills. Other companies add up the Value Added Tax in the end to the total sum of costs. For this reason it is necessary to specify some universal cost categories, which will be the subject of the next section;
The form and amount of used energy differs per house. District heating, natural gas and electric energy are three forms of energy commonly used in the Netherlands, but each can be used for different purposes and in different amounts. When the financial benefits of energy measures are addressed, it is therefore important to reflect on the way the energy price per m^3, per kWh and/or per MJ was calculated and which variation can exist in regard to this energy price. An electric conversion rate of 3.6 MJ/kWh was used, so no compensation for the electricity production was incorporated. A conversion rate for natural gas of 35.17 MJ/m^3 was used, being the upper caloric value of natural gas in the Netherlands.
The time periods will differ per house and are seldom exactly one year. An additional difficulty in this matter is that electric energy use and natural gas consumption are disproportionate to the number of days, because of differences regarding ambient temperature, wind speed and the availability of natural daylight. When collecting the data, start dates and end dates of the time periods specified in the energy bills were listed. In this paper this specific issue is of little relevance. The time periods were assigned to calendar years by means of rounding off.

Attention will be paid to the composition of the costs, developments regarding price levels and to the level of flexibility to influence the energy costs being a household. The last aspect will be important in financially analysing energy measures that reduce the energy use or make the energy use more sustainable in terms of the use of renewable sources.

COST CATEGORIES ON ENERGY BILLS

The basic raison d'etre of an energy bill for an energy company is to receive payments for the delivered product being a certain amount of fossil fuels, thermal energy and/or electric energy. From the point of view of the customer an energy bill needs to specify the delivered product or products, the costs per product (including and excluding VAT) and details of how the payment needs to take place. The basic principle underlying an energy bill does not differ from a bill for clothing or groceries. However, big differences are 1) clothing and groceries are tangible and energy is not and 2) clothing and groceries are directly paid for. The costs of energy use are often billed once a year, after doing eleven monthly payments in advance.
The studied energy bills show many different subjects where the consumer is billed for. In the past it was common to incorporate the costs of cable television and radio. Besides these not to energy related costs, one of the energy bills still mentions up to 23 different costs that are related to the household's energy use.

Analysing the Dutch energy bills, the different energy costs can be divided in four main categories:

1. Product costs: costs for consuming fossil fuels or using electric energy;
2. Transport costs: costs related to the transport and infrastructure enabling the provision of fossil fuels and electric energy at a certain address or connection;
3. Measurement costs: costs involved in measuring the amounts of delivered fossil fuels and electric energy at a certain address or connection;
4. Taxes: additional costs due to legislation, strongly depending of the political regime.

Comparing the Dutch energy bills with some Australian, Swiss and German energy bills of eight different companies, it shows that in these countries the measurement costs are not addressed by the energy bills. In general it can found that the number of different costs in these foreign energy bills is smaller.

Product costs

Natural gas is the most common used fossil fuel in the Netherlands to heat living space and heat tap water. In many dwellings natural gas is also used for cooking. Nevertheless, electrified ways of cooking became more popular in the last decade due to the introduction of multiple new systems using induction and ceramics.
A Dutch user of electric energy can choose to be priced based on a single tariff or a double tariff. During night time the electricity prices are low and during day time high. Depending on consumer behaviour and specific energy prices, a single or double tariff can be financially preferred. Besides these variable costs, fixed annual costs for delivering the electric energy are charged.
Four percent of the approximately seven million dwellings is heated making use of district heating (EnergieNed, 2010a). In this case study houses number 6 and 7 are connected to district heating, representing this category of dwellings. The price of heat is every half year calculated on the basis of a comparison between a house connected to the gas grid and a house connect to district heating. An averaged electric energy use and an averaged natural

gas use and their accompanying prices are compared to the situation of a dwelling connected to district heating. By using this method the energy companies and the government try to guarantee that in both situations the owner needs to pay the same price for fulfilling his or hers energy needs. The three main subcategories of product costs are described in Table 2.

Table 2: Different subcategories of product costs involving energy.

Cat	Variable	Description
Product	Price of producing and providing natural gas	Natural gas is provided for a price per cubic meter €/m^3 and a relatively small annual fee €/year. In the Netherlands the price of natural gas is related to the international oil price. Besides these variable costs, some fixed annual costs for delivering the natural gas are charged €/year.
	Price of producing and providing electric energy	Electric energy is provided for a price per kilowatt hour €/kWh and a relatively small annual fee €/year. In general electric energy is being produced by making use of natural gas, coal and biomass. A single or double tariff system can be applied. The latter results in a relatively high tariff during daytime and a low tariff during night time
	Price of producing and providing heat	Thermal energy for households is provided for a price per gigajoule €/GJ based on the Not More Than Different principle, stating that district heating should not be more expensive to consumers than using natural gas directly for heating purposes.

Transport costs

The Netherlands, with a surface less than 34.000 km^2, have a dense natural gas network with a total length of almost 139.000 km to provide 6.981.100 connections in buildings natural gas. The electricity network encompasses 259.241 km and 7.872.000 connections. The multiple small and large scale district heating networks have a combined length of approximately 4.711 km (EnergieNed, 2010a). The costs for the infrastructure are billed on the energy bills as described in Table 3.

Table 3: Different subcategories of costs involving the transport of energy forms.

Cat	Variable	Description
Transport	Price of transporting natural gas	Infrastructural firms maintain and improve the gas grid. A price per cubic meter of natural gas €/m^3 and/or an annual contribution per connection €/year needs to be paid by the consumer to the network company.
	Price of transporting electric energy	Infrastructural firms maintain and improve the electricity grid. A price per kilowatt hour of electric energy €/kWh and/or an annual contribution per connection €/year needs to be paid by the consumer to the network company.
	Price of transporting heat	Based on the principle that owners of a house connected to a gas grid pay the same connection costs as a house connected to district heating, house owners will pay an annual contribution for their connection to the provider of district heating €/year.

Measurement costs

In all buildings with a connection to the natural gas network and to the electricity grid meters are installed to measure the amount of energy used. These meters are owned by companies applied to measuring natural gas and electric energy flows. Compared to the other costs the measurement costs are in a standard household relatively low. In the case of district heating

the costs for measuring the energy use are incorporated in the delivery and transport tariffs (see Table 4).

Table 4: Different subcategories of costs involving the measurement of energy use.

Cat	Variable	Description
Measurement	Natural gas meter	An annual rent needs to be paid by the consumer for using a natural gas meter €/year. Maintenance costs and costs for reading the meter to check the actual energy use of households are included in the tariff.
	Electricity meter	An annual rent needs to be paid by the consumer for using an electricity meter with one or two counters for a low tariff and high tariff pricing system €/year. Maintenance costs and costs for reading the meter to check the actual energy use of households are included in the tariff.

Costs due to taxation

In the time period 1987-2010 multiple forms of energy taxes were introduced and one has already been abandoned. Energy companies function as an intermediate in collecting these taxes. At this moment the Regulating Energy Taxes (RET; Regulerende Energiebelasting) and Value Added Tax (VAT; Belasting Toegevoegde Waarde) form the fourth category of energy costs (see Table 5).

Table 5: Different subcategories of costs involving taxation of energy use.

Cat	Variable	Description
Taxes	Regulating Energy Taxes (RET)	In 2010 a standard household pays € 0.1114 per kWh of electric energy (excluding VAT) and € 0.1629 per m³ of natural gas (excluding VAT) to the government.
	Tax Credit Regulating Energy Taxes (RET)	An annual tax credit applies for the use of electric energy of € 318.62 (excluding VAT) per household per year.
	Value-added tax (VAT)	The value-added tax accounts for all (energy) products and the regulating energy taxation. In the Netherlands the VAT rate is 19 %.

GENERAL DEVELOPMENTS ENERGY COSTS

The average electricity use of a Dutch household was 2829 kWh/year in 1985 and 3558 kWh/year in 2008 (EnergieNed, 2010a). According to Statistics Netherlands (2011) the electricity prices increased from 0.278 €/m^3 for natural gas and 0.125 +/- 0.005 €/kWh for electric energy in 2000 to 0.591 €/m^3 and 0.282 +/- 0.019 €/kWh respectively in 2009. The average natural gas consumption per household was reduced from 2475 m^3/year in 1985 to 1625 m^3/year in 2008 (EnergieNed, 2010a).

The early energy bills in our collection show that consumers were billed for delivery costs only. Variable delivery costs per cubic meter and per kilowatt hour and relatively small fixed charges were billed for natural gas and electric energy. In later years 2000-2005 it can be seen, depending on the specific energy company, that variable and fixed costs for the transport of natural gas and electric energy use were charged for using the grids.

The variable costs for transport came to an end by the first of January 2009, when a fixed annual fee was set based on the capacity of the individual connection. Depending on the specific network provider the fixed costs for a connection to the natural gas grid were in 2010 approximately € 100,- to € 110,- per year for a basic connection up to 10 m^3/h. In the same

year the fixed costs to be connected to the electric energy grid were approximately € 160 to € 180,- per year for a basic connection of 3x25 A or 1x40 A.
The energy bills indicate that measurement costs needed to be paid as a rent for the energy meters starting in the time period 2002-2005. These fixed prices gradually increased to approximately € 16,- to € 20,- per year for a gas meter. The fixed prices for electric energy meters move around € 25,- per year. These costs also include labour costs, when the meters need to be replaced or when the meters need to be read.

Table 6: Energy taxation in the time period 1987-2010 (a.o. CBS, 2010)

Year	Regulating Energy Taxes Gas €/m^3	Regulating Energy Taxes Electricity €/kWh	Environmental Quality Electricity Production €	Discount Taxes €	Value Added Tax %
1987-1988	-	-	-	-	20.0
1989-1991	-	-	-	-	18.5
1992-1995	-	-	-	-	17.5
1996	0.01452	0.01340	-	22.34	17.5
1997	0.02902	0.01340	-	33.94	17.5
1998	0.04325	0.01340	-	45.32	17.5
1999	0.07251	0.02220	-	75.77	17.5
2000	0.09448	0.03720	-	105.34	17.5
2001	0.12025	0.05830	-	141.58	19.0
2002	0.12400	0.06010	-	142.00	19.0
2003 January	0.12850	0.06390	-	142.00	19.0
2003 July	0.12850	0.06390	34.00	176.00	19.0
2004	0.14290	0.06540	39.00	181.00	19.0
2005	0.14940	0.06990	52.00	194.00	19.0
2006	0.15070	0.07050	52.00	197.00	19.0
2007	0.15310	0.07160	-	199.00	19.0
2008 January	0.15540	0.07270	-	199.00	19.0
2008 July	0.15540	0.07520	-	199.00	19.0
2009	0.15800	0.10850	-	318.62	19.0
2010	0.16290	0.11140	-	318.62	19.0

Taxes are strongly related to the political regime. In the time period 1987-2010 households needed to pay the common Value Added Taxes of a percentage of 17.5 % up to 20 % (see Table 6). In 1996 the Regulating Energy Taxes were introduced, nowadays often referred to as Energy Taxes. These taxes need to be paid per kWh of electric energy and per m^3 of natural gas and was increased up to € 0.1114 per kWh and € 0.1580 per m^3 in 2010. In that same year an annual discount was given of € 318.62 on the electric energy taxes. In the first time period 1996-2000 the discount was given as a deduction on the energy use in the form of 800 kWh of electric energy and 800 m^2 of natural gas.
In the time period 2003-2006 additional taxes were introduced to finance subsidies to reduce the emissions of the Dutch electric energy production. This so called Environmental Quaility Electricity Production (EQEP; Milieukwaliteit Elektriciteitsproductie) was directly settled in the general energy discount. Nevertheless, in this time period the RET still were increased, without compromising the discount tariff.

SPECIFIC DEVELOPMENTS ENERGY COSTS OF SEVEN HOUSES

Having described the national developments regarding energy costs, this section will describe the developments in energy costs more specifically for the dwellings in the case study and per cost category.

Product costs

A standard Dutch household with a connection to the gas grid and the electricity network is free in choosing one of the many energy companies to deliver natural gas and electric energy. One is free in choosing for a sustainable or so called “green” form of energy, in choosing for a certain quality level of services and in choosing (maybe most importantly) the price of the natural gas and electric energy. In other words one can freely choose for a certain product (natural gas and electric energy) with variable and fixed costs in the category “A. Delivery” as long as one is connected to the natural gas network and the power grid.
A household occupying a house connected to district heating is bound to the company that provides the heat and maintains the local heat infrastructure. The households occupying Houses 6 and 7 are not able to choose another company (in this case Essent Local Energy Solutions BV) that can provide heat in the form of heated water. These two households can only chose their electric energy providers. Nevertheless, when a household purchases electric energy without purchasing natural gas the fixed annual costs are often relatively high, because discounts often apply when natural gas and electric energy are purchased at the same energy company. With 48 to 54% in the last three years the delivery costs form the biggest part of the energy costs for the dwellings studied.

Transport costs

Based on its location, a house is connected to a certain part of the national gas grid and electricity network. The household receives a separate bill of the regional network provider or the costs are incorporated in the energy bill of the energy company delivering and providing the natural gas and electric energy related to section “A. Delivery”. There is no possibility for a household to switch to another company, when it comes to the transport of these energy forms, besides moving to another location outside the region of the former network provider. Therefore, transport costs can not be influenced by households through the adoption of more or improved energy techniques.
In the past a major part of the transport costs were related to the amount of natural gas consumed and electric energy used. Transport costs for the houses using natural gas in the case study were around 12 to 18% of the total energy costs. Since fixed annual prices are used, these percentages are for households with an average or high energy use decreasing. Houses 6 and 7 always pay annual fees. Based on the energy use they have higher transport costs than houses connected to the gas grid.

Measurement costs

The company responsible for providing measurement equipment and services was originally related to the regional network provider. Nowadays, the possibility exists for consumers to freely choose a certified company offering these energy measurement services. Nevertheless, not many consumers are aware of this possibility and little financial benefits can be expected in switching to another company. The measurement costs are relatively little, namely just around 2 to 3 % of the total energy costs.

Taxes
Again little influence can be exerted by households or consumers to reduce this particular category of costs. The taxes are partially variable in the way that per kWh electric energy and per m^3 of natural gas a certain fee needs to be paid. In the past a fixed amount of taxes needed to be paid to improve the environmental quality of energy products and a compensating fixed tax credit was offered. The discount for 2010 is high enough to reduce the energy taxes on ± 1000 m^3 of natural gas and ± 1400 kWh of electric energy. On top of the costs in all four categories A to D Value Added Tax (VAT) needs to be paid. A household that is able to bring back its energy use to below ± 1000 m^3 of natural gas and ± 1400 kWh of electric energy, will have a discount that even reduces the VAT. Nevertheless, in Houses 1 to 5 taxes over 2009 and 2010 are 34 to 36% of the total energy costs. Houses 6 and 7 are connected to a local heat network, which means that some taxes are incorporated in the heat delivery costs.

CONCLUSIONS

The energy bills of the eight houses in the case study show that many costs involving energy use are set and need to be paid annually. When the three categories variable costs, fixed (annual) costs, and taxes are used, it can be noticed that in 2008 on average the variable costs were 57.2% of the total costs. In 2010 this value was only 42.7%. The fixed costs increased from 14.2% to 18.5%. This means that in 2010 households had fewer possibilities to influence the energy costs by adopting new energy saving techniques than in 2008.
To make the difference between marginal costs and average costs more vivid, an example will be given considering the energy use of a standard Dutch dwelling. In this situation the most appropriate figures seem to be the figures that are being used in calculating the energy prices for district heating. In this way Houses 7 and 8 from the case study can also be regarded. EnergieNed (2010b) uses the following energy usages 1372 m^3, 4116 kWh and 34.99 GJ for the year 2010. The prices are taken from the Essent energy bills of Houses 4 and 8 (price level end 2009). The total energy costs are calculated as follows:

$$P_{energy;total} = (1 + \%_{vat}) \cdot (P_{energy;delivery} + P_{energy;transport} + P_{energy;measurement} + P_{energy;taxes})$$

Table 7: Differences between average and marginal energy prices in the Netherlands

	Electric energy /kWh	Electric energy /MJ	Natural gas /m^3	Natural gas /MJ	Heat /GJ	Heat /MJ
Average costs including taxes	€ 0.1948	€ 0.0541	€ 0.6339	€ 0.0180	€ 27.89	€ 0.0279
Marginal costs including taxes	€ 0.2273	€ 0.0631	€ 0.5105	€ 0.0145	€ 20.02	€ 0.0200
Relative price difference	+16.7 %	+16.7 %	-19.5 %	-19.5 %	-28.2 %	-28.2 %
Average costs excluding taxes	€ 0.1297	€ 0.0360	€ 0.3715	€ 0.0106	€ 17.21	€ 0.0172
Marginal costs excluding taxes	€ 0.0796	€ 0.0221	€ 0.2678	€ 0.0063	€ 10.59	€ 0.0106
Relative price difference	-38.6 %	-38.6 %	-27.9 %	-27.9 %	-38.5 %	-38.5 %

Using this equation the electric energy price is calculated as € 802.- per year. The natural gas price is € 869.72 per year and the price for thermal energy within an area using district heating is € 975.97 per year. Taxes have a strong impact on the energy costs, as can be seen

in Table 7. Furthermore, these calculations show that average and marginal prices strongly differ. Also the prices per energy form can strongly differ.
This leeds us to the conclusion that due to the increasing percentage of fixed annual costs over last years, the use of average energy prices can lead to financial analysis of energy techniques that are incorrect. The financial savings will in many cases be less than expected. Our expectation is that the use of marginal energy costs will lead to a more realistic result. In general all energy costs are rising every year. However, due to the adoption of multiple energy techniques by the different households the variable energy costs can partially compensate the rising fixed or annual costs. Finally, taking into account the adoption of energy techniques, standard price inflation and increasing incomes, the total energy costs are probably increasing less significant than statistical data tries to imply.
Nevertheless, from a financial point of view of the households we expect that the adoption of energy measures can be stimulated by changing the energy bills in two ways. The first way is to improve readability of the energy bills by decreasing the number of cost components. The Australian energy bills, we shortly addressed, with only one sort of variable energy costs and one sort of annual energy costs (before adding tax) shows how energy bills for households can be simplified. The second way is to increase the influence of variable costs per unit of energy, simultaneously decreasing the influence of fixed (annual) costs, which will increase the financial effects of energy saving techniques that are able to reduce the amount of energy used.

ACKNOWLEDGEMENTS

The authors would like to thank the owners of the houses involved in this case study for providing their energy bills. Agentschap.NL is acknowledged for providing financial support of the present research (EOS LT02003).

THE ENERGY PERFORMANCE OF OFFICE BUILDINGS THROUGHOUT THEIR BUILDING PROCESS

A.G. ENTROP Ir.[1]
G.P.M.R. DEWULF Prof. Dr.[1]

[1] Department of Construction Management & Engineering, University of Twente, PO Box 217, 7500AE Enschede, the Netherlands, a.g.entrop@utwente.nl, g.p.m.r.dewulf@utwente.nl

Abstract
Many innovative techniques and policy measures have been introduced to reduce energy consumption. Despite the high ambitions and societal pressures, the adoption rate of energy measures in office buildings is still low. Using adoption theories this paper provides a framework to analyse the adoption process of energy saving techniques in building processes. This framework is used to analyse the design and building processes of four Dutch office buildings. In these processes the roles of the stakeholders, in relation to the adoption of energy measures, are identified during every phase of the building projects. It enables us to better understand by which means certain stakeholders can exert influence on adopting or rejecting certain energy concepts and measures. The complex network of temporary relationships among stakeholders makes it hard to turn high ambitions into a broad adoption of multiple energy techniques, which can lower the energy use or which make use of renewable sources.

Keywords: stakeholder, decision making, energy measures, office

INTRODUCTION

The energy consumption in the built environment accounts for more than forty per cent of the total energy consumption in Europe (EC, 2002). Improving the energy performance of the built environment has an important impact on the reduction of carbon dioxide emissions and sustainability in general. Many innovative techniques have been introduced to lower the energy consumption or to use renewable energy sources, but the adoption of techniques is hampered by multiple barriers.
Innovative sustainable techniques differ in terms of complexity and costs. In some cases new techniques can directly replace the conventional product, in other cases large adjustments in a building have to be made. Energy saving techniques can reduce life-cycle costs, but often lead to higher investment costs. Although many measures are widely accepted in society and high ambitions regarding the energy performance of forthcoming buildings are often expressed during the initial phase of a building project, these ambitions are not always realised in practice. We expect that this can be related to the influence of specific stakeholders in the design and construction process of buildings. Policy measures focusing on the environmental impact (or more specific energy use) of buildings might not have the expected impact, if there is a lack of social acceptation of those measures (see e.g. Raven 2006). Therefore sustainable energy measures will not be successfully implemented as long as we do not have a clear understanding of the behavior of the main stakeholders in the construction process, e.g. architects, developers, builders, clients and end-users.
It is expected that the stakeholders involved in the building process are of influence on the adoption process (Cooke et al, 2007), whereby the ambitions stated by the clients before construction and the achieved energy performance after construction often do not correspond with each other, due to reduced budgets or the need for less investments costs during the

design process or architectural, constructional and installation failures during the construction process. In the whole building process some organisations or persons are only for a limited time path involved and all have different interests and targets. Therefore, many individual reasons to adopt or to reject energy techniques will exist.
Our objective is to make a contribution to the knowledge on decision making processes by developing a framework to analyse the influence of stakeholders on the adoption of energy saving techniques. Our framework is based on innovation adoption theories. We focused on the stakeholders who are involved in the adoption process of innovative techniques that lower the energy consumption or make use of renewable energy sources. The case studies are design and building processes of Dutch office buildings.

FRAMEWORK TO ANALYSE ADOPTION IN BUILDING PROCESSES

This section addresses the innovation adoption theory as presented by Rogers (2003). Afterwards innovation adoption processes will be placed in the context of the built environment. Finally, this section presents a framework to analyse building processes.

Adoption theory

Many studies have been published on adoption of innovations. Well-known is the work of Rogers that gives insights in which characteristics of energy saving techniques are relevant, how the adoption process can be phased, and which kind of adopters exist. His work is being used to come to a framework on the adoption process of energy saving techniques in the built environment.
Rogers (2003, pp. 12) states that: *an innovation is an idea, practice, or object that is perceived as new by an individual or other unit of adoption*. In this paper the *idea, practice, or object* are techniques that lower the energy consumption or techniques that make it possible to fulfil the need for energy in a renewable way. The *individual or other unit of adoption* in building projects are a variety of stakeholders. A stakeholder is in our case an individual or organisation with an interest or concern in a building project. Not all stakeholders can exert influence on the progress and outcomes of a building project. The group of stakeholders that can exert influence is further referred to in this paper as 'actors'.
Rogers (2003) defines five attributes that strongly influence the rate of adoption of innovations, namely relative advantage, compatibility, complexity, trialability and observability. This means for example that a high level of complexity will more likely result in a lower adoption of an innovative energy saving techniques than a low level of complexity.
In the process of adopting or rejecting an innovation five phases are distinguished, namely (ibid., pp. 171-189):

1. Knowledge: in this stage an individual (in our case actor) is exposed to an innovation's existence and gains an understanding of how it functions;
2. Persuasion: the individual forms a favourable or unfavourable attitude toward the innovation. The mentioned perceived attributes are important in this stage;
3. Decision: activities are undertaken that lead to a choice to adopt or reject an innovation;
4. Implementation: this occurs when an individual puts an innovation to use;
5. Confirmation: in this stage the individual seeks to avoid a state of dissonance or to reduce it if it occurs.

Adoption processes in the building context

Dieperink et al. (2004) and Hartmann et al. (2008) stress the importance of studying adoption in its context. The specific characteristics of the context have to be understood in order to

analyse the decision-making process of innovations. Dieperink et al. (2004) for instance expands Roger's model by linking the adoption process with macro developments, technical aspects, economic aspects and the company's context.
The integrative model of Dieperink et al. (2004) explaining the diffusion of innovations offers a detailed structure to align motivations and arguments of actors for adopting or rejecting energy saving techniques. Vermeulen et al. (2006) elaborates on the model of Dieperink et al. (2004) by specifying first and second level variables, which explain the adoption of energy innovations for new office buildings. They mention that the actor's characteristics and the networks in which the actor participates have impact on the decision making process and therefore on the adoption rate. This network forms the heart of our framework.
Research of Hartmann et al. (2008) focuses on the adoption of innovations by professional public clients, in which four conflicting factors were strongly affecting the innovation perception of this actor. They offer a model of the adoption process that links the public dimension and professional dimension of the client with the innovation perception. These scholars see *risk* as an important additional innovation attribute. Risk by uncertainties can be reduced among others by bringing actors together in an early stage, by referring to similar solutions, and by cooperative behaviour.
Based on these studies we distinguish four contextual dimensions, namely: the characteristics of the actors in their segment of the construction industry, the context of the project, the macro developments, and the state of technology. The state of technology is based on Dieperink's "technical aspects" and Hartmann's attribute "risk". By specifying which techniques are in which stage of the innovation life cycle, risks can partially be assessed. Energy measures that have proven themselves are considered to be less risky than non-proven measures.

Framework to analyse building projects
Building projects can be characterised as inter-organisational projects. In building projects, where organisational connections exist adjacent to inter-organisational connections, decisions are taken in a complex context. In every phase of the building process actors and stakeholders join or leave. Different phases of building processes can be profoundly explained by using the process protocol of the University of Salford as specified in Table 1.

Table 1: *Phases in the design and construction process (Kagioglou, et al., 1998).*

Group	**Phases**
Pre-project phases	0. Demonstrating the need
	I. Conception of need
	II. Outline feasibility
	III. Substantive feasibility study & outline financial authority
Pre-construction phases	IV. Outline conceptual design
	V. Full conceptual design
	VI. Production design procurement & full financial authority
Construction phases	VII. Production information
	VIII. Construction
Post completion phase	IX. Operation & maintenance

This arrangement shows some similarities compared to the innovation decision process of Rogers. The awareness of a certain necessity and generating an attitude are prevailing in the first phases (phase 1 and 2). In the final drawings and documents, before setting a price for construction, adoption or rejection decisions need to be taken (phase 3). The construction process needs to cope with the installation procedure for the specific energy techniques

(phase 4). In the end the user of the building will experience if the techniques perform and really can save energy (phase 5).
In the building process at least ten actors can be considered to have direct influence in the adoption or rejection of energy saving techniques (see Table 2). The actors are involved in different stages of the building process. The trajectory to come from an energy saving concept to specific energy saving techniques, the contextual factors influencing the process, and the roles of the actors are included in our framework, being the horizontal axis (see Figure 1). The five phases of Rogers are expected to be only partially in line with the phases of the general design and construction process. Individual actors are persuaded and are taking decisions on energy saving measures at different stages in the process. In other words, the overall diffusion process consists of various personal adoption cycli which vary per actor. The vertical axis expresses the level of influence a certain actor has on the adoption of the energy concept, energy measure(s) or energy technique(s).

Table 2: *Descriptions of the ten actors regarded in this research*

	Actor	Description
Granters	Client – Principal (Cl)	Actor requesting the constructive service of a professional person or organisation. In some cases a client can be a property developer.
	Customer- User (Cu)	Actor making use of the provided building
	Warden (W)	Actor responsible for the supervision of and maintenance on the building and its location
	Property developer (PD)	Actor that converts land to a new purpose, especially by constructing buildings
	Project manager (PM)	Actor that plans, organizes, and allocates resources to come to a successful completion of a specific project (as specified by the client)
	Municipality (Mu)	Town or district having a local government that enforces building regulations
Takers	Architect (A)	Actor who designs buildings and in most cases supervises their construction
	Consultant (Cs)	Actor that provides expert advice professionally
	Contractor (Co)	Actor that undertakes a contract to provide materials and/or labour for a construction project
	Subcontractor (Sc)	Actor that carries out work for a company as part of a larger project
	Manufacturer (Ma)	Firm that fabricates construction components and/or materials

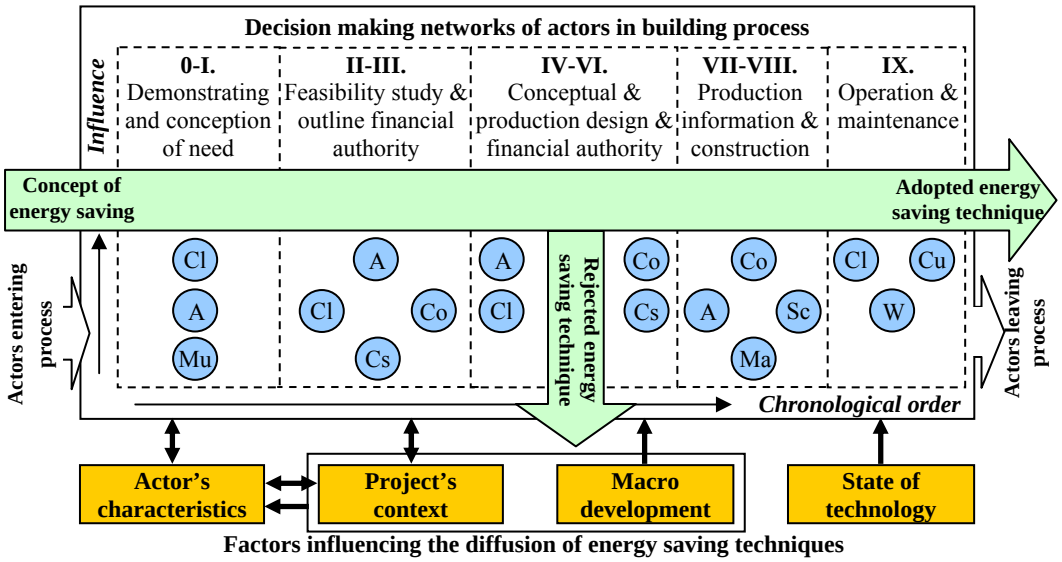

Figure 1*: Framework to analyse the adoption process in building processes.*

CONTEXT OF BUILDING OFFICES

In this section the framework will be operationalized in order to analyse social housing projects by specifying the context in more detail. There are multiple reasons to study the design and construction process of office buildings. Firstly, office buildings use relatively much energy compared to residential buildings. Especially the electric energy use can be significant higher. Secondly, among office buildings large differences exist in building design and in energy use (see Table 3). Thirdly, office buildings often have a relatively short economic and functional life time compared to residential buildings. Therefore, the rate of replacement is relatively high and new innovations or gained experiences can quickly be applied in new project reducing the energy use involved in operating and using this category of buildings. In this section we will further explain the context expressed by the four factors at the bottom of Figure 1.

Table 3: *Energy use of Dutch office buildings (SenterNovem, 2007).*

	Natural gas consumption ($m^3/(m^2 \cdot year)$)			Electric energy use ($kWh/(m^2 \cdot year)$)			N
	20 %	50 %	80 %	20 %	50 %	80 %	
Office buildings 200-500 m^2	6	21	37	35	109	182	44
Office buildings 500-10.000 m^2	6	13	20	32	85	138	37
Office buildings > 10.000 m^2	6	10	14	28	79	82	32
Office buildings insurance comp.	6	15	24	14	129	160	54

Macro development

The developments are clustered in political, juridical and economic events within the construction industry in the Netherlands during the time-period 1998-2010.

Political developments

National and regional governments often try to create conditions that support entrepreneurial activities in order to improve the employment rates in an area. Land plots to construct office buildings or industrial buildings is offered by municipalities for significant lower prices than plots for residential purposes. For companies that operate internationally the Netherlands tries to be as attractive as possible by offering good infrastructure, stable government, public security, well educated population and interesting financial conditions regarding taxes. The costs to run a company in the Netherlands need to be in line with the costs to run a company for example in Germany, Belgium or France in order to keep companies within borders.
Therefore regulations leading to increased investments costs for companies are not favoured. Regulation on the energy performance of office buildings and utility buildings are less ambitious than regulations for residential buildings. Recently, initiatives were undertaken to strongly influence political developments to come to a broad energy transition. By the name of “the Netherlands get new energy” (Anonymous, 2010) and “Energy provision of the Netherlands; today (and tomorrow?)” (Hellinga, 2010) multiple politicians and engineers try to address the urge to make the energy provision more sustainable.

Legal developments

In the time period 1998-2010 the national Building Code of 1992 and 2003 applied for new buildings. Regarding the energy use of office buildings are required: a minimum insulation value of 2.5 $(m^2 \cdot K)/W$, a minimum value for ventilation of 1.0 $dm^3/(s \cdot m^2)$, a maximum value for air infiltration of 0.2 dm^3/s per area with one and the same function and an Energy Performance Coefficient (EPC) of 1.1 at maximum. This EPC expresses a theoretical

construction and installation related energy performance of a building under certain standard conditions regarding usage, indoor temperature preferences and outdoor climate. The EPC is namely based on an equation that relates forecasted and permissible building related energy use, incorporating the installed systems for heat production, heat resistance of the building shell and the size of the house, etc. The EPC for office buildings was introduced in 1995, stating a value of 1.9 at maximum. By January 2000 this value was lowered to 1.6. In 2003 a value of 1.5 was issued and in 2008 the current value of 1.1 was introduced. Due to personal preferences, deviant outdoor conditions, and the adoption of non-building related appliances, the actual energy use of a building during usage can strongly differ from the forecasted or hypothetic building related EPC computed during the design phase.

Economic developments
Due to the economic crisis in recent years much office space came available in the last years and few new building projects were initiated. The total service costs of office space increased from $ 363,- /m^2 in January 2001 to $ 542,- /m^2 in May 2010. From November 2007 to November 2009 the costs per square meter were higher than in May 2010 (CBS, 2011). According to DTZ Zadelhoff (2011) the annual rent per square meter was € 146,- in 2009; 2.7 % less compared to 2008. In 2009 almost forty million square meter of office space was in use in the Netherlands to accommodate almost 2.3 million so called office jobs. These two values were 1 and 1.4 % respectively lower compared to 2008. A staggering 13.3 % of the total office space was not in use (DTZ, 2011). Besides these relative bad economic conditions, energy prices are increasing.

State of technology
Technical developments are highly important in the field of energy saving techniques and the authors would like to address that for every building project the current state of available energy techniques, which can be regarded by the actors involved. However, actors might attempt to rely on traditional techniques that are known to them by means of former projects. Last decade many new technologies were introduced to save energy. At this moment the high efficiency natural gas boiler, insulation packages with a heat resistance of 2.5 $m^2 \cdot K/W$ and energy saving lighting with presence detectors are common in Dutch offices.
The adoption rates of solar collectors, photovoltaic panels, and heat pumps are still rather low, although the techniques are already available for many years. The expectation is that these adoption rates will improve with the current EPC value of 1.1 or lower. New techniques recently introduced in the construction industry are Phase Change Materials and LED-lighting for example. In the nearby future the availability of techniques is likely to increase, because of growing environmental awareness and higher energy prices. Techniques that are already available will be improved and will probably become cheaper.

Project's context
The context in which offices are designed and constructed, can not easily be described in general terms. Projects with the goal to construct or renovate an office building will bring multiple actors and stakeholders together in different relations. Seldom two projects will bring together the same parties in comparable circumstances and relations. This will also become clear in the following sections.
For offices multiple environmental and energy assessment tools became available worldwide. In the Netherlands GPR Gebouw and GreenCalc$^+$ are for example available to characterize the environmental impact of office buildings. In the European Union the energy performance of new and existing buildings, including offices, can (and in the nearby future needs to) be expressed by a label. The use of assessments and performance indicators can help in

communication among the actors and stakeholders. The indicators enable them to directly have a glimpse of the energy performance. In combination with rising energy prices and banks providing financial stimuli for green or energy efficient buildings the aspect of energy receives increasing attention.

Actor's characteristics

Like already stated, multiple actors and stakeholders are brought together, when office buildings need to be constructed or renovated. Different to designing and constructing houses in private ownership, the design and construction process of offices often show different parties regarding the role of financial investor, project developer, principal, user of the building and warden in regards of maintaining the constructed office. Furthermore, multiple organizations are linked these projects to give advice about for example cost management, constructional issues and the mechanical and technical systems. These different organizations all have their own commercial drive to join the project. An office can be constructed from the point of view that it will be rent or that it will be bought by a party that is joining the construction or not. In the last case the object needs to be developed without having one specific user or customer in mind.

RESULTS OF THE CASE STUDY RESEARCH

The cases consider the actors involved in the design, construction and usage of four new office buildings in the Netherlands. Table 4 shows the basic specifications of the studied office buildings. These office buildings were chosen based on their energy performance that goes beyond regulation, the fact that the building processes were finished, enabling us to make an inventory of applied techniques, and the fact that the building processes took place rather recently. Data was collected regarding the different roles of the stakeholders by conducting 22 interviews in total.

Table 4: *Basic specifications of the four case objects being Dutch office building.*

	Case 1	**Case 2**	**Case 3**	**Case 4**
Name office building	Communal Waterworks Amsterdam	De IJsseltoren	QX & QY	De Eempolis

Energy performance	Q/Q = 0.680 EPC ≈ 1.09	Q/Q = 0.807 EPC ≈ 1.21	EPC_{QX} = 1.44 EPC_{QY} = 1.40	Q/Q = 0.829 EPC ≈ 1.32
Applied energy techniques	$R_{cons,}$= 3.0 m^2K/W U_{glass} = 1.2 W/m^2K Improved air tightness Heat pumps CHS Heat exchanger Enclosed outdoor area Open thermal ceilings T5 lighting	$R_{cons,}$= 3.0 m^2K/W U_{glass} = 1.2 W/m^2K Improved air tightness Heat pump CHS Heat wheel Occupancy sensors	$R_{cons,}$= 1.6-3.0 m^2K/W U_{glass} = 1.2 W/m^2K Improved air tightness Heat pump CHS Heat exchanger Occupancy sensors Ventilated armatures Shading	R_{cons}= 2.0-3.5 m^2K/W U_{glass} = 1.2 W/m^2K Improved air tightness Heat pump Twin coil Ventilated armatures Shading

Case 1: Communal Waterworks Amsterdam (CWA)

The central office of Waternet is located at the west side of Amsterdam. Waternet is the new name for what was before known as Gemeente Waterleidingen Amsterdam (Communal Waterworks Amsterdam; CWA), which was the formal principal and the first user of the

building. The architecture and project leadership were in hands of Van Tilburg & Partners. Seven interviews among the actors in this building process gave insights in the adoption process of the ambitious EPC and the specific energy techniques.
The building has a gross floor area of 10.855 m^2. The construction activities started in 2001 and finished in 2003. The energy performance is stated as an Q/Q of 0.68, which means the EPC is 32% below the by law requested value. This energy performance was achieved by working with the principle of the Trias Energetica. Firstly, the energy demand of the building was reduced by applying among others a highly insulated shell of 3.0 m^2·K/W. Secondly, it was possible for the remaining energy demand to make use of a thermal storage system. Two electric heat pumps provide thermal energy to cool or to heat the building. These heat pumps use green electric energy. Therefore, it seems no carbon dioxide emissions occur by maintaining a comfortable indoor climate in this building.
The owner of the office building was the municipality Amsterdam (expressed as Client (Cl)), that was willing to support the CWA director (expressed as Customer (CU)) in setting an example in sustainability. The ambition was to design an object with a 25% improved energy performance. The technical consultants (DGMR and Techniplan) were asked by the customer and later by the client and architect to specify measures which would reduce the energy consumption.
In principal every measure having a payback period of less than fifteen years was within this project acceptable. The relative advantage of specific energy measures was assessed based on energy analyses, employee's interest, and environmental impact. Photovoltaic panels were mentioned as a technique by the actors that did not fit in the necessary payback period. A green roof was suggested by the architect. Due to limited budgets only that part of the roof that is visible to employees and guests has been covered by sedum instead of the whole roof. Observability was an important issue for still partially applying this specific measure.

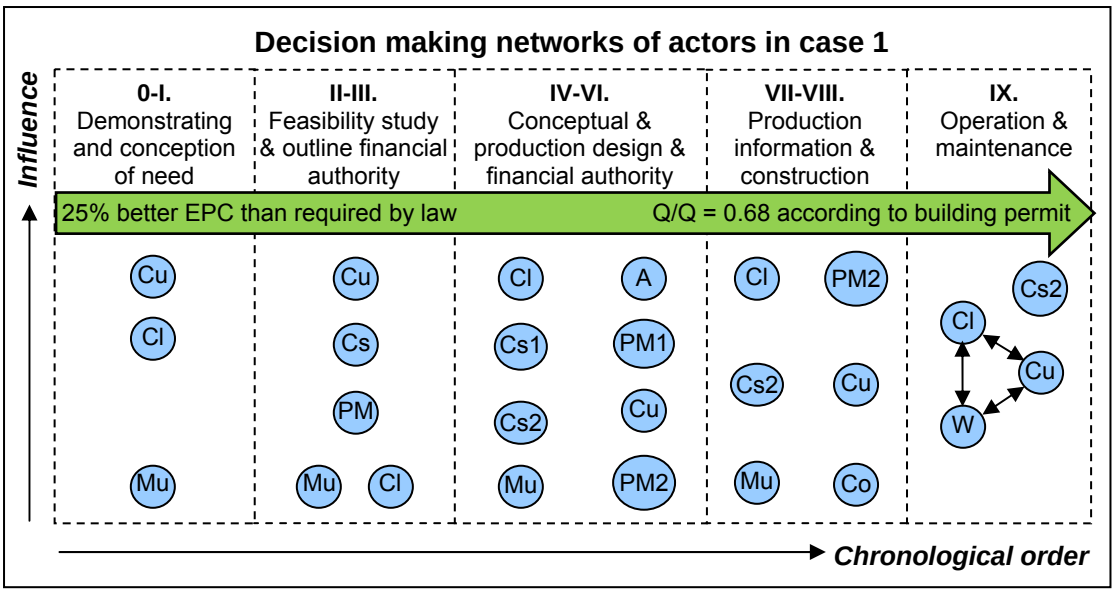

***Figure 2**: Stakeholders involved in the design and construction process of Case 1.*

Case 2: De IJsseltoren
In 2004 the building activities started to come to "De IJsseltoren" complex in Zwolle. The complex consists of three constructions and was designed by René Steevensz of PPKS Architects. The development was initiated by MAB Development. The gross floor area of approximately 34,000 m^2 is largely being used by ABN AMRO. The tower, consisting of nineteen floors, reaches up to almost 96 meters. Directly to the east the two lower buildings

of four and six floors are placed on columns. Because of agreements with the national government, which were already initiated in 1996, ABN AMRO committed itself to use timber produced in a sustainable by means of the Forest Stewardship Council (FSC) trademark and to reduce energy consumption.
The buildings encompass for example a proper insulation package, daylight responsive lighting, presence detection for lighting, timed lighting sweep, and automated shut down options for computers. In this case also a thermal storage system and a heat recovery system for air ventilation have been applied. The additional investments to make the building more environmental friendly and to give it a better energy performance were made financially available by ABN AMRO region Zwolle (customer (CU). Bouwfonds computed what the basic costs would be and which additional costs could be expected (project developer (Pd)). The basic costs were paid for by ABN AMRO (client (Cl)). The energy investments needed to have a payback time of seven years or less. In this case the financial relative advantage due to reduced energy costs prevails when comparing multiple techniques. Although a commitment exists to reduce energy use, the compliance with it seems only to be based on the mentioned payback time of seven years or less. In an early stage the idea of a wind mill was abandoned due to foreseen technical complications. Therefore this technique seems to have failed in the means of compatibility in a architectural and juridical context.

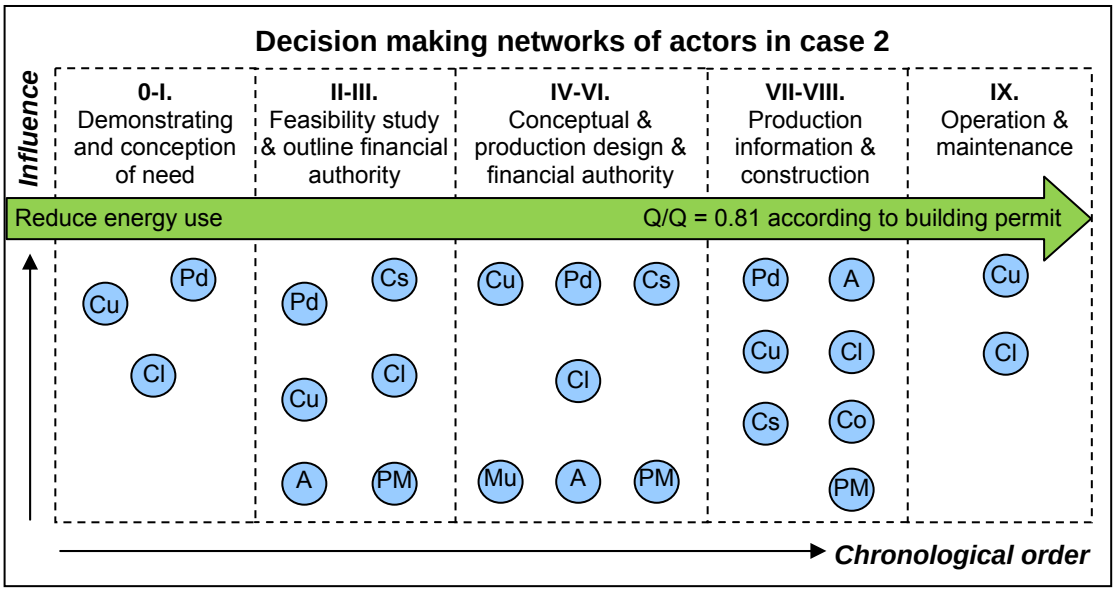

***Figure 3**: Stakeholders involved in the design and construction process of Case 2.*

Case 3: QX and QY

In Best two office buildings named "QX" and "QY" offer a combined gross floor space of 14,700 m^2. These offices form the entrance of the Philips Healthcare facilities on that location. Philips Healthcare was also the principal in this project. The architectural firm 01-10 Architecten is responsible for the design. The buildings have three floors and an additional top layer to encompass the installations. EPCs of 1.40 and 1.44 were achieved by applying a well insulated shell with a heat resistance of 3 $m^2 \cdot K/W$. The thermal storage system and a heat recovery system both had a major impact in achieving the good energy performance.
Together with some major industries, Philips has voluntarily committed itself to a governmental agreement to reduce energy use by applying all energy investments with a return on investment period of five years or less. This means that the relative advantage, in the form of cost reductions in energy use, was assessed for different energy techniques. Philips pays for the building (Client (Cl)). During the design and construction process Philips

Healthcare (customer and project developer (Cu)) was allowed to take their own decisions. In this case the insulation, thermal storage system, lightning system and heat resistant glazing were regarded. Observability and trailability were additional attributes in this case. Because Philips is famous for its lighting systems, energy saving lighting systems are by means of observability, more or less, must-haves. The thermal storage system was considered to be a proven system. Although the return on investment period was calculated to be longer than fire years (namely seven years), this techniques was applied.

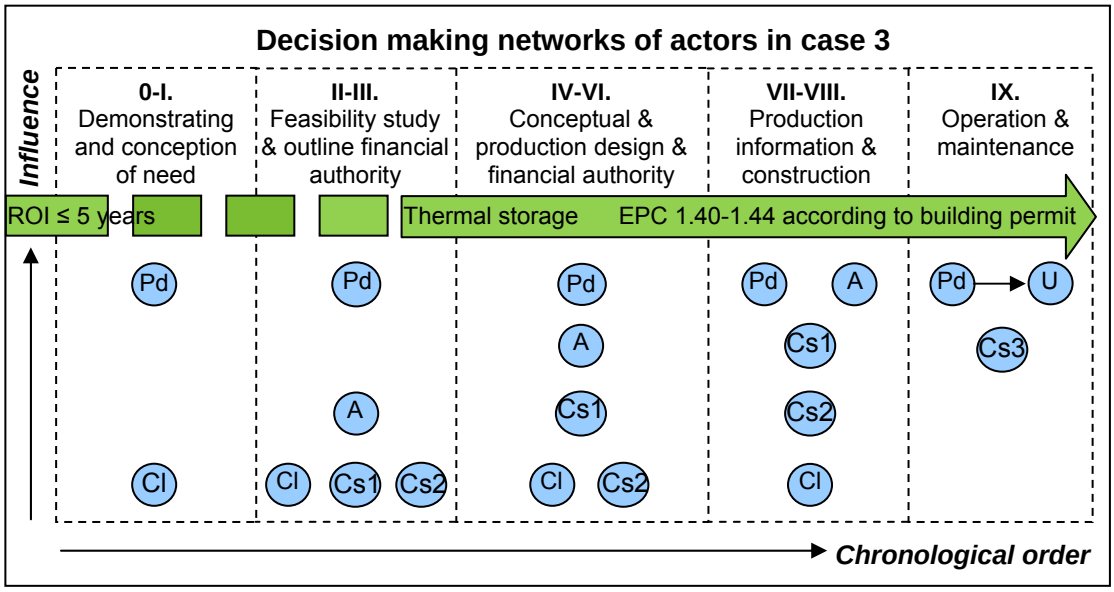

Figure 4: *Stakeholders involved in the design and construction process of Case 3.*

Case 4: De Eempolis

"De Eempolis" forms a long stretched block of office buildings along the northern side of the central railway station in Amersfoort. In this way it functions as a sound barrier. The architect of "De Eempolis" is Jan van Belkum of Arcadis and the principal is NS Poort. The total gross floor space is 36,750 m^2. The total block consists of six sections, which have three to nine floors. At ground level and around the entrance of the station some shops are located. Beneath the ground level parking places for cars and bikes are located.

The construction process started in 2003 and the building activities were finished in 2004. During the design and building process an EPC of 0.55 was mentioned. Nevertheless in the end a less ambitious EPC of ± 1.32 was mentioned in the building permit. The final energy performance was partially achieved by using thermal storage system that uses water of 120 meters below ground level in combination with a low temperature thermal transmission system in the ceilings. These systems are being used for cooling and heating purposes. Unfortunately, it took three years to let these systems operate properly. Furthermore, relatively high thermal insulation values of 3.5 $m^2 \cdot K/W$ and more are applied in the building shell.

The interviews learn that before the building process started, the principal NS Poort (project developer (Pd)) had already stated ambitions regarding the reduction of energy use in their company policy. The company policy is based on the commitment to long-range plans of the national government. These plans aim at twenty percent energy reductions in 2010 compared to the energy use in 1997. These ambitions combined with the wishes of the municipality resulted in a lower Energy Performance Coefficient than necessary to get a building license. Although the investor NS Pension fund did not stimulate energy saving, NS Real Estate being the client (Cl) requested to develop a thermal storage system using heat pumps. At that time

the actors did not have any experience with thermal storage systems. The high complexity and low trailability did not seem to be an issue compared to the supposed relative advantage by means of energy use reduction and observability by means of environmental charisma.

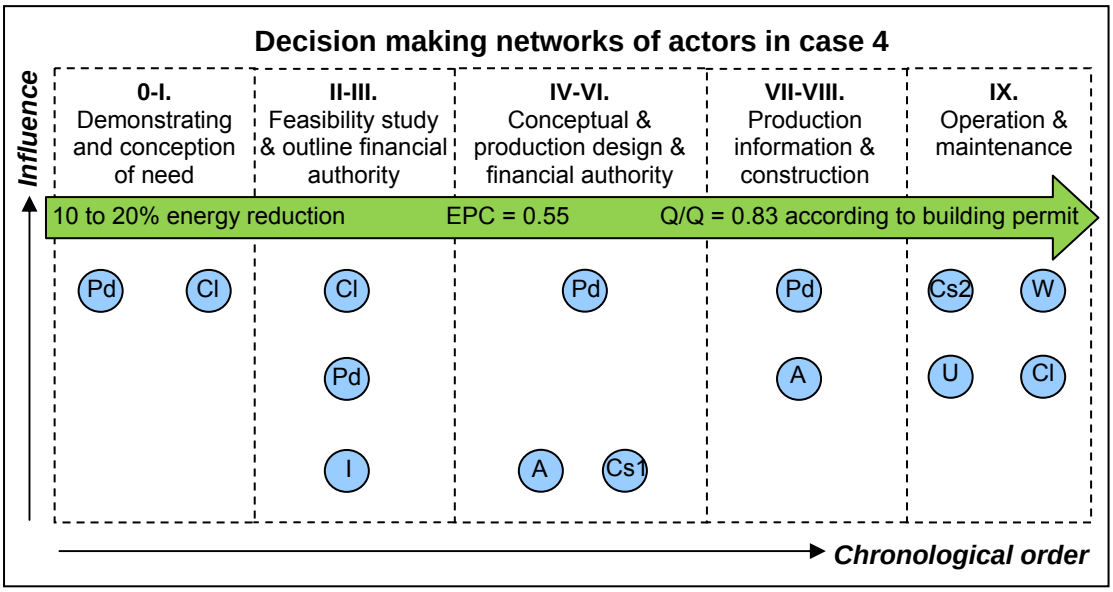

Figure 5: *Stakeholders involved in the design and construction process of Case 4.*

DISCUSSIONS AND CONCLUSIONS

The presented research aims at improving our understanding of adoption processes of energy techniques in building processes. A framework was developed to make the influence of stakeholders visible during different stages of the building process. The framework was applied on four projects. The projects and interviews show that in all cases energy was directly from the start an aspect to consider. In three out of four the need to reduce energy use existed within the organizations, namely Philips, NS Poort, and ABN AMRO. Although one might have expected that a public governmental organization, like the municipality of Amsterdam, would have additional environmental requirements regarding their own facilities in order to set an example, this does not seem to be the case.

Nevertheless, the ambition within the CWA project to reduce the energy use by 25% compared to the energy use required by law, seems to be exceeded by approximately 7%. The ambitions of ABN-AMRO were rather loosely formulated. Within case 4 De Eempolis the ambitions were not that clear either. Large shifts from 10 to 20% and an EPC of 0.55 to a final 17% energy reduction in form of a Q/Q of 0.83 can be seen, although this project had a relatively small number of stakeholders compared to the other cases.

In all cases the project developer had an important role in setting the ambitions. In case 1 CWA the customer filled in the role of project developer in the first fases (0-III) of the project. After that it became apparent that the techniques were adopted and could be implemented, the customer placed himself at the background. Only in the case of CWA the architect was able to influence the energy performance of the design in creative way. In the other projects technical advisors prepared the energy measures in such a way that the architect only needed to insert it in the design. After that, during construction, the architect functioned more or less as a project manager.

The influence of the customer became in case 2, De IJsseltoren, especially apparent when the additional investment costs were not paid for by the client. The fact that the customer was the future user of the building and not the client made it possible to finance the investment based

on the prognosis that future energy use and costs will be lower. In case 4 a higher rent was expected, when the client was able to offer the future users of the object, being the customers, a more energy efficient building.
When we take a close look at Rogers' attributes, multiple attributes are addressed when the actors address the features of adopted and rejected energy techniques in the interviews. Although in most interviews relative advantage in the form of cost and/or energy reductions is mentioned, it is striking to see that almost all considered techniques can be regarded as proven technologies. This can indicate that compatibility with past experiences or trailability (as a degree to which the innovation might be experimented with) are not attributes, but in these cases are conditions to be met first.
Finally, the case studies reveal the relevance of the availability of an energy performance indicator like the Dutch EPC. Although in these projects consultants were asked to look for and investigate possible measures and to calculate the financial and energetic impact of these measures, the ambitions and final marketing of the achieved performance are often based on the EPC and accompanying Q/Q ratio. However, it is not necessarily proven that a low EPC or Q/Q ratio will actually result in lower energy use or lower energy costs. In the case of QX and QY, where the ambition was based on a return on investment within five years instead of a target focusing on energy performance or use, relatively little advancement was made compared to the energy performance in force at that time.
When the energy use of buildings needs to be reduced by an increasing adoption of energy measures, it seems possible and wise to put a focus on disseminating knowledge to project developers, clients and customers. Furthermore, the EPC and its underlying methodology seem able to function as a design tool during the first phases of a new design and construction process.

ACKNOWLEDGEMENTS

The authors like to express their gratitude to ir. Martin Vos for his research activities and AgentschapNL for providing financial support for "Exergy in the Built Environment" (LT02003).

Abstract
The CSIR Housing Research Group in collaboration with a number of partners has been investigating the concepts of sustainable building transformation in the South African housing sector. These studies have relied heavily on a number of theories, including Habraken's Supports, Open Building levels as well as concepts of material/component re-use. All of these theories provide approaches with regards to the way in which materials, building components and the buildings themselves are re-used or salvaged, based on life cycle analysis. There are numerous terms used to describe this approach to the design of the built environment and these are sometimes confusingly interchanged.

Thus, this paper presents descriptions of concepts and working definitions and then proceeds to carry this investigation further by analysing housing case studies with regards to sustainable building transformation. In this process it is attempted to assess if the approaches are relevant and applicable in the South African context. While it is acknowledged that these approaches to design and delivery need to be considered for the whole housing market, there is a pressing challenge to government to deliver low-cost and affordable housing. We also saw an assessment tool for existing buildings as an important way to try and influence thinking, design and planned delivery approaches at the conceptual stages, before future projects proceed in the typical manner which we perceive to be unsustainable.

The capacity for sustainable building transformation will be rationally assessed by studying the internal planning, construction methods and material selection of the selected projects. The paper presents a tool for assessment and comparison, studies the possible changes in the existing projects and also makes some basic recommendations for new projects.

Keywords: Open building, South Africa, housing, sustainable building transformation

BACKGROUND AND AIMS OF RESEARCH

The CSIR Housing Research Group in collaboration with a number of partners has been investigating the concepts of sustainable building transformation in the South African housing sector. Documents such as Medium Density Mixed Housing: sustainable design and construction of South African Social Housing (Osman and Herthogs, 2010); Environments of change: a design solution for an informal settlement in Mamelodi (Gottsmann and Osman, 2010); "Time" as a key factor in design and technical decision-making: concepts of accessibility, affordability, participation, choice, variety and change in the South African housing sector (Osman and Sebake, 2010) are products of these investigations.

As a continuation of this process, the CSIR is currently looking at issues of quality in housing and residential neighbourhoods through developing tools for assessment of housing projects. This comprehensive tool is not only intended to assess existing housing projects, but also to guide housing processes from the outset. The intended users are developers, designers, project managers and Social Housing Institutions. The tool encompasses a diverse set of criteria including technical aspects such as the integration of housing and servicing solutions and social aspects such as social cohesion through the design of shared open space proximate to housing developments.

This process emerged from a concern that, while South Africa is successful in delivering housing numbers, the quality of the environments being achieved is questionable. The two extreme poles in the housing sector are government-subsidised housing (so-called RDP houses which are give-away houses under the government's Reconstruction and Development Programme) and very upmarket developments. Both ends of this spectrum are based on the detached house on the middle of a plot in a sub-urban style planning layout.

It is the market between these two extremes that can perhaps offer opportunities for innovative housing solutions and multi-family typologies such as medium-density, mixed housing. Therefore, for the purpose of developing a tool for building adaptation, three case studies are selected that offer alternatives to the current, unsustainable housing models that dominate the South African urban landscape.

The theoretical background for this study is firmly rooted in an approach to architecture where the design of systems and the interface between systems is given importance. This is believed to generate a richer environment that caters for different categories of users, while at the same time achieves long-term relevance by allowing buildings to adapt and transform over time with minimum waste and minimum disruption to a higher-order level of the built environment that is more permanent and gives an urban setting its identity. This is also an attempt to achieve a balance between the shared domain of an urban environment and areas of individual control. In this sense, the environmental benefits that result from the increased potential for adaptability are further supported by the achievement of higher social benefits.

By assessing existing projects, it has been possible to argue that these theories are not only relevant and applicable in the South African context, but are of high priority if long-term sustainability of residential building stock is to be achieved. This assessment also allows for the identification and ranking of existing buildings that have high potential for adaptation (Teo et al, 2010) and therefore allows for strategic targeting of buildings for upgrades in urban regeneration projects, as an example. Teo (ibid) has also argued that this allows property managers to properly maintain buildings with least impact, as opposed to traditional upgrading mechanisms. The same author explains that building stock may become obsolete

due to physical, economic, functional, technological, social and legal criteria. Many existing buildings will have to be adapted in order to enhance their sustainability performance – adaptions such as rain water collection, modification of openings or installation of solar geysers. It can therefore be seen that the concept of "change" or "adaptability" is very broad and not restricted to one or other parameter, but rather encompasses a whole range of future possibilities that the designer will not be able to determine upfront.

SOME DEFINITIONS AND DESCRIPTION OF CONCEPTS

Two main factors determine the static nature of the existing built environment: irreversible connections (e.g. welding or cement joints) and the entanglement of constructional components with different lifespans (e.g. putting services in bearing walls). Design for Disassembly (DfD) is the strategy focussing on the reversibility and disentanglement of constructional components. According to Durmisevic (2006), the degree of disassembly is determined by two component characteristics: their independence and exchangeability. The first is a measure of their entanglement, the latter determines the reversibility of the connections.

These two disassembly criteria can be evaluated using complex relational diagrams. A high number of dependencies between constructional components results in a building that is difficult to transform. Durmisevic (2006) gives the example of an assembly of five components: if all components share connections, the result is a large number of interdependent relations; on the other hand, if four components would be plugged into an intermediary fifth component, the number of relations is minimised.

There is a differentiation between "adaptability" potential of a building and "disassembly" potential. Disassembly potential implies component re-use while adaptability potential implies building re-use. Disassembly relies heavily on a deliberate and optimal sequence of assembly using reversible connections. Building adaptation relies on the "robustness" or "resilience" inherent in a designed building – the ease at which it can adapt to unbalancing changes in its context (Carmona et al. 2010). Because robustness can be introduced by using broad design guidelines, building adaptation is generally easier to achieve. On the other hand, the disassembly potential of a construction oris the key factor determining the re-use potential of the building, its components and the materials they are made of (Durmisevic, 2006). Therefore, this study tries to incorporate both aspects.

The built environment is comprised of various systems – it is the intelligent interface between these systems that allows for greater change by allowing for "disentanglement" of the various building components with minimal disruption and waste. Therefore, the sequence of construction assemblies is important to be taken into account as the process might have to be reversed to access one or other system that needs to be changed. This sequence also needs to be aligned to the higher- to lower- level configurations, implying a progression from more permanent/fixed functions at the higher levels to functions with a higher frequency of change at the lower levels.

SELECTION OF CASE STUDIES

It is important that adaptable approaches to design and delivery are considered for the whole housing market. However, due to the pressing challenge of the South African government to deliver low-cost and affordable housing, the focus of this study is on three projects built for low- to medium- income dwellers. The selected case studies are the K206 and Elangeni, both

in Johannesburg, as well as the Potters' House development in Pretoria. These projects have been selected based on the following criteria:

Typology: the architectural typologies of the projects are different in that a clustered double storey building is considered in the case of K206, allowing for interesting comparisons to be made with a double storey communal development with unique vertical access (Potters' House) and 4-storey walk up blocks with centralised vertical access in the case of Elangeni.

Use: it was also aimed to study buildings that have uses other than single-tenure residential – so the K206 was included due to the fact that it includes rental rooms adjacent to the family unit and Elangeni includes live-work units, both offering opportunities for income generation for the residents. Potter's House includes a communal facility on the ground floor to be used by the residents, who have individual rooms but share ablutions and other facilities.

Form of tenure: the aim was to look at ownership (as is the case of K206) as well as private rental (K206) and social (government-subsidised) rental (Potters' House and Elangeni).

Location: the K206 is a greenfield development in a typical South African black township setting. Elangeni and Potters' House are more centrally located, with Potters' House being an infill project as part of a larger urban regeneration scheme.

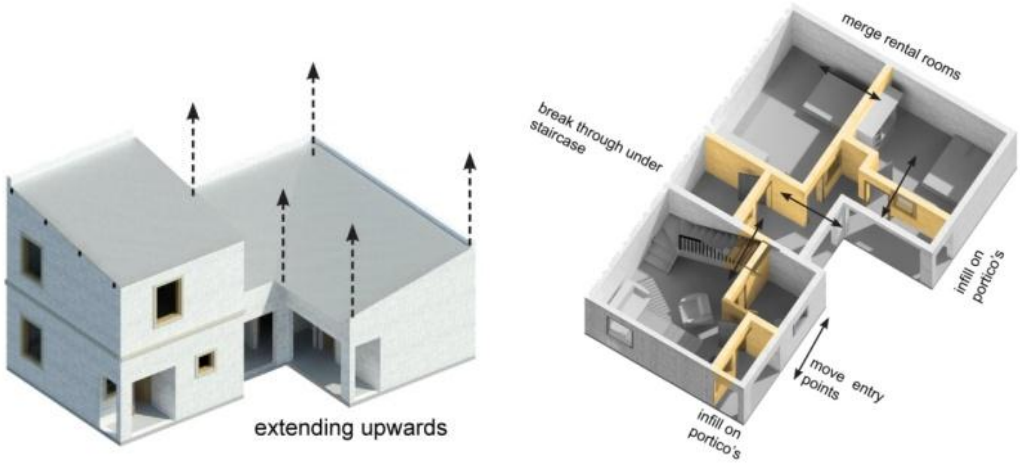
ANALYSIS OF HOUSING CASE STUDIES WITH REGARDS TO SUSTAINABLE BUILDING TRANSFORMATION

K206

The K206 project is designed by Anca Szalavicz and was developed as a low-income development in the urban township of Alexandra, Johannesburg. The project forms part of the greater Alexandra Renewal Project (ARP) development. The project aimed to increase housing densities and combines tenure of ownership and rental occupation.

Eight to ten housing units are grouped together, forming smaller clusters of communities around semi-private communal courtyards. Every unit has a 40m² double storey RDP dwelling intended for ownership as well as a 40m² two-bedroom rental unit with ablutions. The total project consists of over a thousand houses. The concept of the project is novel for the township and the inhabitants seem generally happy about the overall project.

Figure 1: *K206, Alexandra, Johannesburg.*



The buildings are constructed from low-cost, conventional and fairly robust materials – an earthy palette of painted and plastered concrete and fly-ash masonry walls covered by mono-pitch corrugated steel roofs with low parapets. On the exterior, the steel-frame windows and first floor concrete floor lines are highlighted with a plaster border and painted white, adding

simple decoration. The entrances to the units have small protective overhangs and the area at the entrance of the unit is intended as a semi-private garden space.

The owners/tenants are allowed to personalise and adapt the buildings within the current building lines. This restriction is imposed for a period of five years. Most residents have added simple security measures to their homes such as burglar-proofing and many have already personalised their units by painting, plastering or tiling the interior or exterior walls, floors, doors and window frames. Some gardens are being planted and some of the external steel doors have been replaced with timber doors. However, alterations to the main spaces would mean having to breakdown load-bearing masonry walls. The internal masonry staircase is robust, plastered and fitted with a simple steel railing. The railing is hinged so to allow furniture to be moved up the staircase. Otherwise, the staircase will not be able to be adapted or moved without making considerable changes to the primary unit; it can only be personalised (by tiling or by removing and changing the steel railings). The current low-cost sanitary fittings may easily be replaced and upgraded.

The simple mono-pitch roof is easy to duplicate, dismantle and re-install. The design would allow harvesting of storm water from the roof but the roof would first have to be fitted with gutters and downpipes which are not currently provided. No provision is made for refuse and washing areas. The existing roof pitches might have to be adapted if solar heaters are to be incorporated in the future – this is a perceived short-coming in the design.

If an external staircase is provided, the rental possibilities can double, or the entire ground floor area could be used as a single dwelling, and the rental tenure moved to the first floor. It would also be possible to move the point of entry to a different location on the same elevation or to a second elevation. Overall, the original structure can be manipulated to some extent but the primary unit itself has very little possibilities for change as it might be a complicated and costly exercise.

Figures2, 3: *K206 general transformation analysis – possible vertical expansion and internal layout variations in the single unit.*

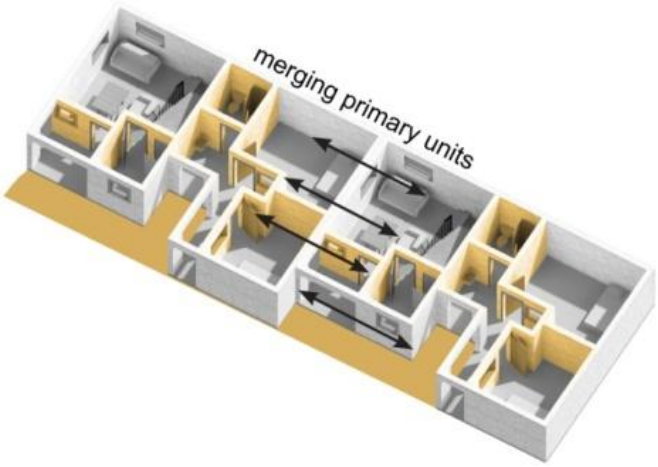


Figure 4: *K206 general transformation analysis – possible merging of primary units.*

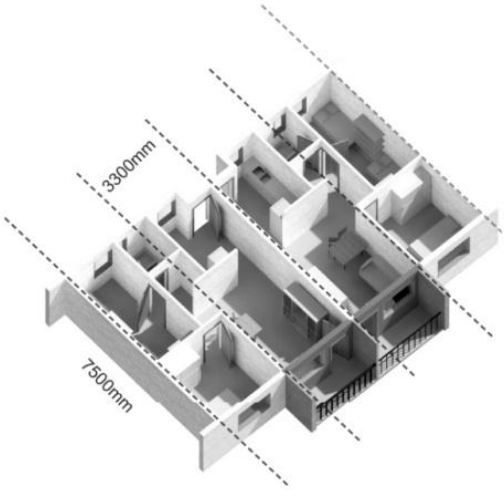


It was noticed that material choice and finishes play an important role in the overall experience of the extremely tight spaces. Therefore, by simply having a white wall finish instead of a dark wall finish internally the quality of the space is perceived to be better. The structural system restricts the replacement of the porous masonry, currently a source of great frustration to the residents because of water seepage into the unit. Inadequate divergence of stormwater around the unit, lack of insulation, lack of natural light and cross-ventilation are other shortcomings that might need increased adaptation potential of the units if remedies are to be implemented at a later date.

Elangeni

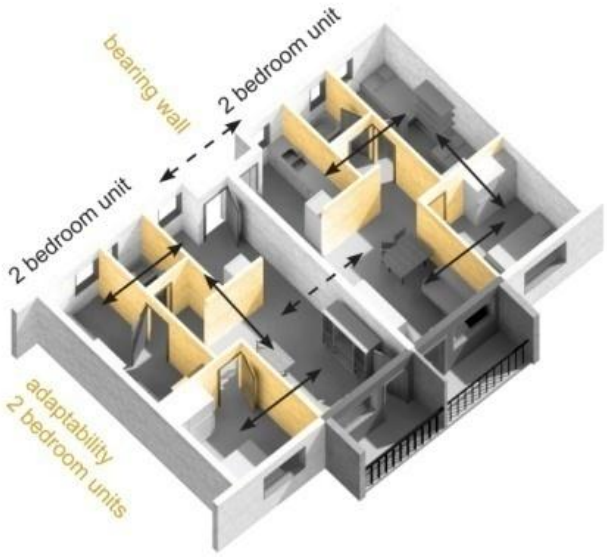
Elangeni Gardens was designed by the architecture firm Savage+Dodd. The social rental housing project is designed as a medium-rise perimeter block and is located in the heart of Johannesburg. The project is administrated by the Johannesburg Housing Company, JHC, and forms part of the City of Johannesburg's Better Buildings Programme. It was completed in 2002. The total project consists of 168 units, ranging from 35m² one-bedroom units to 59m² two-bedroom units. Other unit typologies are live-work units on the ground floor and loft units on the upper two floors. The building is divided into four main structures, linked by a concrete masonry brise-soleil on the circulation areas, and therefore reads as a single, robust, face-brick complex. The monotony is also broken by extruding shallow balconies, south-facing circulation spaces and general service shafts from the living units. These abutments are then framed with steel frames. The units are designed with stringent economy of space in mind in a typology reminiscent of row-housing – rectangular, narrow and compact.

The housing units are clustered into groups of three units per floor in an attempt to encourage a lifestyle of community living. The corner retail unit and the live-work units face a fairly busy street and filling station. The total project consists of 168 units, ranging from 35m² (one-bedroom) to 59m² (two-bedroom). Most of the rooms and units are adequate enough for either a single person in a single-bedroom unit or two people in a double-bedroom unit. Despite the small areas, young families also occupy some apartments. It is difficult to arrange furniture in the living areas according to the tenant's preferences, making for a very deterministic living arrangement within the unit, but the bedrooms are big enough for some variation. The rooms are well lit and ventilated.

Figures 5, 6: *Elangeni gardens, entrance and structural bays.*

To reduce the overall building costs and ease of maintenance, the materials used throughout the project have been kept to a simple specification. The building is structured in a modular fashion with a grid spacing of 3300mm centre to centre and the units are primarily aligned north-south. The main building structural components are uniform reinforced face-brick masonry walls at a double grid spacing (every 6600mm centre to centre). Steel beams protrude beyond the exterior masonry skins of the units to support concrete balconies, steel staircases or passageways.

There are no ceilings fitted except on the loft units. Bathrooms and kitchens are tiled and the original carpets in the living and bedroom areas are also gradually being replaced with tiles. The built-in cupboards in the bedrooms have been removed and replaced with just a rail and in some cases a small shelf. On the stair landings, behind the brise-soleil screens, there are small enclosed yards for hanging washing. There are no solar water heaters nor is there any water collection from the roof. The building does not have recycling amenities but provides a standard refuse yard for waste disposal.



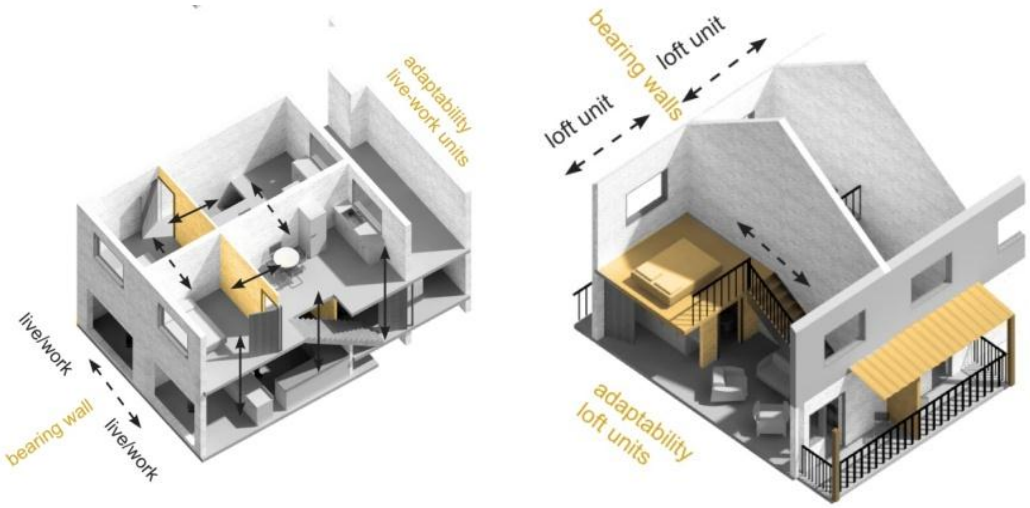


Figure 7: *Diagrammatic analysis of Elangeni Gardens*

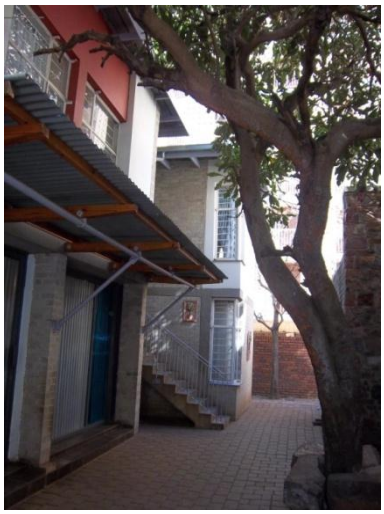
Figures 9: *More diagrammatic analysis of Elangeni Gardens.*

The overall design and layout of the building would not allow for much adaptation or extensions beyond the current building lines. The scheme can accommodate some internal adaptations that the tenants could implement themselves, but these changes appear to be limited to the two-bedroom units. Expanding the area or merging of units requires the breakdown of bearing walls. However, it is noted that adaptability potential relates to the section of the building being considered, as some units are perceived to be easier to adapt due to differing structural and spatial features. The need to design singular units within the narrow grid spacing results in a tight fit of entrances and wet services while units that span over the double grid might offer more potential for flexibility.

In accordance with the architect's general policy to designing for efficient maintenance, the unit materials, detailing and components provide relatively low maintenance requirements to fit the economic profile of the target group.



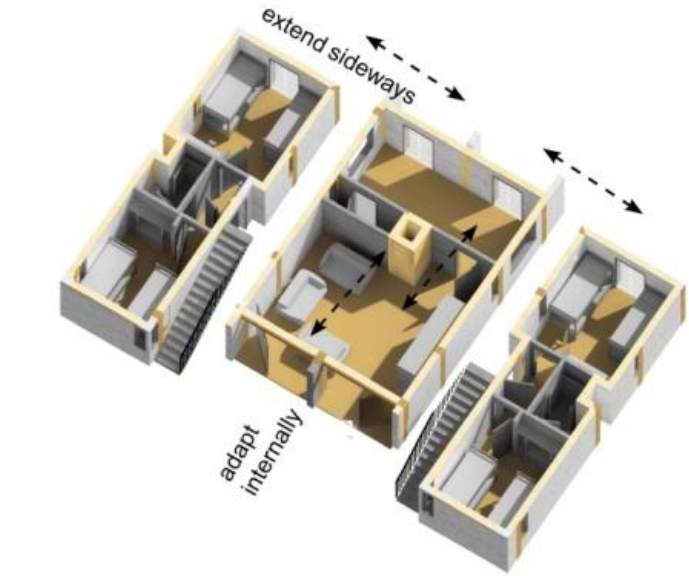
Potters' House

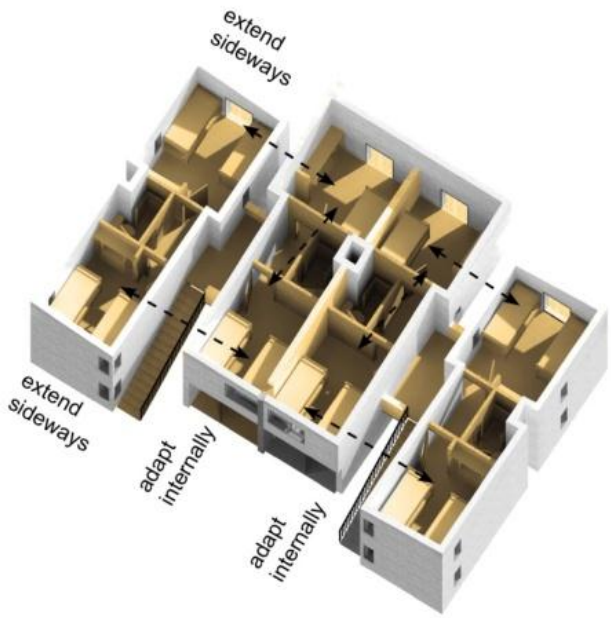
The Potters' House is situated in Burgers Park Lane, Pretoria city centre. The project provides various housing options mostly for people in need of shelter, social support and economic upliftment. The concept was developed by the Consortium for Urban Transformation (CUT), IDASA, the Centre for Housing and Land Development at the University of Pretoria. Burgers Park Village is conceived as an urban rejuvenation project involving the recycling of old buildings. Potters' House is a part of the Jubilee Centre mixed-use complex from which Yeast City Housing administrates the overall project. Established in 1993, the building provides rental tenure and is a transitional housing facility for women in need. It forms a part of a greater community of buildings and small courtyards and is situated behind the main office building. The exterior spaces are perceived to be relaxed, safe and calm and the interior spaces are simple and efficient. However, while the buildings are cool and protected during the summer, tenants report that the winters are very cold.

Potters' House has a symmetrical design in an H-shape formation and the ground floor has a central living-room area with large swivel doors. The ground floor units have a semi-private garden space that can be directly accessed from the northern rooms through steel-framed glass doors. This is quite a pleasant area, but the nature of the tenure means that the garden space is not well-maintained.

The building accommodates 25 bed spaces in 10 rooms. The 24m² units have simple longitudinal layouts, with one room at each end with ablutions in the middle. All the interior walls within the units have a clerestory window. The rooms are well-lit but the bathrooms are fairly dark, with the electric lights kept on most of the time. The rooms in themselves can be passively ventilated and windows are well placed for natural cross-ventilation. All the wet-service shafts are located on the exterior of the building and covered with long strips of corrugated sheets. Most entry points on the ground floor usually have a stepped threshold and entrances are covered and protected from the elements. The rooms have insulated ceilings. Every room has a simple built-in cupboard.

The two-storey building is a hybrid structure with a reinforced concrete frame on the ground floor with load-bearing concrete masonry on the upper level. The exterior surfaces are mostly covered in concrete or clay pavers. The building is robust and upkeep is low. The building has three insulated, corrugated steel sheet roofs on timber rafters, each fitted with gutters and downpipes. The building is fitted with steel-frame glass windows and primarily hollow-core doors.





Figures 10, 11: *Views of Potters' House.*

The majority of the building exterior is unplastered, but the interior spaces are plastered, painted or tiled according to the occupation. The nature of tenure in the building mean that more significant changes, additions or extensions would have to be implemented by the Yeast City Housing company. The simple frame on the ground floor makes changes at that level relatively easy. The centrally located ablution areas might restrict adaptation to some extent. However, this same positioning of the wet-core offers various opportunities in the central block of the building. The two flanking rooms on each floor are difficult to merge, but the rooms could be adapted to change from a two bedroom unit to a self-contained one-bedroom unit on the south and a north-facing living area.

Due to the placing of passages and doorways, a room from one unit would be able to merge into the opposite unit in an L-formation, or across the entire building. By inserting an opening into a wall, it is possible to merge an entire floor completely without making significant variations to the building's appearance or structure. As a whole, it would be possible to extend the building upwards by two or three storeys, depending on the foundations provided.

ground floor
basic frame

typical floor
frame and infill

Figures 12, 13: *Analysis of Potters' House.*

General upgrading of finishes would be possible as would retro-fitting sustainability features. The ground floor area could also merge with the first floor and become a duplex or larger independent unit. It could also become one large unit with the northern portion of the building, or in contrast be divided into two smaller units as the structure would not be influenced by these adaptations. The covered exterior cast in-situ concrete staircases allows that the building can be almost decapitated from the first floor and something completely new can be built without change in the basic structure at ground floor level.

SUMMARY OF FINDINGS AND COMPILATION OF ASSESSMENT CRITERIA

	First level	Second level	Comments on adaptability potential
K206	 K206 ground floor	 K206 first floor	-Semi-private threshold space is easily enclosed -House may be extended upwards over the two rental rooms -The two rental rooms may be merged with the primary unit – however this means losing the threshold and creating an awkward passage in one scenario or breaking down a structural wall, under the stairs, in another
Elangeni 1-bedroom	 one bedroom L-shape		-Narrow grid spacing and structural walls limit the interior alteration possibilities -However, with some effort and wastage it is possible to create an open plan in one unit or merge two units by removing a wall and adding structural support
Elangeni 2-bedrooms	 two bedroom		-This unit provides real possibilities for major changes due to the large spans and non-structural walls -The balcony spaces can be built-up adding on average 4m² of space, but this entails removal of doors and walls and does not add much value to the quality of the space
Elangeni live/work	 live-work ground floor	 live-work first floor	-The small areas limit the interior alteration possibilities of the unit but the non-structural walls allow possible merging of two units
Potters' House	 ground floor not to scale	 first floor not to scale	-Frame and infill at ground floor allows for easy changes, however the hybrid structural system poses restrictions on the adaptability potential of the structure as a whole -Central space with central wet core allows for more change and combination possibilities -While there are restrictions to extension beyond current building lines, it is not impossible to do so, especially if the building is to be linked to the surrounding buildings

Table 1: *A summary and general comparison of the plans of the selected projects. It must be noted that this information has been compiled from available drawings and documents and still needs to be verified by the architects in some cases.*

Based on the case studies, several features of the buildings are already undergoing change, by the owners or social housing institutions, with no professional input and no requirement for complex approval processes. These are therefore assessed as being easier to modify, adapt or change. These features with "easy adaptation" potential are also perceived to have high social value in some cases (such as the replacement of steel doors with timber doors in the K206) and high functional value in others (such as the incorporation of theft- and vandal- proof features in Elangeni as well as easier-to-maintain tiles as opposed to the original carpets).

While some features may have social as well as functional value, it is perceived that some features which will truly enhance functional performance are more difficult to implement as these would involve spatial alterations and the disruption of major building components which implies higher technical impact. Some high level adaptations, such as changing the facades may also have a high level of social impact, especially when a facade is considered low quality as is the case the K206. In this project a facade material change implies breaking down a structural wall.

However, it should also be remembered that the components that undergo frequent change and that are easier in a technical sense to change, may also have very high environmental impact if re-use potential, disposal options and embodied energy aspects are taken into account. "Easy adaptation" may thus encourage greater "frequency of adaptation" resulting in higher environmental costs.

From this discussion, the assessment of adaptability potential may be carried out based on features that are easier to adapt to those that pose greater difficulty and have higher impact. Frequency of adaptation is here linked to the degree of ease or difficulty of adaption:

Easy adaptation
Easy adaptations are usually short-term changes in that they deal with changing the appearance of units and (regular) maintenance work. They benefit the users (have high social value) because they could be used to increase the uniqueness of the occupied unit (use, colour, finishes). The assessment of short-term adaptability depends on architectural analysis (multi-functionality of the plan layout) and housing regulations (to what extent users are allowed to make changes). Examples are:

- changing doors (without changing the door opening) (referred to as an "independent component")
- removing carpets, paving, tiling, painting (functional- or status- linked "finishes")
- adding burglar bars ("independent component")
- add features such as solar heating or rainwater collection (general fittings also as "independent components")

Moderate adaptation
Moderate adaptations are generally medium-term frequency and generally include those changes needed to update a building to changing market demands or government requirements, e.g. replacing or upgrading finishes, increasing or decreasing unit sizes to match evolutions in demography, updating the unit layout and services according to changing societal standards, etc. The feasibility of these kinds of changes can usually be assessed by analysing the structure and construction of the building, and the degree of entanglement of constructional components and functions. Because moderate adaptation is done on the level of building components, improving the adaptable capacity on this level strongly influences the other levels. Examples:

- reconfiguring internal layouts (this implies knocking down an "internal non-structural wall")
- reconfigure internal vertical or horizontal circulation ("private circulation")

- adjust a partially-enclosed space or change a point of entry (change "building envelope" or "openings")

Intensive adaptation
These intensive changes in a building usually only happen in the long-term and only become viable when entire buildings or projects need to be refurbished. They include elaborate adaptations like vertical unit extensions (i.e. through an existing floor slab), horizontal unit extensions using new structures or cantilevers and changing the typology of outside circulation. Long-term changes require analysis and design done by architects and structural engineers. Examples:

- reconfiguring internal layouts (knocking down an "internal structural wall")

- expand vertically and horizontally (which implies adjusting various "system-dependent components" which are governed by the location of higher-order systems such as the "wet services" and "vertical service cores" as well as "communal vertical or horizontal circulation" areas which are more complex to change, not only for technical reasons but also because they are shared areas where a group decision needs to be taken as compared to "internal circulation" where individuals take the decision)

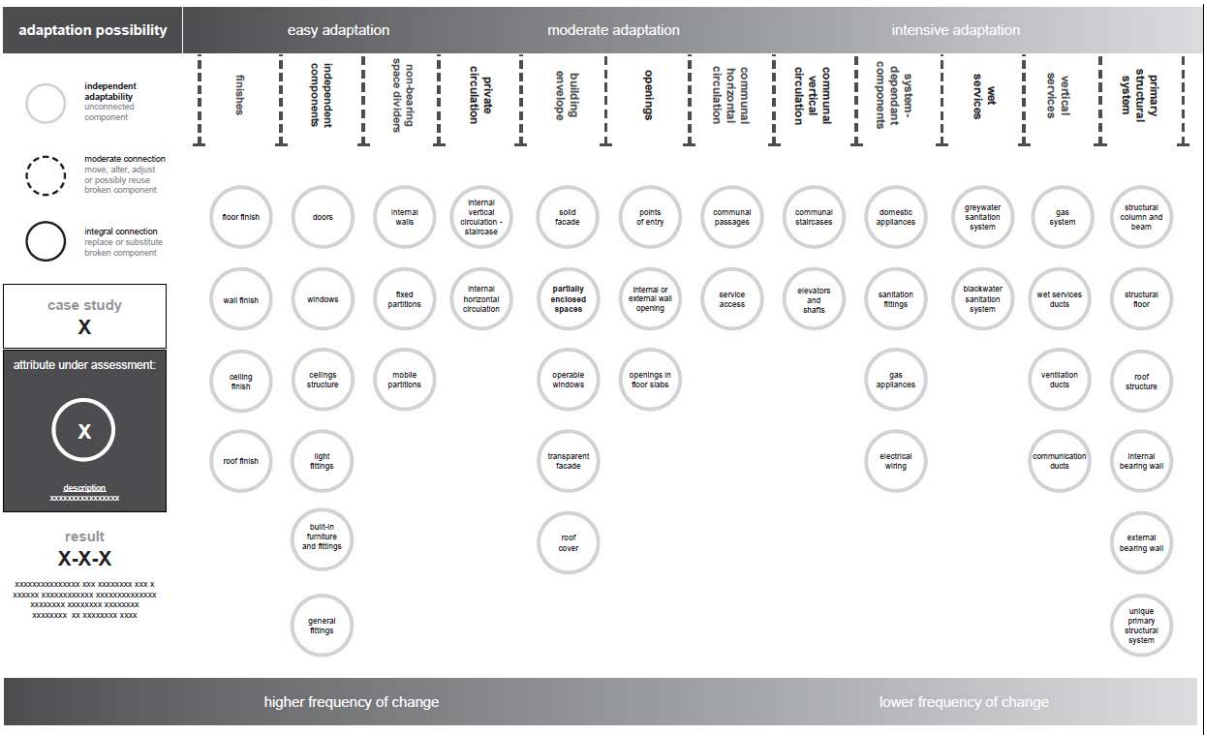
The transformational capacity of a building is, of course, largely determined by the building itself. As most aspects of adaptability come into play when trying to implement moderate/medium-term changes, it could be argued that this intermediate phase is the most important. The feasibility of medium-term changes is based on the complexity of the construction (whether components are functionally independent or interdependent) and can be assessed by the degree of professional involvement necessary to implement the changes.

ADAPTABILITY ASSESSMENT TOOL

From the above it can be seen that, while the existing housing projects do not appear to have been designed with adaptation potential as a high priority, this does not imply that they can't be adapted. An approach to assess the adaptable capacity of the existing housing projects is thus attempted.

This paper presents a broad, rather than in-depth, assessment of the selected case studies. As the projects under assessment were not designed to be adaptable, an in-depth analysis of the disassembly options of the existing construction would most likely result in low scores for all projects and would be unnecessarily time-consuming. The priority is a general assessment of the adaptability potential, rather than a detailed analysis of every aspect of disassembly or re-use of the construction and its components. This makes assessment more straight-forward, and requires a lower level of expertise.

The outcome of this process has been a list of possible adaptations and comparisons between buildings with regards to the ease with which these adaptations may be achieved. In order to be directly usable for housing practitioners, the presented tool lists possible adaptations, impact on other features/components of the building and categorises these ranging from easy to intensive adaption potential. The tool theoretically allows for scoring and computation, though this is to be done in the future and has not yet been achieved.



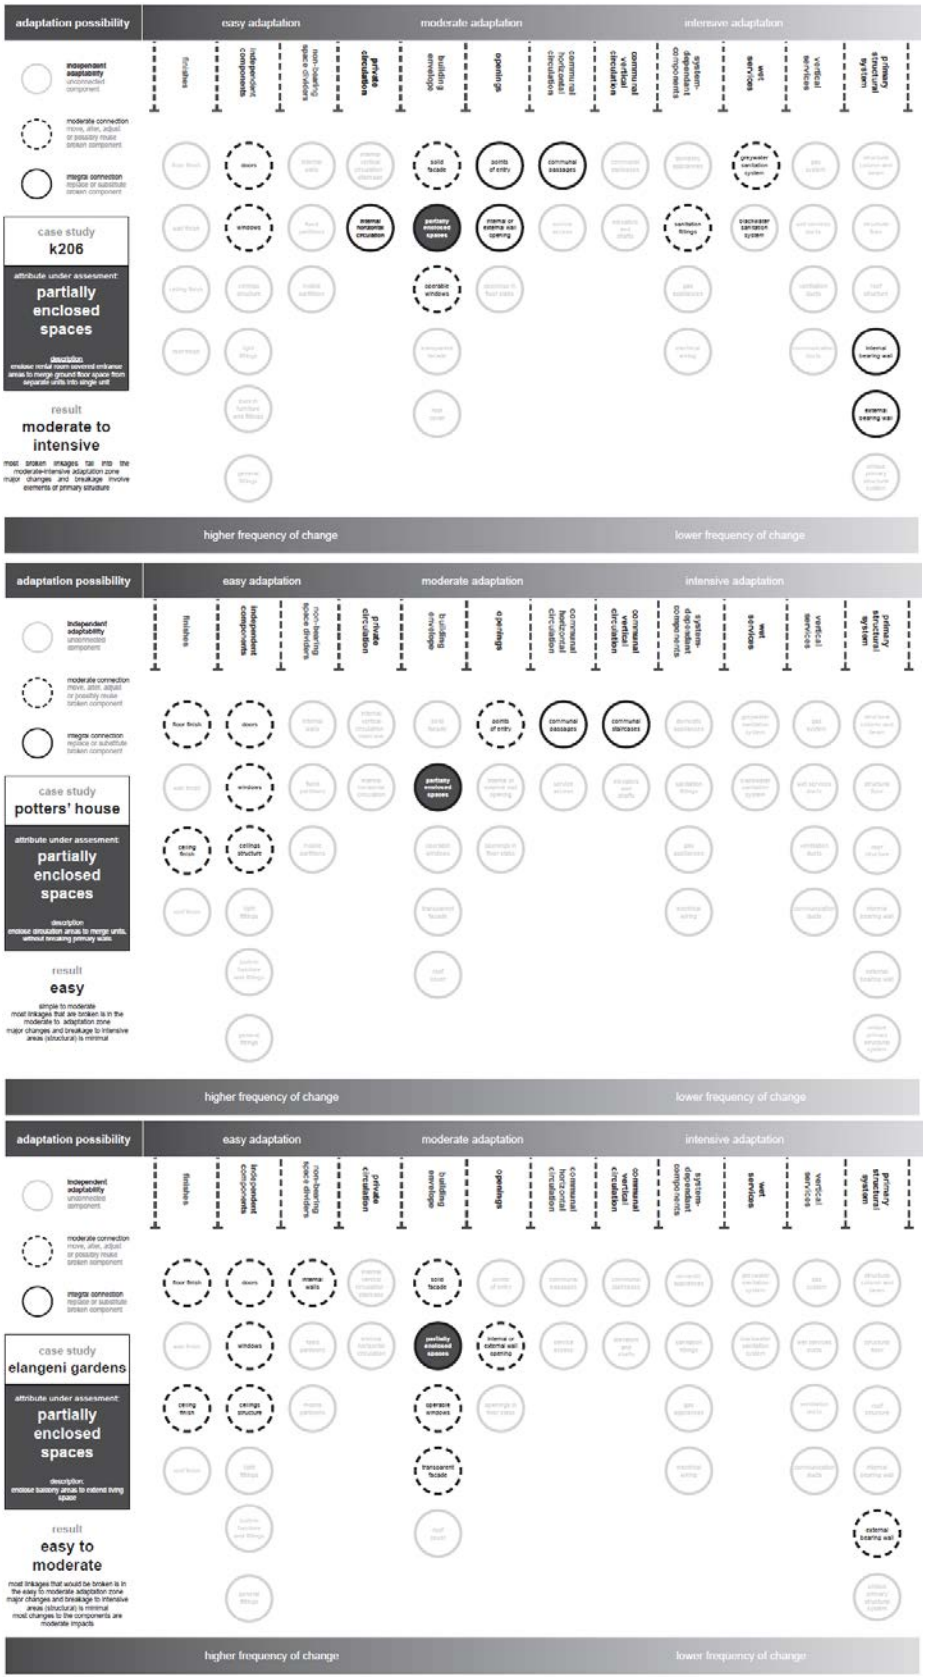


Figure 14: *The format of the assessment table.*

Currently, it is intended to simply present when change in an attribute of a building component breaks or serious alters another component/s, when there is possibility of re-using removed components, when a component can be removed and substituted without breaking anything else and when there is absolutely no impact on other components. Thus, the degree of entanglement is assessed by the number of features/components affected indicated by the number of circles on the diagram that are marked in a grey, dotted or black circle – this indicating the degree of damage to attached features/components.

A more in-depth tool might differentiate between an adaptability rating, disassembly rating or reuse of components rating and it would also incorporate aspects such as owners/users behaviour and preferences. A more complex and accurate assessment would also separate between unit adaptability and building adaptability.

Rating and comparison between projects may be achieved by assessing the number of aspects of a building affected by the same change in attributes in the buildings being compared. The number of affected circles on the table (building components/features) determines the degree of entanglement of the attribute under assessment. The more affected circles on the right side of the table, the more difficult it is to adjust that particular aspect of the building. These relations and their degree of entanglement may ultimately be scored.

Figures 15, 16, 17: *Application of assessment to the three case studies.*

DISCUSSION

The capacity for sustainable building transformation has been assessed by studying the internal planning, construction methods and material selection of some case studies. Some results of this study may be presented as follows:

- Simple column and beam structures offer more opportunity for change when compared to load-bearing masonry
- Alternative technologies (sandbag construction, adobe construction, or bamboo-reinforced concrete masonry) could be even more cost-effective and should be investigated
- If not the entire structure, perhaps only one or two walls can be considered with alternative materials to counteract some site specific issues such as drainage or heat gain or allow for a more varied potential in adaptability of the building.
- Narrow grids limit spatial manipulation, especially when the bays are separated by structural walls
- Variation in the grid may allow for a variety of spatial experiences and areas according to preferred taste and need
- Open plans allow for varied interpretations; this may also be investigated vertically with a structural system over two floors instead of per floor
- Alternative building components should be considered to demarcate spaces in the double grid units, such as adaptable composite panelling structures or the use of mobile storage units

It should be noted that this list is used as an example and is not intended to be exhaustive. It has also not considered the cost implications of this approach – however, it is believed that the long-term financial and environmental cost implications of not taking adaptability into account are is very high – especially when a building has to be completely demolished with no possibility to dismantle components for re-use.

We therefore proceeded to develop an assessment tool to study possible adaptation in more detail. While this has been described as “broad” rather than “in-depth” assessment, a preliminary conceptual tool is presented to allow for further comparisons between projects with regards to adaptability potential.

CONCLUSION

By studying existing housing projects, it has been possible to develop an approach to assessing the potential for adaptability as well as to offer some guidelines for new projects. This research intends to contribute to the debate on transformable structures and to raise awareness on the topic. The proposed assessment tool may be used by designers or project managers increase their comprehension of basic concepts of transformability and disentanglement of functional layers. Hopefully, it will show that sometimes only small changes are required to drastically increase the future options available to a project that needs to be renovated. Once the tool is further developed, the intention is to use it in the field and to get input from professionals. While the ultimate aim is to develop a design guide, this would

require a greater level of detail planned for another stage of this research project. This design guide will aim to influence thinking, design and planned delivery approaches at the conceptual stages. It is concluded that this approach to design is highly relevant to the South African context and deserves serious attention in the building of future housing projects.

NOTE

All photographs were taken by Calayde Davey or Amira Osman, all models/graphics are drawn by Calayde Davey and sources for plans were either the architects themselves or they were sourced from ASA and Yeast.

DUTCH STRATEGIES FOR THE HISTORIC URBAN CORE, THE HISTORIC INNER CITY, FADED GLORY OR CORE BUSINESS

WOUT VAN DER TOORN VRIJTHOFF

Julianalaan 134, 2628 BL Delft, The Netherlands
e-mail: W.vanderToornVrijthoff@tudelft.nl

Abstract
This article is about the strategies of Dutch cities for the historic urban core, based on empirical research done on the policy reports of twenty Dutch cities. In addition to the policy reports plans for spatial and functional interventions, initiated by the local government, were analyzed.
The analysis were made in the years 2006, 2007 and 2008. The years just before the start of a possibly long lasting economic recession. Apart from some reflections on this subject at the end of this article no attention is paid to this in an analytical way.
Keywords: historic urban core, strategy, transformation, identity

INTRODUCTION

Cities are more and more competing with each other in different leagues, for the favor of the high educated creative settlers, the cultural visitors, companies looking for a new location and to keep those already bound to the city (Gardiner, Martin, & Tyler, 2004; Gospodini, 2002; Greffe, 2004; Kavaratzis, 2008; van der Borg, Costa, & Gotti, 1996; Wiesand, 2005).
The historic urban core seems to have characteristics which are significant in the context of that competition. Characteristics often referred to as unique qualities and specified in terms of identity, authenticity, historic continuity, organic grown street patterns etc. (Lewicka, 2008; McCabe & Stokoe, 2004; Murtagh, Graham, & Shirlow, 2008; Murzyn-Kupisz & Gwosdz, 2011; Pendlebury, Short, & While, 2009) Zirubavel argues that the past and the present are not entirely separate entities (Zerubavel, 2003) and that people have a need to bridge the gap between the two. The physical surroundings which remain relatively stable constitute a reliable locus of memories and often serve as major foci of personal as well as group nostalgia. That underscores efforts to preserve those parts of the city that provide us with a link to the past. Lowenthal argues that in western society, because people live longer and are more mobile, they seldom remain surrounded by the things they grew up with. That is why there is an increased interest in history and why people stick to the last recognizable things (Lowenthal, 1985). The historic urban core gives the opportunity to make contact with previous generations and step in the footsteps of our ancestors.
The same message as Lowenthal, is given nearly twenty years later, in a policy document of the central government of the Netherlands. The following statement is made in that document: "The need for historical embedded identity, for slow movement in time, for distinction ability, for nuances, familiar situations and variety, can also be seen as the counter point for the dominant influence of the levelling global culture. Handling the cultural heritage with respect guarantees the historical continuity and opens up possibilities to preserve the cultural identity of a village, city, region and even the whole country" (VROM, 1999) Kotkin is explicitly referring to the historic urban core giving a sense of place and history amidst a society in which the barriers of time and space are under constant assault. "As centres of arts and culture, repositories of our past history and architecture, the core retains a powerful tug of consciousness. It reminds us not only who we are but also what we have been" (Kotkin, 1999)

The function and significance of the still present characteristics of the historic urban core has changed over the last decades and will develop further, giving support to the presentation of the city image. In order to fully equip the historic urban core for its actual and future function spatial and functional interventions are maybe needed. Or certain interventions by private parties maybe support opposing objectives and need to be prevented. Because of the delicate structure of the historic urban core interventions have to be planned and executed very carefully (Doratli, Hoskara, & Fasli, 2004). There are many parties, private as well as public, which have an interest in the historic urban core. Because of the general interest the historic urban core can be considered a common good particularly on a local level. That does impose the role of mediator, navigator and initiator on the local government for the way the historic urban core is utilized and optimized.

This project, of which this paper is about, is primarily concentrated on Dutch cities with an historic urban core, dating from around 1000 a Chr. In Gospodini‟s terms (Gospodini, 2002) Dutch cities are smaller cities. He classifies the cities in the European global system in three main categories: metropolitan cities, larger cities and smaller cities. According to Gospodini, with reference to Commission of the European Communities (CEC), 1992, smaller cities are considered to be the dynamic force of modern urban Europe and the majority of them are expected to continue growing successfully in the new competitive milieu. According to eurostat statistics concerning more than 300 European cities more than 50% of Europes population is living in cities with less than 500.000 inhabitants. For the smaller cities in Europe the maintenance, preservation and enhancement of the qualities of urban space is a dominant selling product in the context of the before mentioned competition. The historic urban core is often, for the smaller cities, their flagship project while the bigger cities have the possibility, and take the advantage, to create new ones.

In order to execute its role as guardian of the historic urban core the local government needs a long term strategy framed in possible future developments. To orientate on this subject research, about which this paper is giving account, has been done based on the leading question:

What is the future strategy, in terms of vision, objectives and means, of Dutch local governments for their historic urban core?

In this paper first attention is paid to what is supposed to be the content of a long term local government policy strategy. Then the selection of 20 cities is explained. The strategies of the 20 cities appeared to be very “look alike”. Therefore the choice is made to present them in the form of an average, being the strategy for the theoretical reference of Dutchtown. In the end conclusions are drawn concerning the main characteristics, focus points and shortcomings of the strategy. This article is illustrated with examples of interventions in the historic urban core in three of the twenty cities.

GOVERNING CHANGE OF THE HISTORIC URBAN CORE, LOCAL GOVERNMENT STRATEGY

What is a strategy? The concept was adopted as a management tool taken from the area of competence of the military generals. In that context the concept is as old as mankind. In the field of management the concept is given various meanings by scholars and managers in the field.

Porter stressed the competitive character and defined a strategy as “a broad formula for how a business is going to compete, what its goals should be, and what policies will be needed to carry out those goals.” (Porter, 1980/1998)

Henry Mintzberg indicated that strategy is a *plan*, a *pattern*, a *position*, a *perspective* and he indicated that it can also be a *ploy*, a maneuver intended to outwit a competitor. (Mintzberg, 1994)

Private corporations were the first to use the strategy concept in their management activities. Public institutions and authorities followed in their footsteps. Also in the field of urban management and the management of specific urban areas, like the historic urban core, local government strategies are used as a guideline for management activities.
A set of local government decisions concerning spatial and functional management activities framed in objectives which are paving the way to a future vision or future brand are forming a strategy. (Figure 1)
The historic urban core is very differentiated with regard to ownership of property. This means that many different parties are involved in the changing process of this area. A process that is, historically seen, a continuum of small scale interventions. The municipality has the abilities to govern that process using a range of management tools or means that can be categorised in regulation, incentives (financial support with public money), initiate and participation in interventions (Figure 2)
Related to real estate and spatial planning a strategy is always covering a long time. Real estate and spatial patterns have a very long life cycle, sometimes ages. Decisions in that context have therefore long term effects. Those effects should be taken into account as important considerations for decisions to make and for the strategy to develop. Qualification and quantification of long term effects is only possible if a strategy is placed in the context of future developments not being part of the strategy but often highly detirmend for the strategy success. Future developments forming the context for a strategy cannot be influenced or predicted. Therefore a strategy is placed in the context of different possible futures or scenarios in order to specify its possible effects and also to test its „strategic response capability". That is the capability to respond adequate on changes in the context, which cannot be influenced, by flexibility and robustness of the strategy. (Bettis & Hitt, 1995; Lindgren & Bandhold, 2009)
The policy reports of the 20 municipalities were analyzed taking the scenario/strategy approach as a basic principle and taking the framework given by figure 1 and 2 as a structure.

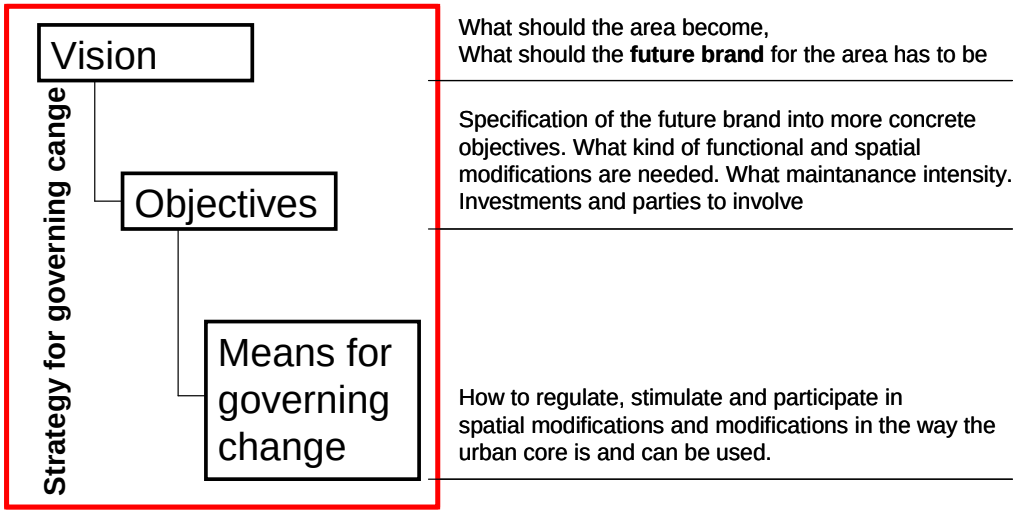

Figure 1 *The strategy components*

Below an explanation is given for the means that can be used as part of a local government strategy.

Governing change

The management means of the local council can be classified in the following main groups:
1. Regulation

2. Incentives
3. Participation in execution

Regulation

Regulation implies the contextualisation of spatial changes of buildings and urban structures through rules. These rules are laid down in legal frameworks, such as:

- Zoning plans
- Registration of conservation areas
- Registration of monuments
- Procedures for applying for planning permission

Regulation implies laying down what is permitted and what is not permitted with regard to spatial and functional interventions.

Regulation also concerns the contextualisation of possible uses. For example, a traffic circulation plan sets rules for how the road system is used.

Incentives

Within the scope of what is permissible, a distinction can be made between what is possible and what is deemed desirable. Incentives can be used to put the focus on what is desirable. Subsidy schemes clearly belong to the category of incentives. One example of an incentive is advice and subsidy for the promotion of the use of authentic colours. However, incentives can also take the form of active cooperation from private initiatives through official municipal bodies, which can lead to quicker and more streamlined procedures.

Participation

The municipality is responsible for the spatial planning and management of public spaces. The municipality also owns a considerable share of the property in the historic urban core. The initiative for interventions in the historic urban core, therefore, often lies with the municipality. The participation of private parties is also necessary, in order to produce an intervention that is qualitatively well-balanced and financially feasible. There are no set norms for the division of roles within local councils.

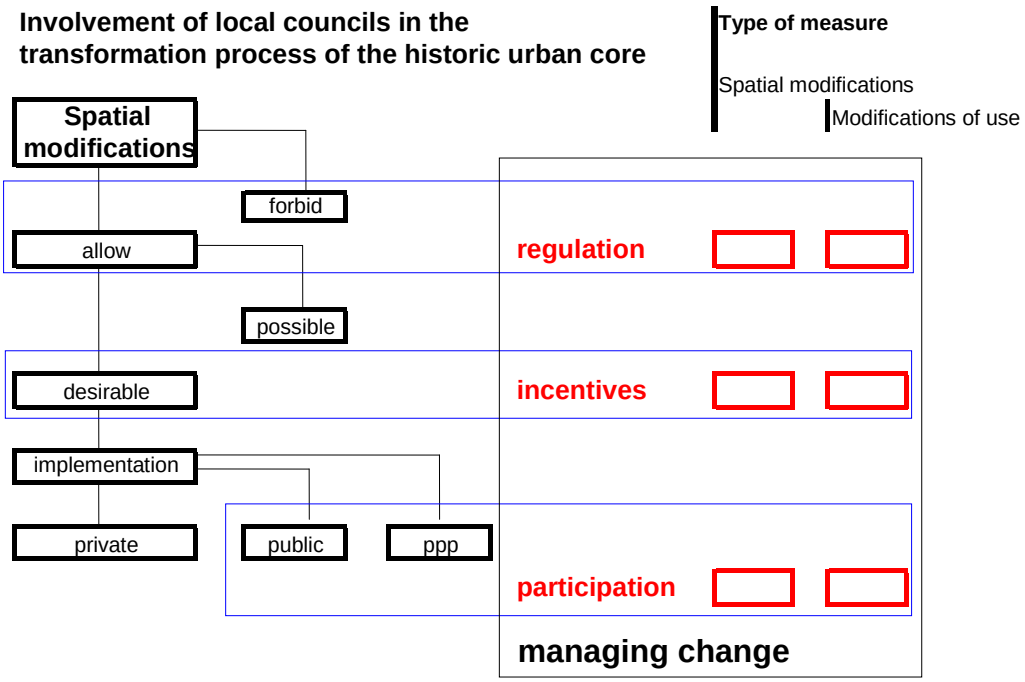

Figure 2 *Managing change*

Traditionally, regulation is the main working area of local councils. To a limited extent, incentives are an extension of this. Risk-bearing initiatives and participation in large-scale transformation investments are less obvious areas of involvement.

THE EMPERICAL FUNDAMENT, THE POLICY OF 20 DUTCH CITIES

In order to gain insight into the strategies applied by Dutch local governments, an analysis is made on the policy reports of 20 municipalities. First an explanation is given on how the 20 municipalities were selected. After that some general characteristics of the local policy reports and strategies involved are presented. Finally an average of the strategies of the 20 cities is worked out.

The strategies of the 20 municipalities involved in the analysis turned out to correspond on many points. This made it feasible to embed the policies of the 20 municipalities within the framework of a theoretical reference municipality, without detracting from the differentiation in policy. We called the theoretical reference municipality „Dutchtown". The focus in the analysis is laid primarily on the way in which the local policy documents described the positioning and the future prospects of the historic urban core. A note was also made of the measures proposed in the policy documents for providing spatial and functional support to the future profile of the historic urban core. Finally, the measures noted were sorted according to the principles outlined in figure 3.

Selection of the cities

Of the 50 largest municipalities in the Netherlands, those municipalities were selected with a historic urban core that still exists for a considerable part (number of listed buildings in the historic urban core/inhabitants of the total city =>2). Fig. 3 and 4 shows an overview of the 20 municipalities thus selected. Some characteristics of the selected municipalities are:

- By far the greater part of the selected cities were granted city charters around 1250. The exceptions to this are Deventer (956) and The Hague (1806).
- Around 20% of the population of the Netherlands live in the 20 selected municipalities (89% of the Dutch population live in urban areas).
- In the area of the historic urban core, there are generally less than 10% of the number of dwellings in the whole city. Exceptions to this are Amsterdam, Leiden, Delft and Bergen op Zoom.
- On average, the Dutch Real Estate Appraisal Act (WOZ) values of the dwellings in the historic urban core are 6% higher than the average WOZ value of the dwellings in the city as a whole. In 14 of the 20 municipalities, the WOZ value of the dwellings in the historic urban core are considerably higher than the average value of the city as a whole.

Letters were sent to all the municipalities in the selection in 2006 and 2007, asking them to provide policy documents relevant to the area of the historic urban core. Information was also sought through the municipalities" websites. The analysis includes a total of 91 policy documents from 20 municipalities.

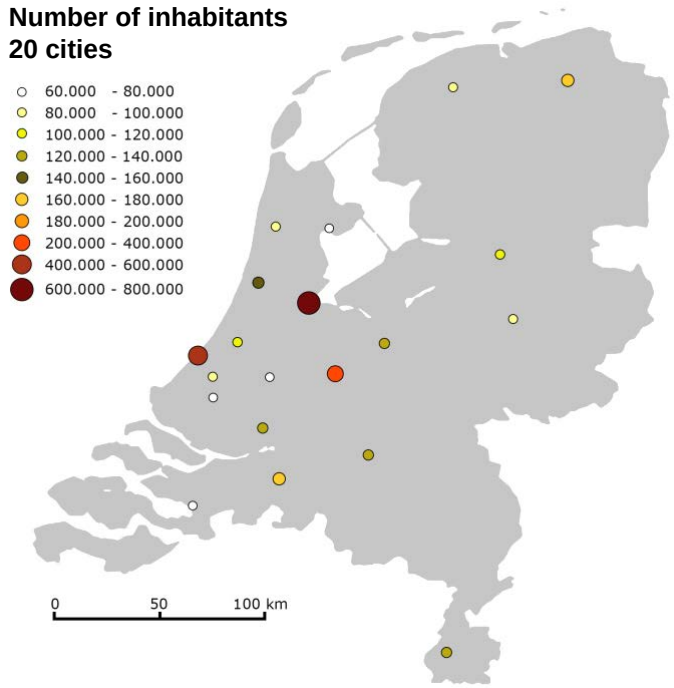

Figure 3 *Selection of Dutch cities*

the 20cities	city inhabitants	monuments/ inhabitants x 1000	number of dwellings	dwellings inner city	year of city legimization
Amsterdam	735.526	9,5	374.952	45.960	1306

Figure 4 *Some figures of the selection of Dutch cities*

DUTCHTOWN STRATEGY

As a consequence of the credit crunch also municipal budgets are cut down and priorities are reconsidered. Related to that there is a tendency towards more involvement of market parties and more restrictions in order to exclude financial not profitable investments.
The Dutchtown strategy, being an average detected from 91 policy reports and presented hereafter was formulated before the credit crunch. Therefore it is likely that, on the short term, there will appear some modification in the strategy to adjourn the investments needed.

Characteristics and significance of Dutchtown core

The Dutchtown urban core has been created over many centuries and is characterised by a great degree of diversity. This development process is illustrated by new and old buildings. The current urban development situation has grown slowly, as the buildings have been replaced and changed over the centuries. The presence of different building periods also means a variety of construction techniques and methods and differences in architectural styles.

The buildings in the urban core are characterised by „unity in diversity". This unity is formed by a common idiom, in which the building height, the vertical character, the classic façades, the roof directions, the parcelling, the use of materials and the small scale are characteristic features. The greater part of the buildings were built in accordance with the traditional means and possibilities of the times. Afterwards, in more recent periods, many buildings were changed in both appearance and function. The diversity of the architectural picture is expressed (within the common characteristics described above) in a rich architectural variety of façade lay-outs, gable ends, ornamentation and numerous small differences in guttering heights, ridge heights and use of materials.

Seen against the background of increasing globalisation of society, competition between the municipalities and the regions will play an ever larger role. It will be increasingly important that the municipality of Dutchtown, too, assumes its own identity and tries to distinguish itself from others, with the goal of creating a positive image by promoting the municipality through its unique selling points. The historic heart is that, or at least a very important selling points of Dutchtown. It is not only of great importance for the urban economy, but also largely determines the character of Dutchtown, and thus functions as a magnet for visitors from the city itself and from elsewhere.

Future Objectives for the urban core

Cultural tourism

In the coming years, cultural history will occupy a central place in ideas about the identity and image of the city. In the new municipal policy on the conservation of monuments and archaeology, links are made with city marketing, cultural tourism and the city"s economy. The heritage of Dutchtown – both below and above ground – will be utilised in order to profit optimally from all the potential in these areas. Sometimes cities formulate something like a „Cultural Profile" master plan, in which the strategic opportunities of the heart of the city are specified.

Readability of history

The objective of keeping the city"s history readable and reinforcing it where possible is a front runner in policy. In meeting this objective, attention is paid not only to the conservation of monuments, but also to the conservation of the structure of urban planning over the whole terrain of the city. The relationship of cultural history to urban modernisation is addressed as well.

Preference for conservation and restoration
Conservation and restoration takes precedence over modernisation. The historic building materials, structures and methods of construction represent an important monumental and historical value. This value must be respected as much as possible, so that the history and development of traditional building, and the daily use of a monument are readable. Replacement would entail this readability being lost forever.
Cultural historical identity must be more decisive in spatial planning. In order to maintain its distinctness from other historic cities, Dutchtown must retain its original image and reinforce it in a modern way, rather than immediately searching for a totally new image or other identity factors.
The pedestrian tourist
The implementation policies that focus on restricting traffic in the urban core will benefit its character and attractiveness to guests. The same applies to the construction of parking garages. It is expected that tourism will occupy an increasingly important place, and this is part of the reason why retaining a small-scale character is extremely important.
Expand the urban core domain
Dutchtown wants to intensify the use of the urban core with permanent and temporary public attractions and to modernise the character of the city as reflected in the architecture and activities. This is possible by reinforcing the working function and urban housing, as well as expanding recreational and shopping facilities. Further reinforcement of such a multicultural urban core requires space, but this space is only available to a limited extent within the current urban core borders. It is therefore important to expand the urban core domain to include some neighbouring areas.

Local government measures

Regulation
Regulation requires good information about matters to which the regulation applies. This explains why attention is paid in many policy documents to the documentation of everything that is situated within the historic urban core. This includes:

- Drawing up a map of areas of historical architectural interest and charting historical architectural values in the urban core
- Charting archaeological values and designating areas of archaeological interest
- Developing digital charts of cultural historical values
- Historical architectural research and formulating historical morphological reports
- Formulating cultural historical investigation and effect reports

Designating and protecting valuable inner areas, on the basis of inventory charts.

Implementing stringent visual quality policy for the urban core, focusing on architecture, use of colour and material, street and façade advertising, spatial planning for public spaces, street signs and street furniture. New buildings in the urban core must fit the historic image of the city, with regard to size, scale and character. Spatial planning for public spaces must be matched to the character of the historic image of the city (important factors include the design of street signs and street furniture). Restoring architectural coherence, so that the shop front and the rest of the façade (which is often historic) is seen as a whole once more.

Spatial extension of the urban core: the case of ’s-Hertogenbosch

The historical background

‟s-Hertogenbosch is an average-sized Dutch city, dating from the 13th century. At present, it has a population of 132,000. The mediaeval structure of the historic part of the city, with its ramparts and pattern of narrow streets, has been largely preserved. The old city is situated on a sandbar, surrounded by marshy land. Because of this, urban expansion was very problematic in the past. Furthermore, ‟s-Hertogenbosch was a fortified city with impressive, sturdy ramparts. The city plan of 1652, shown in fig. 1, is still very recognisable in the present city plan. In the 19th century, the city was forced to find solutions to the growing need for space by opting for a high concentration of buildings within the city walls. It was only in 1874, when a law was passed stating that the fortifications of Dutch towns and cities were no longer functional, that creative solutions were sought for making the surrounding marshy land suitable for building. The railway and the station were built on the periphery of the historic urban core, where 590 national and municipal monuments are situated. These buildings strongly determine its authenticity and historical character, and therefore its attractiveness. The area has therefore been given protected status, making it difficult to realise any spatial and functional interventions. The urban core also plays an important role in the economic functioning of the city, because more than a third of employment is situated here. Though ‟s-Hertogenbosch has maintained and reinforced its past role as an urban centre, this has been accompanied by a growing need to extend it.

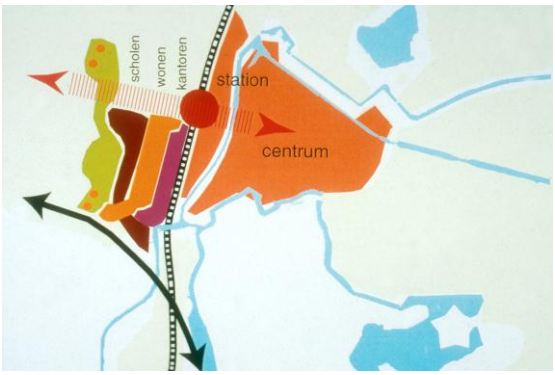

Fig. b *A historical map of the city of ’s-Hertogenbosch Source: Blaeu's Toonneel der Steden (1652).*

Plan of the city and the extension to the west

The need to extend the city centre

The economic growth of ‟s-Hertogenbosch put ever greater pressure on the urban core to accommodate offices, shops and housing. From the eighties onwards, the municipality searched for possibilities to extend the urban core.

At the end of the eighties, the decision was taken to extend the urban core in a westerly direction. The challenging title given to this risky undertaking was the „leap over the railway‟. On the western side of the railway was an industrial site that had been developed around the war years. Many of the businesses that had originally occupied this site had moved in the meantime to locations that offered more space and were more accessible, and where carrying out the business was less of a nuisance for those in the immediate surroundings. Existing buildings started to become empty in the eighties, which offered perspectives for large-scale redevelopment. Fig. 1 gives a schematic view of the extension.

The main specification for redeveloping the area around the railway was to „lift‟ the inner city over the railway to create a place in the western section of that zone for city centre functions that could not be accommodated in the historic urban core due to lack of space. The location was one that offered possibilities for creating a new, high-quality urban environment, with new, high-density architecture and modern solutions. An additional specification was to create space for the new „spatial claimants‟ on the market - large-scale organisations in education, the service industries and banking - which had resulted from mergers. The functions of these organisations, as far as scale level was concerned, no longer fitted into the finely meshed parcelling of the historic urban core.

Developments in the urban core are based on such points as finely meshed parcelling, human size and scale, individual buildings, historic parcelling and street patterns. The stone size of individual buildings in the urban core forms the basis for the degree of combining different functions and joining parcels. Paying attention to appropriate use of colour and material, moulding, scale and human size, in order to maintain the desired small-scale intimacy.
Retaining a building as the base unit for a function (instead of a pre-determined maximum floor area, for example). Opposing the joining of historic buildings, so that there is sufficient differentiation between larger and smaller buildings. In principle, it is not permitted to unite two buildings into one. The unit must remain intact as far as possible.

Stimulation

Historic colours
The historic image of the streets is strongly influenced by the colours of the façades. Consistently using historic colours on woodwork, such as doors, window sills and frames ensures a recognisable character of Dutchtown colours. Owners of monuments and buildings that determine the image can be offered assistance by compiling a palette of historic colours. The historic colouring of façades of dwellings in the Protected City Image (Beschermd Stadsgezicht) is being researched and translated into a colour fan (following the example of the Dordrecht municipality). Research into the colouring (which has now disappeared or faded) of the façades of these buildings, particularly the original coloured reliefs, is being translated into concrete colour restoration projects – where possible and desirable.
Parking rates
Parking problems are an important point for attention in the policy of many cities. The steady rise in car ownership gives a temporary character to every solution that has been thought up in the past. The historic urban core can offer no more space for cars in combination with a policy that focuses on increasing the attractiveness of the area. The raise of parking rates will discourage visitors to come by car. The Amsterdam historic urban core has the highest parking rates in the world.
Restoration financial support
Many private owners of property in the historic urban core do not have sufficient financial means to renovate their property to a high standard. With regard to this, the creation of a Dutchtown Revolving Fund as a financial instrument for restoration will be investigated. Investigation will be carried out into the possibilities of an integral, more area-oriented subsidy system, besides subsidies for individual monuments and complexes. The formulation of Long-term Maintenance Programmes may be made obligatory for restorations to be subsidised. A variety of initiatives will be undertaken for this, ranging from distributing informative leaflets and expanding the website and publications to talks with owners/residents, interest groups, restoration institutions and housing associations about cultural history.
Establishing a depot for old building materials for repair work to monuments.
Empty storeys above shops
During the day, the shopping streets in the historic urban core present a lively picture, but when the shops shut their blinds at night, the street image changes starkly, with negative consequences for the quality of life and the attractiveness of the area. Reinforcing the residential function in the urban core can contribute to combating these consequences. One way of doing so is to put now empty storeys above shops to good use again. This will involve technically complex and financially difficult interventions, particularly in relation to

Public space intervention: the Breda Harbour restored

In Breda, a city of 163.500 inhabitants, plans were developed in the nineties to restore the filled-in inner harbour. Since the very beginnings of Breda, the harbour had fulfilled a function that helped determine the city‟s right to existence. 700 years after Breda was granted its city charter, it was decided in 1964 to fill in this „monument‟ in order to make the city more car-friendly.
Meeting accessibility demands in order to support the economic interests of the historic urban core was a decision that fitted the spirit of the times. However, forty years after the decision to fill in the harbour, it has been decided – once again on the grounds of economic interests – to restore the buried monument. The plans for restoring the harbour in Breda are combined with modernisation interventions. The Belvedere Memorandum refers to this type of plan as follows: „In essence, current shared opinion is that cultural history is not only worth saving, but that it also offers exciting opportunities for development whenever and wherever a synthesis can be found between the retention of existing historic values and the creation of new spatial values‟.
The **Belevedere Memorandum** is a Dutch policy document on the relationship between cultural history and spatial planning. The memorandum was published in the summer of 1999 and signed by four ministries: the ministries of Education, Culture and Science, Public Housing, Spatial Planning and the Environment, Agriculture, Nature Management and Fisheries, and Transport, Public Works and Water Management. The development plans for Breda form an illustration of the synthesis referred to in the quotation above, in a set-up where public and private parties work together.

Figure a The original harbour, transformed into a four lane road, the new 21 th century harbour and real estate development along the water

In Breda, there was agreement on:
-The importance of restoring the city‟s oldest monument
- The significance of this for the city‟s identity and competitive position
- The significance for the increase in value of land and property in the direct vicinity of the harbour.
The municipality took on by far the largest share of the costs of this intervention in the public space. The project, which was completed in 2006, needed an investment of EUR 29.5 million. During the development of plans for the restoration of the historic urban waterway, there were many discussions about authenticity. Far-reaching concessions were made in this area, particularly under pressure of financial feasibility. Identity needs were apparently satisfied to a sufficient extent through something that evokes associations with the current, socially upheld view of history. In Breda, the choice was made to return the water (the harbour as the source of Breda‟s origins) to the city – but then to the city of the 21st century.

accessibility. The municipality provides incentives for initiatives in this area, including subsidies and procedural and organisational support.

Communication/education

Intensifying education about surroundings and heritage. Knowledge about the past and the surroundings of Dutchtown will contribute to pupils‟ appreciation of their city. Central cultural historical information point for architects, urban planners, building contractors and clients. Presentation of results of archaeological and construction history research in an open depot set-up. Incidental exhibitions (construction history, archaeology or conservation of historic buildings). Publication of cultural historical magazine. Giving on-the-spot information about the location of the archaeological and construction history research. Accessible information about subsidy regulations for monuments. Giving lectures and guided tours. Permanent and semi-permanent public presentations about the results of archaeological and construction history research and conservation of historic buildings. Listing and describing spatial characteristics, valuable cultural historic elements and valuable historic green elements. Coordinating and organising an Open Monument Day. Putting Dutchtown on the map through publications.

Participation

Re design public space

Reducing „searching‟ traffic, e.g. through better street signs and better access to information about compartmentalisation and traffic flows. Making it easier to load and unload. Realising delivery routes for freight traffic to the urban core. Traffic light systems that give priority in the urban core to bikes and public transport instead of cars. Expanding the low-traffic area of the urban core. Introducing one-way traffic. Constructing attended bike sheds in the urban core. Realising a system of signs to parking garages and promoting parking garages.

Erecting urinals, creating taxi stands near entertainment areas, and ensuring socially safe lighting. Creating historic street lighting in the urban core. Existing fences, posts and basement grilles, etc. must be protected. Coherence of street furniture, in keeping with the historic image. The Urban Core Tree Preservation Society (Behoud Bomen Binnenstad) ensures an approach to planting and preserving trees that is in line with policy. Protecting city gardens, trees with preservation orders and ecologically valuable structures.

The green in the urban core does not often consist of continuous stretches of green, as is the case, for example, in post-war districts. In the urban core, there is much less grass and low greenery than elsewhere. Nevertheless, many urban cores give a green impression, which is due to the distribution of many trees over public spaces and along canals, etc.

Refurbishing squares, streets and avenues, paying attention to historic building lines, use of sustainable materials and research into historic predecessors. Choice of materials, structure and colour for road surfaces and pavements are essential for setting off monuments.

Underground refuse collection. Centrally organised graffiti control. Discouraging dog dirt, graffiti and illegal bill posting, and controlling weeds.

Attending to and maintaining the structure of canals, streets and alleyways, vacant areas (inner courtyards), building and parcel borders and premises.

Management and marketing cultural tourism
In many cities, centre management is a joint initiative by the municipality and companies in the urban core. Within that collaboration, agreements are made about management, maintenance of the public space, lighting historic buildings, street signs, advertising, character of shopping streets and promotion.
Using the characteristics of the urban core as a unique selling point and keeping in line with the municipal promotion policy to highlight the possibilities of Dutchtown.
The tourist function of the historic urban core can be reinforced by building conference facilities and expanding hotel capacity. Making space for large-scale events and festivals in and around the historic urban core. Creating new developments that link up to the cultural historical tradition. Combining the forces of cultural organisations, tourist organisations, the marketing and information branch, the municipality, and residents and (cultural) entrepreneurs, in order to strengthen cultural historical tourism. The cultural historical centre of the urban core forms the setting within which cultural tourist attractiveness is reinforced.

Out of site parking
The aim is to exchange the parking areas on public roads for parking space in constructed facilities.
The constructed facilities are often realised in the form of multi storey underground car parks just on the edge of, but outside the historic urban core.

Extend the urban core domain
Realising „overspill" locations. Here, space can be offered to functions that are too big, or have grown too big, for the historic heart of the city. In these outskirts, there is also space for high-density new buildings. In this type of initiative, the municipality can restrict itself to creating incentives for initiatives by private parties. The municipality can also choose for a more active approach. Den Bosch is a good example of this.

Strengthen the cultural function
Cultural and recreational functions will be given incentives. Cultural facilities in the urban core that focus on ethnic and cultural minorities will be promoted.
Concentrating the accommodation of cultural institutions in monumental buildings in the urban core, in order to safeguard this compact cultural experience and promote cooperation. The monuments in possession of the municipality are destined with precedence for cultural functions.

The municipality as owner and custodian of cultural heritage
Renovation of Utrecht Town Hall

Fig.c The old and new townhall in one

The town hall in Utrecht has a long history dating back several centuries. It was over 650 years ago that the government of the city of Utrecht took up residence on this spot.

In 1997, the Spanish architect Enric Miralles (1955-2000) was commissioned to create an open, transparent and accessible building. Miralles was chosen for the job mainly because of his respect for history, combined with his innovative and daring architecture. Miralles was particularly renowned for the way in which he interwove the old and the new. “The main thing is to make history readable”, he wrote himself.

Miralles created a new entrance at the back of the town hall, which gives the building two faces, as it were. The town hall has an exciting but logical structure, so that visitors and users can find their way around almost automatically. The entrance building of concrete, steel and glass spatially integrates the square behind the town hall with the town hall itself.

The public space around the town hall has been redeveloped in accordance with the architect‟s plans. Miralles‟ design has transformed the square into an outdoor space with trees and a water feature. In the road surfacing, bluestone outlines indicate where houses stood in the (distant) past. Cars are excluded as far as possible. The new wing rises up above a couple of small listed buildings, and is linked and interwoven with them. Part of the façade of the demolished part of the old town hall has been retained, and it is incorporated in the new wing. The council chamber is situated on the first floor and stretches to the ridge of the building. Here, it is clearly visible how Miralles has linked the old and the new. Open-work beamed ceilings give a view of the wooden roof boarding, and the exposed mediaeval beams, which are staggered halfway along, show that two buildings with storeys of different heights have been joined together. The inner wall of the council chamber displays a palette of materials and styles that have been used throughout the centuries: cast-iron profiles, arched windows, plasterwork sections and windows with a view onto the staircase or the new corridors.

In the building, components of constructional historical value have been re-exposed or re-used. Parts of the existing complex that were „just nice‟ have also been retained and often given a new function. For instance, old ceilings are visible in several places, as well as joists, strips of brick, old staircases, mediaeval gutters, doors and windows, and gables, etc., which have all been exposed in surprising ways.

The budget made available for the commission by the local council was EUR 13 million. In the end, the intervention cost almost EUR 20 million. An intervention that paid less attention to historical details would have been considerably cheaper.

CONCLUSIONS

- In most policy reports there is no clear distinction between what generally is seen as the historic urban core and what generally is seen as the city centre. In almost all the policy reports the focus is on the city centre, which covers a bigger area then the historic urban core.
- The time scope municipalities use in their policy reports to specify their future vision is very different, most of the times very short and sometimes they cover several decennia and everything in between. Most of the reports have a time scope of about ten years. That is short regarding the time that is involved in making functional and spatial changes in the core.
- The visions are not formulated in terms of the future function of the historic urban core within the context of the city as a whole, referring to the interaction between the different areas that together form the city. However the urban core is seen by all the cities involved in this analysis as their flag ship, especially aiming for the interest of the pedestrian cultural tourist.
- The characteristics and significance of the historic urban core are described in "soft specifications" like for example "unity in diversity". That kind of specification cannot be used as operational assessment criterion for interventions in the historic urban core.
- The same problem occurs when taking a closer look at the objectives. For example the objective of "Keeping the city"s history readable and reinforcing it where possible" will awake a large number of different meanings given by different people. Most people can read a book but only a few learned how to read a cities history.
- In many municipal policy documents, there is a lack of specification of measures that would give a concrete dimension to the strategies. The measures are still often formulated in terms of goals and good intentions.
- Most municipalities use a one track strategy. There are not alternative strategies presented as taken into consideration. There are no future scenarios, describing the scope of the possible future context for the strategies, taken into account. What we see is a single strategy approach placed in the context of a single scenario future. It is evident that taking a time scope of about ten years the approach with future scenarios does not fit with the objectives. The future developments used as a context for the strategy can be seen as a projection of trends that characterize the actual situation. Big changes in the future context, like the credit crunch or something likewise, have not been taking into account. What we see is a single strategy approach placed in the context of a single short term scenario future. Because of that approach the strategy (s) are not tested on their „strategic response capability"
- The focus of the municipality is on modifications in the public space and on marketing, aiming for the attention of the on culture oriented tourist.
- The financial feasibility is always a major criteria. Despite this decisive importance strategies very seldom have a financial paragraph in which is worked out what figure there is on the bill to pay and who is paying which part of that bill. In specifying the policy set out in the memoranda for the future of the historic urban core, local councils do not immediately take on long-term financial obligations that go further than what comes under regular expenses. Specific project-related investments are included separately in the political decisions.
- Investments by local councils for specific projects in the historic urban core are implicitly legitimised from the point of view of common interest. Participation by the local government in these projects is in most cases not financial profitable for the municipality. Local politicians use arguments related to the common interest for the city to legitimize

the input of tax payers money. That implicates that there needs to be a positive social attitude for giving priority to investments that support the quality and attractiveness of the historic urban core.

Based on the analysis and conclusions drawn from that, a need can be detected for an adequate theoretical framework for local government future strategies for the (Dutch) historic urban core

Following the ingredients from which a strategy is build up, being also the ingeredients for the theoretical framework:

1. A vision in which the future social economic function of the historic urban core in the context of the city as a whole is stipulated
2. The objectives, which make the rather abstract vision more concrete.
3. The means, which describe the kind of activities the local government will initiate in order to meet their own objectives.
4. Criteria. The characteristics and significance of the historic urban core and the objectives for the future of the historic urban core are often described in "soft specifications" . That kind of specification cannot be used as operational criteria in which a strategy can be formulated and assessed on forehand and tested on its effects later on.
5. Strategic response capability in the context of different future scenarios. Most municipalities use a one track strategy. There are not alternative strategies presented as taken into consideration. There are no future scenarios, describing the scope of the possible future context for the strategies, taken into account. What we see is a single strategy approach placed in the context of a single scenario future.
6. Cost and benefit. The financial feasibility is always a major criteria. Related to the social economic function of the historic urban core and related to the content of the proposed strategy a cost benefit analysis should be part of the framework.

BALANCING BETWEEN FEASIBILITY AND RELATIONSHIP. INTERVENTIONS TO PREVENT DYSFUNCTIONALITY OF CONFLICT IN PUBLIC PRIVATE PARTNERSHIP PROJECTS.

Abstract

Research shows that there are many bottle-necks in Public Private Partnership (PPP) Projects in Dutch spatial development. Due to the specific properties of Public Private Partnerships, these bottle-necks can lead to dysfunctional conflicts which are damaging the project. Hence the question is: how to prevent these conflicts?
Literature doesn't answer this question on an operational level in the context of a PPP project in spatial development. So ten cases of PPP in spatial development are selected in which a conflict escalated in a way that the existence of the project was on the edge. The research strategy is to compare cases in a cooperative climate with cases in a competitive climate. Data are collected by interviewing representatives of the public side as well of the private side. Analyzing the data, several interventions are found. Analysis shows that in a cooperative climate a rich variety of interventions is used, while in a competitive climate the interventions are limited. The analysis also shows that in a competitive climate interventions are more focused on the relationship between the partners than on feasibility, while in a cooperative climate both aspects are equally attended.
Regardless of a cooperative or a competitive climate, the interventions found are concerning the feasibility of the project or the relation between actors. One moment it proves to be necessary to emphasize feasibility and the other moment the relationship. Therefore it is concluded that in spatial development dysfunctional conflicts in PPP projects can be prevented by balancing between feasibility and relationship. As such this research contributes to organizing collaboration.

Keywords: interventions, dysfunctionality, conflict, public private partnership, spatial development.

INTRODUCTION

Public Private Partnership in The Netherlands started a long time ago. „The Verenigde Oost-Indische Compagnie (VOC), founded in march 1602, was already an example of Public Private Partnership in The Netherlands. The city of Amsterdam participated for more than 50 % in the risk-bearing capital of the VOC at the time of its foundation and the VOC was involved directly in the lay-out of the city.“ (Bult Spiering 2003: 8). Since then Public Private Partnership in The Netherlands has had from time to time many applications, e.g. in rebuilding the country after World War II, but it became regular after the use of the concept in the coalition agreement of the Dutch government in 1986. Two kinds of PPP in the

building industry evolved: projects with or without shared risk-bearing investments. An example of the first kind is an area development in which the price of the land to be paid to the public side is made dependent of the price of the real estate on it, to be paid by the market. An example of the second kind is in which the public side as a client drafts a contract with a private party about the Designing Building Financing Maintaining and sometimes also Operating, in short DBFM-O contracts, of e.g. a high way or a school building. Different from other countries as the UK, Germany, France or the USA, PPP projects with a shared risk-bearing investment has become a regularity in the Netherlands. The cause of this sometimes is located in institutional constraints. In the UK for example the public side is only by special allowance permitted to take part in Public Private Partnerships when it is possible that market-risks will be within the public realm and in the United States there is a stringent separation between Public and Private (Hobma, 2008: 7). Yet, still PPP projects with a shared financial risk appear in the UK as well is the USA, e.g. in joint venture projects as the Docklands in the UK and Baltimore or Portland in the USA (Bult-Spiering, 2008: 134-172). This article is only concerning PPP projects with shared risk-bearing investments; PPP projects in spatial development, where spatial development projects encloses projects in area development, infra structural projects and real estate projects. Because bottle neck research shows that the most and most intense bottle necks appear in the phases prior to the realization or construction contract (De Vries et al, 2003 en Dol et al, 2005, 2007), the case research at hand is limited to these phases.

FROM BOTTLE NECKS TO DYSFUNCTIONAL CONFLICTS

Research shows that many bottle-necks do occur in PPP projects in Dutch spatial development (Lousberg, 2009). Examples of these bottle-necks are:
- conflict of interest: public interest of quality versus private interest of profit (Spiering et al, 2001: 18);
- public decision making & procedures (Blanken et al, 2004: 41);
- in some practices, policy rhetoric instead of policy urgency is at hand (Van Rooy, 2009: 104-126, comp. Flyvbjerg et al, 2003).

A question is whether these bottle-necks can lead to dysfunctional conflicts.

What a conflict is or what a dysfunctional conflict is, is normative. It depends on what is considered as a problem. In this article a dysfunctional conflict is defined as a conflict in which, although parties involved want otherwise:
- no result is achieved that is shared and desired by all (compare Duke et al, 2004: 169);
- winning or losing becomes the key question (De Dreu, 2005: 77, 48);
- an unwanted delay or breaking up of the relationship occurs that is detrimental to the project.

Four indications of a relationship between bottle-necks and dysfunctional conflicts are found in literature.

First, due to sharing market risks, one of the most important properties of PPP projects in spatial development is uncertainty. In uncertain situations assumptions, defined as fact and values, play an important role and are affiliated closely with a belief that is emotionally

charged (Weick, 1995: 114). In an uncertain situation compared to a stabile context there it is more likely that a conflict becomes social-emotional (Schruijer, 2007: 208, De Dreu, 2005:71, 72). Second, PPP projects in spatial development are ambiguous (Teisman, 2004: 14). By lack of objective criteria in ambiguous situations players with a different orientation on values rely on more personal or professional values while making sense of the situation. The clash of the different values often charges the situation politically and emotionally (Weick, 1995: 93).
Third, PPP-projects in spatial development are characterized by social diversity of public and private parties (Van der Meij et al, 2000:39, Bult-Spiering, 2003: 260, Karré et al, 2007: 192). Social diversity, defined as different in social terms: demographic properties, value systems determined by culture, religious convictions etc. enhance the possibility of social emotional conflict (De Dreu, 2005: 112, Pinto, 2004: 208).
Finally, in a business context social-emotional conflicts are dysfunctional (Robbins et al, 2010: 263).

These indications suggest that in the context of Public Private Partnerships in spatial development, bottle-necks can lead to dysfunctional conflicts which damage the project. Hence the question is: which interventions are used in practice to prevent dysfunctional conflict in PPP projects in spatial development?

IN SEARCH FOR INTERVENTIONS

Intervening is defined as one or a series of planned activities for change that are directed on increasing the effectiveness of an organization (De Caluwé et al, 2009); in this research interventions are defined as one or a series of planned activities on an operational level that in the interest of the project try to prevent a conflict becoming dysfunctional. In search for such interventions a rigorous and comprehensive literature study was conducted (Lousberg, 2009). Covering ground that has been covered many times before was expected. It did only partly. What was missing was a description of the interventions on an operational level specific in the context of a PPP project in spatial development. Time for a case study.

SELECTION OF THE CASES

The case study was conducted in 2009. Because of their expertise, more than 20 professionals were asked if they knew PPP cases in spatial development in which a conflict on feasibility escalated in such a way that the very existence of the project had been on the edge.

The earlier mentioned literature study indicated that in studying negotiations and conflict it is important to make a distinction between a competitive climate (group A) and a cooperative climate (group B) (compare Tjosvold, 1998). Comparing interventions in opposed conditions holds research findings more robust as far as a finding in one condition is not found in the other one (comp. Yin, 2003: 47). So the goal was to select cases with a cooperative climate as well as cases with a competitive climate.
A minimum of two to three cases in each group was required (Yin, 2003: 47) in order to make comparison between cases within a group possible (Yin, 2003: 51).

Twelve cases were recommended by experts after an extensive exploration, even after contacting relations of these experts no further cases were found. Out of these twelve, two cases were rejected; they didn‟t match the requested profile. So ten cases were left. Using the criterion that the respondent from the public side should agree on the qualification of the climate with the respondent on the private side, one case was undefined, one appeared to have an average climate, two cases appeared to have a competitive climate and six a cooperative climate.

RESEARCH PHASES

The case study consists of three phases: Setting up the list of questions, Field work and Analysis.

Phase 1: Setting up the list of questions

The list of questions is structured in three parts:

- The first intended to check whether it is a suitable case;
- In the second part questions are as open as possible and broadly oriented in order to get the picture as complete as possible;
- The third part is directed in detail and made of closed questions.

Phase 2: Field work

In phase two the cases are examined by interviewing key role players:

- First in a number of telephone calls it was figured out who these key role players were;
- Next two, or in a single case three, interviews were conducted in order to gain insight in the circumstances under which the conflict threatened to become dysfunctional and to gain insight in what was done to prevent an escalation;
- Finally transcripts of the interviews were made. On the base of that case descriptions were made. These descriptions were send to the participants for approval.

Phase 3: Analysis

The analysis of the response to the control questions consisted of checking the response on the requirement that this was a case of PPP in spatial development in which a conflict on feasibility escalated in a way that the existence of the project was on the edge.

Analysis of the response to the open questions was focused on essences and not on patterns in or relations between concepts that were used in the answer. Therefore a method was used that consisted of tracing the essences in the answers by underlining text fragments, summarize these and interpret this summary on used interventions. As indicated before an intervention is defined as one or a series of activities on an operational level that in the interest of the project try to prevent a conflict becoming dysfunctional.

The analysis of the response to the closed questions consisted of qualification in terms of Yes, No, +, +/- and -.

The research strategy was to compare cases, so a cross case analysis was conducted. This cross case analysis was based on the data of a single case analysis. The single case analysis is described first.

Because of the limited number of pages of this article, only two out of the ten cases are presented here. They represent two extremes in the spectrum of possible climates: one case in a competitive climate and one case in a cooperative climate.

SINGLE CASE ANALYSIS

The response to the control questions in the first part of the interviews confirms that the cases match the requested profile. The response to the second part of the interviews is presented below. The answers to the third part of the interviews, the closed questions, will be attended in the cross case analysis next to this single case analysis.

The case in a competitive climate

Project and Public Private Partnership
A mid-sized municipality in the Netherlands decides in the nineties to transform the existing center into a modern center attractive to inhabitants of the city and the region. Goal is to unite two areas that are divided by urban barriers. The municipality organizes a competition that is won by a project developer. The first phase of the project requires 150 million euro‟s on investment. The case is restricted to the period prior to the moment of the actual development agreement, early 2000.
Together with relevant parties, including the developer and the investor, the municipality commissioned an architect to design a plan. This plan not only included urban, financial and legal affairs but also the way in which all parties cooperate. At the end of the project the bill will be settled with money left over from subtracting costs from revenues paid by the market. No PPP legal entity is at hand, but a PPP wherein public revenues on land are dependent of private revenues on selling real estate on this land.

Heart of the conflict and escalation
The municipality: „It went wrong in the phase that we had to agree based on a base amount. And we didn‟t agree on this base amount(-). Originally it were some millions, but in the end it was two hundred thousand euro‟s.‟ The developer noticed: „Two hundred thousand euro‟s, you can call that no conflict. But it was a kind of escalation of a long lasting mutual irritation‟.

De developer continues on how the conflict escalated: ‟It was a kind of escalation of a very long process in which we felt: “Guys, this is the limit, it‟s not possible any more, the project won‟t last any longer”. And a municipality that continued to say: “And this has to be added, and that has to be added, and those have also to be added”, anyway that was our perspective. So finally we visited that restaurant, were it escalated. I‟ve never been so angry in my career! A special moment anyway…‟.
The municipality: „We went with a complete delegation from here to eat elsewhere and that didn‟t work: we didn‟t succeeded in any way. Of course we had informed our alderman extensively, but he interpreted it all much to literally. His stake was: “They won‟t get these

two hundred thousand euro‟s!" and he really went to sit on it; he said: "You are really delivering these two hundred thousand, or the cooperation is over!" Yeah, really, it almost went out of control. Finally it was "If you don‟t call me tomorrow morning before half past eight and agree, you will be kicked out!".‟

Analysis of the response to the open questions
Besides general questions about the project and the conflict, four open questions were asked:

1. What was the climate for cooperation over time and how was this created?
2. What actions took place in the realm of feasibility?
3. What actions took place in the realm of the relationship?
4. What actions were taken in order to proceed succesfully?

In the tables below in the first column it is indicated whether a response is given by the Municipality (M) or the Developer (D). In the second column the response to the questions is presented, the essences are shown in italics. In the third column these essences are summarized and, if possible, interpreted as interventions. Interventions are defined as one or a series of activities on an operational level that in the interest of the project try to prevent a dysfunctional conflict (compare De Caluwé et al, 2009).
To make the summary retraceable, it is placed directly beside the essences in italics. In the summary interventions are shown in bold.

The table with the response on the open questions is followed by a table with the response on the closed questions.

	Question 1: What was the climate for cooperation over time and how was this created?	Summarized and interpreted
M	„*Difficult*‟(-) It‟s totally not, it‟s not filled with hatred. But it is sometimes like "Come on, *it really annoys me now*. I‟ve given you all the arguments *that I can think of why I am right and so why you are really wrong", well at that moment sometimes you get irritations".* And on how this was created: „With some developers you agree within a couple of months and that means that you don‟t diverge much of what you have estimated. With other developers it‟s not the same. My lifelong experience with this developer, also from my earlier period, is quite simple: *it goes on and on and on*. According to me it has to do something with the instructions the project staff receives: *"Get the most out of it".*	Tending to competitive by endless efforts to get the utmost out of it
D	„We had, as we experienced it, *a difficult relationship with the municipality.* We *never had a real ambition together* for the plan (-). No, it wasn‟t easy.‟ And on how this was created: „We came closer and closer to that 26 [the deficit]. Always in very tiny steps. And that gave me with this boss very much the feeling of "how can I turn the ship". Sometimes one has also a feeling of lack of power, of not performing well. *We didn"t have something in common, in a sense of: "Let"s do a project together".‟*	Doubtful by a lack of shared ambition

Question 2: What actions took place in the realm of feasibility?		Summarized and interpreted
M	„We always start with a land development sheet. There we fill in the numbers on the revenue side. We then thus hear that this is way too high. All the parameters that are in there, they are *all subject of negotiation.* But then *in the end* on the base of the design, *the cost side dominates*.“	Factors that determine the revenues are negotiable. Discussion finally focuses on the cost side.
O	„It went very much into *detail*. It went along with a large mutual *distrust*. We often said: "This cost about this and this cost about that and then it"s ok" but the municipality they went to sort it out, all details. This fed also a little bit the *distrust* of the municipality as a kind of *"They take it all too easy"*.“	Mutual distrust fed by nonchalance on costs.

Question 3: What actions took place in the realm of the relationship?		Summarized and interpreted
M	„I"ve always learned one thing: (-) if you just talk on a relaxed level, things really go well. And that needs *organizing a climat* and that, also with this alderman, and that absolutely doesn"t always has to be a negotiation. It"s much more fun to get together once in a while. *There must evolve a certain relation and trust between people* and hence everyone that"s sitting there has a certain responsibility to arrange things in a way that what we do agree on. *Only, what you see with developers is that this level between the operational and policy or management part, that it"s unbelievable how far these levels do diverge.* On a certain level *beautiful deals are made and the people that are under it, it"s their cup of tea to execute it. But they get targets…you"ll get sick of* . That"s something that"s never discussed up there, really, but anyhow, it"s not possible to exclude that a war is going on here. *It"s really always the interaction between people that determines whether it"s going to work or it is damned to die.*“	**Informal contact** is needed to generate trust The level of trust differs per level of position due to targets. Working together as a critical factor of success
D	*„Not"*	Not

Question 4. What actions were taken in order to proceed succesfully?		Summarized and interpreted
M	„Meeting off side. In the official meeting it"s tough, and then you think: "this is not getting us anywhere". Next you just take them apart and try to give the other party insight in: "If we stay as stubborn as we are now, the cooperation will be over".“ And specifically on the conflict: „So what happens the next day [after the conflict in the restaurant] before half past eight, or around half past eight, the developer called: "Ok, we do agree".“	In general: **Informal contact** During the conflict: **Give in**
D	„Honestly I think that we didn"t manage the relationship with the municipality at all. *We have more looked outside the municipality* in order to get things right, than to improve the relationship with the municipality. I might admit.“	Geen

The case in a cooperative climate

Project and Public Private Partnership
The case is the development of an area of a big city in the Netherlands. It‟s about 650 houses with an estimated investment of 200 million euro‟s. The private parties were involved through an European tender during the nineties. Finally two developers joined together, an investor and a housing association represented by one project executive: the Developer. The public side is also represented by a project executive; in the following indicated as the Municipality. The case itself is around 2005/2006, in the final stage of contract negotiations.

How risks were divided among themselves is reflected in the following quote: „It‟s rather simple, normally we say: we deliver the prepared land, we equip the public area and take care of the legal and urban procedures. And they take care of the realization of the houses according to specifications that we agreed on. You design an urban plan, we made it together, but it is up to him to really meet the urban profiles of the that we agreed on. Also the number and the categories of houses that we agreed on. These are mainly houses, so normally a municipality has a certain system that means that the price for the land is what is left in the end after selling the houses and other buildings. Here it is different, we did it normatively. We say, yes, of course you can pump up the building costs as much as you want, but this is the price we need for the land. Because we know what happens, otherwise calculations will be so expensive that no price for the land is left.‟ Just as in the former case, in this PPP there is no legal entity for the project wherein risks and revenues are taken public as well as private, but there is a PPP in which public revenues finally are dependent on private revenues.

Escalation and heart of the conflict
The municipality on how the conflict almost escalated: „The first phase was when the developer was just indoors and immediately started about the price for the land. He immediately started a discussion about the senselessness of the way that we calculate this price for the land. I said “we do it in our own way” and he said “that‟s nonsense, you really have to do it non-normative, you really don‟t understand how it works”...well, that‟s not a sensible remark in the beginning.‟

According to the developer the heart of the conflict was in: „We were stuck. We say we are waiting for the non-normative price, they say normative. They say the revenues must be that much, we say it‟s impossible. They say it has to be like this, we say it has to be different.‟ And according to the municipality: „Well, the heart of the conflict was that we estimated their possibility for profit much higher than they did and that they on the other side of course estimated our costs far too low.‟

Analysis of the response to the open questions

Question 1: What was the climate for cooperation over time and how was this created?		Summarized and interpreted
M	„It was *cooperative* (-) There are a few things you can‟t exactly describe, it‟s about *chemistry between people*, that was part of it. Once I had to attend a meeting somewhere in Rotterdam en the developer,	Cooperative by chemistry between people and by

	he lived in Rotterdam. When he heard that I had to go to Rotterdam and that I had my return trip arranged, but not getting there…well, he said "we drive together then and eat something en route". *Than the conversation is about other things…you don"t talk immediately about your work.* That was a very important moment, *…if you only talk to them during meetings, things go wrong.* (-) On the other hand…the municipality is under magnifying glasses; it"s of course *not possible to make hole-and-corner arrangements.* That"s the other side, but what I sometimes observe is that people keep distance out of fear, that occurs. I"m not going to eat with a developer, that"s nonsense. The only thing I can do is to pay my own bill. It"s that simple".	cautious informal contact
D	„*Well, very nice*(-) We"ve had our moments, if I"m honest, but finally it proves to be *that the will to do it together, that settles it.* The climate was influenced at that time by the will of both sides to be successful and after that moment the climate was also very cooperative. A very positive mutual respect evolved and understanding of each other interests (-) The representative of the municipality had of course his political bosses and I had my bosses; that gave a strong relation, as in: "*I'll get by to drink a cup of coffee or when we had a meeting. I"llget by half an hour earlier, is that possible…"* and then also say "but when I do this I"m in that much trouble…that I won"t do", but the representative of the municipality also said: "Yes, I"m stuck here with politics and I do understand that we can"t go any faster, but what can we do next?" What matters is that you *create understanding with the other party* for the problems that you have and vice versa."	Cooperative by the will to cooperate and by informal contact create understanding

Question 2: What actions took place in the realm of feasibility?		Summarized and interpreted
M	„Working on feasibility was making transparent the *cost* side to the municipality and to *give the other party insight* into that and offering them the opportunity to do it cheaper as a matter of fact."	Discussion focuses on the cost side and the back grounds of it
D	„We *negotiated the price of the land* of course. I went through calculations again and again and I thought…the municipality is *exaggerating immensely"*	During conflict negotiating on the price of the land

Question 3: What actions took place in the realm of the relationship?		Summarized and interpreted
M	„You can"t sincerely work *together if the personal relationship is poor.* What is convenient for later negotiations, is that *the business side is connected with the personal side.* So *the art is to do this business side as sharp as possible without a nasty way of talking getting the upper hand*. So you build a relationship in order to make a shared plan. That"s what I mean with the social side…practical things…*you have to visit together things, preparation of the project*...when you	A good relationship as pre condition for cooperation, connecting the business side with the personal, negotiate on the edge in a friendly way and work together on a shared plan. Building a relationship by **Co operation**

	have done all this you can negotiate on the edge. ‟	
O	„By talking, *by understanding what their problem is e*n what we can do…so by creating a common ground…by *creating a shared problem.* So we have searched very consciously in order to find a solution. What we have orientated on is *to keep our relationship balanced,* it‟s also a part of peoples characters, I suppose. As a matter of fact we *appreciated each other* very much in the role we had, so we did *understand* each other.	By understanding the problem of the other party as **Creating a shared problem and solve it**. Next keeping relationship balanced. Appreciation of each other‟s role as pre condition for understanding

Question 4. What actions were taken in order to proceed successfully?		Summarized and interpreted
M	„If you have a difference in price as large as we had….with a difference of 10 million on a sum of 37, that‟s rather dramatic…what you do once again is to *explore things* in a total different way…you investigate *what else you can come up* with…because these 37 million that we asked as the price for the land, were equal to our costs in his case. So my proposition was…as a municipality *we are not going to lose on this one,* as simple as that…this is the end. And in a way this was reasonable. They didn‟t think so and a discussion emerged: "Yes, but we have *done also some calculations* and we think that 37 million is an awful lot of money". Municipalities usually don‟t give any insight in their calculations. We said "*If you can do it for less*…it‟s negotiable". Then they recalculated everything and said: "we think that we can do it for 27 million and then we are even".‟	During conflict: **Confrontation** and **Exploration** **BAWA** - Best Alternative Without an Agreement (Fisher et al, 2004: 123) **Offering an alternative**
D	„I said to my colleague: "If it‟s up to me we are going to tell them tomorrow that we take over, that we take the risk. We have looked very well into it and we want to help you by taking over the risk of developing the land".‟	During conflict: **Taking over the risk of the other party**

CROSS CASE ANALYSIS

Above, two examples were given of how the ten cases were analyzed. In analyzing the ten cases several interventions were traced. Cross case analysis started with making an inventory of the interventions that took place in a cooperative climate next to interventions in a competitive climate and labeling the interventions as concerning feasibility or the relationship, see figure 1.

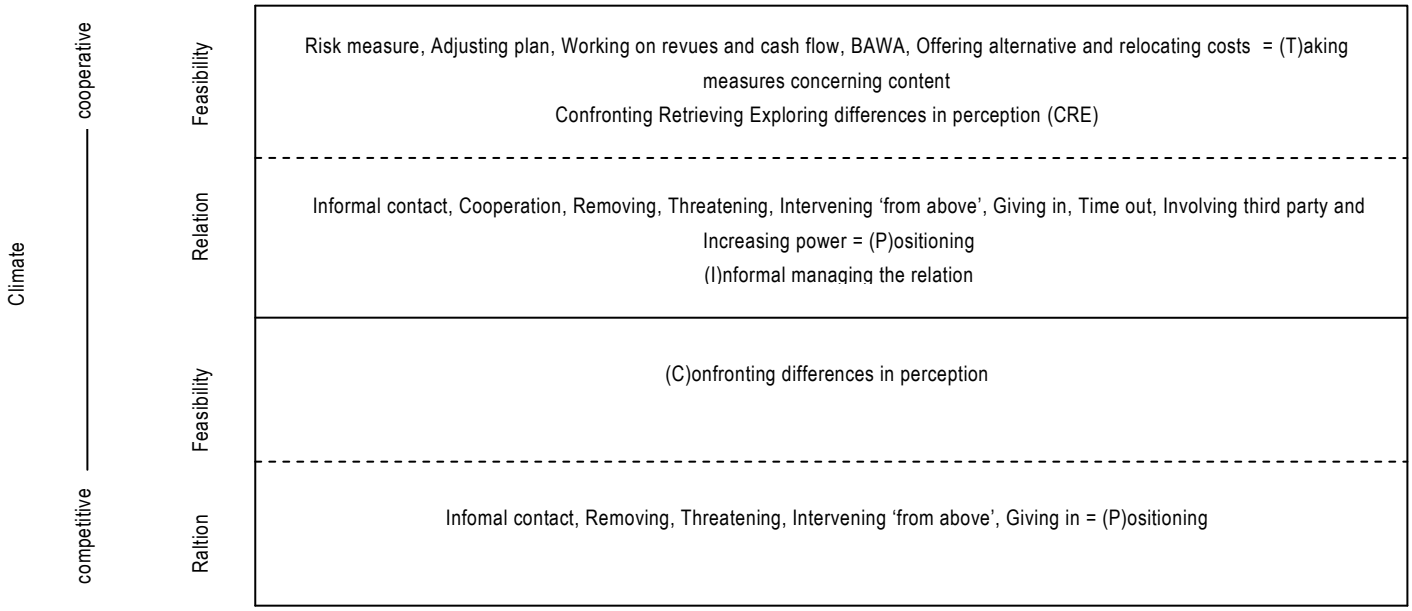

Figure 1: *aced in the case study.*

The figure shows that in a cooperative climate a rich variety of interventions is used, while in a competitive climate the interventions are limited.
It is remarkable that, contrary to a cooperative climate, in the competitive climate only one intervention is found concerning feasibility, namely Confrontation of differences in perception, and several concerning the relationship, namely Informal contact and Threatening, Giving in, Intervening „from above" and Removing. In a competitive climate attention seems to be more directed towards relationship than feasibility.

So, analysis shows that in a competitive climate interventions are more focused on the relationship between the partners than on feasibility, while in a cooperative climate both aspects are equally attended.

Next, the interventions will be described by examples as found in the case study.

Interventions in a cooperative climate
The figure shows that in a cooperative climate intervening in feasibility contributes to preventing a dysfunctional conflict by:

- Taking risk measures such as converting an investment that is depending on revenues to a guaranteed investment or by taking over the risk from the other party;
- Adjustment of the quality or quantity of the plan such as transforming it to other functions or adjusting the number of houses;
- Working on the revenues and the cash flow such as increasing the quality of the houses in favor of the revenues or speeding up the cash flow because of reduction of the cost of interest;
- Prior to the negotiations determining a Best Alternative Without an Agreement (BAWA) (Fisher, 2004: 123) such as cancelling the project if no agreement is

reached;
- Offering alternatives as taking over preparing the land from the other party;
- Relocating costs as cut backs or increasing the price of the land.

In short: by (T)aking measures concerning content (see the figure).

Further Confronting Retrieving and Exploring of differences in perception on feasibility (CRE) proves to be contributing to the prevention of a dysfunctional conflict.

Intervening in the relationship also proves to be contributing to the prevention of a dysfunctional conflict in a cooperative climate by:

- Having informal contact prior to a meeting in order to elaborate on political back grounds of points of view or to brain storm about possible solutions;
- Cooperation such as making a shared problem statement or sketching a plan together;
- If it appears to be necessary: removing a party that undermines the cooperation by reasoning solely from his own interest;
- Threatening such as threatening with the possibility that if negotiations fail the whole project will be taken over or threatening with negative publicity.
- Intervening „from above" such as convincing a minister to make a telephone call to the CEO of the other party;
- Giving in as a way of investing in the continuance of the relationship in the future;
- Taking a Time out in order to give the parties involved a chance to reconsider;
- Involving a third party when negotiations have reached a deadlock such as a mediator or not deciding by yourself but letting your backing decide;
- In case of an unbalance in power giving one of the parties more or less power in order to restore the balance.

In short: by (P)ositioning.

Finally in a cooperative climate it proves to be that preventing a dysfunctional conflict coincides with private conversations, calling at the end of the day in order to coordinate and tune fine, prior to negotiations meet informal, call sometimes in between hours to test ideas, sitting apart for a minute or celebrating mile stones together; in short: by managing the relationship (I)nformal.

Interventions in a competitive climate

In a competitive climate regarding the intervention Confronting Retrieving and Exploring of differences in perception on feasibility (CRE) only the (C)onfrontation of differences in perception takes place, no Retrieving of back grounds or Exploration.

Concerning the relation in a competitive climate partly the same interventions as in a cooperative climate occur, namely Informal contact, Threatening, Giving in and Intervening „from above", all part of (P)ositioning.

CONCLUSION

The research question for this case study was: which interventions are used in practice to prevent dysfunctional conflict in PPP projects in spatial development?

Analysis shows that in practice the interventions (T)aking measures concerning content, Confronting Retrieving and Exploring of differences in perception of feasibility (CRE), (P)ositioning and managing the relationship (I)nformal contribute to the prevention of dysfunctional conflicts. Further, the prevention of a dysfunctional conflict cannot exclusively be related to a cooperative climate, but in a competitive climate the interventions (C)onfronting differences in perception on feasibility and (P)ositioning can also prevent dysfunctional conflicts.

Regardless of a cooperative or a competitive climate, the interventions found are concerning the feasibility of the project or the relation between actors. One moment it proves to be necessary to emphasize feasibility and the other moment the relationship. Therefore it is concluded that in spatial development dysfunctional conflicts in PPP projects can be prevented by balancing between feasibility and relationship. As such it contributes to organizing collaboration.

Abstract

Well meaning high-level construction industry reviews, and recommendations from those reviews, usually lead to many industry development initiatives. Promoting a safer work place and environmentally responsible industry was one of the seven themes under which recommendations were made in Construction Industry Review Committee (CIRC) Report of 2001 of Hong Kong. These were followed with many related initiatives for industry development by industry stakeholders. The findings reported here are part (limited in focus to environmental responsiveness of construction industry) of a wider research project titled 'Construction Industry Development Comparison and Acceleration' (CIDCA) designed to track implementation programmes against the original objectives in the CIRC report and some changing priorities thereafter, actual achievements, drivers, enablers and barriers, residual issues and concerns; in comparison with UK and Singapore scenarios in interlocking studies.

The original CIRC recommendations laid the responsibility of promoting an environmentally responsible industry on public sector agencies with an assumption that the private sector would follow suit. In this regard, a case study of a proactive public sector client was conducted. The data from the case study was supplemented with interviews with key personnel from other stakeholder organisations. The findings reported here identify environmentally responsive initiatives from the case study and isolate high impact initiatives among them. Their implementation is tracked and their impact on the rest of the industry is analysed. Also, key challenges and enablers/ barriers are identified in terms of achieving (i) desired results within the organisation and (ii) desired impact on the industry. Lessons learnt are then discussed with an emphasis on transforming innovative initiatives into acceptable industry norms. The reported findings though specific to the Hong Kong Construction Industry should provide pointers on implementing public sector led initiatives for other countries.

Keywords: Environmentally Responsible Construction Industry, Industry Development Initiatives, Public Sector

BACKGROUND

Despite the recent surge in international focus and universal aspirations, „reduced environmental impact" and „sustainability" are phrases that still trigger apprehensions in many construction contractors, as these are still associated with added and non-reimbursable costs. This is especially true in the private sector where project schedule acceleration and profit generation remain the primary drivers. An effective solution to this problem, as well as a way to gradually change the mindset and culture of the industry, is to have a sufficiently influential public client leading the new initiatives, as a catalyst and test-bed.

Triggered by some ethical and quality control related issues in the Hong Kong construction industry in the late 1990's, a government directed, comprehensive industry review was conducted by Construction Industry Review Committee (CIRC). The review report (CIRC, 2001) made 109 recommendations under seven themes, one of which was promoting a „safer workplace and an environmentally responsible industry". Under this theme, many recommendations advocated a more environmentally responsible industry, with specific recommendations tailored for public sector clients, whom it was expected would become a leading example and catalyze the industry in general.

In this regard, this paper presents interim findings from a case study which targeted one of the leading public sector clients entrusted with championing environmental initiatives in Hong Kong for the construction industry. This case study was part (being limited to environmental responsiveness of construction industry) of a wider research project titled „Construction Industry Development Comparison and Acceleration" (CIDCA) designed to track implementation programmes against the original objectives in the CIRC report and some changing priorities thereafter, actual achievements, drivers, enablers and barriers, residual issues and concerns; in comparison with UK and Singapore scenarios in interlocking studies.

INTRODUCTION TO CASE STUDY

The CIRC report advocated championing of select themes by select public sector clients as mentioned earlier. The case study presented here is of one such public sector client (termed as PSC hereafter). The strategies suggested in the report for championing the themes were to incentivise the adoption of initiatives as well as to link the procurement (tendering opportunities) to adoption and performance of these initiatives by contractors. It has to be noted here that environmental responsiveness initiatives are long term objectives and hence need to be championed for a longer term to demonstrate their impact. Also, they are often not in the commercial interests of the contractor if they are cost intensive and non-reimbursable. From partnering experiences in construction industry (Bennet & Jayes 1995, 1998; Barlow et. al. 1997), it has been demonstrated that in aligning long term adversarial goals, sustainable workload (continuity of work) is the key, along with economy of scale. In this regard, the selected PSC appropriately fits the bill as it is mandated to provide housing for the economically weaker sections of the society, hence a continuous and steady work flow in their domain.

CASE STUDY METHODOLOGY

The methodology followed for this case study was the same as for the other case studies for the wider research project mentioned above. The target institution for the case was identified first, following which the case study was conducted in three stages as described below:

Stage 1: Setting up the Case Study Agenda - This stage consisted of an initial meeting with a few key representatives of the target institution. For this meeting, a list of initiatives that that the research team was aware of as having been implemented and were directly/ indirectly linked to the HK construction industry self improvement initiatives was sent in advance. Target institutions representatives were asked to supplement the items on our list if required, and help us identify a few (3 or 4) initiatives that were perceived as having achieved high degrees of positive impact. In addition, other key personnel from the institution who were involved in implementing these high impact initiatives were identified as possible interviewees for the next stage.

Stage 2: Series of individual interviews on identified high impact initiatives - This was to delve deeper into these initiatives. A series of interviews with personnel identified in the first meeting were set up at convenient times for them, to track how the initiatives were implemented, identify barriers to implementing them and strategies used to overcome these etc. In this stage, access to relevant data in the form of documents, statistics etc was also requested.

Stage 3: Case Study Report Preparation - In this stage data collected from above was analyzed and a report prepared.

The following sections describe the key initiatives identified in the case study, their implementation process and impact on the general industry and discuss the key challenges and drivers in implementing them.

KEY INITIATIVES IMPLEMENTED

Life Cycle Strategies

The CIRC report recommends that PSC‟s are to take a lead in practicing life-cycle costing strategies. Following the CIRC report, the PSC published its very own Environmental Procurement Policies in the same year, seeking to minimize the use of natural resources in main building components and materials. A consultancy study on life cycle costing (LCC) and life cycle analysis (LCA) of various building materials (as well as their respective alternative materials) frequently used in housing projects was completed in 2004. As a result, an in-house database and technical guidelines of the major building materials for the PSC‟s projects was established. A procurement strategy and specifications for more environmentally friendly materials, which are technically and economically viable was also developed (HKHA 2010a).

Based on the study, a software tool for selecting construction materials in terms of LCC/LCA, waste generation, energy consumption as well as environmental impact was made available free of charge to the industry in 2005. Several other public sector bodies have made use of this tool in the design stages of four pilot projects to examine its effectiveness and practicality,

which are currently being reviewed by the industry. The adoption of the LCC/LCA scheme not only aids the designers in project planning stage, but will also offer value for occupants especially in the Hong Kong housing market. The PSC is also responsible for maintenance of its assets. Thus the long term economical values and durability are decisive factors from its perspective. The finished products which utilized LCC/LCA material selection tool have also played an educational role in advising the general public about the environmental and economical benefits from adopting selected building materials. It was hoped that this demonstrated the advantages of adopting this approach to the private sector developers and that they would follow similar LCC/LCA strategies to attract buyer‟s who are concerned with quality products, and long term value for money.

However, the existing database does not fully address the long term strategic directives of the PSC in terms of having a comprehensive performance and economic appraisal/ assessment for many alternative building materials. Such a database requires a full life cycle monitoring and assessment (both financially and environmentally) of the material performance, in which case it must span long periods of time before the result can be obtained. As construction materials vary greatly in substance, function, sophistication and method of construction, an universal LCA assessment methodology has been difficult to establish. Internationally, although countries have developed their own LCA tools, very few of them have linked LCC module (with updated cost information). The highly fluctuating construction material costs require any particular LCC software tool to be updated actively at least monthly to the most current market prices of materials, which again can be difficult (HKHA, 2005).

Recycling and Waste Minimisation

The CIRC report recommends the public sector clients to take a lead in promoting wider use of recycled materials for new construction projects. In recent years, a greater amount of building waste from redevelopment projects is being recycled in construction. The specifications for public works and public housing projects have also been updated accordingly to facilitate the use of recycled materials in building foundation, sub-base in road construction and in concrete that requires less structural strength such as concrete paving blocks (CIC, 2009).

In an attempt to maximize recycled content in new construction, recycled steel from demolished hoardings and recycled concrete are put together to produce furniture for its new projects. In the new Kai Tak development where the old Hong Kong airport was situated, marine mud is being used, after strengthening and stabilizing conditionings, for backfilling at the project site itself. Being one of the largest consumers for concrete and related materials, there is huge potential for the PSC to use recycled aggregate concrete (RAC) in its projects. The PSC, therefore proactively invested in numerous studies before RAC was used in real projects. These studies unveiled RAC‟s structural and chemical properties as well as its suitability in various building applications (HKHA 2010b). With local experiences apparently lacking in the long term properties of RAC in new construction, the PSC explored international experiences and found that RAC, when used appropriately, is comparable in quality to ordinary concrete. With the confidence gained from the review, the PSC is examining the possibility of extending the use of RA in structural concrete as a sustainable building material.

On specific projects, according to the PSC statistics, 1700 tonnes of RA from the demolition of Wong Chuk Hang Estate were used as backfill at Tung Tau Estate Phase 9, and 180 cubic meters of rock core was used in the outdoor areas of Choi Wan Estate (HKHA 2010a). In

total, until 2009, about 3,100 tonnes of RA have been used in the PSC‟s projects in Hong Kong (CIC 2009). Cement replacement materials such as pulverised fuel ash and ground granulated blast furnace slag are also put into the concrete mix to partially substitute cement content in pre-fabricated façades (HKHA 2010b). From the cost perspective, contrary to common public perceptions, the cost of preparing RAC such as setting up and operating crushing facilities to produce RA is in fact comparable with that of transporting and disposing demolition wastes to landfill facilities (HKHA 2010b), while limited landfill capacities pose a related problem.

This demonstration coupled with the rapidly increasing construction material cost, maximizing use of recycled content has become a popular practice in the construction industry in Hong Kong. The apparent and significant cost saving gained, drives its usage to increasingly higher levels. In addition, the levy of landfill charge scheme implemented by the HKSAR government will further incentivize developers and contractors to turn construction and demolition wastes to their respective recycled usages. However, the perceived high cost of crushing RA and the limited sources (government is the only supplier of RA for the time being) of purchasing RA are two main obstacles in its propagated implementation. Due to the latter, contractors may be exposed to higher liability as they are unable to control the source of RA and subsequently the performance of RAC. Therefore, a fully commercialized and regulated supplier of RA is needed.

Prefabrication

Prefabrication in construction has a number of advantages in terms of environmental responsiveness such as reduce (i) noise, (ii) construction waste and (iv) pollution. Greater use of pre-fabricated components was also called for in the CIRC report. In response to that and in addition to the conventional precast elements that were already in use, the PSC piloted the use of other non-conventional building elements such as volumetric precast bathrooms, and precast lift core as a holistic unit in such a way that things like waterproofing, M&E semi-fittings are all completed off-site. Aside from its sustainability benefits, volumetric precasting offers easy and fast assembly procedure, better quality control, and cost saving in the long term if implemented in large quantities. In addition, prefabricated facades are already used extensively in the PSC‟s projects.

However, the initial investment in product development has hindered the popularity of prefabrication. In addition, the absence of a local manufacturing industry adds additional transportation costs for the precast elements to be transported from factories in Mainland China. Therefore, unless proven long term cost saving is observed which requires economy of scale, it may be difficult for many private clients and contractors to adopt more prefabrication. In this case, having an influential public sector client to take a pioneering role becomes especially critical, while a long term and strategic commitment from such client for its promotion, testing and use is essential.

Green Design

The CIRC report specifically called for wider use of green designs in the PSC‟s projects. The PSC introduced its first departmental environmental objectives in 1999, and subsequently updated it to reflect rapidly developing environmental perspectives as soon as the needs arose. These objectives are the guidelines and also drivers of many initiatives implemented by the PSC. Some of these are described below.

Micro-climate study has been introduced since 2001 on all the PSC‟s projects to refine design to ensure optimized use of natural features at that particular location, and to implement appropriate sustainability measures. The design initiatives are then measured at the completion of the project to check against its projected effectiveness. These have hitherto shown positive results.

The PSC places strong focus on maximizing the comfort level and well-being of residents. In achieving it, new standards of greening have been put in place. The current guideline specifies that for every 15 domestic housing units built, at least one tree has to be planted; and for every housing development project, a greening ratio of no less than 20% to 30% is to be followed (HKHA 2010a). In addition to greened rooftop planted with self-maintainable vegetations in newly built low-rise estates, vertical green panels are also being installed to increase the greening areas. Vertical green panels not only provide increased areas of greening, but also help to reduce the heat of the concrete wall behind it by up to 16 degrees Celsius and thus lower the interior temperature (HKHA 2010a). These greening initiatives reduce heat island effect and energy consumption, and also enhance noise absorption to abate noise pollution in the estates.

Other green measures that the PSC has adopted in pilot projects include installation of photovoltaic systems, solar water heating systems, wind and solar hybrid powered street lighting. As these initiatives are still in their early testing stage, the high initial investment as well as the intangible and uncertain ROI (Return on Investment) is a key challenge for them to be extensively adopted.

Procurement

A large part in the above mentioned relevant section of the CIRC report was devoted to the suggestion to give weight to environmental performance in assessing tenders and performance of contractors. In response, the PSC has incorporated environmental aspects into its procurement process starting right from the tender stage. An „Environmental Management Plan‟ from contractors is now mandatory for demolition, piling, building and civil contracts. In the tendering process, additional credits are given to those with environmental proposal that exceed the basic contractual requirements. More weights are inserted into the Performance Assessment Scoring System (PASS) which was developed by the PSC to maintain the standard of works for its new building works projects in 1990. Its main functions are for work performance monitoring, registered contractor list management, and for streamlining tender process (Tao 2009).

Of the eight assessment categories in the PASS criteria, section F measures contractor‟s performance in terms of environmental, health and other related provisions. Assessed on a quarterly basis, the scores of a particular contractor performing work in a project are then totalled and calculated (Tao 2009). The score, together with other past performance scores, will then become part of the assessment criteria in subsequent project tenders submitted by this particular contractor. The PASS system is updated and improved from time to time to reflect the concurrent needs and focus areas of the industry. With the implementation of “pay for environment” scheme mentioned in the next section, the PASS score is more of a reflection of the contractor‟s obligated efforts in optimizing the environmental performance of the their respective construction discipline. In the private sector, some clients, although may not be as aggressive, are following the public sector in terms of placing a strong focus in environmental aspect of the construction in the tendering and contractor assessment processes.

A new procurement method which may potentially place more focus on sustainable design and construction was developed and implemented by the PSC in a pilot project. The PSC calls this new approach the "three envelope system". This is distinct from the now common "two envelops system" by adding a third envelope which proposes innovative ideas and technologies with the associated costs (Fung 2010). The new system opens the door for more environmentally innovative designs and building technologies. The majority of the accepted innovations in the pilot project contributed towards improved sustainability. However, concerns have been expressed over this new approach by designers and contractors that they may lose a competitive edge by disclosing their technologies in this system, especially in the case of a losing tender.

Construction Nuisance Mitigation

A number of initiatives derived from construction nuisance mitigation objective outlined in the CIRC report were implemented by the PSC in recent years with an encouraging response from the industry. One of these is the integrated "pay for safety, environment and hygiene" scheme introduced in 2003. Aside from encouraging better safety and site hygiene initiatives, the program incentivized contractors to translate adequate measures under the project‟s Environmental Management Plan into responsible actions without having to sacrifice profits. Such Environmental Management Plans address various issues such as noise control, water pollution control, dust control and protection of existing facilities, depending on the nature and location of the particular project. While meeting these main objectives, the scheme indirectly promotes a healthy tender process in a way that contractors bidding for the project would not need to cut corners to meet environmental requirements during the construction process, as may be later set by the clients.

With positive responses from the industry, particularly contractors, similar schemes have also been adapted by some progressive private sector clients. The Construction Industry Council (CIC) of Hong Kong has published guidelines in this regard (CIC 2008), hoping that the rest of private sector clients will soon catch up and thus transform it to become a norm in the industry.

Promotion of Public Awareness

New initiatives need to be accepted and appreciated by the people who are using and benefiting from them. The CIRC report recommended promoting public awareness of energy efficiency and wider adoption of energy efficient designs a priority. In this regard, the PSC works closely with other government departments, district councils and institutions to facilitate exchanges with the communities. Forums and workshops are also conducted at the design stage of its projects to encourage public engagements. Also, post completion review workshops are held with the residents and contractors, as a way of understanding the performance of green technologies and materials – and assessing whether they have achieved design objectives and expectations (HKHA 2010a).

Tenant‟s involvement in greening their own estates not only can contribute to fostering a better environmental community, but also plays an effective role in promoting environmental concepts in the community at large. Launched in 2007, the Action Seedling program provides tenants the opportunities to nurture and raise plants until they are mature enough to be transplanted as part of the greening in the estates. In the past year, over 15,000 seedlings have been nourished and eventually moved to community gardens in various estates (HKHA 2010a).

KEY CHALLENGES AND DRIVERS

The impact of championing the above initiatives on the industry as a whole has been mixed, as described under individual initiatives. Cost intensive initiatives have been slow to be cross pollinated to the private sector. This is probably because many of these initiatives involve new technologies which require investments and the fact that the benefits of some of these initiatives are yet to be demonstrated as they can only be proven in the long run. Therefore, the initial costs are considered as a barrier. Suggested remedies include subsidies to the industry until the initiatives are widely propagated and become the norm.

Within the public sector, it was felt that commitment to environmental initiatives is the key driver to promote them. The PSC is ready to bear additional costs in demonstrating them in pilot projects but foresees that it can only sustain them if they can show cost advantages in the longer run. It was also felt that the contribution of these initiatives to the society has to be clear and acceptable to the general public if they are to be sustained. The success of many of the initiatives has been attributed to linking procurement (tender opportunities) to performance scores. Another key driver that is important to the extensive implementation of environmental initiatives adopted by the PSC is the support from CIC, the industry"s coordinating body, which needs to effectively educate the industry by disseminating information about the initiatives, their advantages and successes.

CONCLUDING OBSERVATIONS

This case study analysis indicates that in general, it is observed that industry wide implementation of many environmental friendly initiatives in the construction industry is step-by-step "work in progress". Most of the initiatives are at the initial stage, with benefits of some being still to be demonstrated. Initiatives such as "pay for safety, environment and hygiene" experience less obstacles to be employed by contractors, because costs are borne by committed clients and have been highly successful. Since nearly all the public projects are now exercising this scheme where applicable, it is hopeful that with the catalyst of CIC"s published guidelines, it is likely to be transformed into an industry norm in the near future.

The PSC has taken an important step forward by pioneering and investing in practicing LCC/LCA exercises which provide a solid foundation and material database for future use. Fostering an environmentally responsible culture is further enhanced by periodically updating procurement and tender systems in such a way that environmental requirements reflect the needs of the developing market. Objectives, inputs and outputs of the most current R&D programs should be geared accordingly. However, the barriers and challenges in driving environmentally responsible industry forward need to be noted and addressed. Although due to the inherent characteristics of each environmental initiative, the challenges are different, what they share in common is that it requires a persistently long term commitment from the investing client. Therefore the industry needs such proactive clients with a responsible vision of the future and a willingness to "test the water" and invest money and efforts to foster an environmentally conscious industry.

ACKNOWLEDGEMENTS

Abstract
Brazilian Trade Contractors (TC), or Subcontractors and Specialty Contractors, are main players in the Brazilian Building Industry competitiveness. They are part of a highly fragmentized and informal chain, with a great diversity in their value propositions and in their organizational forms. Nonetheless, despite their heterogeneity, most of them are SMEs lacking resources, capabilities, and other assets. This lack of assets and a competition led by the lowest bid offering produces the bankruptcy of 50% of them in their fourth year of operation, with negative consequences in the competitiveness of the whole Industry. Hence, understanding the causes of that performance is an important issue to improve TC management practices and, consequently, their performance. This paper focuses on internal factors, specifically, on the internal processes that allow Trade Contractors to achieve a good performance in their specific competitions. For this purpose, data were gathered from a qualitative research in 24 Trade Contractors with good performance and in 7 other agents that hire them, mainly in Sao Paulo - Brazil. Two are the main results: First, fourteen processes conducted by TC were identified. Second, those processes are performed in different configurations in accordance with different value propositions and size of the TC.

Keywords: Trade contractors, subcontractors, competitiveness, process, Brazil.

INTRODUCTION

The Construction Industry is a fundamental sector of the Brazilian economy. It is composed of agents that perform construction activities, industrial activities associated with it (suppliers of raw materials and equipment for the construction process) and support services (CBIC, 2001). In it, the construction activity accounts for 61.2% of the GDP in the industry - or US$ 76 billion - and 69.3% of its workforce (Abramat, 2010). The main agents that perform the activity are the construction companies and Trade contractors (TC), known as subcontractors and specialty contractors (Oviedo Haito, 2010).

Between these two agents, TC is very important for its systemic impact on the sector performance. This importance can be illustrated by the fact that they have a significant

participation in the sector with over 350,000 companies operating in it (Cardoso et al., 2007), which are mostly micro, small and medium businesses - SME, 93% have less than 29 workers (Cardoso et al., 2007). Their participation is paramount in the production process of the 'building product'; besides, TC are important to projects success (Haltenhoff, 1995; Love, 1997) and also increase the sector competitiveness requires to update TC technological and managerial capacity (Cardoso, 2003).

Despite this importance, in Brazil, 50% of TC go bankrupt in their fourth year of operation (SEBRAE-SP, 2008), due to deficiencies in internal and external factors.

Oviedo Haito (2010) summarized the deficiencies related to internal factors of TC. The lack of resources and competences or even the the lack of strategic assets (Amit and Schoemaker, 1993); understanding them as "a firm-level factor that has the potential to contribute economic benefits [to the company]" (Galbreath, 2004, p. 106). One of such assets is the Organizational Capital, and also the processes performed by the firm.

In a related research, as an external factor, Oviedo Haito (2010) found that a general perception in TC is that the agents that hire them impose predatory conditions for their survival in the market, being the relationship with its contractors antagonistic (Hinze and Tracey, 1994; Kumaraswamy and Matthews, 2000) and paradoxical, since their contractors impose high requirements, but hire TC at the lowest price (Pereira, 2003), and the poor conditions provided for many prime contractors at the construction site prevent TC from achieving the desired results.

In this context, those requirements are expressed in terms of quality, scope, time and cost (Kale and Ardity, 2003; Kormaz and Messner, 2003), while the adverse working conditions in construction sites refer mainly to the physical space for production, the means and space to transport materials and workers, the unfinished products of other trades, and changes in technical sequences of site works (Oviedo Haito, 2010).

In this Brazilian TC context, how do they organize in order to achieve a good performance in their specific competitions?
The aim is to contribute to fill the gap of TC's organizational knowledge and to discuss which processes TC of good performance deploy in Brazil. Due to the importance of this matter, other organizational dimensions are out of scope.

THE PROCESS APPROACH OF A FIRM PERFORMANCE

Mastering the factors that determine a firm's success is every manager's dream. Activity-based view as in Porter's 5 forces (Porter, 1980) and Barney's resource-based view (Barney, 1991), are the main conceptual theorizations of how firms attain success in the market (Ramos-Rodriguez, Ruiz-Navarro, 2004). In those theories, a superior performance, the so-called competitive advantage (Porter, 1985) or the Sustainable competitive advantage (Hoffman, 2000) results from different sources, such as the activities they conduct, or from what the firm have to do to reach their results.

On the other hand, as it occurs also in Brazil (SEBRAE-SP, 2008), Schaufelberger (2003) argue that the Construction Industry has the third highest rate of bankruptcy among all industries in the United States. Moreover, Thornhill and Amit (2003) outlined the value of

studying businesses failures as a source of knowledge about firms performance, and not only from studying their success. In this sense, among others, works by Schleifer (1987), Russel (1991), Kale and Arditi (1998) and Schaufelberger (2003) converged on some internal and external factors related to the failure of the Construction Industry firms, specially Main contractors and Trade contractors.

Based on those works, among the internal factors, Oviedo Haito and Cardoso (2009) pointed out as weaknesses in their business and production management, lack of resources, oversight relationship with customers and other agents involved in their external environment, and limited bargaining power caused by the large number of TC and their lack of associative forms, as in unions. Among the external factors, Oviedo Haito (2010) outlined the conditions of construction sites and the conditions of competition imposed on TC. Also, Kale and Arditi (1998) discussed that organizations are open systems with the mission of transforming inputs into outputs in an efficient and effective manner. Those authors highlighted two factors, or key processes to the firm survival: 1) to receive enough inputs from their environment (external processes) and 2) to have the capacity to transform those inputs into outputs (internal process).

But TC compete in building different trades and, thus, in different competitions. Based on Porter's work (Porter 1980), Kale and Arditi (2003), and Kormaz and Messner (2003) described that the competitive positioning of the firms of the Construction Industry is determined by mode (cost, time, quality and innovation) and by the scope of their specific competition (segment, mix of products and clients, etc.). Hence, different factors are required for different competitive positioning.

In addition, Oviedo Haito (2010) discussed that TC are service firms. To Vargo and Lusch (2008), service firms reach the value of the service with the co-production of their clients. This is applicable to TC, because their performance in cost, time, quality or innovation depends on adequate conditions such as: well finished previous trades, adequate information about the work done, an adequate supply of materials, and so on; provided by other agents involved in the production process.

Because of that, TC can only propose a potential performance, a promise that the firm makes to clients to deliver a particular outcome (Bititci et al., 2004). That promise is the value proposition of the firm. Oviedo Haito (2010) discussed that, to TC, that value proposition is composed of several factors such as resources, competences, activities and performances that are part of the firm and that can be delivered to their customers for the production of their specific trades.

Therefore, what factors must be considered to analyze TC performance? Porter´s (1985) activities or Barney's (1991) resources? Alternatively, Ray, Barney e Muhanna (2004, p.35) stated: "*Activities, routines, and business processes are the mechanisms through which resources and capabilities get exposed to market processes where their ultimate value and ability to generate competitive advantages are realized*".

Hence, a process approach to studying firms, such as TC, is useful to investigate TC performance. It also has another advantage; the analysis of firms on a process-based view (Gruchman, 2009) allows linking other factors such as resources, competences and activities for each process identified.

For a Main contractor, Lu, Shen and Yam (2008) concluded that a good performance is related to mastering factors such as Project Management, Organizational Structure, Organization Resources, Competitive Strategy, Relationships, Bidding Techniques, Marketing and Technology.

For Parung and Bititci (2006) and to Galbreath (2004), factors such physical assets, financial assets, organizational capital, relationship capital, human capital and reputational assets, are factors generating value to the firm. By developing a model to understand construction firms performance, productivity specifically, Thomas et al. (1990) analyzed construction firms as open conversion systems, relating factors such as labor, capital, material, equipment, organizational structure, products and projects, among others, with three generic stages: input factors (e.g. physical resources), internal environment factors (e.g. organizational competences), and output factors (e.g. performance, reputation).

One can thus say that factors such as physical assets, financial assets, organizational capital, relationship capital, human capital and reputational assets can be used to represent that a firm has to reach a certain performance and, from this, to represent their value proposition.

Specifically, based on works by Shimitzu (2003) and Pereira (2003), Cardoso (2003) found nine processes performed by Brazilian TC, namely: Planning and Management, Commercial, Design, Production Planning, Human Resources, Occupational Safety and Technical Assistance.

Nevertheless, according to the works by Schleifer (1987), Russel (1991), Kale and Arditi (1998), Stewart et al. (2003), Schaufelberger (2003), Lu, Shen and Yam (2008), and Maneschi and Melhado (2010) - in Construction Industry - and the works by Amit and Schoemaker (1993), Eisenhardt and Martin (2000), Thornhill and Amit (2003), and Flamholtz e Hua (2003) - in management science-, firms success depends on how firms can capture more resources from their external environment and, in an efficient and effective manner, transform them into outputs to meet the requirements of their specific competitions.

For that, as a way of improve their performance, Oviedo Haito (2010) discussed the importance of TC to execute functions such as: Information Technology (Stewart et al., 2003), Financial and Accounting, Research and Development (R&D), Marketing (Slack et al., 1996), and to divide the design process into Product Design and Design for Production (Maneschi and Melhado, 2010).

Consequently, Oviedo Haito (2010) outlined the importance of managing 13 processes, namely: Planning and Management, Commercial, Information Technology, Technical Assistance, Marketing, Financial and Accounting, Procurement, Product Design, Design for Production, Production Planning, Human Resources, Occupational Safety, and Production Process. Table 1 shows a summarized description of these processes. It is important to mention that processes such as legal, R&D, among others, are important. Nevertheless, they are not always feasible for Brazilian TC, specially for SMEs, as discussed by Oviedo Haito (2010).

Process	Description
Planning and Management	Management of strategy, objectives, division of labor and bussines management indicators (physical and financial)
Commercial	Management of contracts life cycle of building trades, from bidding,

	formalization, execution and closing.
Information Technology	Management of a support system for decision-making and management of the documentation of their information
Technical Assistance	Management of customers´ satisfaction related to the product built and its performance
Marketing	Management of the relationships of TC with their external environment (e.g. customers, suppliers, etc.) as to assets development
Financial and Accounting	Management of financial transactions, accounting and tax issues related to TC business and operation
Procurement	Management of internal and external logistic efforts (acquisition of goods and services, transport and distribution of materials on site, etc.)
Product Design	Management of the design defining physical attributes for the trade to be built
Design for Production	Management of the design defining the main characteristics and conditions of what the trade will build
Production Planning	Management of the strategy for the execution of trades and management of its requirements in terms of resources and competences
Human Resources	Management of people in the firm
Occupational Safety	Management of safety and health at work and its suitability with existing regulations in force
Production	Management of the conditions and of the organization for the execution of the trade, as well as its conservation and the preservation of other existing trades

Table 1: *Identified Processes for Brazilian Trade Contractors (OVIEDO HAITO, 2010)*

Therefore, assets composing value proposition and processes performed by TC are used to understand some TC sources of competitive advantage.

RESEARCH METHOD

For this research, we had a main question: how is good performance in TC are? In order to approach it, we studied what processes TC perform and their relationship with a number of factors. The research method used was a qualitative research involving twenty four TC and seven other agents that hire TC. All of them were selected by purposeful sampling (Coyne, 1997), specifically, by Intensity sampling (Patton, 1990) from good performance TC. Data was collected in open and in semi-structured questionnaires.

The research has two main stages. First, we inquired seven agents who hire TC, being one Construction Project Manager, two Construction Quality Managers, a Construction Technical Manager –all of them from top Brazilian Main Contractors–, a consultant on SME issues, a Product Manager from a Construction Mortar manufacturer, and a representative of an association of laminated flooring manufacturers. They were questioned on: 1) What good performance characteristics do TC have? and 2) What building trades are best performed in São Paulo?

Analyzing their answers, we got a list of 18 building trades, and we understand that there is not a convergence about what characteristics define good performance for a TC. Even more, we understand that the factors they use to evaluate good performance are primarily related to cost, time, quality and scope, and on what assets TC have to build their trades, case by case.

In the second stage, we associated those assets to what Parung and Bititci (2006) and Galbreath (2004) considered as strategic assets and, in order to choose what TC to research, we sought acknowledged TC for their good performance in their specific trade. Then, TC were questioned about what processes they deploy to perform their specific trades. We interviewed TC representatives from company directory, such as the owner or a representative who knows how the firm works. As not all of the TC representatives interviewed had higher education, they were not asked directly about what processes they deploy. Instead, they were questioned about some activities related to some of the processes studied. For example, for the production planning process, they were questioned about what kind of preparations they have before the execution of their specific trades.

Interviewed TC were asked about the identified factors: assets that compose their value proposition (Parung and Bititci, 2006; Galbreath, 2004; Bititci et al., 2004), the age of the firm (Kale and Arditi, 1998), the size of the firm, the time they spend in producing their building trades; and asked about the processes they deploy (Oviedo Haito, 2010).

Data gathered were tabulated, and the identified factors were compared against the 13 processes proposed by Oviedo Haito (2010).

As a result, we interviewed 24 TC that build trades included in the 18 building trades recommended by the agents that hire them. Table 2 shows the data collected.

RESEARCH ANALYSIS AND RESULTS

Firm	Building Trade	Firm Age (years)	Number of employees	Production Time (month of 22 days)	Firm Size	Physical Assets	Financial Assets	Organizational Assets	Human Capital	Relational Capital	Reputational Assets	Quantity of assets	Procurement	Human Resources	Production	Commercial	Technical Assistance	Financial and Accounting	Production Planning	Occupational Safety	Planning and Management	Marketing	Design for Production	Information Technology	Product Design

Note: SEBRAE-SP (2008) criteria for firm size: Large (> 100 employees and turnover > US$ 1.33 million), Medium (99 < employees < 50 and turnover < US$ 1.33 million), Small (49 < employees < 10 and turnover < US$ 133.333), Micro Small (employees < 10)

Table 2: *Characteristics of 24 TC studied (Adapted from Oviedo Haito, 2010)*

By analyzing data from Table 2, we found:
a) Even for TC that perform the same building trade, the factors investigated (firm age, firm size, firm assets / value propositions and firm production time) vary without an identified pattern, showing the heterogeneity of TC in what do they do and the heterogeneity in their proposal of assets to build their trades. Despite this disparateness, we found that TC perform different configurations of the 13 processes investigated.

b) Regardless of the different factors studied, we only found that there is some relationship between the 13 processes and the size of the TC, identifying a tendency that the more employees the firm has, the more processes they perform.

Another issue we found is that the frequency of the processes identified varies, and we can classify the sample studied into four categories:

1) Processes always performed by TC (Procurement, Human Resources, Production, Commercial, Technical Assistance); related to the core of the production capacity of TC, from gain a bid, procure the people and resources, produce it, and to the warranty of the building trade.

2) Processes almost always performed by TC (Financial and Accounting, Production, Planning, Occupational Safety); associated to a major concern of TC with regard to the consequences to the people of the company and their performance to their external environment. Those processes are strongly linked to the production process.

3) Processes frequently performed by TC (Planning and Management, Marketing, Design for Production); related to a major concern about the firm organization, about the relationship of the TC with their competitive environment, and to the improvement of their results through implementing support activities.

4) Processes not often performed by TC (Information Technology, Product Design); being other support activities, and their practice is not generalized among TC. They are related to the necessity of formalize the communication across the organization and, mainly, with the production team through more detailed specifications.

So, we can say that Brazilian TC have four organizational stages: 1) oriented to control their production capacity; 2) oriented to control the impacts of their production on their interested parties; 3) oriented to control the impacts of their production in front the performance expected by their external environment; and 4) oriented to control the firm organization and, mainly, to control the quality of the information across the organization.

Therefore, despite this heterogeneity in TC characteristics, one can say that there is a core of processes performed by TC (Procurement, Human Resources, Production, Commercial, and Technical Assistance) and, from them; the TC deploy others in order to meet their competitive environmental demands.

Now, by analyzing supply of strategic assets, we understood:

There is no relationship between the firm size and the scope traded, or the age and scope of the company marketed. It depends on the strategic positioning of TC.

Despite the difference between the assets they offer, all the studied TC offer the manpower to produce their building trades. The second scope, reputational capital, was the most supplied, which indicates that most of TC are hired by references to their good performance in previous services. The third element commercialized corresponds to the financial asset, which indicates that the TC prepare their bids based on their ability to finance their own production.

Fourthly, we have the organizational capital and physical assets. This lower amount of the supply of those assets can mean that many TC are hired just to perform their building trades, and the contractor provides the physical means necessary for production. In the case of organizational capital, one of the reasons identified for the TC not providing such capital was that the Main Contractor assumes all production management, subcontracting only the provision of means of production that will be managed directly by them. An example is TC12, which expressed that he only recruits and provides manpower to perform masonry walls

The asset less provided by these companies is the relationship capital. Some causes were identified as the lack of bargaining power, lack of collaboration in networks or trade unions, and lack of support obtained from external agents.

Thus, by analyzing the variation of assets and processes owned by TC, we understood that those elements are not randomly configured, but they are established to meet the requirements of their competitions. That response can be delivered or undelivered, and we also understood that the configuration of value proposition in TC is a response that can be managed within another process. Hence, the core of the response given by TC to their environment (in terms of what assets they offer to build their trades) is defined in the 14th process, the Strategic Process.

CONCLUSION

Researching organizational issues, especially TC, is a major challenge. This is mainly due to the heterogeneity of the trades built by TC and because of the diversity in the set of resources and competences needed by TC to build their trades. Nevertheless, 14 processes defining TC performance are found, specifically: Strategic Process, Planning and Management, Commercial, Information Technology, Technical Assistance, Marketing, Financial and Accounting, Procurement, Product Design, Design for Production, Production Planning, Human Resources, Occupational Safety, and Production Process.

Also, the process approach used to analyze different types of TC was useful to identify some patterns. In this sense, despite the TC specific trades built, our approach allowed finding:

- What TC do, in terms of processes deployed, to build their trades;
- What kind of TC their clients want, as a function of what do they do;

Thus, by studying the TC processes, four processes profiles were found, essentially related to the size of the TC analyzed.

Different sets of processes were understood to be related to different value propositions and that the value proposition of TC is defined, in a manner delivered or not, by a Strategic process. In addition, it was understood that TC are heterogeneous. Hence, the fact of their

developing more processes or of offering more assets in their value proposition, does not mean that they are more capable, but more adequate to compete in their specific competitions.

As in other countries, Brazilian TC are mostly SME and face similar challenges to its worldwide peers. One of them is the challenge of growing. Consequently, we can say that issues as the organizational development is a similar one. By analyzing the set of processes a TC deploys is a way to approach this issue.

So, in order to improve their results and their competitiveness as a consequence, TC must set a determinate set of processes, in order to equilibrate their organizational development stage with the requirements of the specific competitions they participate. That equilibrium can be reduced to two aspects: 1) to produce, and 2) guarantee the adequate quality of their (larger) production scale.

This paper limited the discussion to the processes performed by TC. Related issues such as the resources, competences and specific activities identified in the TC studied are out of the scope of this paper. In spite of that, we encourage the development of that kind of research, mainly because those elements allow TC to deploy their processes, in a competitive manner. Another limitation is the scale of our research, which affects the consolidation of the profiles of processes deployed by TC.

Abstract
The positive nature of partnering to resolve adversarial relationships in the construction industry is well-rehearsed. However, critics have argued that espoused benefits of partnering have not materialised because business-as-usual prevails. Furthermore, some scholars insist that more needs to be done to analyse the practices of partnering by scrutinising more deeply the emergence of inter-organisational collaboration. This study examines a contemporary, emerging collaboration, which initially sought to investigate effective knowledge sharing during the early stages of a real-life collaborative venture between three infrastructure companies. The case study was based on participant observations and interviews with key people involved in forming this collaborative venture. Findings reveal a number of paradoxes that are perplexing on the one hand, yet generative in terms of actions on the other. These paradoxes relate to the three areas of sensemaking, formal methods and time synchronicity.

Keywords: collaboration, paradox, observations, sensemaking, time synchronicity.

INTRODUCTION

Advocates of partnering have often claimed that effective collaboration reaps benefits of improved productivity, waste reduction and better client satisfaction (see e.g. Loraine, 1993; Bennett and Jayes, 1998; Construction Industry Institute, 1998; Black *et al.*, 2000; Proverbs *et al.*, 2000; Naoum, 2003; and Wood and Ellis, 2005). At the same time, partnering promises the possibilities of bridging the age-old gap between the key social actors (i.e. clients, designers and contractors), as well as integrating ever more complex supply chains, in construction (see e.g. Latham, 1994; Egan, 1998; Akintoye *et al.*, 2000; Vrijhoef and Koskela, 2000; and Saad *et al.*, 2002). Despite the somewhat intuitive claims of the wonders of partnering, and repeated exhortations of how partnering can arrest the problems associated with fragmented relations in construction, there are still gaps in understanding how inter-organisational collaboration in construction really works (see e.g. Wood and Ellis, 2005;

Bresnen, 2007; Gadde and Dubois, 2010; and Bresnen, 2010). Critical scholars have highlighted how the realities of collaborative working are often detached from rhetorical claims of its positive nature (see e.g. Bresnen and Marshall, 2001; and Nyström, 2008); some question whether benefits can really be delivered to all stakeholders involved (e.g. Green, 1999; and Dainty *et al.*, 2001), whilst others argue that the status quo of adversarial working relationships persists (e.g. Briscoe and Dainty, 2005). There is also greater acknowledgement of the limits of prescriptive notions of partnering (e.g. Beach *et al.*, 2005; Phua, 2006; and Chan *et al.*, 2006), and growing acceptance that partnering in construction is simply elusive (e.g. Bresnen, 2009).

Nonetheless, supporters and critics of partnering in construction share one common feature. That is, the arguments rallied for and against the use of partnering have implicitly focussed on the essence of partnering (i.e. *being*), and rarely examined the process of how partnering comes into being (i.e. *becoming*). So, on the one hand, partnering is treated as a desired concept fiercely defended by its proponents, such that explaining the pre-requisites, components and performative goals (see Nyström, 2005) appears to be their central mission. On the other hand, opponents tended to question the validity of the concept of partnering by emphasising the failure by advocates to demonstrate the existence of partnering arrangements and associated benefits in construction. Both camps have thus taken the concept of „partnering" for granted, and neglected a deeper understanding of how the concept – incoherent and shifting as it is – comes into being. To put simply, how does partnering practice emerge to become „partnering" as we know it in these debates?

This article draws on the analysis of participant observations in a single case study. The study sought to make sense of emerging practices (see Bresnen, 2009) entailed in the formation of a new partnership through participant observations. The main objective of the article is to provide a better understanding of the processes of how inter-organisational collaborations come about (see Cousins, 2002; Bresnen, 2007; Bresnen and Marshall, 2010). In this article, perspectives of collaborative working are initially outlined, which traces the key debates of disconnections between the rhetoric and reality of partnering in construction. The review highlights the need to refocus the attention on the process, rather than the essence of, partnering. Thereafter, the background to the case study and details of the participant observations are presented. Finally, findings from the analysis of the observations are discussed, which reveal three main paradoxes that are noteworthy, including the paradox of sensemaking, the paradox of formal methods, and the paradox of time synchronicity.

Perspectives of partnering: two sides of the same coin

Calls for reform of the construction industry have become, certainly in the Western world, a regular feature since the post-WWII era (see Murray and Langford, 2003). Such restructuring consistently points towards the need to move away from adversarial working relationships towards developing more effective forms of collaboration, encapsulated in the contemporary agenda of partnering (e.g. Latham, 1994; and Egan, 1998). In this section, the literature on partnering in construction is reviewed under two main streams. The first deals with the *aspirations and mechanics* of partnering since it is hailed as a universal panacea to cure the ills of the industry. Critically, the second stream serves as a counterbalance to highlight *problems with the desired state* of partnering. Through a review of the salient points of the construction partnering literature, an argument is put forward to shift the attention away from essentialist views of partnering to examine the *practices* of how the partnering process comes into being.

Aspirations and mechanics of partnering

The introduction of the language of partnering seeks to invoke the reshaping of working relationships in the construction industry, primarily in terms of the relationship between the client and contractor (Alderman and Ivory, 2007). Partnering is considered to offer a plausible improvement strategy to mend the adversarial relationships that have long troubled the industry. It promises a paradigm shift towards longer-term commitment between partner organisations, sharing of often-scarce resources, and enhanced cooperation to deliver a set of mutually-agreed objectives (e.g. Construction Industry Institute, 1989; and Bennett and Jayes, 1998). Such aspirations have meant that considerable research effort have gone into explaining the nature, conditions and mechanics associated with partnering, as well as to demonstrate the realisation of the intended benefits.

So, Bennett and Jayes (1998) comprehensively articulated seven fundamentals of partnering. These serve to consider in great detail the strategy for enhancing commitment and improvement, adequate and appropriate membership of partner organisations, equity arrangements, social and structural integration, formal project processes, continuous improvement and feedback. Barlow and Jashapara (1998) suggested a need to distinguish between partnering that happens at a strategic (longer-term) level and more tactical project level. Many have sought to identify critical success factors and benefits of partnering, often through self-perception questionnaire surveys (e.g. Black *et al.*, 2000), or small-scale case studies (e.g. Beach *et al.*, 2005). There are also studies dedicated to examining project processes in great depth (e.g. Cooper *et al.*, 2004) to encourage development of the partnering ethos among stakeholders as early on in the project life cycle as possible (e.g. Matthews *et al.*, 1996). Formal tools and procedures (e.g. Loraine, 1993) are also frequently emphasised, alongside investigations into such social dimensions as trust (e.g. Wood *et al.*, 2002) and chemistry (e.g. Nicolini, 2002), with a view to encourage seamless integration of working practices across partner organisations. The use of information technology is also highlighted to encourage information and knowledge sharing (e.g. Tan *et al.*, 2007). Research into partnering has also evolved to consider the role of suppliers (e.g. Jones and Saad, 1998; and Saad *et al.*, 2002). Partnering in construction has also attracted international interest, even though a majority of studies are rooted in an Anglo-American perspective (see e.g. Cheng and Li, 2002; Cheung *et al.*, 2003; Chan *et al.*, 2004; and Tang *et al.*, 2006).

Problems with the desired state of partnering

Despite much research endeavour to promote the ideals of partnering in construction, difficulties of implementation and problems of unified understanding persist (e.g. Gadde and Dubois, 2010). Several commentators have argued that the empirical basis for claiming benefits of partnering remains weak (e.g. Naoum, 2003; Alderman and Ivory, 2007; and Nyström, 2008), because methods used to highlight performative outcomes of partnering simply fail to consider the contingent and localised nature of construction work (Bresnen, 2007). Furthermore, tracing the causality of better performance to the introduction of partnering practices remains a challenge (e.g. Beach *et al.*, 2005). Others are more critical to suggest that the language of partnering does little to help eradicate adversarial business-as-usual practices that encourage a corporatist agenda, which subverts the possibility of developing genuine, collaborative working relationships (e.g. Green, 1999; and Alderman and Ivory, 2007). One such example often cited in the literature is the absence of material benefits accrued to partner organisations further down the supply chain because of the perpetuation of cost-reduction strategies (e.g. Dainty *et al.*, 2001; Wood and Ellis, 2005; and

Briscoe and Dainty, 2005). Formal methods and procedures aimed at systematically introducing partnering practices have also been charged for being too prescriptive and over-engineered, and thus unworkable in reality (e.g. Phua, 2006; and Chan *et al.*, 2006).

Emphasising the „practice-turn" of partnering: a need to scrutinise paradoxes in the process of forming partnerships

By reviewing the two streams above, it is observed that the essentialist view of partnering in construction predominates in the literature. So, the term „partnering" is taken at face value by supporters and critics alike. Enthusiasts amass evidence (often uncritically) to demonstrate the existence of „best practice" approaches and positive outcomes, whereas contenders see the absence of „partnering" in reality and challenge its orthodoxy. In order to understand how collaboration can be a good thing for all involved, there is a requirement to shift the perspective of partnering in construction away from an essentialist view to one that is based on the *ontology of becoming* (see Chia, 1995). As Cousins (2002) assert, partnerships do not exist, and certainly not as cosy constructs. According to him, it is critical to refocus on the process of partnerships rather than its static, idealised form. Indeed, as Bresnen and Marshall (2001; 2010) argue, there is still a lot of scope to study the emerging practices of partnering in construction to understand how the process of partnering becomes accepted and applied in reality.

In the heat of the battle between proponents and opponents of partnering in construction, one critical dimension that has hitherto been given scant attention is the resolution of paradoxes and contradictions in the early stages of forming partnerships. Whilst studies have been undertaken to explain the general nature of organisational paradoxes (see Smith and Berg, 1987) and tactics for dealing with these (e.g. Poole and van de Ven, 1989; Clegg *et al.*, 2002; Beech *et al.*, 2004; and Smith and Tushman, 2005), the exposition of paradoxes in the construction industry is much rarer (see exceptions on strategy in construction by Langford and Male, 2001; Price and Newson, 2003; Chan and Cooper, 2010). Yet, there are inherent contradictions associated with inter-firm collaborations that need to be scrutinised, so that problems arising from these paradoxes can be dealt with when constructing partnerships in construction. For example, London and Kenley (2001) highlighted the tensions created by simultaneously maintaining competition and cooperation in integrating supply chains. Bresnen (2007) also deconstructed seven paradoxical effects of partnering vis-à-vis Bennett and Jayes" (1998) recommendations, including wishful strategic thinking and unrealistic targets, the dangers of fostering exclusive relationships, exploitation, reinforcing a false sense of control and over-engineering of processes, and failure to encourage organisational learning.

Notwithstanding the identification of these paradoxes in partnering, the dynamics of how these paradoxes emerge, and how these might usefully be tackled when developing the process of partnering in construction, remain relatively under-explored. Thus, the present article seeks to contribute in two main areas. Firstly, the study reported in this article adopts a practice-based approach to explain the process of early formation of partnering in a single ethnographic case study. In so doing, a number of paradoxes have been identified, and their manifestations observed. And so, the second contribution of this article is an analysis of the dynamics these paradoxes, which would help shed light on how tackling these paradoxes might go some way in affording better collaborations in practice. The next section will describe the observational context and method.

Case Study Observations: Context and method

This case study arose out of the involvement of one of us – the last author – who was working as a project management support officer to a railway company known as RailCo1. RailCo1 is a local client organisation, governed as a quasi-public sector organisation, with a long history of providing railway infrastructure in London. As a client organisation, it is responsible for providing capacity enhancement to the railway infrastructure managed under its authority, which includes upgrading of existing stations. At the time of the research (between March and November 2009), an opportunity emerged that permitted her to engage in ethnographic research. She was involved in a project to build a new station facility (named as the „Project"). This facility was to be constructed by RailCo3, a newly set-up railway client, also governed as a quasi-public sector organisation, charged with building new railway infrastructure in London. However, the „Project" meant that infrastructure owned by RailCo2, a national railway client wholly owned and regulated by the government that is responsible for the ownership of the national railway infrastructure, had to be relocated to another part of the station. The relocated part of the station is to be built and owned by RailCo2 and operated by RailCo3.To complicate matters further, the relocated facility would then become adjacent to infrastructure owned by RailCo1, which in turn restricted RailCo1"s ability to implement its strategy to enhance capacity. Concomitantly, RailCo1 had within the previous 12 months of the commencement of this research completed a long process of subsuming a loss-making public-private-partnership responsible for upgrading stations within its network boundary.

To coordinate the project across the three companies, it was decided that an integrated project team (named here as RailPro) involving members from each company was set up. This decision was also driven by senior officials at the governing authority of Greater London as a way to rationalise resources. One senior representative from each of the three companies – each were accountable to the board of directors of their respective companies – also formed a Liaison Group (named here as RailLG) to facilitate strategic discussions around the formation of RailPro. As discussed above, it is critical to study how the process of partnering comes into being. Moreover, it is important to understand this in the context of the early phase of a project (Kolltveit and Grønhaug, 2004). Hence, this case study presented a unique opportunity to get rich and deep insights into the formation of a new partnership that happened during the early stage (i.e. concept design stage) of the „Project". Data sources used for this research included interviews with key participants involved in the „Project" and „RailPro" (see Table 1 below), observational data, and documentary evidence.

Table 1. Profile of project participants interviewed for the research.

Interviewee	Role	Organisation
A	Senior project manager *(operational)*	RailCo1
B	Sponsor and representative on RailLG *(strategic)*	RailCo1
C	Project management support *(operational)*	RailCo1
D	Sponsor and representative on RailLG *(strategic)*	RailCo2
E	Project engineer *(operational)*	RailCo2
F	Sponsor and representative on RailLG *(strategic)*	RailCo3
G	Building services engineer *(operational)*	These were design consultants involved in delivering the concept design for the 'project'.
H	Design lead for architecture *(operational)*	
J	Design lead for engineering *(operational)*	

The research questions informing the data collection were initially concerned with identifying critical issues, enablers and barriers that contribute to effective knowledge sharing at the outset of the „Project". So interview questions included the role of the participant and their perspectives of notable events encountered in the „Project". Observations were recorded in the researcher's diary to make sense of the (visible and audible) social dynamics of participants during meetings and review workshops at the concept design stage of the „Project". Where appropriate, cross-references were made to minutes of meetings. The interviews were recorded and transcribed for analysis. The findings will be discussed in the next section, including the detour made during the research to focus on emerging paradoxes that surfaced in the formation of the partnership RailPro.

Discussion of Findings

As mentioned in the preceding section, the initial inquiry sought to explain knowledge sharing behaviours of participants in this case study. The motivation came from previous *"show stopping"* experiences between the three RailCos when undertaking site acquisitions and negotiations on land use. There was then an observable absence of effective knowledge sharing within and across each of the three companies, which led to the pursuit of this research project in the first instance. At the start of this research, high-level meetings that occurred at the RailLG level and „Project" review meetings were concerned with two key issues, namely geographic and systematic integration of operations across the three RailCos into the formation of RailPro. Questions were raised about the possibility of co-location of staff and setting up of operating procedures for RailPro. Put simply, the procedural form and scope of the partnership were being developed (Loraine, 1993). It was also clear to the participant observer and interviewees that the formation of RailPro meant that resources were not only being shared, but rationalised as well since there were clearly duplicity in terms of roles and responsibilities. It is worth noting that there were redundancies that actually took place soon after the research. Given this backdrop and the chequered past of difficult working relations in the past, participants had expected that the sharing of information would not be forthcoming. Surprisingly, this was not what the researcher observed at the initial stages of the formation of RailPro. Participants exceeded expectations in that they appeared to be very keen about sharing the information they had about the „Project". The observations also yielded another interesting finding; that is, as procedures were increasingly formalised, the openness observed at the outset of the research started to dwindle. This led us to take a detour to explore the dynamics of this paradox, explained in terms of sensemaking, formal methods, and time synchronicity.

Paradox of sensemaking

It is widely known that as projects progress in time, participants travel from a phase of relative uncertainty towards producing outcomes that are more certain. Therefore, sensemaking (Weick, 1995) plays a significant role in this process. The need for participants across the three companies to make sense of what this „Project" was about and what setting up RailPro means for their work accounted for the relative openness observed in the initial stage of the research. Yet, this was not so straightforward. Rather, the keenness shown in terms of sharing information about their thoughts of the „Project" was a means for participants to assert one's authority in framing the scope of what the „Project" was seeking to do. As Participant A suggests, when people were introduced to RailPro from each of the three companies, some still needed persuading as to why RailPro was necessary. He added that they clearly *"had their own objectives and goals"* to articulate. In some respects, the sharing

of their perspectives of what the foundations of the cooperation should look like is more of a *sensegiving* (see Gioia and Chittipeddi, 1991), rather than a simple, emergent *sensemaking*, process. Thus, as Cousins (2002) aptly pointed out, the process of forming partnerships is often rooted in a hard-nosed reality than many enthusiasts would concede. As the shape of the collaboration takes a more structured form, participants tend to shift their positions to make statements like *"this is not how we would do things in [our respective companies]"*, indicating dissatisfaction with how the partnership arrangements are being articulated, and creating an impression of *sense-hiding* (see Maitlis and Lawrence, 2007) instead.

Paradox of formal methods

Proponents of partnering in construction place much emphasis on formal tools and procedures. Yet, when RailPro was first conceived, participants at both strategic and operational levels were „doing" collaboration designing the „Project". Formal contracts were only signed and agreed between the design consultants (Participants G, H and J) and RailCo1. Yet, discussions were observed to continue fairly openly between the consultants and members of RailCo2 and RailCo3 as well. It would seem that delivering the „Project" mattered more than the formal rights and responsibilities articulated in the contract document, even though the „Project" – at least for RailPro – was still being reified (see Hodgson and Cicmil, 2006). Contracts have been known to invoke communicative acts and social interactions in projects (e.g. Marshall, 2006; and Bresnen and Harty, 2010). It would seem that the absence of contracts also have the power to stimulate, in this case, information sharing between participants. As a typical comment suggests, the *"lack of contractual arrangements did make for more openness."* Paradoxically, for Participant E, the finalising of contracts did prohibit him from *"getting pally"* with some of the other participants, and he stressed that *"informal arrangements definitely broke down the barriers normally found in communications between the two organisations."*

Paradox of time synchronicity

Time is an important dimension in projects. Yet, the partnering literature has ignored this critical aspect. In prescribing often-linear stages of the partnering life cycle, time is often treated as synchronous, and that partners necessarily know where and when they fit in within such a framework. Moreover, partnering in project-based environments normally downplays the idea that members have shared histories and futures. This is certainly not the case here. In the formation of RailPro, members have had past experiences of working with each other, and so they have entered this collaborative arrangement with some sense of a shared history. Despite sharing a past, the expectations of members about the future of the new collaboration were nevertheless far from uniform and synchronised at the outset. As discussed above, members had to make sense of the complex realities of how collaboration could be fostered effectively between the three RailCos. This required members to go through, in their own time, the processes of sensemaking, sense giving and sensehiding, which are often messy and difficult to delineate into neat categories of a life cycle. Put another way, whereas it is relatively easy to recognise the need for participants to develop a common future in principle, the reality is such that the participants were constantly trying to understand where their contribution to RailPro"s future lies. As Participant E puts it, members were reflecting on *"their experiences and know whether they hold knowledge that is of use"*, as they struggled to formalise the collaborative arrangements in RailPro. As illustrated in the paradox of sensemaking, this resulted in some members becoming winners and others becoming losers in this collaborative venture. As Participant A pointed out, not all the members are willing

and able to go along with the shared future concretised in RailPro. Participant A remarked, "*it was tricky to do what was best for the „Project" and still protect the interests of respective companies."* This would suggest that not everyone abided by the „programme" of this partnership formation. Bresnen (2009) coined the phrase "living the dream" to stress the lived realities of partnering in construction. Perhaps the participants in this case study are *chasing the dream*, burdened with past histories and passing through time, however asynchronously, into a possible shared future? Indeed, the notion of time and how it shapes partnering practices, and the paradox of time synchronicity, deserves more research attention.

Conclusions

"Personalities played a key role in the [partnering] success (Participant A)." At a very basic level, human relations do matter in achieving effective collaborations. But this is not the full picture. This case study research contributes to a more holistic view of how the process of partnering could potentially (and simultaneously) be driven and hampered by a range of paradoxical issues. Yet, paradoxes are rarely examined in detail in the construction management literature. Here, sensemaking, formality and time synchronity have been exposed as paradoxical constructs in the start of a new collaboration, albeit with „old" partners. These paradoxes raise a perplexing, if interesting, question to advocates of formal and prescriptive tools used in partnering (and in project-based working more generally). How did the absence of formal mechanisms lead to the observation that members were actually „doing" the collaboration and the „Project"? Clearly, the station facility was still being designed and planned for construction, despite members being clear where they stood with the relationship between their respective organisations and newly-formed one. Of course, human agency still prevails in this situation, afforded no less by the emergence of these paradoxes. Whilst the contradictions may have disrupted the idea of formal, prescriptive methods, they were also found to be generative in terms of social interactions and dialogue. What is clear from the case study is that conversations and arguments happen as individual agendas become articulated and legitimised. The only certain conclusion is that the members involved have, by living through these paradoxes and chasing the dream of more effective coordination between partners, legitimated the form of partnering that eventually makes sense (see Oliver, 1997; and Vaara and Monin, 2009). Such insights gained through ethnographic research are therefore required to explore fully the process of how partnering comes into being. Whether the outcomes are positive or negative (or even coherent with the intended strategy) does not matter so much!

Abstract
Project evaluation is an effective tool in project management as it provides stakeholders with a management process through which they can learn from the past and perform better in the future. Although various project monitoring and evaluation methods have been used in the construction industry, most of these traditional evaluation approaches emphasize the three basic success criteria of time, budget and quality. However, recent research emphasizes the importance of 'satisfyting' key stakeholders. It is therefore necessary to develop a more holistic evaluation tool to evaluate projects from perspectives of all key stakeholders. However, it appears that no systematic project evaluation approach focusing on project stakeholder perspectives, has been developed.

This paper aims to develop a systematic evaluation model, based on the concept of whole life cycle value (WLCV), which integrates all the key stakeholders' value objectives and can be used to evaluate an infrastructure megaproject more holistically and comprehensively.

Projects aim to deliver value, including cost savings for client, desired functions for all end-users and other stakeholders over the whole life. It is therefore important to be able to identify, analyze and deal with the expectations of each group of stakeholders over the entire project life time, i.e. from client requirements formulation stage to demolition / re-use stage. In order to measure WLCV, we must identify its essential components, namely: significant criteria for measuring project WLCV, as well as related indicators which will help evaluate specific dimensions of the parent criteria. To be holistic as intended, both criteria and indicators should together reflect the value objectvies of all stakeholders including the client.

Based on a comprehensive literature review in evaluation and value studies, several semi-structured interviews with experts in academia and industry, and findings from the first stage of a relevant case study, this paper proposes a preliminary WLCV model for infrastructure megaprojects. A preliminary WLCV framework will be formulated in the next stage of this research, based on the findings of a planned questionnaire survey. This paper concludes with a discussion of some of the major difficulties in identifying, balancing and formulating WLCV criteria and some useful directions and opportunities for further research in this field.

Keywords: project evaluation, whole life cycle value, stakeholders

INTRODUCTION

A megaproject is described as a remarkably complex, large-scale project that has considerable influence on the economy, society and environment. The contract sum of a megaproject is usually very large, normally exceeding $ 1 billion in Hong Kong (Works Bureau, 2002).

In the past decades, while many countries planned and undertook more and bigger infrastructure megaprojects, many shortfalls have emerged in their delivery, such as poor performance in term of cost overruns, schedule delays, and shortfalls in expected benefits. This has been the case for many years and existing data show no immediate end to this situation. This megaproject paradox and shortfall was demonstrated in a seminal book (Flyvbjerg et al., 2003).

However, the rapid economic growth and the growing public expectations from public projects reveal the emerging concept that better value is more importance than the lowest cost. Saxon (2005), ASCE (2007), Levitt (2007) advocated that the construction industry should compete on the foundation of ‗added value' rather than only on cost efficiency.

Due to the strong economical and social impact of infrastructure megaprojects, it is suggested that their performance should be measured from a broader aspect – value instead of a cost perspective only. Based on this assumption, this paper presents the preliminary findings of an on-going research project titled ‗Integrated whole life cycle value framework for infrastructure megaprojects' which focuses on evaluation & monitoring project whole life cycle value (WLCV). The paper delves into the current infrastructure project evaluation situation in Hong Kong and brings out the need of a WLCV evaluation approach. The development of this WLCV model integrates all the key stakeholders' expectations into the client value system. This provides all the stakeholders a sense of ‗fairness' and ‗ownership' which encourages them to co-operate with common value objectives.

THE NATURE OF PROJECT EVALUATION

Project evaluation is an effective tool in project management which requires appropriate measurement of performance levels. It is a systematic analytical method, which is conducted aperiodically to measure and explain project performance issues (Samset, 2003). Figure 1 is derived from a relevant research conducted by Samset (2003) who presented three levels of evaluation.

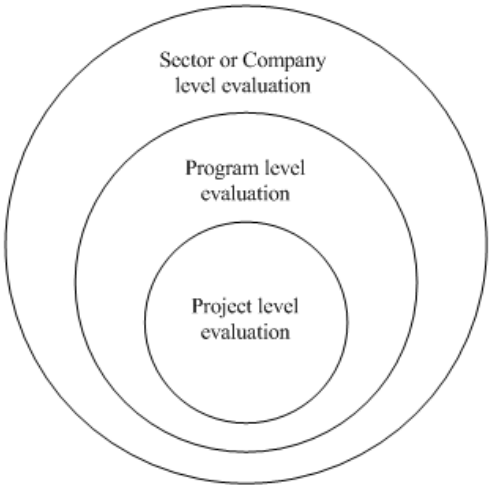

Figure 1: *Three levels of project evaluation (Samset, 2003)*

The single project evaluation can be divided into three stages – ex-ante evaluation, interim evaluation and ex-post evaluation. Nowadays, for single project, the emphasis of evaluation are put on the ex-post and interim stages and limited to the cost and quality dimensions.

It is critical to evaluate a project before commencement, as this can help determine whether the right decision is made at the start. It does not matter whether you implement a project extremely well or extremely poorly, if you are working on the wrong project.

It is also importance to involve all the relevant stakeholders from the start. As stated by Samset (2003) there will be several key stakeholders whose interests need to be considered in the process of any evaluation. In order to satisfy their needs, their preferences and attitudes should be ascertained carefully. Moreover, the earlier stakeholders are involved in the project, the better it is for effective and efficient project delivery.

In order to resolve the issues in infrastructure megaprojects, the evaluation emphasis should be on value. Also the evaluation stages should be more comprehensive. These aspirations need to be recognized in future megaproject formulation and implementation. Although, the requirement of evaluating project value during a project whole life cycle has been recognized, few studies have been conducted in this area.

THE PRACTICE OF PROJECT EVALUATION IN HONG KONG

The project evaluation & monitoring of local industry has its own uniqueness and requirements. In order to understand the current evaluation situation and identify whether it is necessary to develop a value evaluation approach, a good start would be by conducting interviews with relevant experts from both public and private sectors.

From early June, 2010 to early January, 2011, 11 semi-structured interviews were conducted with interviewees from academia, Architectural Services Department (ASD), MTR Corporation Limited (MTRC), EC Harris, AECOM and Hong Kong International Airport. Through these interviews, general opinions on the current practices of project evaluation were obtained from major clients in the local construction industry.

Based on the interviews conducted with the experts, it was observed that there has been no systematic project evaluation based on project value throughout the infrastructure projects in ether public or private sectors. Although, many major Hong Kong project clients including the ASD and the MTRC have introduced the whole life cycle concept into their evaluation, their evaluation still mainly based on the LCC not WLCV. However, the consensus now is that value is more important than only cost.

The majority of interviewees believe that a framework to guide the project WLCV evaluation process is needed to improve the overall project whole life performance, provided that it is comprehensive enough to be applicable to different types of projects, offers a sufficient degree of flexibility in different situations and will be easy to use in practice.

Another finding was that obtaining the stakeholders point of views are critical, for which stakeholder engagement is already conducted in ASD, MTRC and the Hong Kong International Airport.

THE USE OF PROJECT WHOLE LIFE CYCLE VALUE IN PROJECT EVALUATION

A review of common tools in project evaluation

Life Cycle Cost

The project life cycle cost (LCC) concept, which emerged since the 1960s, is an economic assessment indicator based on the relevant significant cost of ownership during the economic life of an item, area, system, or facility, expressed in terms of equivalent dollars (Dell`Isola 1982).

Although the LCC approach purports to include non-economic costs including those related to safety, environment, customer satisfaction etc, these factors are often only used to temper the result rather than incorporate in the final calculation. The fundamental consideration in LCC is cost which is so dominant, that it can lead to omitting, if not neglecting, these non-economic factors. Therefore, it is often likely that ‗cost' is the only consideration in the process of comparing alternatives. Furthermore, emphasis on lowest cost may lead to some significant problems. The lower cost may be obtained by mean of compromising project quality or environment. Nowadays with the increasing emphasis on sustainability both at project construction, operation and maintenance stages, these non-economic factor become more and more critical. Furthermore, LCC approach is usually based on the client point of view without considering ‗costs' of other stakeholders such as all end-users, contractors, suppliers etc, who also play an important role in the project.

Key Performance Indicators

Many previous performance measurement criteria such as Key Performance Indicators (KPIs), involve identifying all the critical indicators and providing a suitable guideline on how to measure them to evaluate project and organizational performance throughout the construction industry. For example, seven main groups including: time, cost, quality, client satisfaction, client changes, business performance and health and safety were recommended in the KPI report for the minister for construction in UK (The KPI working group, 2000). The

information obtained from the aforementioned set of KPI is used for benchmarking and helps organizations to achieve best practices. Lueng and Edum-Fotwe (2005) stated that critical performance indicators can and should be applicable to evaluate projects. However, there are limitations in applying this approach to existing project management practices. For example:

- Limitation 1: It has been noted that there should be connections amongst the indicators. The current KPIs system are used to evaluate projects typically by providing parallel comparison existing factors of time, cost, quality and client satisfaction etc (Lueng and Edum-Fotwe, 2005). Kumaraswamy and Thorpe (1996) stated that the interactions between indicators can be expressed through linkage factors / indicators. However, in most KPIs systems this kind of relationship is not presented appropriately.

- Limitation 2: The approach of the KPIs is by and large based on evaluation by client, contractor, designer and other organizations which have contractual / legal relationships with the project. Considerations of the other stakeholders such as the end-users, green groups etc are not included. According to Ward and Chapman (2008), most projects especially infrastructure megaprojects have a large number of stakeholders who contribute important components of uncertainty that can have a greater or lesser extent of impact on the project delivery process. So their opinions should be addressed appropriately. Furthermore a system value can only be measured from the stakeholders' point of views, as the purpose of the system is to provide service to them.

- Limitation 3: Inadequate contribution to the value objectives as described in the previous sections from all the stakeholders, albeit to differing extents and priorities.

Introduction to Whole Life Cycle Value

Historical development

Over the last several decades, a number of studies have focused on value such as that of Burt (1975), who stated that value includes two dimensions that are quality and cost in the construction field; Best and De Valance (1999) pointed to quality, cost and time. These previous studies mostly focus on value in a narrow sense. However, presently with the increasing injection of sustainable development criteria and concerns in construction industry planning and operations, industry and project stakeholders are widening their interpretation of value and reconsidering and redefining value by adding other factors, such as those related to the environment and society (Thomson et al. 2003a and 2003b, Abidin and Pasquire 2007). Furthermore, the value outcomes could be influenced by many factors during the project whole life cycle and the interactions between the various factors may lead to inefficiencies and ineffectiveness in the processes of delivering projects. It is thereby concluded to be necessary to research value in a broader sense that is Whole Life Cycle Value (WLCV).

In previous studies on WLCV, different researchers have chosen different definitions. Browning and Honour (2008) stated that "Whole life value is the system's attribution (which includes benefits and sacrifices)." This definition was developed in the context of system engineering and not in infrastructure megaprojects. Kerzner and Saladis (2009) developed anther definition: "The value of a product or service within the context of project management refers to the relationship between the customer's expectations of product quality and product usefulness, short and long term, to the actual amount paid for it." This definition focuses on the customers' points of view. Kelly (2009) suggested that "Whole life value is the benefit

given less the sacrifices required, related to the renewable and non-renewable resources used in the construction or manufacture and maintenance stages over a number of time periods in a given length of time, less the residual value at the end of the project."

Proposed WLCV concept

However, all above definitions were developed in special context for the purpose of those particular studies. None of them can fulfill the current needs as identified in this research. Through combining the previous definitions and injecting the findings from the current study, the following definition was developed: the project value is the sum total of the expectations (expectations here meaning: what they want to obtain from the given project and what they are ready to give up in return, including positive perspectives-benefits and negative perspectives-sacrifices) of different stakeholders for a given project. Project WLCV is the aggregated expectations of all the stakeholders for a given project over its life cycle. The client's expectations form the primary / high priority part and the other stakeholders' expectations contribute to the secondary / lower priority part. This definition is conceptualized in Figure 2.

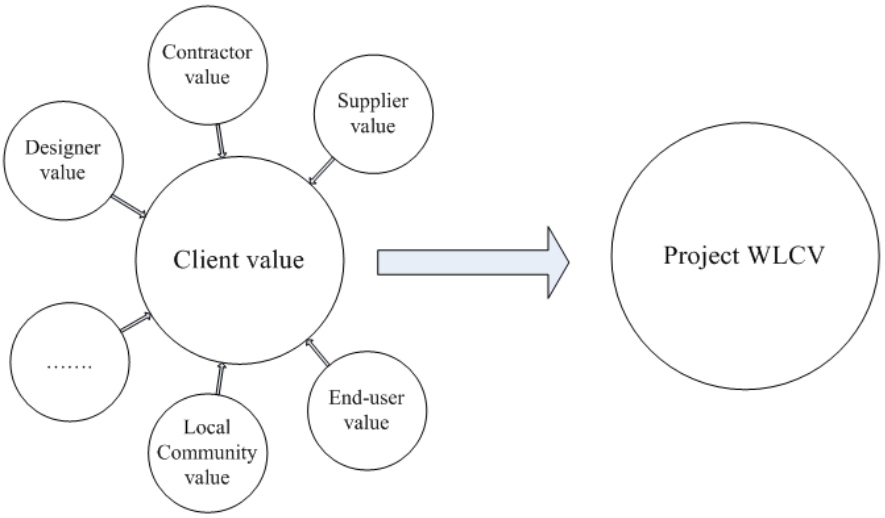

Figure 2: *The concept of project WLCV*

Characteristics of the proposed WLCV concept

The proposed WLCV concept is framed from three perspectives: multi-stakeholders, multi-stages and the dynamic nature of value. These perspectives are described as follows:

Multi-stages

In the context of the construction industry, there are many interpretations concerning the taxonomy of a project whole life cycle. For example, John et al. (2003) classified five stages: typically these are client requirements and briefing, design, installation, operations and maintenance, and disposal / reusing / recycling phases; Evans et al. (1998) divided the life cycle into three stages: design and construction, operational period, and demolition/recycling; Bennett (2003) stated that project whole life includes pre-project phase, planning and design phase, contractor selection phase, project mobilization phase, project operation phase, project closeout and termination phase.

In the current research, the project whole life cycle refers to client requirements stage i.e. formulation & briefing; design & construction stage; operation stage; demolition / re-use stage.

Multi-stakeholders

Many researchers presented different definitions of stakeholders. From the perspective of Freeman (1984) stakeholders are any groups or individuals who can affect or be affected by achievement of a corporation's purpose. Phillips (2003) presented two definitions: (1) "Those who have any input in decision making" and (2) "Those who benefit from the outcomes of a decision". Newcombe (2003) stated that stakeholders are groups or individuals who have a stake in, or expectations of a project's performance. According to Donaldson and Preston (1995) stakeholders are those who experience or anticipate experiencing potential benefits or dis-benefits as a result of the organization's actions. Despite the many definitions, most are within the context of an organization, with few focusing on project stakeholders.

In this paper, project stakeholders refer to groups or individuals who have special expectations from and vested interests in a given project; and can positively or negatively influence or be influenced by project performance. Chung (2010) developed a figure shown in Figure 3 which can assist to identify stakeholders in the current research.

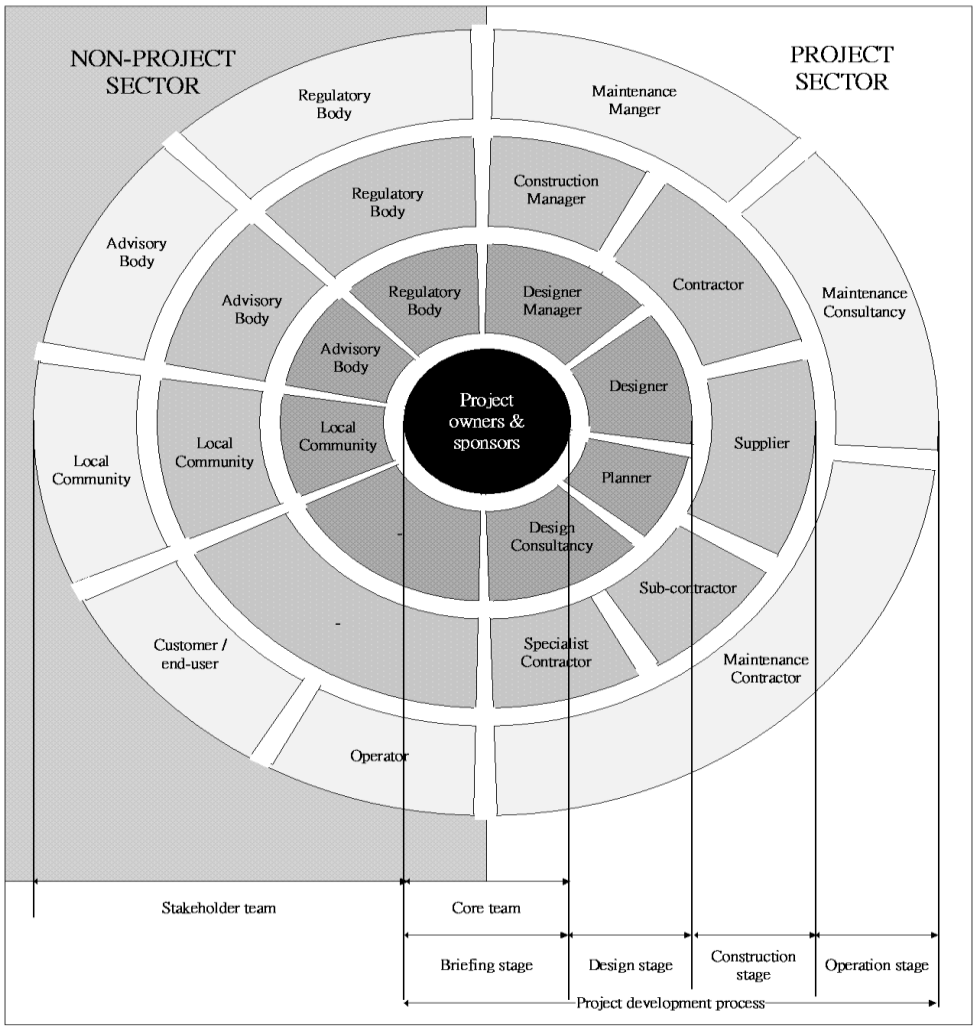

Figure 3: *Project stakeholders (Chung, 2010)*

The traditional view of the client as a single entity, who should make most of the important decisions about a given project has already obsolesced. The clients‘ views can not reflect the reality expectations of the other stakeholders. The importance of other stakeholders is widely recognized, as they can have positive or negative influence on the project performance. Newcombe (2003) applied an innovative technique to conduct stakeholder mapping in the context of a large construction project, demonstrating the importance for project managers to analyze the power, predictability and interest of key project stakeholders.

Despite many studies conducted about stakeholder management, scant attention has been received to joint stakeholder management for enhanced project value, leave along project WLCV. It is critical to consider stakeholders expectations from the project whole life cycle perspective, as the life cycle thinking applied during the decision making can provide a holistic view about the project to the key stakeholders (Thabrew et. al 2009).

The concept of combined multi-stakeholders and multi-stages is shown in Figure 4.

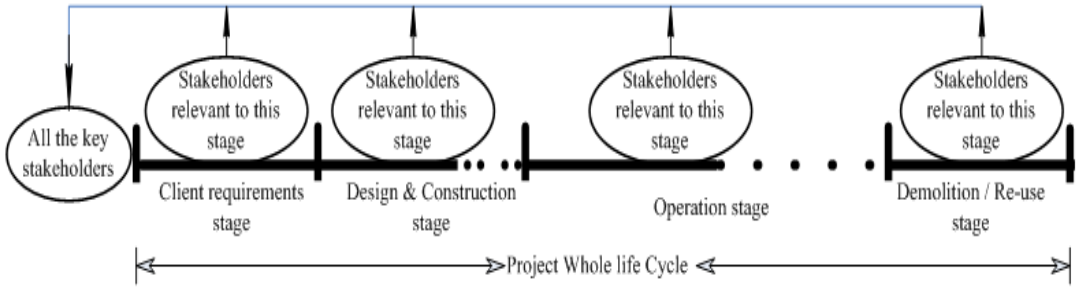

Figure 4: *The Concept of Multi-stakeholders and Multi-stages*

The dynamic nature of value

Kerzner and Saladis (2009) argued that sometimes project value can also change over time, but a project manager may not appreciate these emerging and dynamic needs. They also stated that factors, such as market-demanded changes, changing constraints and assumptions and technology advances were either not available or resources lacked the necessary skills etc, can lead to appropriate value expectations not being established, and hence trigger value shortfalls in the delivered project. So it is necessary to evaluate a project over time to detect if there are any changes that will influence the project value, and then take the necessary _ompensatory‘ actions, e.g. to change the plan or even abort the project.

Based on previous discussions, the conclusion is that it is necessary to apply the WLCV concept to evaluate the project over the whole life time. WLCV is a more holistic approach, which considers cost, quality, time and all other relevant performance factors and treats them impartially, compared with the LCC. The WLCV approach can make up for some of the disadvantages of LCC. Hence, it is possible and reasonable to introduce WLCV considerations to the process of evaluation & monitoring infrastructure megaprojects.

Feedback from industry professionals and a mini case study

Other findings from aforementioned 11 interviews with industry experts in the previous section are presented as follows:

It is very difficult to measure some qualitative factors, such as environmental protection and influence on regional economies etc.

It is also clear that we could face great difficulties in introducing a single set of value evaluation criteria for various types of infrastructure megaprojects, as each project is unique, so developing a project-specific WLCV criteria system is necessary. A more flexible model is required for project teams to formulate the most suitable evaluation system according to the specific nature of various projects. However, the new project value evaluation model should serve another objective, i.e. to provide a mechanism for the industry to benchmark project WLCV. Therefore, we should try to balance the two requirements in developing the new project value evaluation model.

After identifying the need for developing a WLCV evaluation system during the interview sections, the next step was to verify the possibility and benefits to conducting stakeholder engagement over the whole life of a project.

An on-going mini case study is being conducted in Hong Kong since October 2010. Data collection methods of the case study involve study of project documentation, interviews and observation of project meetings. This mini case study focused on the public engagement during this research stage. The project was to deck the existing Nullah and to construct an urban park on the decked Nullah. It would also expand the adjoin Road Roundabout. The project construction was commenced at the end of December 2009 and the decking work has been completed.

The preliminary findings from this case study prove that it is helpful to conduct stakeholder engagement at the beginning of the project. The public engagement in this project includes distributing leaflet to the community, liaising with Police, and DC member etc. After obtaining their viewpoints, the managers devised several strategies such as installation of Trash Net, guiding pedestrians and installing a sedimentation tank.

The key observation in terms of inefficiencies in value creation and value capture for the stakeholders in this case study are: (1) there are many different kinds of views from public and it is very difficult to get a consensus and satisfy everyone; (2) some factors can not be quantified so it is difficult to incorporate them into the decision making process, as well as to measure them.

On the positive side, the early informing of the community and relevant government departments helped the client to proceed the project with fewer complain and more co-operation. As the stakeholders had already expressed their opinions and learnt about the project progress, they felt a kind of _fairplay‘ and _ownership‘ which were incentives for them to support, or at least not oppose the project. The efficient management of the approval process for stakeholder engagement assisted in managing the issues and stopping them from flaring up into disputes.

THE PROPOSED WLCV BASED PROJECT VALUATION MODEL

Conceptual design of the model

The basic concept of this model will be illustrated in this section. This model can help the client to consider all the stakeholders‘ expectations for a given project.

Elements

An appropriate optimization mechanism will be chosen and used, along with statistical analysis to improve the WLCV model. Some information collecting methods are borrowed from a relevant research project completed in Loughborough University (IMCRC, 2005). The proposed model covers three stages: information stage, evaluation stage and re-analysis stage. The function of each stage and the database are presented in Table 1. Within the information stage, four kinds of data will be collected including: all the stakeholders of a given project; all the stakeholders‘ value objectives; weights of different groups of stakeholder; and weights of the value objectives.

Table 1: *Elements of the WLCV model*

Item	Function
Database	Providing generic data and benchmarks for comparison
Information stage	Collecting the four kinds of data for evaluation
Evaluation stage	Assessing whether the project WLCV within a reasonable range
Re-analysis stage	Re-analyzing the four kinds of data to identify the reason why the project WLCV can not live up to the client's expectations and what can be done to improve it.

Structure

The structure of the WLCV model is presented in Figure 5.

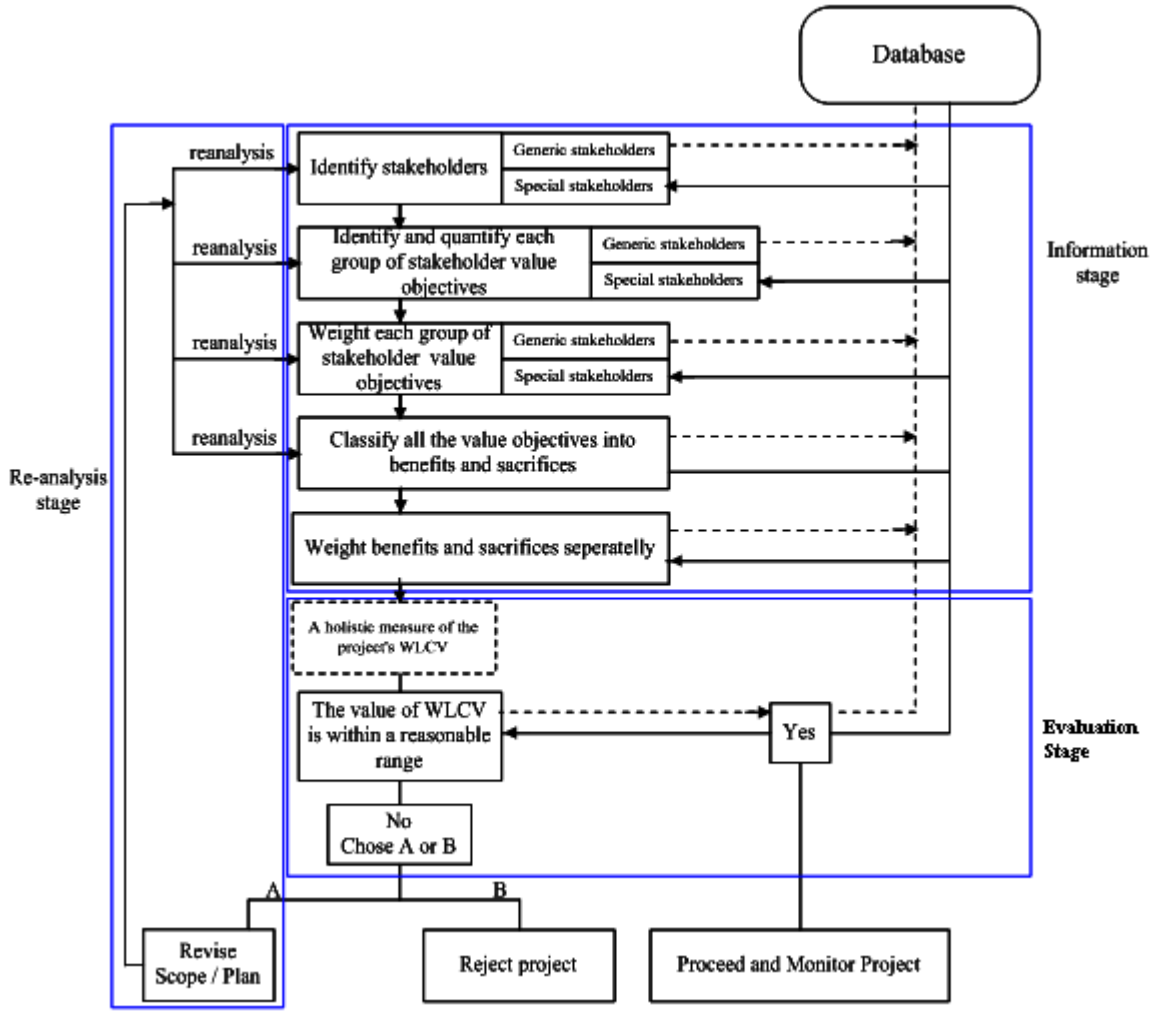

Figure 5: *Structure of the WLCV model*

These stakeholders will be divided into two kinds — project sector stakeholders who have contractual/legal relationships with the client and non-project sector stakeholders who do not have contractual/legal relationships with the client as shown in Figure 3. In operationalising the model, all the stakeholders will be identified during the whole life cycle of a project employing the aforementioned method. Next various value based decision making concepts such as lean approach, fuzzy theory etc will be evaluated for applicability and an appropriate method will be chosen. Furthermore, some experiences will be draw on from previous research work such as on ‗network value' (Kumaraswamy et. al., 2009), stakeholder management (CICID, 2007), project briefing (Chung et. al., 2009) etc and with a supplemental literature review to incorporate into the value dimensions and design of the evaluation criteria system.

Criteria system

As project value is too abstract to measure as one item, a multiple level criteria system is proposed. The strategy behind this approach is to divide project value into several sections which are much easier to evaluate & monitor. The concept proposed is as shown in Figure 6. The six levels are Project WLCV, Value Objectives (VO), Value Criteria (VC), Primary Indicators (PI), Secondary Indicators (SI), and Tertiary Indicators (TI).

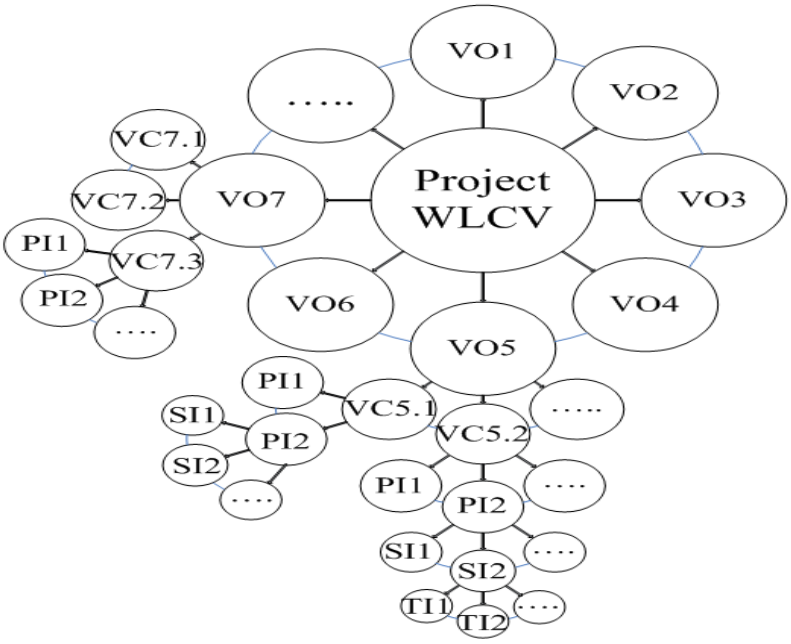

Figure 6: *Project WLCV Criteria System*

These value objectives can be divided into three categories which are the economic value objectives, the social value objectives and the environmental value objectives. This categorized approach integrates the sustainability concept into the WLCV. Also, the value objectives within each category include quantitative and qualitative types. It is much easier to quantify the former type. However, for qualitative value objectives, we can usually only obtain linguistic descriptions. Appropriate approaches (such as from fuzzy theory) will be identified to translate these descriptions into quantitative data.

The linkage factors/indicator will be introduced into this model after certain understandings of the factors interactions obtained. Thus the relationships among all the criteria and indicators can be expressed more realistically. The overall measure of the project value performance can then be more credible.

Limitations of the model

The preliminary model presented here is derived from the initial background work for a research project on ‗Integrated whole life cycle value framework for infrastructure megaprojects'. This model is thus still short of a fully researched, well structured and tested framework. It needs to be developed and adjusted with further practical data inputs and validation. Moreover, a well populated database is needed to be formulated to support this model and the formulation of a detailed guideline is indispensible. Many of these limitations will be addressed as the research project progresses as described below. However, some of them will remain beyond the scope of this research.

ROADMAP FOR FUTURE RESEARCH

An in-depth investigation on evaluating project value will soon be launched with an aim to unveil and incorporate other ‗value' factors to be considered into the detailed guidelines while evaluating & monitoring project WLCV, as well as unearth barriers to maximize project

WLCV with specific reference to Hong Kong. This will be approached through questionnaires and in-depth case studies. Further, strategies to overcome these barriers will be derived from best practices elsewhere and from experts‘ inputs. The model will be refined to reflect these limitations and accommodate the developed strategies; and will be validated by means of focus group meetings at appropriate research stages.

The findings of this particular research together with the findings for a framework of infrastructure project evaluation & monitoring, which forms the other part of this research will be the final output of the Integrated whole life cycle value framework for infrastructure megaprojects‘ research project.

CONCLUSION

The research introduces an innovative idea of using a project WLCV to evaluate projects over their whole lifetime, while addressing the conflicting value objectives among stakeholders. The final purpose is to evaluate & monitor project WLCV realistically.

The model is based on the premise that the value of a megaproject is impacted by the relative importance attributed to different dimensions by all stakeholders rather than only some stakeholders such as client, contractor etc. This model can assist the client to consider the involvement of various types of stakeholders (multi-dimension), such as all end-users, neighbors, suppliers and contractors, and different levels of stakeholders (multi-level), such as senior project manager and frontline staff. Moreover, involving stakeholders as early as possible, which can keeping potential problems from pushing stakeholders into adversarial posturing and consequential disputes, helps clients to achieve better project value.

Monitoring WLCV will also contribute to reduction of waste and environmental friendliness during the construction, operation, and reuse / demolition stages. In this regard, the need for an evaluation model of project WLCV has been proposed, especially for infrastructure megaprojects which have critical influence on the economy, society and environment. Also, this approach is seen to be capable of dovetailing well into current sceneries in the Hong Kong construction industry and in the long run will help improve infrastructure megaproject WLCV management.

The proposed evaluation system is expected to provide a sound approach to measure infrastructure megaproject WLCV in the context of Hong Kong, but can be modified and applied generally to other countries. However, the key is how to measure qualitative value objectives as well. How well the connections between the criteria / indicators can be defined and modeled will also pose a major challenge.

ACKNOWLEDGEMENTS

The authors gratefully acknowledge the CIDCA project HKU713209E and the co-operation of the interviewees who contributed to the study as well as for the kind assistance received from the personnel of the project during the case study data collection phase.

Abstract

This paper draws on a major study the authors conducted for the Australian Government in 2009. It focuses on the diffusion issues surrounding the uptake of sustainable building and construction products in Australia. Innovative sustainable products can minimise the environmental impact during construction, while maximising asset performance, durability and re-use. However, there are significant challenges faced by designers and clients in the selection of appropriate sustainable products in consideration of the integrated design solution, including overall energy efficiency, water conservation, maintenance and durability, low-impact use and consumption. The paper is a review of the current state of sustainable energy and material product innovations in Australia. It examines the system dynamics surrounding these innovations as well as the drivers and obstacles to their diffusion throughout the Australian construction industry. The case product types reviewed comprise: solar energy technology, small wind turbines, advanced concrete technology, and warm-mixed asphalt.

The conclusions highlight the important role played by Australian governments in facilitating improved adoption rates. This applies to governments in their various roles, but particularly as clients/owners, regulators, and investors in education, training, research and development. In their role as clients/owners, the paper suggests that government can better facilitate innovation within the construction industry by adjusting specification policies to encourage the uptake of sustainable products. In the role as regulators, findings suggest governments should be encouraging the application of innovative finance options and positive end-user incentives to promote sustainable product uptake. Also, further education for project-based firms and the client/end users about the long-term financial and environmental benefits of innovative sustainable products is required. As more of the economy's resources are diverted away from business-as-usual and into the use of sustainable products, some project-based firms may face short-term financial pain in re-shaping their businesses. Government policy initiatives can encourage firms make the necessary adjustments to improve innovative sustainable product diffusion throughout the industry.

Keywords: sustainable products, innovation, construction industry, Australia

INTRODUCTION

World economic activity is expected to increase five-fold and global manufacturing activity to triple by 2050 (Matthews et al., 2000). With this predicted growth, increased importance is being placed on the development of sustainable products that minimise environmental impact, but also maximise performance, durability and re-use (Terry et al., 2007).

As a result of increasing public awareness of sustainable development and legislative and financial drivers, manufacturing firms are developing sustainable building and construction products to meet growing demand. Simply, sustainable products in the built environment refer to building and construction components that have environmental attributes or a lower environmental impact than alternative products (Terry et al., 2007). Sustainable products can be stand-alone, but are mostly used as a part of an integrated sustainable design strategy; and selection is rarely made in isolation. For example, the selection of a spectrally sensitive glazing product (that reflects radiant heat) would be used in conjunction with an external shade product to maximise energy efficiency.

Thus, a major challenge for designers and clients is the selection of appropriate sustainable products that are compatible in an integrated sustainable design solution. In selecting a suitable product, design considerations for the entire system should be considered such as: energy efficiency, water conservation, maintenance and durability, low-impact use and consumption (Terry et al., 2007). Construction and manufacturing considerations should also be taken into account such as distribution, efficiency in production and recycling.

This paper presents a review of the current state of sustainable energy and material product innovations in Australia. It highlights four case products, as examples of cutting edge development and discusses their proposed innovative contribution towards improving building and construction sustainability in Australia. Given the significant breadth of the topic, it has been necessary to profile selected innovations from across the full range available. However, despite the subjective nature of selection, authors sought advice from subject matter experts to confirm selection.

SUSTAINABLE PRODUCT INNOVATIONS

Case product types are now presented followed by a discussion of the system dynamics surrounding these products. The drivers and obstacles of product diffusion across the Australian construction industry are then discussed. The four case product types namely: solar energy technology, small wind turbines, advanced concrete technology, and warm-mixed asphalt, are presented in light of their expected system-wide impacts.

Solar energy technology (Photovoltaic)

Solar photovoltaic (PV) arrays generate electricity through solar energy with very little aversive environmental effects such as pollution or waste. Generally, they are also reliable products as they do not have moving parts, translating to ease of maintenance and long life spans.

Although PV solar panels are not a new technology to the building industry (the base concepts of the technology date back to the early 1900's), the technology is constantly evolving and is currently offering considerable benefits over earlier innovations. One of the

major barriers to the widespread use of this technology has been its limited efficiency in converting light energy into electricity. But as the technology has developed, so has its efficacy, which is continuing to improve. The latest performance from a photovoltaic cell device saw 40.8% of light energy converted to electricity, achieved in August 2008 (NREL, 2008). In Australia, the key market for this technology has been for 'off-grid' systems in the industrial, telecommunication and agricultural industries, followed by off-grid building residential systems (ABCSE, 2006). The off-grid applications for residential buildings include supplementing standard utility power and electricity backup. Large PV arrays have also been used in commercial buildings for offsetting power distribution during off-peak times. Recent cutting-edge research by scientists at the Australian National University (ANU) has developed transparent 'printable' PVs on a thin film polymer (Stohr, 2009). It is expected this innovative manufacturing process will not only significantly increase PV's cost-effectiveness, but open up a range of applications on buildings such as glazing integration.

Another emerging application of PVs is Building-integrated Photovoltaics (BIPV). Simply, BIPV refers to the use of photovoltaic materials as a replacement to conventional building materials, such as roofs, façades and glazing, thus improving aesthetics and integration within the architectural features of a building (Bhargava, 2007). In the Australian building industry, this innovative approach has been successfully trialled and has proven to achieve valuable electricity generation under Australian conditions (Prasad and Snow, 2004). It is expected the market for such products will expand as the PV technology further evolves.

Small wind turbines

Australia is known to have abundant and powerful wind resources, unrivalled in most of the world, which have yet to be fully tapped (Herbert et al., 2007). Wind technology has seen rapid growth worldwide (Price, 2006) and wind power currently attracts the most investment in the renewable energy resource sectors across the globe (Boyle et al., 2008). The investment in wind power generation has mainly focused on large wind farming, but an emerging area of innovation is small wind turbines that can be used to supply remote, off-grid electrical loads on various built assets.

Currently, the wind energy generation industry has invested heavily in large wind turbine aerodynamic profiling, with much less emphasis on the smaller wind turbines (Ackermann and Söder, 2000). However, small wind turbine research groups are emerging due to the increasing government emphasis on self-sufficient energy generation. For example, the Australian Government announced in August 2008 it would provide funding for a 'small wind turbine' test centre at the Research Institute for Sustainable Energy at Murdoch University in Perth, Western Australia (Garrett, 2008). Such research will assist in the development of small wind turbine technology to be used in the residential and commercial building sector. According to a global market report on small wind turbines by the American Wind Energy Association (AWEA, 2008, p.9), the recent technology advances globally in this field include:

- active pitch controls to maintain wind capture during high winds and automatic adjustments to blade pitch for best angles of attack
- vibration isolators and slower rotor speeds to lessen sound (wind turbines are traditionally very noisy)
- advanced blade design
- operational capabilities in low wind
- self-protection mechanisms during extreme wind conditions

- single models for on-grid and off-grid use
- wireless display and software support
- integrating turbines into existing structures such as utility poles, and
- aesthetically more attractive designs.

Wind turbines can be used not only for energy generation on residential buildings but also to power central air extraction/ventilation systems in large commercial or industrial buildings. A successful example of this latter approach is the CO2 building in Melbourne. The CO2 building has six wind turbines to power an air extraction system through ducts on the building's north façade. The wind turbines were purpose-built and replace the requirement for electric fans that would traditionally power air circulation systems (ABSJ, 2006).

Advanced concrete technology

Concrete technology has advanced rapidly over the last ten years. These advances have been in the areas of mixture proportions, aggregate materials, structural design, durability requirements and testing. However, many of these advances remain outside standard practice worldwide (Vanikar, 2004).

One product that has gained greater acceptance in the construction industry is High Performance Concrete (HPC). HPC contains specialised aggregate and admixture materials that are combined with traditional Portland cement (with generally high cementitous levels) to assist in achieving high durability and strong compressive performance. According to Vanikar (2004), emerging refinements include:

- the development of advanced chemical admixtures such as accelerators, retarders, corrosion inhibiters and water reducers
- advanced supplementary cementous materials such as fly ash and silica fume
- extended use of recycled materials in concrete, which are generally used as concrete and slag aggregates
- new concrete mixture proportions, as a result of improvements in concrete batch trailing and research, where continuous grading and workability tests are gaining greater acceptance
- new variations in concrete structural and durability properties suitable for specific conditions, e.g. high strength concrete for bridge design and durable concrete mixes for pavement design
- advances in concrete test procedures (such as shrinkage and air-void testing), which improve strength and durability outcomes, and
- improved concrete construction control – including advances in curing processes and the use of software to monitor concrete strength development and prevent cracking.

A recent innovation in supplementary cementous materials is a product called 'Eco-cement' developed by TecEco in Australia. Eco-cement replaces the calcium-base lime ingredient that is traditionally found in Portland cement with reactive magnesia (a form of magnesium oxide). The traditional manufacture of Portland cement requires high kiln temperatures to form calcium carbonate (and thus high energy use). However, Eco-cement can be kilned at around half the temperature (Pearce, 2002). This decrease in energy consumption can be quite significant as it is estimated the manufacture of cement accounts for approximately 7% of total man-made carbon dioxide emissions (Pearce, 2002).

According to Pearce (2002), the greatest benefit of Eco-cement over traditional Portland is its ability to rapidity absorb carbon dioxide from the air when it has been cured through a carbonation process. Therefore, if Eco-cement is used to produce masonry blocks, it has the potential to remove carbon dioxide from the air much like the function of a growing tree. Other benefits include incorporating recycled materials as the aggregate without losing structural strength. To date, this product has not gained wide acceptance within the construction industry and the base source materials remain expensive (e.g. magnetite).

Warm-mixed asphalt

An interesting and emerging product innovation in the road construction sector is a road surface application called Warm-Mixed Asphalt (WMA). Traditionally, hot-mix asphalt is created by heating a bitumen binder and aggregate to very high temperatures (around 170 degrees Celsius), which is then laid on the road surface hot and cures while it cools. Warm-mix asphalt (developed in Europe in the early 2000s), uses a two-stage process, where firstly, the asphalt is made using a specialised soft binder that allows the binder/aggregate mix to be heated at much lower temperatures (approximately 120 degrees Celsius); and secondly, a second binder is added (mainly a foam bitumen) that forms a combined mixture in similar grade to standard hot asphalt (AAPA, 2001). The use of WMA can significantly reduce cost as it uses up to 30% less fuel (a major ingredient in bitumen). It also produces a third less carbon dioxide emissions and dust than traditional methods (Whelan, 2009). Although testing is continuing to evaluate enduring performance, it is expected the warm mix may become a new benchmark for road construction worldwide (Whelan, 2009).

This paper now presents the product system dynamics surrounding the uptake of these innovative sustainable products; followed by a discussion of the issues impeding sustainable product diffusion in the Australian construction industry.

PRODUCT SYSTEM DYNAMICS

Project-based firms (such as contractors and consultants) are increasingly becoming aware of the importance of Ecologically Sustainable Design (ESD) for their future commercial viability, with many contractors expecting ESD and the use of sustainable building products to be mainstream in the next five years in Australia (Crabtree and Hes, 2009). Also, as a result of the increasing emphasis placed on ESD by construction clients and government, product supply networks (i.e. manufacturing firms and distributors) are focusing on the production and distribution of sustainable products to meet increasing demand. Currently, this demand is creating specialised markets, comprising small to medium-sized manufacturing and project-based firms in many cases.

The promotion of sustainable products is focused on the activity of the supply network (i.e. manufacturing firms and distributors). However, the development and implementation of innovative products in the marketplace is strongly driven by demand from clients and owners, and by users/facility managers who are concerned about long-term asset efficiency (e.g. life cycle cost savings). The uptake of sustainable products is also driven by project-based firms through a facilitation role. Project-based firms facilitate the diffusion of these products by prescribing to their clients the benefits that can be gained. For example, cost consultants can play a key role in promoting sustainable building options by quantifying the financial rewards and life cycle costing benefits to their clients and the design team (Clark, 2003). Also, technical support infrastructure actors (such as industry associations) play a role in promoting

the benefits of the innovative products at an industry level, and drive advances in product technology through research and development.

Regulatory and institutional actors (e.g. government authorities) within the product system assist in driving technological development and in increasing diffusion rates. The use of innovative finance options and positive government incentives are currently major drivers for the uptake of sustainable products in the Australian construction industry – particularly the residential building sector. It is expected that once the incentivised products gain market penetration and the technology advances, economies of scale will potentially bring prices down. For example, the Australian Government Solar Credit scheme offers a financial rebate for home owners, small business and community groups on the purchase of energy production systems up to 1.5 kilowatt capacity. This includes photovoltaic arrays, wind turbine and micro-hydro electricity generation (DEWHA, 2009). It is expected that increased demand, competition and production volume may bring prices down.

Government regulation also has a major role in the development and uptake of sustainable products. The Building Code of Australia (BCA) has incorporated minimum mandatory energy efficiency requirements for buildings, and Australian Standards dictate the minimum performance standards of products and new technology (such as minimum standards for the manufacturing of residential photovoltaic arrays). Also, Australian local and state governments have their own building environmental performance standards to encourage ESD in their regions. The combination of these regulatory and financial incentive approaches has been successful in promoting the uptake of innovative sustainable products in Australia; however, further education for project-based firms and the client/end users about the benefits that can be achieved may be beneficial. This would include both residential home buyers and commercial and government infrastructure clients.

SUSTAINABLE PRODUCT DIFFUSION

Innovation awareness is critical to the 'technology transfer' process. Many construction industry commentators agree that despite the increasing importance placed on ESD and sustainability, there remain barriers to wide spread adoption of these principles (and thus the acceptance of new products) (McGee et al., 2007, Crabtree and Hes, 2009). The levels of diffusion of sustainable products that are commercially available (and are set to be rolled out) is partly influenced by regulatory and pricing mechanisms in the industry (Crabtree and Hes, 2009). For example, a recent move towards the ratification of a uniform 'feed-in tariff' scheme in Australia potentially could improve the adoption of renewable energy-producing products (such as solar photovoltaic arrays) in the residential building sector. Currently, all Australian state governments have their own feed-in tariff schemes that offer residents the opportunity to be paid a premium for their locally generated electricity, to be fed back into the main power grid. Usually, locally generated electricity is metered separately from household energy usage, and is offset at a higher rate than the retail cost of the electricity from the utility company. In 2008, the Council of Australian Governments agreed to develop a set of national principles for new feed-in tariff programs (COAG, 2008). Regulatory improvements to the feed-in tariff systems in Australia have the potential to increase the cost-effectiveness of local energy production (as a part of a building system).

According to Terry, Walker-Morison et al. (2007, p.12), some of the real or perceived barriers to the diffusion of sustainable building products and materials in Australia include:

- sectoral conservativeness and slow building turnover, limiting exemplar projects to showcase new products
- diversity of rating tools resulting in confusion over the evaluation processes
- inconsistency in the industry's response due to a lack of mandatory sustainability standards
- high perceived costs, as cost evaluation is erroneously based on up-front costs, rather than on 'whole of life' costs
- inadequate in-depth knowledge to understand and assess new products and their integration and broader implications within the building system, and
- the need for new mindsets including a willingness to revise design and construction processes and timeframes to accommodate new product 'constructability' requirements.

The development of innovative sustainable products and processes are driven by the involvement of organisations large enough to absorb R&D and implementation costs. However, a major barrier to the development of these products is that the majority of the industry is made up of small to medium-sized firms who do not have the capacity to develop and implement such innovations in an emerging market. The industry needs to see the formation of new alliances between manufacturing and project-based firms to overcome cultural and resource obstacles to the development and diffusion of sustainable products and processes (Binder, 2008).

According to Crabtree and Hes (2009), a consistent approach is needed for dissemination of building product information (characteristics, costs and performance) to Australian designers and contractors. This includes improved collaboration and knowledge sharing to 'dismantle the myths and confusion perceived to be surrounding the financial implications of widespread implementation of sustainable design aspects' (p.223). It is expected that once the industry matures (and sustainable products gain greater acceptance), environmental performance will become a key consideration in the design and construction process and a consolidation process will occur (Terry et al., 2007). As more of the economy's resources are diverted away from business-as-usual and into sustainable products, some firms will face short-term pain in re-shaping their businesses. Government policy initiatives can help firms make the necessary adjustments.

CONCLUSION

This paper has profiled emerging sustainable product innovations offering significant performance improvement across the Australian building and construction products industry. These innovations contribute in a significant way to creating a more sustainable built environment in Australia. Given the significant breadth of the topic, it has been necessary to profile selected innovations from across the full range available. This selection has been necessarily subjective, but is nevertheless based on the advice of subject matter experts. It is expected future research will be able to quantify the relative promise of the profiled innovations, but as a starting point, this paper has mapped the product system dynamics surrounding the uptake of these innovative sustainable products; and identified key obstacles impeding their wider uptake.

Overwhelmingly, this paper points to the important role played by Australian governments in facilitating improved sustainable product adoption rates. This applies to governments in their various roles, but particularly as clients, regulators, and funders of education, training, and research and development. In their role as clients, Australian governments can better facilitate innovation by reviewing their specification policies and adjusting them to encourage the uptake of advanced sustainable products and associated innovations. As a result of a major shift in government policy towards this goal, it is expected private sector clients would follow suit. In their role as regulators, Australian governments face particular challenges associated duplication and uncertainty in how sustainable products are approved for use. This means that innovators often face high costs associated with gaining approval for products across multiple government jurisdictions. Also, regulatory and pricing mechanisms to encourage sustainable product use by consumers/clients require ongoing ratification across government jurisdictions. In relation to the BCA, recent reforms in environmental standards/benchmarks have helped to encourage the uptake of innovative sustainable products, yet greater emphasis on environmental performance, mandatory sustainability standards and performance-based regulations is encouraged.

Finally, in relation to education, training, research and development, the literature and subject matter experts agree that there is a lack of adequate understanding of the net benefits associated with particular sustainable product innovations. It is recommended Australian governments place further emphasis on education programs, training and demonstration initiatives to encourage a cultural shift towards decision-making based firmly on the consideration of long term whole-of-life costs and wider environmental benefits.

Abstract
Recent developments in the construction industry led to the need for both more and changing formal contractual arrangements and for improved informal cooperation. In this context, the Competitive Dialogue (CD) was introduced by the European Commission in 2004. This procurement method consists of several discussion rounds between the principal and potential suppliers, during which all aspects of the tender can be discussed. The CD procedure aims to align complex demands of principals with possible solutions that contractors have to offer. It is, however, unclear how formal and informal structures and processes in the CD are interrelated and are determining its effectiveness. Major question is how processes and products differ between CD-procured projects and comparable projects which are traditionally procured. *Insights of both formal and informal contracting processes are combined in a theoretical framework. Differences in (in)formal process and contract development between projects procured by the CD procedure and by traditional procurement procedures are studied in four comparable construction projects.*

Keywords: procurement, contracts, relationship development.

INTRODUCTION

The combination of increased project complexity (Baccarini, 1996; Laufer *et al.*, 1996; Alderman *et al.*, 2005; Walker, 2007), changed role of the government (Blanken, 2008) and the sector‟s poor professional functioning (Latham, 1994; National Audit Office, 2001; Dorée, 2004) form the context in which several changes in the construction industry are embedded. These changes are twofold: on the one hand they are aimed at new structures (formal processes and contracts) and on the other at new working relationships (informal processes and understandings).

Formal tasks and roles of the market and of government have changed. Public clients have less influence on the contents of works and confine themselves to monitoring and checking the public‟s interest. Conversely, market organizations have, alongside the executive, also more substantive tasks. Stemming from these changing tasks and roles, structures have been amended and are continuously developing. Integrated contract forms, PPP constructions and active discussions on aspects such as prices, risks and contractual terms are becoming more common during the procurement of construction projects. Further, there is also growing attention paid to the „soft‟ aspects of construction. The call for new cooperative forms, increased mutual trust, improved communication and mutual understanding becomes louder.

In this context, the Competitive Dialogue (CD) was introduced by the European Commission in 2004. This procurement method consists of several discussion rounds between the principal and potential suppliers, during which all aspects of the tender can be discussed. The

CD procedure aims to align complex demands of principals with possible solutions that contractors have to offer (Hebly and Lorenzo van Rooij, 2006). It is, however, unclear how formal and informal structures and processes in the CD are interrelated and are determining its effectiveness. In essence, there are two perspectives. In the first perspective, formal and informal structures and processes in the CD are serving as alternatives: what is arranged in a contract does not need to be discussed informally and vice versa. In the second perspective, formal and informal structures and processes are considered as complementary. Formal contracting processes can lead to informal processes such as the development of mutual expectations and social relationships.

Major question is how formal and informal structures and processes differ between CD-procured projects and comparable projects which are traditionally procured. Insights of both formal and informal contracting processes are combined in a theoretical framework. The outline of this study is as follows. In the next section, formal bargaining and informal sense making *processes* and the *products* of contracting - the formal and informal contract - are discussed into detail. It is explained that the linking concept between process and product is understanding. Based on the previous steps, propositions are developed based on both the policy rhetoric for the design of the CD procedure and on the theoretical insights. Subsequently, the empirical research design is presented. Differences in (in)formal process and contract development between projects procured by the CD procedure and by traditional procurement procedures are studied by selecting four comparable cases. Finally, the result are discussed and conclusions drawn.

THEORETICAL FRAMEWORK

Basis of the theoretical framework is the process model of Ring and Van de Ven (1994). This model gives an overview of how both formal and informal processes are involved in relationship development. However, in order to understand how these processes are interrelated, especially during the (in)formal contracting with the CD procedure, this model is expanded with the models of Ring and Van de Ven (2000) and Vlaar, Van den Bosch and Volberda (2006). These three relationship development models are combined into one framework for studying formal and informal contracting processes in procurement by the CD procedure. Central elements in this framework are formal bargaining, informal sense making (Weick, Sutcliffe and Obstfeld, 2005), the formal legal contract and the informal psychological contract (Rousseau, 1998). These elements will be further elaborated upon in the following sections and will guide the data collection and interpretation.

Formal bargaining

Relational development academics identify the following four mechanisms that occur in bargaining:

- *Focusing attention*: Vlaar et al. (2006) show how formal processes focus attention by pointing at order and content of decisions which are to be made.
- *Forcing articulation, deliberation, and reflection*: when bargaining over possible terms and conditions, parties are forced to make their individual and mutual goals explicit (Blomqvist et al, 2005, p. 501).
- *Interaction*: formal bargaining implies that parties exchange ideas about future tasks and outcomes by conversations and dialogues (Nellore, 2001; Yakura, 2002; Putnam, 2003).
- *Reducing biases, judgment errors, incompleteness and inconsistency*: the fact that in interorganizational bargaining processes usually several people are involved, compensates

for deficiencies in individual thought processes (Katz and Kahn, 1966; Ketokivi and Catañer, 2004).

The identified output of the bargaining process form conditions for the second part of the negotiations stage of procurement: informal sense making. Vlaar et al. (2006) state that formalization "enables, or even forces collaborating parties to engage in sense making, helping them to create common ground and achieve mutual understanding" (p.1622).

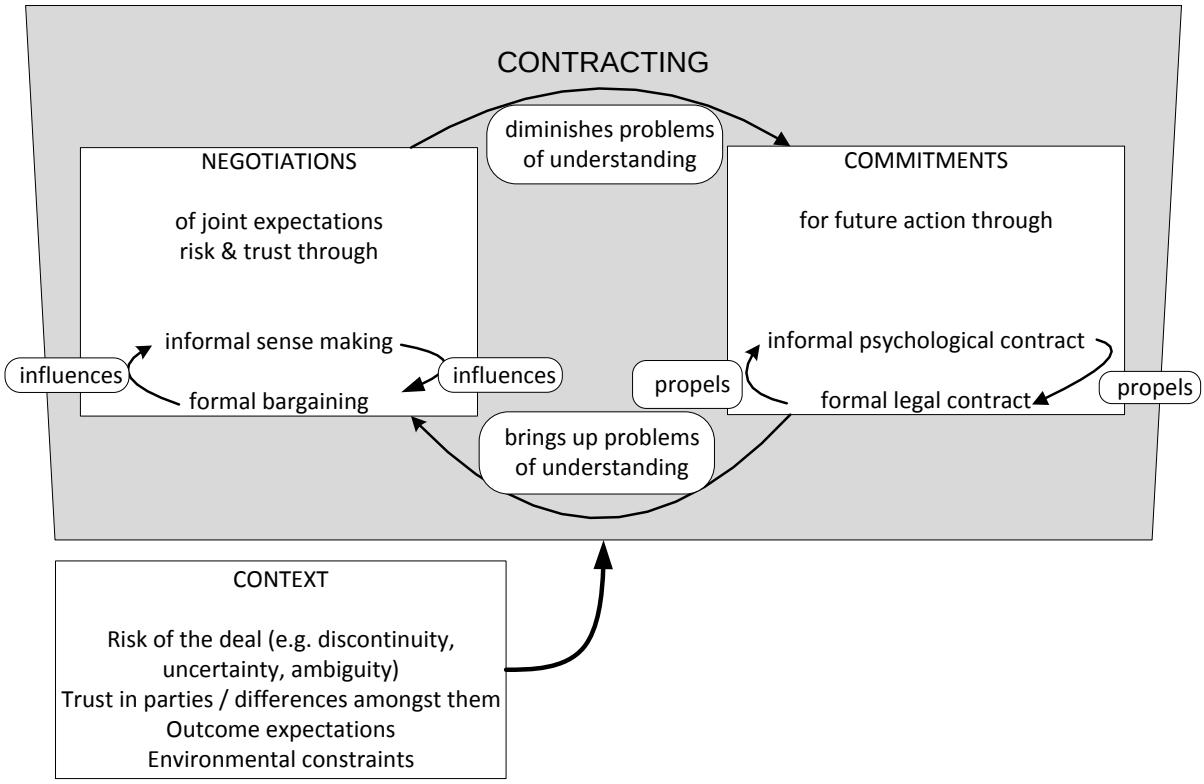

Figure 1: *Theoretical framework*

Informal sense making

Sense making is a social process during which organization members interpret their environment in and through interactions with others, thus constructing observations that allow them to comprehend the world and act collectively (Sandelands & Stablein, 1987; Starbuck & Milliken, 1988; Isabella, 1990; Sackman, 1991; Weick & Roberts, 1993). During the contracting process, two parties with differing patterns of beliefs and assumptions are to create coherent understandings in order to come to collective action (Maitlis, 2005; Weick, 1993). Since the two parties intend to work together, they will strive for congruency in views on purpose and expectations of the relationship. Sense making processes are therefore assumed to play a central role in the procurement of a project. These processes form "the primary site where meanings materialize that inform and constrain" action (Weick et al. 2005, p. 409, citing Mills, 2003: p.35). Weick (1995) describes the sense making process as an enactment process: parties produce part of the environment they face (p.30). The result of the sense making process in interorganizational contracting is to understand the transaction, the context of the transaction, the value of it to the other party and to oneself. Shared understanding between the two parties is reflected in mutual beliefs, norms, values and routines. These form the basis of the first part of the Commitments stage of procurement: the informal psychological contract.

Informal psychological contract

The psychological contract consists "of unwritten and largely non verbalized sets of congruent expectations and assumptions held by transacting parties about each other's prerogatives and obligations" (Ring and Van de Ven, 1994, p.100). Following the literature review of Van Den Brande et al. (2002), four aspects of these contracts are considered: subjectivity, reciprocity, implicitness, and obligation. These "elements of quasi-moral involvement among parties" are much more common among members of an internal organization, but can and do appear in a market context as well (Williamson, 1975, p. 38). Yet, in this research the term *informal (psychological) contract* is used. This term is used to make clear that it is opposed to the formal (legal) contract. Kadefors and Laan (2010) state that *informal control* is "about purposefully establishing norms, values and routines, to reduce discrepancies in goal preferences and inclinations towards opportunism. Consequentially, informal control reduces risk through the establishment of shared values. In this study, the informal contract refers to the implicit set of expectations between the client and the contractor and which is, unlike the written contract, continually changing.

Formal legal contract

Ring and Van de Ven (1994) describe how the informal contract becomes formally codified. As individuals act as agents for their organizations, these organizations will require formal documentation and standardization. Thus, the informal commitments made by negotiating individuals will be left in writing for their organizations and for other individuals acting as agents for those organizations. When the formal legal contract is perceived as a reflection of formal control, it contains both limitations of opportunities for opportunism and limitations of material incentives to utilize these opportunities. There are several mechanisms by which contracting parties could address these forms of control. The mechanisms, which are derived from transaction cost economics, are shift in rights/power of decision, rewarding systems, monitoring, and bonding. Vlaar et al. (2006) argues that formalization may also have negative effects on sense making, causing new problems of understanding. It may make events more comprehensible and controllable than they really are; it may lead to formalism, causing rigidity and a loss of creativity and flexibility, and diminished trust. Next to that, the writing of formal contracts may cause large efforts and huge transaction costs.

Understanding as a key concept

In the previous sections, the cycle negotiations – commitments – negotiations is elaborated upon. Key concept in this cycle is *understanding.* When having made sense of new situations, people desire to enact the input to their sense making processes back into their world to reorder it (Weick, 1995). The resulting collective consciousness, common reality, or shared *understandings* offer them a unitary basis for action. For those points on which this collective consciousness, common reality or shared *understandings* are reached, parties are in the commitments stage of contracting (Ring and Van de Ven, 1994). Yet, processes of informal sense making do also propel new formal bargaining processes. These new bargaining processes facilitate new sense making processes, which in turn could improve *understanding*. Ring and Van de Ven (1994) indicate that formal and informal processes are interacting during each stage of the development process. It is not just as if formal bargaining leads to a formal contract and informal sense making to a psychological contract. However, where Ring and Van de Ven (1994) assume formal and informal contracts to be each other‟s substitutes (existence of an informal contract diminishes the need for establishing a formal contract), the insights of Vlaar et al. (2006) suggests that formal and informal contracts serve more as complements. Developments in the informal contract effectuate developments in the formal

contract and vice versa. Understanding is assumed to be the main force in these developments.

PROPOSITIONS ABOUT THE WORKING OF THE CD PROCEDURE

The model developed, depicting how formal and informal processes and products are playing a role in inter-organizational contracting gives us an idea of the dynamics in (in)formal contracting processes involved in procurement processes like the CD procedure. This leads to the following propositions.

Context

The CD procedure was meant for the procurement of complex projects, of which technical, legal and/or financial solutions were not objectively specifiable by the contracting authority. Complex projects could be characterized by high levels of risk and insecurity about what to expect. This context is therefore included in the theoretical frame. Following Ring and Van de Ven (2000), we assume that the environmental aspects which are of importance are risk, initial trust levels, outcome expectations and environmental constraints.

Proposition A: The contracting process is influenced by aspects from its environment, like risk, initial trust levels, outcome expectations and environmental constraints.

Understanding, negotiations stage and commitments stage

The CD procedure is a new approach to tendering, with the expectancy to influence the execution of the project. One could argue that tendering equals the negotiations stage of the model developed, whilst the construction of the project starts in the commitments stage. This might sound logical when considering the contract which is signed at the end of the tendering as the formal legal contract. However, this is not in line with the assumption in the model developed that understanding and problems of understanding determine whether or not negotiations start or commitment is reached. Given this assumption, contract close cannot be seen as a demarcation point where the negotiations stage becomes commitment stage. Even the contract which is signed will be renegotiated in new series of formal bargaining and informal sensemaking. However, the contract which is signed at the end of tendering is meant as a formalization of the understandings reached during the tender negotiations and parties intend to commit to the agreements reflected within.

The parties involved might understand each other on some aspects of the contract and face problems of understanding on others, during any stage of the project. However, since it is not possible to both understand and have problems to understand at the same time, the parties are in either the stage of commitment or in the stage of negotiations for each of the aspects apart. This means that commitments and negotiations are substitutes of one another.

Proposition B: During all phases of a project, from initiation up to delivery, the parties involved go from commitment to negotiations and back, depending on whether there is understanding or not.

Proposition C: On several aspects of the project the parties are in either the stage of commitment or the stage of negotiations. Commitment and negotiations do, however, not coexist within an aspect: the two stages are serving as substitutes.

Formal and informal processes and products

Within the stage of negotiations, both formal and informal contracting processes take place. The processes of formal bargaining and informal sensemaking are both meant to decrease problems of understanding. When understanding has been reached, the stage of commitment

contains both formal and informal contracting products. The formal legal contract and the informal psychological contract are both reflecting the understanding which has been reached. The assumption in the model that within stages formal and informal processes or products are interacting, holds that formal and informal processes are each other‟s complements, just as formal and informal products.
Proposition D: Formal and informal processes and products serve as complements of one another.

These propositions are a starting point from where we will be looking at the practice of CD procurement.

EMPIRICAL RESEARCH DESIGN

To study the difference in (in)formal process and contract development between projects procured by the CD procedure and comparable projects procured by different procurement procedures, it is important that the selected cases are comparable. An embedded multiple-case study required in this case at least four comparable projects: two projects procured by the CD procedure, and two projects which are traditionally procured. Within those projects, four formal and four informal contracts are analyzed. The four projects selected are part of a maintenance program of highways including fly-overs, overpasses and other related objects in co-operation with the private parties.

Data are collected through a series of in-depth face-to-face interviews with both a contractor and a principal in four construction projects and additional interviews with informants who can say more about the projects in general (see Table 1). The description and analysis of the four case projects is based on concepts as discussed in the theoretical framework. By comparing the parties‟ experiences in both the tendering and the execution stage of traditional procured case projects with the parties‟ experiences in those stages in CD procured case projects, conclusions are drawn about the effect of differences in tendering for the construction stage of projects and the effectiveness of the CD procedure.

		Participation level		
		Fully participated in a traditionally procured project	Fully participated in a CD procured project	Generally involved in projects
Role	Principal	2	2	3
	Contractor	2	2	1

Table 1: Number of interviews, differentiated by participation level and role

Each interview took 60 to 90 minutes and was guided by case study protocols. The interviews were recorded and transcribed for systematic analysis, and complemented with information from the evaluation report, the procurement documents, contractual documents and requests to change contractual terms after contract close. This was all loaded into the data analysis program QSR NVivo, which was used to attach labels from the theoretical frame to empirical information. Using the program, text fragments with identical labels were easily compared, patterns were discovered and from that, conclusions were drawn. We sought for formal and

informal interaction patterns, and especially for similarities and differences between the traditionally procured projects and the CD procured projects. In the upcoming sections, attention is given to the traditionally procured projects and the CD-procured projects respectively.

TRADITIONALLY PROCURED PROJECTS

Problems of understanding

When the construction stage started, right after contract close, the Dutch Highways and Waterways Agency (the principal in the cases studied) and the winning contractor did not have had much contact. Except for the public inquiries during the procurement stage, no information exchange had taken place. Therefore, the mutual understanding about the meaning of the contract, its scope and the plans which were made by the contractor had to grow during the construction stage. There were several situations which caused problems of understanding in those early stages of the construction stage.

The first problems of understanding arose from different interpretations of tasks and duties. This had mainly to do with the fact that neither Agency nor contractors were having experience in the procurement of contracts with a design component under System-based monitoring (a new monitoring system of the principal or Agency). At the one hand, there were the contractors who thought it was odd that the Agency did not know what to conclude from the state assessments (did the whole bridge had to be replaced or would it be sufficient to reconstruct parts of it?). At the other hand, there was the Agency, feeling that it was the contractors‟ responsibility to make that decision and then put a price on it.

When the contractors started their work, they were confronted with an actual state of objects and roads, which turned out to differ from what was written in the assessment of the Agency. This caused problems of understanding. In the contracts it was agreed upon that in case of incomplete or insufficient data, or when the actual state of objects and roads turned out to be worse than one might expect from the state assessment, extra work would be for the Dutch Highways and Waterways Agency‟s account. The clauses of the contract provided that contractors would claim nonexistent extra work, by stating that when differences were discovered, the Agency would have to be contacted. Extra work should only be carried out after the Agency‟s consent. In practice, this was not as simple as one might expect, since works were mainly carried out during the night. And then, no agency employees were present or reachable at their offices.

The contractor‟s plans which were assessed by MEAT criteria to win the contract were only the outlines of the working and monitoring plans. These had to be specified after contract close, and accorded by the Agency. System-based monitoring was new to both the Agency and the contractors, which made that in both projects the contractors had a hard time finding the right abstraction level (resulting in loads and loads of paperwork to prove their efforts), and the Agency took its time to check the plans, and refuse them several times. It somewhat hovered between monitoring the process from distance and checking upon the details of the product itself. However, there was not all the time to keep checking and re-checking since the closure of roads involved was due on a fixed date, which came closer soon. This put high pressure on the development of the working and monitoring plans.

Summarizing, the early months of the traditionally procured projects were not contributing to positive development of the relationship between the Agency and the winning contractors. At contract close there were small problems of understanding about the working roles which each party should take. When the actual state of objects and roads turned out not to match with the description in the state assessments, these small problems of understanding grew big. The discussions over extra work which had been performed without consulting the Agency at forehand and the long time and extra versions it took before the working and monitoring plans were accepted, added to the mutually sensed feeling of misinterpretation of working roles

Negotiations and commitment

From the previous part it showed that especially the informal understanding of what was written in the formal contract differed between the Agency and the contractors. This caused that the relationship in both projects developed in negative vicious cycles. However, both the Agency and the contractors involved in the projects were committed to the projects. They were, therefore, willing to cooperate for the benefit of the project

Besides practical solutions with regard to entering the objects and highways without accepted working and monitoring plans at the closure dates, also the working relations became looser. In both projects a project re-startup was organized, which helped in the sense making process of both parties involved. After renegotiations, the parties had reached mutual understandings about the job which had to be done and the roles both parties had to take. This helped to finish the last part of the project by changed working routines and in a better working atmosphere than was the case during the first part.

Summarizing, whereas at the start of the construction stage of the traditionally procured cases the parties involved had no strong expectations, their attitude towards each other had become somewhat negative after the first construction months. Pragmatism and some project re-startups created renewed mutual understanding though, so that the last months of the construction stage went much more cooperative and smooth.

CD PROCURED PROJECTS

Problems of understanding

Already during the dialogue, the first problems of understanding arose. The first issue was the time to go through the Agency‟s available information. Candidates felt they could not assess how (in)-complete this information was, so that they could hardly determine what the assignment to the engineering firm would have to include. The available information was too much, and too poor. Besides, the engineering firm‟s appointed assessment time (15 minutes per object) was judged as too insufficient. Furthermore, candidates felt that the state assessments in their selves had to be judged too soon after delivery. However, they did not make a big deal of this towards the Agency, causing it being not discussed yet noticeably an issue.

Second cause for problems of understanding was assigning an engineering firm. It was the Agency‟s intention that candidates would jointly be responsible for drawing the engineering firm‟s assignment. However, the fact that this firm was appointed and paid by the Agency gave a different signal to the candidates. Besides that the contractors did not feel responsible for the contents of the state assessments, the given situation did also cause them to behave

opportunistically. Respondents from both the Agency and the contractors state that the drawing of the assignment to the engineering firm ended up being more a game between the candidates than a proper attempt to get the right information.

All five Agency respondents and two of three candidates agree that the candidates were more active with each other than with getting the right information in the state assessments. As if eliminating competing candidates was more beneficial to win the bid than cooperating to get clear sight of the risks of the project. This caused friction at the Agency‟s side about the candidates‟ interpretation of tasks and duties. Contractors held the opinion that they would not have to check the situation of the objects and roads themselves, since all knowledge had been delivered on paper. These problems of understanding were, however, not expressed during the dialogue. So although all parties came out of the dialogue with the expectation of having signed proper contracts, the execution of the projects showed that the understanding of these contracts was not mutual at all. Agency and contractors came to stand against each other when the actual state of objects and roads appeared not to match the expectations, formed by the state assessments.

There were several problems. First, in one case it is not clear whether a problem is the contractor‟s responsibility or the Agency‟s. Secondly, during the state assessment some things have been overlooked and later on it turned out that something was wrong. The Agency felt that the candidates had to have this checked upon, and since they did not do so, the Agency held them responsible to pay for the extra costs. Contractors held different opinions, and put claims on the Agency. Third, whilst the Agency employees were unanimous in their opinion that contractors did not feel responsible enough and were not truly committed to the project, the contractors complained about the Agency taking the contract too literally, not thinking in terms of project interest, but from the Agency‟s single-angled interest only. This was especially reflected in issues concerning the system-based monitoring. Both contractors and Agency employees felt that the system was too extensive for the small job maintenance actually is. However, with two parties holding different working routines, with claims being put and a monitoring system which is new to all parties involved, negative vicious cycles were developing. This caused for contractors that small shortcomings could result in large payments which were retained

Summarizing, problems of understanding during the procurement stage of the CD procured cases were increasing throughout the construction stage of those projects, due to differences in interpretations and expectations. During the dialogue conversations most of these issues were not discussed and therefore unexpressed towards each other.

Negotiations and commitment

Just as in the traditionally procured projects, the CD procured projects developed along negative vicious cycles as well. From the previous part it showed that especially the informal understanding of what was written in the formal contract differed between the Agency and the contractors. In attempts to make sense of the situation, both parties in each project sought for explanations. These were found mostly in doubting the other party‟s professionalism.

The parties kept fighting their differences about the actual state of works and roads, so these were only solved by tough renegotiations. The first situation (defining which scenario the found problem concerns) was looked at per occasion by the Agency. For the second situation (things were overlooked during the state assessments) the Agency and some contractors went to court. When in the first case verdict was given in favor of the contractors, the Agency and

the concerning contractor entered in a mediation process which lead to settlement. This settlement was then translated to all the other cases so that new agreements were reached about the responsibility for the state assessments.

Along with the settlement over the responsibility for the state assessments an arrangement was made over the shortcomings. Contract managers did not have to decide for themselves any more whether or not something was a shortcoming or defect; their bosses from the Agency in Utrecht took care of it from then on. It helped, according to the informants, however this did not bring in empathy or affect.

Summarizing, due to the fact that problems of understanding remained unspoken, the negative attitude of both parties towards each other influenced the manner in which they both made sense of new cues. Problems of understanding only increased during the construction stage, due to negative vicious circles of internal sense making instead of expressing problems of understanding towards each other. Tough negotiations and even law suits gave verdict in the worst cases, but could not relieve the relationship between the Agency and the contractor.

DISCUSSION

When problems of understanding due to differing ideas about risk allocation arose, the starting situation at contract close was different in the CD procured cases than in the traditionally procured cases. In the traditionally procured cases, both parties entered the construction stage rather blank: the principal and the contractor did only start to get an idea of who the other party was and what was important to him. In the CD procured cases, however, when the construction stage started, both parties had formed an image of the other one already.

Whereas in the CD procured cases renegotiations did only emphasize existing differences in norms and values, working routines and inability to empathize, which caused problems of understanding only to become worse, the contrary happened in the traditionally procured cases. There the renegotiations lead to understanding, empathy / affect and mutual working routines, even though the norms and values of the parties involved did not correspond at all spheres.

Summarized, when problems of understanding about the risk allocation had been discussed during the dialogues, it would have been likely that what happened in the traditionally procured cases would have also happened in the CD procured cases: starting to make sense of the situation without having an idea of the other party already. But since these conversations did not take place during the dialogues, the implementation of the CD procedure turned out to be less effective than expected. Both parties held the idea that the dialogue conversations had lead to proper understandings at both sides of the table. Renegotiations would not have to be necessary if the other party would act as agreed upon.

Given that the parties were not aware of the differences in understanding between them, negative cycles began to develop: observed shortcomings by the Agency were followed by proposed amendments of the contractors, followed by rejections of the amendments and putting payments on hold by the Agency, after which there was only one way out of the negativity to make the projects succeed: a conciliation board. After settlement, the parties in the CD procured cases did not work along fine and easy as was the situation in the traditional

procured cases. Instead, the working routines remained distant and stiff, due to the fact that notwithstanding open, trust-building CD conversations, the relationship was disturbed by both parties‟ responses to disagreement about the risk allocation.

CONCLUDING REMARKS

The major question was how processes and products differ between CD-procured projects and comparable projects which are traditionally procured. The actual *formal* contracts do not differ much between CD procured and traditionally procured projects. It was shown that problems of understanding were key in the development of contracts in both types of contracts. The *informal* contracts and the processes to solve problems of understanding in the construction stage of the project do differ when comparing CD procured projects with traditionally procured projects. Processes of sense making determine how parties enter into the bargaining process to a large extent. This explains why renegotiations over risk allocation differ between the CD procured cases and the traditionally procured ones. In the CD procedure parties get to know each other better during the procurement stage. This makes that sense making processes at contract close develop different than in traditionally procured cases. Interaction between principal and contractors during the contracting process make that informal contract and formal contract develop simultaneously. When the informal contract is mutually understood by both contracting parties, this might result less problems of understanding during the construction phase of a project. However, in the cases problems of understanding were only bigger for the CD procured projects compared to the traditionally procured projects. We explain this by the stressing that the dialogue conversation did not cover the whole contract. Although developing simultaneously, formal and informal contract did not develop parallel. Instead, the two grew away from one another. The answer to the major question indicates that the CD procedure‟s design and its side-effects influence the forming of both formal and informal contract. The results also indicate that formal and informal contracts are dynamically interrelated. Problems of understanding have showed to be key in the development of both formal and informal contract.

ORGANISING LARGE SCALE GREEN COVERED ROOFS

Classification of green roof specifications and green roofs implementation; the economics of green roofs

Abstract
Last two decades the use of plants on rooftops has grown fast. Municipalities use different arguments to initiate policies for large-scale programs for green roofs. However, there is an intriguing intertwining of two scales: building and city. To accelerate policy execution the scales should be combined, but they are not. The stakeholders, not accustomed to collaboration in this new context, keep their natural roles in their traditional organisational patterns. New patterns and new collaborations have to be established soon to speed up the process of change. This paper shows the arguments for mitigation and adaptation approaches on the scale of buildings and cities, from the point of cost and benefits for the major stakeholders. Calculations of municipalities showed that benefits for private partners, investing in green roofs, are less compared to the public benefits. Private benefits may even be negative, nevertheless the summation of private and public benefits is mostly positive. However, the accountability of calculations is minor. There is no uniform method of calculating or monitoring the effects of green roofs on building or city scale. This calls for change. A classification of uniform methods to calculate and measure effects is needed to enlarge customers confidence in the product and to suppress emerging bureaucracy due to different local approaches of policy making and policy implementation.

Keywords: green roofs, public policy, classification of specifications, classification of policy implementation.

INTRODUCTION

All over the world cities proclaim policies to support the construction of green roofs. It seems easy to argue why large areas of roofs covered with plants may contribute to mitigation of and adaptation to e.g. climate problems. One argument is that green covered roofs contribute to reduction of CO_2 emissions on the local scale of the building, which is mitigation. CO_2 reduction can be realised because there is a contribution to extending the life expectancy of the roof. There is a potential reduction in fossil energy use, especially for cooling. On green roofs water can be retained and particular matter (PM) can be captured, which are adaptation approaches. This would reduce the effects of urban heat island. Literature of green roofs specifications is available in several countries according to local circumstances (Getter Rowe

2006). When roofs are covered with plants on a large scale this will also contribute to adaptation, often being part of sustainable water management. It became clear during the last decade that an accelerated implementation of green roofs on a large scale is necessary but not easy to realise.

EFFECTS OF GREEN ROOFS FOR A BUILDING

Green roofs have positive effects on the environmental impact of a building and on the comfort in the building. Green roofs are also known as functional extra space on top of buildings with aesthetic value. How consistent are these claims?

Additional space and aesthetic value

Plants grown roofs provide space for people and provide a place for plants and animals to live. People may use the roofs as a visual object, or as a place to stay.
Clearly, a plants grown roof can make up for a lack of green, and it can be a place for living in the summer (if the roof is slightly tilted or flat). We may conclude that green roofs also can be used as an outside space for living and as a source of greenery. However, we may conclude that it is unlikely to be useful using the roof for the production of food include meat.
Some advantages are more or less intangible. These intangible claims are difficult to discuss, because they deal with subjective matters, such as aesthetic and psychological matters. Aesthetic claims state that a green roof is attractive and it can be an architectural highlight in a city. Of course this claim can also be reversed. Other people may say the roofs are extremely ugly. Psychological claims include the exciting experience you get seeing and smelling plants grown roofs.

Extension of lifetime of roofing

When a layer of soil has been applied on a roof this layer protects the construction of the roof. The roof is protected due to different effects. First, the skin of the roof is not exposed to sunlight. Secondly, people walking on the roof do not easily damage the roof. Finally, the skin of the roof is not exposed to a great variety of temperature. Usually gravel layers are used on roofs to provide a smoothing of temperature fluctuations on a roof; vegetation layers have the same effect so much more. This may even be the main thermal argument for construction green roofs. The fact is that the less the temperature fluctuations the longer the lifetime of the roofing. The influence of the green covered roof on temperature differences on the roof and consequential the influence on the durability of the roof can be technically measured and proofed (Teeuw Ravesloot 2011).

Thermal isolation

Some manufacturers of green roofs claim their particular green roof systems provide extra insulation for heat and cooling. These claims can be substantiated with calculations and measuring. However, even if these calculations and measuring would be more or less accurate and accountable, which they probably are, it would not help accelerating the application of green roofs in cities. Although cooling may be likely due to the plants and the mass of the roof, only in some rare cases a green roof system is claimed to insulate thermally, where no evidence is available. Moreover, the specifications on thermal isolation cannot be used in comparison of different green roofs systems of different manufacturers (Teeuw Ravesloot 2011). Consumers are confused by different claims that cannot be compared.

Water management
On the scale of one building the buffering of rainwater and the slowing down of rainwater run off is in rare cases profitable for the building owner or user. Substantial amounts of water on the roof will contribute to extra thermal cooling in summer, but on the other hand it cannot be excluded the same water contributes to extra thermal losses in winter situations, due to de-icing and vaporizing. On the scale of the city nevertheless, buffering and slowing down of rainwater run off can be claimed to have a profitable effect for the municipality.

EFFECTS OF GREEN ROOFS FOR A CITY

From epidemical research it is known that in cities inhabitants die earlier if exposed to extreme periods of high temperature and after exposure to smog from ozone and particular matter (PM) (Buringh Opperhuizen 2002). Especially elderly people will be affected (Luscuere et.al. 2002). The Urban Heat Island effect directly indicates the early death of people around hot and dusty areas. This is why, it is claimed that green roofs contribute directly to healthier conditions in inner cities.

Urban heat island effect
Green roofs have a positive effect on the city climate and have a buffering effect on the temperature and humidity. This dampens the Urban Heat Island effect (UHI).
Because green roofs radiate less heat, temperatures in the city would not rise as high compared to the surrounding land (city) without green roofs. The Ryerson University in Toronto has conducted studies on the impact of green roofs on the temperature in the city (Ryerson University, 2005). The studies were made for the city of Toronto (Ontario, USA). The research revealed that local and incidental green roofs reduce not really the Urban Heat Island in the city. But if really widespread green roofs were applied, the average temperature in the city of Toronto would decrease with 0.5 to 2.0 degrees Celsius, depending on the season.
Also a good green structure with parks and corridors may reduce heat stress and provide thermal reduction. Green roofs may contribute importantly to this concept. In case city planners and urban designers would cooperate, policies to counterattack UHI effects would probably be more successful (Teeuw Ravesloot 2009).

Urban water management
Cities in general and high-density inner city areas in particular have problems cooping with heavy rainfall. Not only will the buffering in open water structures be compromised, also sewerage can become incapacitated. Managing urban water becomes an important matter of hygiene.

Buffering rainwater
When the green roof is designed to store water, only a very limited amount of water reaches the drains. Rainwater pipes may even be unnecessary.

Slowing down rainwater run off
The most important characteristic is the reduction of peak load in case of heavy rainfall. When raining, the rainwater falling onto the roof will not immediately flush away into the drains. It is easy to understand the principle. Normally rainwater falling on a roof directly flushes away into the drains. On a plants grown roof water is retained by the soil-layer (or draining) of the roof. Later on, some of the water evaporates and partly the vegetation

absorbs the water, only a minor part disappears into the sewer. Due to this one can have smaller drains. Besides the wastewater may be cleaner because of the filtering effect of the roofs.
It is likely that greening of roofs can contribute to urban water management, however it will be a modest contribution (Mentens 2006).

Urban clean air program
A lot of municipalities have programs to get cleaner air. Combustion engines and other devices using fossil fuels emit particulate matter possibly causing early death of inhabitants of inner city areas. Clean air programs often include policies to cover roofs with vegetation.
Vegetation binds dust and particulate matter (PM) from the air and reduces smog as is shown in practice and research. It is unlike however that green roofs will contribute significantly to the binding of PM from city smog. Green walls are more likely to contribute since there is usually a larger leaf surface and counting PM on leaves is more accurate and valid (Ottelé et.al. 2008).

INVESTMENT IN ADAPTATION AND MITIGATION OF EFFECTS

Some effects of covering flat roofs in cities with vegetation will, on the scale of the city, contribute to mitigation of environmental pollution and degradation, especially in case of large-scale introduction of the green roofs. The mitigation effects will mainly be the reduction of cooling energy and in some cases the reduction of energy use for heating buildings. Expansion the life span of roofing materials can probable also be accounted as a mitigation effect.
Effects on the noise-reduction in cities and inside buildings, health effects as a result of clean air and intangible effects like aesthetics and the resultant direct health impact might be more adaptation. Using green roofs for buffering rainwater and slowing down the rainwater run off from roofs is most definitely a clear adaptation measure cities can provide.

Each tangible and intangible effect, adaptation and mitigation, will have a different set of stakeholders, interested in participating in the costs and mostly in the benefits of greening programs.
Each local initiative will have to face similar complex conditions to maintain interest in public benefits from investments, taking into account the context of smaller financial benefits for private investors. Several perspectives can be distinguished. From the designers perspective e.g. it seems not clear how the potential of green covered roofs can be fully organised.
Remarkable results where achieved in a London City survey for participants in the design and construction process (see figure; Voll et.al. 2007). The hypothesis was: “The physical structure of many buildings prevent the use of green covered roofs”. Only yes and no answers were allowed. It is very interesting to see that especially the initiators and decision makers do not specifically approve to using green covered roofs. Even 92 percent agrees with the thesis, whereas only 27% of the construction engineers agreed.
The explanation can be found in lack of knowledge on this aspect. Other - secondary - explanations could be:
- Lack of policy from public authorities.
- Benefits and positive effects are unknown.
- Many participants assume that costs are higher, but do not have a clue about how much higher.

– Many parties do not want to take risks in design tasks they do not know.
– Most of all the collaboration between design parties is insufficient.

Profession	Percentage of agreement
Actor analysts	67
Architects	40
City designers	33
Construction engineers	27
Developers and investors	92
Advisors ecology and water	13

***Figure**: Results of the London city survey*

From the construction contractors perspective it is important that their product will fit the private investors needs as well as the public subsidies interests and still make a profit.
The common interest of all parties involved is that no green covered roof will ever have any kind of problem. Any leakage or other damage will cause damaging of the public image of green roofs.

ECONOMICS OF GREEN ROOFS FOR BUILDINGS

The environmental effects or the image of a green roof might not be in accordance with the interest or the wish of the architect or the client. The decision making to realise a green roof involves many criteria, some of these are of economic nature.

Costs of green roofs

The costs of green roofs versus the costs of traditional roofs can easily be estimated. The roofing itself will be a little costly, further supplemented by the costs for the substrate and vegetation on top of the roofing. Considering the total building the extra costs are minor. The maintenance costs of a green roof, if grown with so-called extensive vegetation, are considered to be equal to that of traditional roofing. On the on the hand, roofs grown with so-called intensive vegetation, e.g. roofs gardens, are more expensive and do not always have a positive cost-benefit ration (Ravesloot Teeuw 2010).

Benefits of green roofs

The life cycle costing of green roofs is positive, since the life expectancy of the roofing is doubled (Voll et.al. 2007). Added value from green roofs is the decrease of the cooling demand in case cooling would be required. In some cases green roofs add extra thermal insulation and heat losses in winter situation will drop, although due to the humidity one may not rely on this. Sometimes a building owner or user benefits from the slowing down of rainwater run off and the buffering of water on the green roof. In cases the dimensions for rain pipes and sewer can be diminished. These will safe money from the initial investment budget as well from the maintenance budget. It can be concluded that apart from the higher investment costs, the life cycle costing of green roofs mostly turns out to be positive.

INTERTWINING OF SCALES

Convincing arguments for fast introduction of green roofs are known. However the calculating of effects on green roofs and the supporting arguments are executed with different methods, as well is the monitoring of these effects. Besides the weights of the arguments and the balancing of the arguments to either the scale of the building or to the scale of the city is not clear yet. Prioritizing seems to depend on local circumstances and local customs. The intertwining of those two scales complicates discussions. Technical knowledge and knowledge of costs and benefits cannot be combined properly and accurately.
It is not always clear how negative and positive environmental effects of green roofs can be explicitly identified by calculation or by measuring. A life cycle assessment (LCA) is not easy to make and it is not always evident how the costs and benefits can be estimated on the scale of a building as well on the scale of a city and how they are related.

Concerning the issues of the discussion about the method to express the environmental effects of green roofs uniformly into numbers a discussion will enrol how to express these numbers into economical estimations on both the scale of the building as on the scale of the city. The economics of green roofs are intertwined on both scales. For companies designing and constructing green roofs it will help to expand their market if it would be possible to estimate specifications more accurately and more uniform. In those case customers themselves can compare performances in relation to costs and benefits. Uniform specifications could relate to procurement criteria and product delivery systems more easily (Huovila Ravesloot 2010). To harvest the potentially major benefits of green roofs for the municipality asks for new organisational methods. Otherwise city policies and innovation of green roofs will suffocate in bureaucracy. If implementation of local policies is uniform throughout the country, private companies can put their effort in innovating their product towards customers' wishes avoiding bureaucracy.
This paper ends with the conditions for positive and successful change, organising innovation from the side of manufacturers and construction industry and de-organising organising bureaucracy of public city policies. Change in the intertwining of economics might simplify the organisation of large scale green covered roofs.

ECONOMICS OF GREEN ROOFS FOR CITIES

Municipalities use different arguments to promote policies for large-scale green-roofs programs. Goal is to achieve benefits for mitigation and adaptation approaches or to achieve sustainable water management on the scale of the city.

Calculations of the municipality of Rotterdam showed that benefits for private partners, investing in green roofs, are less compared to the public benefits on a larger scale. If the benefit from expanding the life span of the roofing material itself is not calculated as private benefit, the total private benefit even becomes negative (Moppes, Klooster 2005). However, the summation of private and public benefits is positive. The calculations also show that the total benefits are the largest in the high-density areas surrounding the city centre and the least in industrial areas. The city centre itself is most beneficial for public benefits.

For the city of Rotterdam many different kinds of calculations can be made to support public investment in private roofs. The simplest calculation would be to compare the cost to create more water buffer areas in the city centre and in its surrounding, highly populated, areas. The construction of one cubic meter of water buffer as adaptation measure in case of heavy rainfall would cost approximately Euro 1000,= to 1500,=. However, this would not be

sufficient, because there is little space to realise such buffers. The public spaces at street level are all occupied until several meters underground. To make an equivalent amount of water buffering of about 15 l/m^2 on a flat roof you would need about 70 m^2 of flat roof. So it is wise to spend Euro 1000 on creating 70 m^2 of green roofs instead. The extra investment of green roofs compared to traditional black flat roofs can vary from 15 Euro (simple do-it-yourself construction with extensive vegetation) to Euro 50 (complicated roof with intensive vegetation). With these numbers you can see that a contribution of Euro 20-25 Euro's of the public authorities for the private investment in green roofs in down town Rotterdam can be motivated.
The more complicated calculation of private and public benefits and costs on a larger scale shows remarkable little sensitivity for variations in input variables of 50 %. Sensitivity is only high on the assumption of life span extension of the roofing material. Changes in investment costs for the greening of the roof also can cause some variation. Otherwise the social return on investment on the scale of the city here is about Euro 15,= per m^2.

Most likely each city with a program and subsidy for greening roofs will have constructed some kind of similar calculation. Of course variables, input data, methods and numbers will vary and different calculation cannot always be compared. Clear understanding of the factors involved and a good management of the process can create a positive balance in a social cost-benefit analysis for all stakeholders at both scales.

DISCUSSION

However the understanding of the factors involved in organising green roofs on a large scale is not the same from all stakeholders' perspective. There is an intriguing difficulty in organising the intertwining of the two described economics. Although green roofs appear in the political policies of many cities, it is rarely part of (urban) planning in the various sectors. New patterns of collaboration have to be established between policy makers, urban designers, building owners and investors. Sometimes new collaborations appear spontaneously, but they may be hard to organise, since the stakeholders keep their natural roles in their traditional organisational patterns. They are not accustomed to collaboration in a new context. New patters and new collaborations however have to be established soon to speed up the process.

Intertwining Organisation

Speeding up the process incorporates the differentiation of subsidised green covered roofs according to local urgency and needs and to stimulate the use of green covered roofs to enlarge the effects of urban water management. Subsidy may prevent that one may hesitate to invest in green roofs and stimulate the efforts to get urban quality by means of green roofs. Instead of subsidising the green roofs it may even be better to subsidise the work of architects and urban designers in their effects to realise green roofs.
Also the management of process and maintenance plays an important role. The logistics of building a green covered roof determines the price. Of strong influence is the market situation during the year. Nevertheless, a designer can influence the price positively by designing with care in an early stage of the process. In this way many problems and thus a lot of money can be saved. Given the different roof structures of green covered roofs, additional requirements should be taken in the Dutch legislation. A major hindrance is the lack of a uniform method of calculating and measuring technical specifications of green roofs, like thermal capacity, capturing of particulate matter, buffering of rainwater and slowing down of stormwater run off. The lack of uniform demands from public authorities subsidising green roofs is creating

unnecessary bureaucracy. Also different approaches in policymaking and in policy evaluation hinder to accelerate.

The introduction of a uniform classification of technical specifications will accelerate the introduction of green covered roofs in Dutch building industry. Companies can concentrate on the innovation of their green roof systems, instead of bothering which daily arguments they have to fulfil to defend that their products meet the various requirements of the granting authorities best. In case a classification to apply for subsidies from public authorities fits within the technical classification of green roofs, rise of bureaucracy may be counterattacked. In fact the market for designing and constructing green roofs may expand rapidly, because the consumer will have less doubts on the benefits of green covered roofs. The competitions between companies will focus on quality and services, more than on declaring claims that cannot completely be substantiated. Differences in systems from different companies can be compared and can be tailored to the subsidy requirements by public authorities. Applying for subsidy will be the same in every city offering an active green-roof-policy.

CONCLUSION

The knowledge how to design, construct and maintain green roofs is available and at a high standard (Getter Rowe 2006; Teeuw Ravesloot 2011). Local initiatives show the importance of public authorities to support the construction of green roofs on a large scale. The cost-benefit of green roofs on the scale of a building is mostly positive for extensive green roofs, if the calculation is made within life cycle costing. The same might be valid for social cost-benefit calculations on the scale of a city. However, the many variables and the uncertainty of the input variables make the accountability small. Green roof technology may innovate more towards the specifications issued from public authorities. It seems that public need is more important than private interest. To align public interest and private potential it is needed to uniform the methods of calculation for green roofs specifications. This would be important for those specifications that serve public interest as well: thermal insulation for cooling and heating, water buffering and slowing down rainwater run off, as well as catching particulate matter. Such a classification would enlarge customers' confidence in green roofs. On the other hand it would be suggested to make uniform formats and procedures for local authorities, legally, financially and politically in order to reduce emerging bureaucracy. Bureaucracy is an important hindrance for innovation by the green roof companies.

Abstract
Climate change has led to the global recognition of the need to reduce the carbon footprint of buildings. In the UK increasingly demanding building regulations require contractors to use innovative products and processes in their construction processes in order to deliver the specified environmental sustainability performance levels. Cost effective innovative solutions for achieving sustainability in construction requires considerable effort and commitment. As a fragmented and project-based industry, much construction innovation is co-developed at the project level. The major objective of this study is to analyse a construction project by exploring the role of design, process, and service innovations in achieving sustainability. In this respect, the eco-friendly accommodation at Lancaster University has been investigated as a case study. The project presents a case of client-driven innovation where building regulations on sustainability were taken into account in developing design and planning the construction process. The paper discusses the leading role of the university client as well as the role of partnering approach and community engagement in the innovation process. Finally, some recommendations are provided based on the lessons learned in this project.

Keywords: Sustainability, client-driven innovation, design innovation, community engagement.

INTRODUCTION

There have been a number of changes and challenges such as globalization of the business environment; demographic change; environmental sustainability and climate change; new materials and technologies; ICT; and governance and regulation that continue to have a significant impact on the construction industry (e.g., Hampson and Brandon, 2004; Boddy and Abbott, 2010). Foremost among these drivers, sustainability has become an increasing concern for the construction industry due to the fact that construction activities significantly impact on waste, energy use and greenhouse gas emissions. As a response to climate change and its effects on the environment and energy academics, practitioners and governmental bodies have been involved in many discussions and applications to create a low-carbon economy. There has been a growing emphasis on corporate sustainability, which is also

reflected by pressure being exerted by clients, government and other stakeholders for the industry to be more accountable for its environmental impacts (Thorpe et al., 2008). Recently issued building regulations such as the Code for Sustainable Homes (CfSH) (DCLG, 2006) in the UK require the contractors to use innovative products and processes in their construction processes in order to deliver the specified environmental sustainability performance levels.

Developing cost effective solutions for achieving sustainability in construction requires considerable effort and commitment to innovation. As a fragmented and project-based industry, much construction innovation is co-developed at the project level. The link between firm level processes and innovation at the project level should be explored to enable a better understanding of how different firms contribute to the innovation process by developing/implementing strategies, assigning resources to create ideas and diffusing them. The major objective of this study is to analyse a construction project by exploring the role of design, process, and service innovations in achieving sustainability. The project analysed is the eco-friendly accommodation at Lancaster University. This student residences scheme was the first replicable scalable model of its kind and was designed to create a social space for the students that would encourage 'good habits' in terms of sustainable living. The main innovations observed in the project were within the residences' bespoke design that adopted the 'sustainable by design' concept using offsite manufacture (OSM) driven and enabled through a lean construction approach and community engagement. The project presents a case of client-driven innovation where building regulations on sustainability and user perspectives were taken into account in developing design and planning the construction process.

INNOVATION IN THE BUILT ENVIRONMENT

Innovation may be defined as creation and adoption of new knowledge to improve the value of products, processes, and services (Ozorhon et al., 2010). The construction industry can benefit from the diverse benefits offered by innovation particularly by adoption of new methods to improve processes and organisational effectiveness. According to Lansley (1996), the occurrence of innovation within the construction industry is often characterised by the widespread adoption of new practices as a result of advances in technological and business processes and much of construction innovation is process and organisation-based (Slaughter, 1993). Innovation in construction is co-developed at the project level (NESTA, 2007).

The construction sector is viewed as a system involving clients, contractors, sub-contractors suppliers, consultants, and designers. Clients are seen by many as having a leading role in driving innovation in construction (Brandon and Lu, 2008) although this viewpoint is contested in for example Ivory (2005). Clients can act as a catalyst to foster innovation by exerting pressure on the supply chain partners to improve overall performance and by helping them to devise strategies to cope with unforeseen changes (Gann and Salter, 2000), by demanding high standards of work (Barlow, 2000), and by identifying specific novel requirements for a project (Seaden and Manseau, 2001). Contractors, on the other hand, play a mediator role in the interface between the institutions that develop many of the new products and processes (materials and components suppliers, specialist consultants and trade contractors) and those which adopt these innovations (clients, regulators and professional institutions) (Winch, 1998). Manufacturing firms invest far more in R&D than contractors and are subsequently more likely to develop technology driven product and process innovations (Gann, 1997), whereas in construction successful innovation often requires

effective cooperation, coordination and working relationships between the different parties in construction projects (Gann and Salter, 2000; Ling, 2003).

Management of innovation is complicated by the discontinuous nature of project-based production in which, often, there are broken learning and feedback loops (Barlow, 2000). Gann (2001) suggests that project-based construction firms often struggle to learn between projects, and often have weak internal business processes. Measurement of the dimensions and elements of construction innovation at the project level is key to improving the innovation performance of companies. An organisation employ a number of tools, techniques and strategies throughout the whole process and external factors such as drivers, barriers and enablers determine the effectiveness of creation and diffusion of innovation. The link between the processes at organizational level and innovation at the project level should be investigated to gain a full understanding of the drivers and underlying factors of innovation in a project setting.

A research project was carried out by Ozorhon et al. (2010) to investigate the ways in which innovation occurs in a project setting and the dynamics between project and firm level innovation. The research team collaborated with the Centre for Construction Innovation (CCI) Northwest to survey the applicants of the 2009 North West Regional Construction Awards. The awards entrants were chosen as they all believe that they are at the leading edge of construction in the region and were willing to share their innovations, and so the sample should provide an insight into perceived 'best practice'. The findings of this survey were used to guide the next stage of the research that involved the production of a series of case studies and interviews with key parties in selected projects. The particular case study presented in this paper describes the eco-friendly student accommodation at a UK University that has demonstrated numerous examples of innovation.

CASE STUDY: ECO-RESIDENCES

The eco-friendly student accommodation at Lancaster University is the first replicable scalable model of its kind and was designed as an environment that would encourage 'good habits' in terms of sustainable living. It is a successful example of collaborative partnership that achieved affordable sustainability through a series of technical and organisational innovations.

Client and regulations as the drivers of innovation

The project was very notable for the pro-active role of the client, whose drive for sustainable practices were the main drivers of innovative activities. This drive was itself reinforced through energy performance regulation such as the CfSH and specific guidance by Higher Education Funding Council for England (HEFCE). The UK Government's initiative to create sustainable homes is specified in the CfSH (DCLG, 2006). The code requires contractors to use innovative products in their construction processes in order to deliver the specified sustainable performance levels. Similarly, HEFCE guidance on universities' environmental performance provides an important benchmark. HEFCE has confirmed that from 2011, all HEFCE capital funding will be subject to Institutional Carbon Management Plans and further, that pursuant to the Climate Change Act, the Higher Education Sector is likely to be set a target of reducing carbon emissions by 80% by 2050.

In addition to the requirements of CfSH and HEFCE guidance, the University's own desire for the adoption of sustainable practices was a major driver for the success of this project. The University recognises the significant environmental impacts associated with its operations and also its responsibility to address these impacts in all areas of its activities through its Environmental Policy and Environmental Management System (EMS). The environmental impact of new or refurbished buildings is very carefully evaluated from conception, through design and construction to operation.

Another key ingredient of successful delivery of this project was the innovative partnership between the University and the developer. The University selected a residential developer as partner to design, build, fund, and manage its eco-friendly accommodation under a unique 48-year contract. This partnership firmly places the emphasis on the use phase of the building and opened the way to the adoption of the 'sustainable by design' concept (Friedman, 2007) in the bespoke design by the architect of the project, which in turn was the result of a more formal collaboration to ensure that the best ideas from around the world are brought into the organisation.

Another business partnership, 'GreenLancaster', was established between Lancaster University Student's Union, the University's Estate Management department, and the residential developer, the aim of which was to help departments across campus promote and deliver environmental initiatives. This has helped increase recycling rates, reduce toxic waste, reduce energy consumption and green the University's supply chain.

Design innovation

The design criteria focused on environmental sustainability, reduced construction and rental costs, enhanced social space, and improved design quality and specification. The key success was to achieve a highly sustainable development at an affordable cost. Affordability has been achieved by looking at the construction process and how the detail design may incorporate features which facilitate construction. The design was mainly based on the work of Professor Friedman (from McGill University, Canada), who is recognised as a world authority on the subject of affordable housing. The key features of this 'sustainable by design' concept focused on a simple design delivering high energy efficiency and heat recovery. The residences have been configured as 4-storey townhouses providing semi-independent, un-serviced accommodation for either 6 or 12 students with a large shared kitchen/dining/lounge space. The key features of this 'sustainable by design' concept are as follows:

- ***Plan:*** The designs are based on the use of modular dimensions which allow the use of building components to their manufactured sizes, such as plasterboard or ply sheets. This speeds the construction process as there is minimum requirement for cutting or fitting of components, and significantly reduced waste generation.
- ***Energy and resource efficiency:*** The design of the building, comprising terraced units is very efficient in terms of site utilisation (good floor to wall ratio), minimization of external surfaces (high levels of energy efficiency), and minimisation of material use. Designed allows the maximum use of natural light, minimising lighting requirements. Low energy fluorescent light fittings are used throughout the buildings with Passive Infra Red (PIR) detectors in communal areas. Water use is minimised by low flow rate fittings and dual flush fittings on toilets.
- ***Sustainability and renewable materials:*** The reduction of waste is central to the concept and the choice of construction materials related to carbon footprint reduction. The BRE 'Green Guide to Specification' is used to inform the choice of materials, and benign

natural materials are used wherever possible to ensure a healthy internal environment. By using timber sourced from sustainable, managed forests for the building's superstructure, the carbon footprint was reduced by one third. Timber frames were also manufactured offsite in order to minimise waste. Recycled construction materials have been used as far as possible in underlying hard-paved areas and floor-pads. Internal fittings such as showers, basins and lavatories are assembled offsite as complete 'pods' improving construction speed and reducing construction impact further.

- ***Heat recovery:*** A passive approach is used to create a very highly insulated, airtight building envelope which requires very little energy for space heating, the major energy load being to generate hot water and this is supplemented by solar thermal panels which are effective and have a relatively short payback period. A heat recovery system operates on the extract ventilation serving the shower/bathrooms, providing warm air into the internal circulation areas; while each room is equipped with a small radiator, controlled by a thermostatic radiator valve and linked to a high efficiency, gas-condensing boiler. Ventilation with heat recovery is primarily whole house mechanical ventilation with heat recovery (re-claiming 70%). Trickle vents and windows that can be opened to provide additional user controllable ventilation. The kitchen cooker extractors switch on and off automatically.
- ***Utility monitoring:*** The eco-residences have a Building Management System (BMS) which constantly communicates utility use to enable the students to monitor their carbon footprint for their townhouse which is calculated from its water, gas and electricity usage. The University also seeks to develop future university estates on the basis of sustainable principles.

Process innovation

In terms of the construction method, closed panel timber frame was the chosen solution to speed up the process and achieve sustainability. Although the systems or products used in the scheme have been used before, the main innovation in this project is that all the various design and construction approaches are brought together in a coherent, holistic housing concept that was both sustainable and affordable. Prefabrication is a major factor in keeping costs and waste to a minimum. Both the structural timber frames and bathroom pods are built off-site and delivered ready for quick installation and connection.

- ***Modern methods of construction:*** Timber frame is a tried and tested structural system. It is widely believed to be the most environmentally friendly form of construction available that conforms to MMC and OSM principles. BRE reported that that modern timber frame construction produces near zero carbon emissions (Reynolds and Enjily, 2005). Timber frame is also renowned for its excellence in energy efficiency terms. As the structures are assembled from components made to manufacturing tolerances, the better fit achieved improves air tightness and hence positively effects energy efficiency. The closed timber frames were used as the structural elements of the superstructure in the project among the many forms to choose from, including advanced and closed panel, volumetric, and hybrid systems.

  To gain the potential benefits of MMC required tighter, more reliable processes which lead to the adoption of lean principles. The lean approach meant that construction could be completed well ahead of schedule due to the unexpectedly quick insallations of the timber frames. Just in time (JIT) deliveries were fundamental to maintaining the construction programme. Lean construction is "the continuous process of eliminating waste, meeting or exceeding all customer requirements, focusing on the entire value

stream and the pursuit of perfection in the execution of a constructed project" (Design for Manufacture Competition, 2005). The adoption of MMC through a lean approach required more time in the design and planning phases, but this attention to detail minimised conflicts that can dramatically change budgets and schedules. Standardisation of the finishing processes brought benefit to the supply chain, reducing wastage of materials on site as well as wasted operations.

MMC and lean construction involved different mindsets and operations that were initially threatening to members of the supply chain. Seminars and project meetings were held at an early stage with regard to the process approach and construction technology involved both to give confidence and exchange knowledge. 'Toolbox talks' were initiated with the workforce of the various supply chain partners to ensure requirements were properly implemented on site. Many detail design or construction issues incorporated in the scheme have been adopted by supply chain members as general practice moving forward.

Service innovation

The project was also notable for its use of a 'user-driven' approach to successfully deliver the environmental performance levels. The university aimed to create a social space for the students that would encourage 'good habits' in terms of sustainable living. The end user requirements were an important component of the scheme and so engagement with students began at an early stage in the design process. This aspect is considerably strengthened by the measures that are in place to monitor and provide information on energy use as a means of directly involving the students with the ongoing operation of the building. Following completion, further engagement on obtaining and addressing initial feedback from new residents was also critical. Initial resident feedback has been very positive. General comments of the students have included: 'probably the best accommodation you will live in as a student', 'light, airy and clean', 'very sociable', 'good space for a family'. This stakeholder participation model will also be used in future student residence developments.

GreenLancaster had a central role in the environmental initiative of the University. They have generated jobs for students, as well as raising the profile of environmental issues amongst staff and students. A carbon competition was launched in the University's eco-residences to motivate the students to be more environmentally conscious. This was set-up in conjunction with GreenLancaster to promote and incentivise reduced energy and utilities use, and reward the townhouses with the lowest resultant carbon footprint. Students could log onto the competition website to view the carbon footprint and utility use for their house in real-time, as well as check on who is winning. By this way, carbon emissions were reduced by 11.3% for January-April 2009 compared with the same period in 2008, when there was no carbon contest. Students achieved this by taking some simple actions such as switching off the TV at the mains, not leave anything on standby, half-filling the kettle, cooking together, and filling up the washing up bowl instead of running the tap.

Achievements of the project

Significant financial, environmental and social benefits have been achieved for both the University and student residents. A key benefit is expected to be reputational, with Lancaster University being seen as a leader in terms of environmental design and construction, but also in terms of stakeholder and end user participation in development and input into the eco-residences design and concept. External recognition and interest in the project has been very significant. Estates Department Directors from many universities have toured the eco-

residences developments. The following details some of the main achievements of the project in use compared to the previous phase:

- The cost of a student room was decreased by 7%, while rent charged to the students dropped down by 15%.
- Gas consumption is anticipated to reduce by 5-10% per student room.
- Carbon emission is predicted as 963kg CO_2/annum/student compared to the design target of 1,147kg CO_2/annum/student based on the Building Regulations.
- The transport linkages from the eco-residence developments have been carefully designed to minimise transport impacts. They are provided with excellent pedestrian linkages to the main pedestrian walkways.

CONCLUSIONS

Climate change and environmental sustainability has become a central issue for construction practitioners, policy makers, and academics worldwide. Key to this is energy efficiency and carbon reduction in buildings and as such the construction industry contributes to a large proportion of carbon emissions. The case study shows that environmental sustainability through the construction value chain can be achieved by a strong commitment to deliver innovative solutions. Due to the project based nature of construction, innovation requires a joint effort throughout the project life cycle.

In this paper, a case was analysed to exploring the role of design, process, and service innovations in achieving sustainability by investigating the role of key parties. The eco-residences project of Lancaster University was examined, where a client and regulation led innovation approach was observed with building regulations and HEFCE guidance on sustainability taken into account in developing design and planning the construction process. The University's devotion and investment in environmental issues played an important role in the design, construction, and operation of the residences. The conditions that created the commitment to a through-life solution were threefold. Firstly, the university client had wider aspirations to engender behaviour change amongst the users of its estate. Secondly, the developer's business model included a novel financial relationship that depended not only on efficient construction of the residences as a product but on their through-life use. Thirdly, the developer was using this development as a pilot in order to deliver similar schemes to universities throughout the UK with declining capital budgets. Thus, the additional investment in design for construction informed by end-users would be repaid over and over again in future projects that would be informed by data of performance in use. Although the paper is based on the achievements of a single project executed in the UK, it is expected to shed light on similar future work on investigating innovative activities in collaborative environments in different countries.

SUSTAINABLE BUILDING PRACTICES: LEGISLATIVE AND ECONOMIC INCENTIVES

J. MARK TAYLOR, Ph.D., JD
Auburn University
Auburn, Alabama USA
taylojt@auburn.edu

Abstract

Sustainable building has become the buzz word of commercial construction in the U.S. during the past decade. While sustainable building practices and energy efficiencies have been on the building industries radar screen for a number of years, the media intensity and owner interest seams to ebb and flow with the cost of energy. However since the LEED system has gained such popularity in the commercial construction arena, more and more owners are demanding that their project be LEED certified; or the owner's are at least having serious talks with their architect and builders regarding sustainability and the LEED certification process.

A natural outgrowth of public awareness of energy efficiencies in the building process is governmental pressure to achieve certain prescribed outcomes. Is the government leading the charge, following a surge or acting as an impediment to the use of sustainable building practices? State and local building practices will be examined to determine if there is a trend towards either of the scenarios. While this research will primarily focus on U.S. building practices, along with federal, state and local laws that have an impact on the built environment; a cursory look at the efforts of other countries and their energy practices will be performed to provide some insight into the worldwide efforts towards sustainable building.

Keywords: Sustainable Building, Law, LEED, BREEAM, HQE

INTRODUCTION

It could be argued that sustainable building practices have always been an issue of concern with building owners. One only has to look at some residential construction practices from centuries ago to see that this is true to some extent. Owners had little choice but to build with local materials according to local or regional customs, constructing the building in such a way that a certain level of comfort was assured with the minimum use of additional resources for heating and cooling. An example of this approach is the adobe structures of the American southwest. Houses were constructed of thick adobe walls providing insulation from the extreme temperatures along with openings designed to promote a free flow of air. Unfortunately, if one moves to more temperate climates, especially in areas where abundant natural resources are available, residential owners had little reason to build in a sustainable manner. They simply built along local and regional customs, often with economy as a major objective.

If one looks at larger buildings from days gone by, sustainable building was not necessarily at the forefront of the decision making process as far as design and construction were concerned. The earliest large, non-residential buildings were religious in nature. These large

structures were built with religious custom as the primary concern. While using local materials to a large degree, the design and construction of the structure had more to do with promoting the tenets of the faith than building in a sustainable manner. A look at early English cathedrals easily demonstrates this point. Often placed on a high point to insure visibility from afar, the cathedrals tended to be large, imposing structures with soaring interior spaces but with poor natural light and ventilation. As the structures were built for a transient occupant, indoor environmental concerns were not nearly as important as with residential structures.

Changes in our design and construction processes evolve quiet slowly and reflect changes in technologies and customs. However, some changes can be promulgated at a more rapid rate if nudged along by some trend or concept. Mechanisms that have sped up the process of change and resulted in different ways of addressing our sustainable building needs can be categorized into four fairly broad groups; 1) governmental statutes, 2) building codes, 3) associations or NGOs, and 4) the marketplace through economic incentives.

While changes in these areas have occurred over the past centuries as it relates to the built environment, many of our sustainable features have come about in the past forty years or less. A significant milestone that, to some extent, marks the beginning of the environmental movement that preceded modern sustainable building efforts was Earth Day; first celebrated on April 22, 1970. This was organized by United States Senator (Wisconsin) Gaylord Nelson as a means of bringing awareness of and appreciation for our natural environment. Earth Day remained a U.S. event until 1990 when it was organized by the Earth Day Network to become a world-wide event. Now close to 200 countries celebrate Earth Day each year and millions of individuals participate in activities promoted by the Earth Day Network (Earth Day Network 2011).

A further development towards sustainable building practices is evidenced by the United Nations Millennium Development Goals (MDG). First promoted in the year 2000, the goals consist of eight international development goals aimed at improving living conditions of the world. All 192 United Nations member states and at least 23 international organizations have agreed that these should be achieved by the year 2015. They include eradicating extreme poverty, reducing child mortality rates, fighting disease epidemics such as AIDS, and developing a global partnership for development (United Nations 2011).

At the 2010 United Nations conference it was reported that some of the goals are having their desired effect, but many countries are lagging behind in their campaign of achieving the goals and will, in all likelihood, not be reached by the target year. While most of the goals are very broad based initiatives as seen in the previous paragraph, one goal – Goal 7A is titled: “Integrate the principles of sustainable development into country policies and programs; reverse loss of environmental resources”. Goal 7A is aimed squarely at those involved with the built environment, calling for governmental pressures to influence the behaviour of designers and builders involved in the development process (United Nations 2011). Although many argue that the UN MDGs are, to some extent, symbolic in nature it is clearly an indication that sustainable building practices are on the minds of many more people now than they were 40 years ago (United Nations 2011).

RESEARCH QUESTION AND METHODOLOGY

The purpose of this research is to determine whether governmental initiatives or the private marketplace is driving sustainable design and building practices? If governmental initiatives are the driving force, sustainable practices will be much more stable and long lasting. On the other hand, if it is the marketplace that is the driving force, sustainable practices will again shift with the inevitable change in the price of oil.

This study looked at various sustainable initiatives used in the commercial construction industry, to determine what drivers were behind each. As the data required by this study is public information, data was gathered through internet searches in order to gain a broad perspective on the issue using a qualitative research approach. Qualitative research can be defined as subjective, and is often structured into two categories of research: exploratory and attitudinal (Coles & Naoum 1998). The purpose of exploratory research, as used in this study, is to understand a situation, look for alternatives, and to propose new ideas (Zikmund 1997).

GOVERNMENTAL STATUTES

A statute is a formal written enactment of a legislative authority that governs a country or some subdivision of the country such as a state, province, county, city or other form of municipality (Black, H. C. 2009). Typically, statutes command or prohibit something, or declare policy. The word “statute” is often used to distinguish law made by legislative bodies from case law decided by courts, and regulations issued by government agencies. Statutes are sometimes referred to as legislation or "black letter law". As a source of law, statutes are considered primary, or the highest, authority.

Much of our legal system in the U.S. and in Western Europe has evolved from the legal system of ancient Rome, primarily the legal developments which occurred before the seventh century AD when the Roman–Byzantine state adopted Greek as the official language of the government. Following the definitional premise that statutes are laws that are written, the first legal text is derived from the Law of the Twelve Tables, dating from mid-fifth century BC. The plebeian tribune proposed that the law should be written, in order to prevent magistrates from applying the law arbitrarily. After eight years of political struggle, the plebeian social class convinced the patricians to send a delegation to Athens to copy the Laws of Solon. Around 450 BC, ten tablets were produced with laws aimed at controlling civil matters of the Roman citizenry. These proved to be unsatisfactory by the plebeians and two additional tablets were added the next year. The new Law of the Twelve Tables was approved by the people's assembly (Kreis, S. 2001).

While the Law of the Twelve Tablets is ancient in time, it provided for provisions of private law and civil procedures that survive to the present day. Primary in this regard is that the focus of rule making should fall to the local group (or, as stated in 450 BC the genos or clan); e.g., the rights of the central government are limited in their scope (Kreis, S. 2001). The U.S. Constitution, U.S. Congress and U.K. Parliament have followed this tenet as it relates to sustainable building. While there are certain central laws regarding this issue is not debated; but rather the purpose of these laws are primarily focused on providing local or regional governmental entities with avenues in which to approach sustainability.

For example, in the U.S. such seminal environmental laws as the Clean Air Act (CAA) and the Clean Water Act (CWA) demonstrate that the law can be, and has been, utilized as an important tool to address environmental challenges (Sussman, E., et al 2010). However, these laws passed in the early 1970's have not been followed by similar legislation as it relates to sustainable building. Sustainable building regulations have been much more fragmented in their approach. But as Sussman goes on to say, "[L]aws and regulations, at all levels of government, can similarly be used to promote adaptation to climate change" (Sussman, E., et al 2010).

Another governmental reaction came about due to the energy crisis of the 1970s. The soaring costs of energy and a growing concern about pollution and natural resource conservation caused the U.S. Congress to pass the Energy Policy and Conservation Act of 1978 (EPCA) that would require states receiving federal funds to initiate energy conservation standards for new buildings (Kraska, J. C. 2006). However, a telling feature between the EPCA and the earlier CAA and CWA that should not go unnoticed is evidenced from the titles of the legislation. Where the CAA and CWA are "acts" with definable requirements and outcomes the EPCA consists primarily of "policy" issues. This is not to say that the EPCA is not an important piece of legislation, because it is. However, as energy prices became lower in the 1980s and 1990s less importance was placed on the possible rigors and enforcement of the EPCA.

BUILDING CODES

A building code is a set of rules that specify the minimum acceptable level of safety for constructed objects such as buildings and civil structures. The main purpose of the building code is to protect public health, safety and general welfare as they relate to the construction, occupancy or use of the building or structure (Black, H. C. 2009). Model building codes are promoted by a group or association; and the code becomes law of a particular jurisdiction when formally enacted or adopted by the appropriate authority.

The idea of a building code is more than 3,000 years old. Even the earliest civilizations recognized that predictable and consistent minimum standards had to apply to construction materials and practice in order to provide practical and adequate protection of human life, safety and the welfare of the community at large. The Code of Hammurabi is often pointed to as the first formal, written building code. This code outlined the responsibilities of builders for the safe construction of buildings and laid out harsh punishment for those who failed to comply. Subsequent advances in building codes are often tied to some catastrophic event as it relates to public buildings or places.

For example, the burning of Rome in 64 A.D. led to improved building practices and code requirements in the area of fire safety. Likewise the great fire of London in 1666 gave rise to another early set of fire safety regulations. Sir Edwin Chadwick published a "Report on the Sanitary Condition of the Labouring Population of Great Britain" in 1842 that, for the first time, placed environmental conditions as a safety concern for the public as related to buildings and neighborhoods. And finally, the San Francisco earthquake of 1906 led to the popularity of the first National Building Code. The severity of the quake highlighted a pressing need for minimum safety standards to protect building occupants and the community

from structural hazards and in areas with seismic activity from the devastating threat of earthquakes (USGBC 2006).

As building codes advanced in the U.S., three major groups promoted their model codes and, for the most part, code usage became regionalized. The U.S. building industry recognized that one national building code, based on engineering, material science and human safety and less dependent on geographic and cultural differences was good for building safety and good for focusing participation in one national model code effort. In 1994 the three regional code organizations came together to establish what would become the International Code Council (ICC). The ICC was charged with developing a single set of comprehensive and coordinated national model codes for building and fire safety, what has come to be known as the International Codes, or the I-Codes (USGBC 2006).

From a sustainability standpoint, the I-Codes did little to promote the concept of sustainable building. However, the ICC has addressed this issue with its International Green Construction Code (IGCC) that is currently in the review process. Version 2 was published in November, 2010 and according to the ICC schedule should be finalized and adopted in March, 2012 (International Code Council, Inc. 2010). While building codes have been slow to address the importance of energy efficiency and sustainable building, they currently are in the process of doing so. It will be a few years at least before one can measure the impact that the IGCC, or other likeminded codes, have on the building industry. It will be up to local governmental entities to officially adopt the code requirements before any discernable impacts can be reported.

Already there is some movement for federal agencies and state and local governmental entities to adopt some sort of sustainable practice or code. Led by the U.S. Green Building Council (USGBC) and its LEED system (discussed more fully later), various sustainable initiatives including legislation, executive orders, resolutions, ordinances, policies, and incentives are found in 45 states, 442 localities (384 cities/towns and 58 counties), 35 state governments, 14 federal agencies or departments, and numerous public school jurisdictions and institutions of higher education across the United States (USGBC 2006).

In addition, states such as California are leading by example in adopting sustainable standards. In December 2004, Governor Schwarzenegger established green building as a priority for his administration with Executive Order S-20-04. Schwarzenegger's Green Building Executive Order (GBEO) requires state-owned facilities to be designed, constructed, operated, and renovated as "LEED Silver", or higher, certified buildings (Sussman, E., et al 2010).

California renewed its efforts in 2010 with the much-anticipated launch of its Green Building Standards Code. This mandatory code will affect all new buildings in the state. As earlier initiatives only applied to governmental buildings, this new code is a remarkable step forward. Now all new buildings in California must meet certain sustainable requirements which address a more holistic set of risks to human and environmental health. In New York City, the Urban Green Council (USGBC's local affiliate) released arguably the most comprehensive analysis and set of recommendations for the incremental greening of any building code. The work of NYC's Green Codes Task force, established by Mayor Michael Bloomberg and the New York City Council, mirrors a national trend of communities taking

action to address today's pressing economic, environmental and community health issues (USGBC 2006, International Code Council, Inc. 2010).

In some jurisdictions, model green building codes may still be several years from adoption, and even further off for enforcement. Nevertheless, the USGBC is developing a template for code compliance that can be adapted for any alternative green building method or material to overcome real or perceived barriers to building green.

ASSOCIATIONS / ORGANIZATIONS

While governmental entities have provided a broad framework of initiatives and goals aimed at sustainable building practices and building codes have responded by developing initial drafts of codes that require sustainable building practices, by far the largest contributor to sustainable building practices to date has been through non-governmental organizations or NGOs. Various associations and organizations have been formed around the world to promote sustainable building. While all have some common elements, they differ in some respects based upon their origin.

Common elements seen in the different sustainable initiatives (taken from the French model) include; 1) harmonious relationship between buildings and their immediate environment, 2) integrated choice of products, systems and construction processes, 3) low-impact worksites, 4) energy management, 5) water management, 6) industrial waste management, 7) maintenance and facility repair management, 8) temperature and humidity comfort, 9) acoustic comfort, 10) visual comfort, 11) olfactory comfort, 12) healthy living spaces, 13) healthy air, and 14) healthy water (HQE - GT International 2008).

Illustrative examples of the sustainable initiatives that have received a favorable following and show promise of adoption by a governmental entity or incorporated into the framework of a building code include BREEAM, HQE, and LEED. These three will be discussed briefly in alphabetical sequence in order to avoid the appearance of favoritism towards one over another. The list is not intended to be comprehensive, only illustrative of initiatives taking place around the world.

BREEAM System

One of the driving forces behind the European energy efficient design standards is the European Unions' 2002 Energy Performance of Building Directive (EPBD). Each of the member states of the European Union (EU) is responsible for individual implementation of the EPBD through national laws. The main focus of European sustainable building design at this time is on reducing energy use directly and carbon emission indirectly. The EPBD has five main themes; 1) certificates, 2) inspection, 3) experts, 4) calculations, and 5) minimum energy performance requirements (Yudelson, J. 2009).

Driving the EPBD is the heightened concern in Europe over the role of building energy and materials use in global carbon dioxide production, constraints on energy supplies, and the potential for catastrophic changes in the global climate as a result of increased carbon dioxide concentrations in the atmosphere. European national governments have been far more willing to accept the conclusions of climate science than American or Canadian governments and have been willing to take that science and develop practical public policies for reversing

the growth of carbon emissions. These policies include the use of subsidies and the passage of laws in order to regulate and implement these policies.

The United Kingdom has been a leader in implementing the EPBD. The government has introduced requirements for Energy Performance Certificates (EPCs) for new buildings and a Display Energy Certificate (DEC) for existing building. Each building is graded from A (best) to G (worst). Public buildings, and those occupied by public authorities, that have a total useful area greater than 1,000m2 and provide a public service to a large number of people (i.e. schools, hospitals, government or local authority buildings) are required to post their EPC or DEC. The current average building energy use lies between D and E (BRE Global Ltd. 2011).

The Building Research Establishment (BRE) was founded in 1990 and has become the leading authority on sustainable design in the United Kingdom. Privatized in recent years, it developed the BRE Environmental Assessment Method (BREEAM), which has certified more than 1,200 commercial buildings and more than 110,000 housing units. More than 800,000 buildings are currently registered and pursuing a rating (Yudelson, J. 2009, Eichholtz, P., et al 2010).

BREEAM rates building according to the nine major categories in order to receive a single score, similar to the LEED system. The scores translate into five rating categories; 1) pass, 2) good, 3) very good, 4) excellent and 5) outstanding. The BRE is also actively involved in the areas of education. As the BREEAM system is based upon a third party certification, BRE is actively involved in training assessors to verify applications and accredited professionals (BREEAM AP) to assist those seeking certification (BRE Global Ltd. 2011).

The BRE has begun promoting BREEAM International and has successfully exported its system to a half dozen other countries which now have certified buildings. In addition, BREEAM Gulf is being developed for mid-eastern countries. In 2008, the International Council of Shopping Centers adopted BREEAM as a standard for rating shopping centers throughout Europe, and the Dutch Green Building Council also adopted BREEAM as its standard (BRE Global Ltd. 2011).

Another interesting aspect of the BREEAM system is its “bespoke” rating system for building types that don’t fall within a previously defined category. The bespoke system allows for the modification of the rating scheme to meet the particular needs of unusual buildings. The LEED international system, while becoming a bit more flexible, provides for a more rigid set of standards to follow. BREEAM is likely to be the dominant rating system in many European countries. It provides a green rating system that actually works because it’s in tune with the marketplace yet retains a sense of higher purpose (Yudelson, J. 2009).

HQE System

Over the past few years, sustainable development has become one of French society's great concerns. Ministries, local authorities and all corporate segments have been making this topic central to their strategic decisions. The initiatives undertaken to ensure a "greener" world have spanned all directions, and it can now be stated that France (following years of lip service) is indeed aware of the stakes involved, as evidenced by the adoption of increasingly stringent environmental protection measures, in association with an ambitious set of objectives (HQE - GT International 2008).

The construction and housing sectors have been lumped into this dynamic. In response to these new demands, all participants in the built environment (real estate developers, social landlords, housing corporations, investors, architects, construction companies or local authorities) must comply with certain sustainable practices and production models. Regulatory changes in terms of urban planning and the application of new building standards now require all participants in the development process to more closely scrutinize the means employed to assess project impacts on the environment (HQE - GT International 2008).

Discussions held on the topic of sustainable development have mainly focused on two schools of thought. The first approaches the context from its economic and social vantage point in addition to incorporating an environmental perspective. This school expands emphasis to the architectural and use attributes of the project, introducing non-polluting materials, pursuing social goals, respecting biodiversity and addressing life cycle issues, to cite a few indicators. The second is referred to as the "energy" school and tends to group sustainable development concepts towards issues directly related to energy usage and specific objectives to reduce greenhouse gas emission. A draft law written subsequent to the Grenelle Environment Roundtable seems to indicate that the construction industry and the "energy" school of thought is moving into position as the dominant model (HQE - GT International 2008).

In terms of benchmarks, France tends to prefer associating qualitative and quantitative indicators. A French approach entitled "High Quality Environment" (HQE) begins by laying out a global conceptual matrix that differs markedly from the American LEED or English BREEAM systems, both of which are aimed at achieving a set of quantifiable objectives. The "French style" model is perceived by some as a more holistic model than its competitors. The difference with the French approach also lies in the organizational pattern among participants. HQE was originally developed in 1992 as a voluntary set of standards featuring fourteen sustainable elements divided into four major groups; 1) eco-construction, 2) eco-management, 3) indoor environment, and 4) health. Since 2004, the French have also utilized HQE as an eco-building rating system (Yudelson, J. 2009).

The current driver of French sustainable development and green building programs is the Grenelle Environmental Policy adopted in October 2007, which created a plan for promoting sustainable development, establishing renewable energy and green building construction as national priorities. In terms of specific goals, the policy calls for all new building to use less than 50 kilowatt-hours per square meter per year by 2012 and to be carbon neutral by 2020. Within the next 5 years, the policy is expected to reduce commercial energy consumption by 20% and residential energy use by 12% (Yudelson, J. 2009).

HQE’s overall goal is to generate 30% energy savings, to reduce overall national greenhouse gas emissions by 40% and to produce 16% water savings. HQE began certifying individual projects in 2005 and to date there are about 200 HQE certified buildings with an additional 500 projects in the process of becoming certified (Yudelson, J. 2009).

LEED System

In the U.S., green building initiatives began to come together more formally in the 1990s. A few early milestones in the U.S. include: 1) American Institute of Architects (AIA) formed the Committee on the Environment in 1989, 2) Environmental Resource Guide was published

by the AIA in 1992, 3) EPA and the U.S. Department of Energy launched the ENERGY STAR program in 1992, 4) the U.S. Green Building Council (USGBC) was founded in 1993, and 5) the USGBC launched its Leadership in Energy and Environmental Design (LEED) program in 1998 (Kaplow, S.D. 2009).

The sustainable initiatives to first gain traction in the U.S. were those promoted by the residential sector. These included Energy Star, Earth Craft House, Built Green – Colorado, NAHB Green Home Building Guidelines, and finally LEED for Homes. Interestingly enough, the first four each have strong regional followings with LEED for Homes playing "catch-up" at the present time. On the other hand, the LEED system is the only one that has truly made an impact in the area of commercial construction.

LEED is an internationally recognized green building certification system, providing third-party verification that a building or community was designed and built using strategies aimed at improving performance across metrics considered the most important: 1) energy savings, 2) water efficiency, 3) CO2 emissions reduction, 4) improved indoor environmental quality, and 5) stewardship of resources and sensitivity to their impacts (USGBC 2006).

Developed by the U.S. Green Building Council (USGBC), LEED provides building owners and operators with a concise framework for identifying and implementing practical and measurable green building design, construction, operations and maintenance solutions. The LEED system evaluates the building upon completion and awards it a certain level based upon the number of points achieved. The building is rated as Certified, Silver, Gold or Platinum. Most involved with the process now say that one can achieve LEED "Certified" at little or no additional cost, except for the administrative fees associated with the LEED process. Many schools or agencies that have adopted the LEED system as a means of meeting their sustainability goals often use LEED "Silver" as the minimum level of acceptability. Since its inception, approximately 7,500 commercial buildings have been LEED "certified" or officially granted the LEED seal at one of the four levels. However an indication of its increased popularity is the fact that about 30,000 commercial building are currently "registered" (USGBC 2011a). A building is registered with the USGBC when a registration fee is paid with the aim to achieve LEED certification. Upon registering a building, the project team has access to the LEED resources needed to achieve certification.

In addition to the LEED certification process, the USGBC is actively involved in educating the public and promoting sustainable building initiatives. There are approximately 80 local chapters at the present time and about 300,000 individual members of the USGBC. In addition, approximately 160,000 individuals have taken and passed the LEED AP (accredited professional) exam (USGBC 2011a).

The LEED model has received some level of international recognition and is expanding an international initiative. The LEED International Program is promoted as a rating system representing global consistency, a regional approach, and local outreach and support. Countries that have a Green Building Councils include Argentina, Brazil, Canada, Chile, Colombia, India, Italy, Jordan, Mexico, Norway, Poland, Romania, Russia, Spain, Sweden, Turkey and the UAE (USGBC 2011a).

MARKETPLACE / ECONOMIC INCENTIVES

Energy certification for a project involves several different types of costs, regardless of the certifying agency. The most direct cost is also the smallest: the fees paid to the certifying organization to register and then to certify the project. The next cost is the time and effort put into compiling and submitting the documentation required and generally managing the compliance process. This cost could be for an outside consultant hired for that task or someone on the staff of the design firm, the contractor, or the owner. This is a significant project for someone doing it for the first time, and not such a big deal for someone who does it regularly and has figured out the process and created or purchased effective tracking systems (USGBC 2011b).

Another cost consideration is the additional time and effort the high-performing building team spends on a range of scenarios to determine how the competing systems will perform and prepare cost estimates to price them out. They also have to investigate alternative products and materials and explore the feasibility of new technologies. In addition, high-performance buildings require additional commissioning that comes at a premium (Building Green, LLC 2010, USGBC 2011b).

While building owners are generally willing to pay the additional cost for certification if they can be shown the advantages, there often are other incentives to consider. One of the most effective and more popular strategies to encourage green building is to incentivize the market through financial or structural incentives. Rewarding developers or homeowners who practice green building techniques spurs innovation and demand for green building technologies (USGBC 2011c).

Structural incentives work by encouraging developers to practice green building through rewards such as additional density bonuses or expedited permitting processes. At low or no cost to the municipality, building green can be made a more attractive option to developers. Review and permitting processes vary widely in length from one jurisdiction in another, in some municipalities these processes can take up to 18 months. Allowing developers to significantly reduce the duration of this process, in exchange for committing to specific green building standards, can result in significant cost savings for the developer. This allows a municipality to offer a significant incentive with little or no financial investment, since it only requires a shift in permitting priority. Like expedited permitting processes, density bonuses require little or no financial investment by the municipality. Many municipalities allow for percentage increases in Floor Area Ratio or other measures of density contingent upon certification or proof of green building practices (USGBC 2011c).

Direct financial incentives in the form of tax credits or grants to developers who propose or build green buildings are offered in some municipalities. However, many of these programs do not directly impact a municipality's finances since the proposed developments will often increase the assessed property value in the city and which allows the city to offer financial incentives without any threat of reduced revenues. Many municipalities already offer tax credits as a means of advancing specific policy agenda (i.e., offering tax credits for a developer to build a tax generating facility). These same principles can be applied to homes or developments that achieve certain green building goals. Some municipalities that charge fees for permit review or other permitting processes have begun offering reductions or

waivers for developers following green building standards. Many times this incentive can be paired with a structural incentive such as expedited permitting (USGBC 2011c).

Unlike the other incentive programs discussed above grants will require a financial investment by the city. These programs can often be funded by one of the revenue generating strategies discussed earlier. Grants can be given to homeowners or developers to go towards certification or other costs associated with green building (USGBC 2011c).

Revolving loan funds are another approach whereby a large fund is established that can be used for low interest loans to those seeking to build or renovate to green building standards. These loans are then repaid to the fund at a rate lower than the operational cost savings from the improvements in order to lower the up-front costs associated with some green building practices and encourage home owners and developers to build green. The fund is continuously replenished by the repayments so that it can be used for additional loans.

Many municipalities are also offering free planning or certification training and assistance. This assistance may allow for a developer who is unfamiliar with green building practices to build green. Another important benefit gained from certifying a project under a formal third party certification banner is the ability to use this as a marketing tool. Some municipalities have begun to offer free marketing assistance via signage, awards, websites, press releases, and other means as an incentive for developers to build to green standards (Building Green, LLC 2010).

CONCLUSION

While governmental entities have approached sustainable building initiatives for a number of years, the marketplace has had the greatest impact. Laws or statutes often omit mechanisms of enforcement and become more of policy statements than tools requiring specific action on the part of the owner. Building codes have historically been used to protect the safety and health of the public. However, safety and health have not, until recently, encompassed factors that are considered a part of the sustainable building initiative.

However, left to our own devices, great strides are being made in sustainable building. These have materialized primarily as market reactors. Sustainable initiatives began as idealized concepts, became a reaction to increasing fuel prices, were left to associations to develop and have, in recent years, caught the attention of the public at large. And finally, sustainable initiatives are beginning to creep into governmental legislation with prescriptive requirements.

Worldwide initiatives are being embraced that will have lasting impacts on the built environment. Just a few years ago, utilizing sustainable ideas and principles came with an economic price tag. However, as sustainable building products are becoming more mainstream and sustainable design and building practices are becoming commonplace, we're seeing that we can build to a moderate level of sustainability with little additional costs. Now a number of certification schemes are being promoted that reflect the building owner's commitment and provide public awareness through the level of certification.

It must also be noted that the topics discussed in this paper are elements of the industrialized world. A significant percentage of the world's population reside in developing countries. Developing countries have yet to embrace the concepts and possibilities of sustainable building. It also must be kept in mind that we truly are in the infancy stage as far as sustainable development is concerned – and this applies to the industrialized countries. Great opportunities exist for associations and individuals involved in sustainable construction and sustainable development in the years to come.

Abstract
The building sector is one of the most strategic sectors everywhere in the sustainability context because of it´s socioeconomic role as one of the largest employers and also because of it´s evironmental role as one of the world´s biggest polluter. The adoption of a performance based procurement process to implement the Brazilian public housing policy is, as shown in this paper, a huge step the State might take towards the promotion of sustainable construction, using it´s significative purchase power to foster a fruitful environment for innovation, sustainability and competitiveness all along the Brazilian building sector value chain, having a leading role towards the path to a global low-carbon economy – with less greenhouse gas emission, contributing to slow down global warming – and also successfully fulfilling the targets of the national housing policy.

Keywords: Public purchasing power, innovation, performance-based procurement, sustainability, housing policy.

INTRODUCTION

The construction industry is known for its huge socioenvironmental impacts and, at the same time, as one of the largest employers. This impact is higher if seen during the whole life cycle of a building, once 80% of a building cost is concentrated in it´s use and operation time (PIMENTEL e LAURINDO, 2008). The national house deficit is over 6 million homes and 95% of it is concentrated in the poor families, that is one reason of the growing public investment in this sector. For the next four (2011-2014, Dilma Roussef´s term as president) the expected investments are over 168 billion dollars – just the second version of Programa Minha Casa Minha Vida (PMCMV) with a target of building two million houses until 2014, has a 43 billion dollars investment.

The purpose of this paper is to present the main achievement of an exploratory study whose main objective was to identify the impact on innovation and sustainability of using a performance-based procurement (PBP) approach in the implementation of the public housing policy. Another objective is to present PBP as a strategic tool for promoting competitiveness, innovation and sustainability in the construction chain through the use of the State purchasing power taking this chain towards a low-carbon, more environmental-friendly, economic model.

This paper is divided in four parts, the first aims to present how the construction chain is included in the sustainability context, in other words, this section presents the main challenges the building sector faces in the transition to a more sustainable context.

The second section presents the role of innovation in the sustainability context, how to promote it and use it to guide the construction value chain towards a low-carbon business model, that is, how to foster innovation in order to enable building professionals to project, plan, build, maintain, rebuild and demolish building that will cause the mininum environmental impacts possible as well as promote socioeconomic development of it´s dwellers.

The third section is an assessment of the impact of the use of Performance Information Procurement System – PIPS, a PBP methodology – by the governmental agency responsible for implementing the public housing policy on the two topics presented before: innovation and sustainability, based on the international experiences and the existing theory about innovation and sustainability summarized in this paper.

The fourth part presents the final considerations of the aforementioned study.

THE BRAZILIAN CONSTRUCTION VALUE CHAIN AND SUSTAINABILITY

The building sector, in Brazil and all around the world, has a strategic position in every country´s development agenda because it is one of the largest employers and also one of the biggest polluter. In Brazil, this sector represents 5% of national GDP – if considered the expanded sector (called ConstruBusiness) this participation goes up to 15% (FDC, 2009) – and contributes with around 17% of all new job posts created in the country (MTE, 2010).

Since the first meetings about the environmental issue in the 1970´s, the pressure for sustainable behavior is fastly getting stronger, be it due to more clarified citizens/consumers or be it due to the more frequent natural catastrophes that shock – and affect – all mankind (JACOBI, 1999; MANZINI; VEZZOLI, 2002). In this scenario, one of the planet´s biggest polluting industry is not immune, therefore, it is fundamental that all actors in the construction chain search and/or develop competences that enables them to deliver solutions that satisfies consumer´s needs and preserve the environment.

Several tools have been developed to guide States, companies and civil society towards sustainable development, whose most accepted definition is the “development that meets the needs of the present without compromising the ability of future generations to meet their own needs”, presented by the Brundtland Report in 1987. One of this tools is Agenda 21 that can be defined as “a planning tool to build sustainable societies, in different geographic basis, that conciliates environmental protection, social justice and economic efficiency” (CIB, 2002) and can be split up from the global agenda into smaller agendas for regional, city levels or even for economic sectors agendas.

On this work of fostering sustainable construction, John et al. (2001) present the story of Agenda 21 for Sustainable Construction that defines sustainable construction as:

> “Sustainable construction is a holistic process aiming to restore and maintain harmony between the natural and built environments, and create settlements that affirm human dignity and encourage economic equity” (CIB, 2002: 8).

Although this Agenda was created to developed nations, this definition can be extended to all countries. According to John et al (2001) what must be rethought are the actions determined in the Agenda when used to guide developing countries in the promotion of sustainable construction.

The discussions about this focus Agenda were presented in 2002 and, as discussed by John et al. (2001), it deals with the specificities of the developing world, such as how to make sustainable houses accessible to millions of people who don´t have enough purchase power to buy houses on their own and the challenge to promote sustainable construction in areas where the basic infrastructure is bad – from the components/materials production according to some specification to bad roads and problems with energy and water supply (CIB, 2002).

The Agenda proposed by is organized in 6 groups of action and outlines the main challenges the building sector´s agents in developing countries will face in the context of sustainability. Several actions proposed in the Agenda 21 are similar to the actions presented as challenges in the prospective study for the future of Brazilian building sector, corroborating the analysis made in that study and presented in this paper.

On the global context of sustainability, the Brazilian building sector must make the ongoing transition from a quantitative model of reproducing standardized houses to a qualitative perfomance-based model that delivers the needed amount of houses, while respecting the environment, the society and being economically feasible.

According to this Agenda, all participating actors must assume their responsability on this transition. The research and education sector, the private sector, the clients and the government and it´s regulatory agencies must unify their efforts and cooperate in order to raise an institutional environment that fosters innovation, the commitment to quality and performance. Partnerships must be sought to finance research of new technologies and techniques. Information and knowledge must be disseminated to promote a more conscient market that understands the impact of purchasing decisions. All roles must be reviewed, all agents must be aware of their importance in the search for a more balanced, sustainable building sector.

In order to understand the competitive situation of this Brazilian industry and to identify the challenges companies would face in the future, a prospective study coordinated by professors Dr. Alex Abiko and Dr. Orestes Marraccini Gonçalves to the Ministry of Developmente, Industry and Foreign Market.was conducted at the Engineering School of Universidade de São Paulo in 2003 for a ten-year period (PCC, 2003). This study presented the main challenges the building sector would have in order to keep growing and be competitive in the new century.

These are the main challenges: need to increase productivity, develop human resources skills, promote integration among all players in the value chain (universities, government, private companies, civil society), expand credit to build and buy houses, solve the 6 million houses deficit concentrated in the poor families, manage the growing land cost, promote a sectorial commitment to quality development, rethink regulations based on prescriptions and standards and institutional organization of the housing policy, foster innovation and sustainability and improve management skills across the whole chain – self-construction, building project, consumer orientation (knowing customer´s needs) and research (PCC, 2003).

Focus on the end-user is essential to promote quality homes and it´s lack is notable in the popular building projects, reflecting the production model stablished after the Military Coup of 1964, that Bonduki (2000) defines as central-developing opposed to the new model he defines as environmental-participative and that is still incipient. According to the author, this central-developing model lasted until Collor government (1993), when "dozens of bad quality and bad location houses were financed and built by suspect companies and people who could afford them didn´t want to live there and those who would accept living there couldn´t afford. In the end, lots of these units were left unfinished or empty".

Corroborating Bonduki´s definition, Leite at al. (2006) studying buildings of the Programa de Arrendamento Residencial (PAR – a leasing program of popular housing to low income population, created in 1998) operated by CAIXA stated that the client that most influences the requirements of the building project is CAIXA. These requirements, on the PAR´s buildings so far, don´t come from a systematic process starting in the end-user, but from guidelines of the program developed by the Ministry of Cities and by technical specifications made by CAIXA´s technicians. There is no community participation in the definition of these house´s charachteristics.

Medvedovski et al. (2006) also studying PAR found results that show there are problems in maintenance of the buildings, on the building management – specially in the relation between the building managing company and the dwellers – and in the houses´ characteristics that are changed by it´s own users because they don´t their needs satisfied. This interventions not only might harm the building structure, safety and integrity but also shows a clear house deficiency to fulfill the user´s needs and expectations.

The improvement of management process, from project to production and delivery of buildings, must also take in consideration the needs of end-users, their participation must be sought in order to avoid delay in delivery due to changes in projects and higher costs due to this changes or even because the buildings, once they do not satisfy users´ needs, must be frequently modified (GUERRA et al., 2009).

An Ernst&Young (2008) study shows that from 2007 to 2030 the economic condition of families will sensibly change; it is expected that until 2017, 57% of all new families (that means new homes) will be on the base of the social pyramid while after 2017, 78% of all 19,9 million families will be part of the middle class, that means they will have different expectations on their homes and that must be part of the house project if we think about sustainability and flexible homes that could be rebuilt rather than totally replaced by another one.

Bonduki´s environmental-participative model is more compatible with the idea of sustainable development than the central-developing model but it is still not a reality all over the country and it´s not an only one organization responsibility to implement it. It is a city plan and not just a housing plan, being fundamental the participation and integration of several actors.

Workforce qualification, partnership among actors, search for continuous innovation and competitivity, a performance-based legal and regulation framework and constant investments are the main tools to overcome the obstacles to achieve the sustainability goal. These challenges towards sustainability are very big and the work to be done is really hard but with the right planning and an effective coordination of policies and strategies of all chain´s actors

it will be possible the construction sector becomes a leading sector in the transition to a more sustainable business environment.

THE SUSTAINABILITY CONTEXT AND THE ROLE OF INNOVATION

As it happens with sustainability, innovation has several definitons, we will adopt in this paper the following concept based on Slaughter (1998 *apud* BLAYSE;MANLEY, 2004), Blayse & Manley (2004), Sakar (2007), Smeraldi (2009) and Drucker (2011) definitions: innovation is the capacity to identify, develop, adopt and explore new uses to existing knowledge in different contexts or new knoledge in exisiting contexts. The first application will be named *incremental innovation* and the second one *disruptive innovation*.

Innovation is nowadays the most important building block of competitive advantage in any company, in the long term this capacity to generate new ideas, new uses for old ideas or any mix of that will determine which companies will survive and which will not in this fastly changing world (HILL; JONES, 2009; LYNCH, s/d).

If we think sustainability – or sustainable development – as the balance of human actions´s impacts among humans and between humans and nature, there is no other alternative but change the actual production and consumption model as well as all social relations – of exploitation, misery and exclusion – that come with it. In order to incorporate the planet´s capacity to regenerate it´s resources and benefit the whole humanity for several generations we must be able to innovate.

The innovation focused on sustainability, is defined by Rennings (2000) as eco-innovation, “all measures of relevant actors (firms, politicians, unions, associations, churches, private households) which develop new ideas, behavior, products and processes, apply or introduce them and which contribute to a reduction of environmental burdens or to ecologically specified sustainability targets”.

We will incorporate the concept of eco-innovation to the previous definition of innovation, so the use of the terms innovation and eco-innovation won´t be distinguished in this paper. Therefore, innovation definition will be used as follow: the capacity to identify, develop, adopt and explore new uses to existing knowledge in different contexts or new knoledge in exisiting contexts aiming the promotion and implementation of sustainability.

Including the promotion of sustainability in the concept of innovation instead of treating this kind of innovation as another type shows there is no other alternative for companies but to incorporate the search for sustainable business in their strategies, objectives and processes (NIDUMOLU, PRAHALAD and RANGASWAMI, 2009). These authors show the implementation of sustainability doesn´t mean higher costs, it´s usually the opposite, several successful cases show the implementation of sustainability leads to cost reduction, higher productivity and market share even during period of crisis.

Loures (2009) summarizes the importance of innovation to achieve sustainability:

> “We must call attention to the essential nature of innovation when we deal with sustainability. The challenges created by global issues, specially climate change, and the natural human desire for continuous life quality improvement, require creative answers and significative qualitative gains in productivity that don´t compromise the future

> generations possibilities. If we really want to use the best humanity has to offer, we must give a special attention to the human dimension, making that knowledge and creative abilities are released emerging the truly culture of innovation" (LOURES, 2009: 94).

Smeraldi (2009) states that rather than incremental innovations, radical or disruptive innovations will lead the path towards sustainability because of their own nature of breaking rules and paradigms.

The development of sustainable products, or at least more eco-friendly products, needs several changes in companies´ structure, culture, market knowledge and also in the assessment of products impacts on the environment. The development process of sustainable products is still in a transition moment from a "green" improvement of the actual products to a real process of creation of new sustainable products that will substitute the existing ones. This transition is companies´ greatest challenge once it transcends the departmental frontiers – and even organizational frontiers – and demands an integration of different professionals and players all along the production chain (PUJARI, 2004).

Focusing the building sector, these trends and needs to promote sustainability become an evident challenge to companies and professionals. The operation period of a house, as shown before, represents 80% of all building cost (PIMENTEL e LAURINDO, 2008). Brazilian data on the resources consumption of the building sector shows that "40% of all extracted natural resources are allocated to in the building sector, 50% of all urban solid waste come from buildings and demolition, 50% of all electric energy consumption is used in the housing operations" (CORCUERA, 2008), 12% of all carbonic gas emission come from Portland cement production in Brazil, sand consumption in the metropolitan region of Sao Paulo is approximately 12 million cubic meters per year, more than 68,5 million tons of waste is annually produced in building and demolition activities, higher than the urban solid waste produced and five times higher than the resources consumed to build (JOHN et al, 2004).

John (2009), citing Kilbert, presents six principles that must be observed when thinking of construction sustainability: 1) Minimize resources consumption (conservate); 2) Maximize reuse of resources (Reuse); 3) Use renewable or recycled resources (Renew/Recycle); 4) Protect the environment (Nature Protection); 5) Create a healthy, non-toxic evironment (Non-toxic) and; 6) Search for quality in the building environment (Quality). Therefore, the following steps are important during the building process: 1) Building implementation, construction project and process; 2) Material selection; 3) Energetic planning; 4) Waste management; 5) Air quality and; 6) Project for flexibility. All this principles and steps demand increasing productivity of all resources – human, energetic and material.

As the house is inevitably a (material) product, only the search for dematerialization and service emphasis cannot promote sustainable constructions. It is fundamental that the incorporation of sustainable principles happens all along the process of project, production, delivery, use and rebuild/demolition of a house. That´s where innovation must happen: the search for new housing solutions that will balance social demands, economic feasibility and environmental protection while promoting human development in all surrounding area.

Concluding, sustainable construction is not only the building project itself, it reaches out these frontiers and includes the surronding area, the building integration in the urban tissue, the social relations generated and the economic opportunities created.

PIPS AND THE IMPACT ON INNOVATION AND SUSTAINABILITY IN THE BRAZILIAN BUILDING SECTOR

One important issue to be discussed is the development of performance norms instead of prescriptive norms and it´s impact on the building sector. This transition from a prescriptive model to a performance model is strategic to the promotion of sustainability and innovation and it is getting stronger (ALMEIDA, 1997) with the strengthening of global markets and real time communication across nations empowering consumers and putting stronger pressure on companies´ reputation – the most valuable asset organizations have nowadays (BORGER, 2001; GUNNINGHAM, 2005).

The main support on the use of economic tools and performance norms is that once this regulations determines what is expected from companies´ activities instead of how companies must operate (command and control model), these companies are free to find the best value alternatives that attend the regulation´s expectation and the economic demands of companies (ALMEIDA, 1997; PEREIRA et al., 2007; VARELA, 2007). Although results are achieved faster in command and control methods, the use of economic tools and performance norms foster innovation and a proactive behavior of companies, however, it is essential the participation of all actors in the construction of these performance demands sharing knowledge and comprehension of what is expected (SEROA DA MOTTA, RUITENBEEK e HUBER, 1996; SEROA DA MOTTA, YOUNG, 1997; PeBBu, 2005).

In this transition context, the performance based procurement is a strategic tool to change the players behavior, once:

> "The intent is to (…) shift the paradigm from traditional 'acquisition think' into one of collaborative, performance-oriented teamwork with a focus on program performance, improvement, and innovation, not simply contract compliance. Performance-based acquisition offers the potential to dramatically transform the nature of service delivery, and permit the federal government to tap the enormous creative energy and innovative nature of private industry" (GSA, 2001: 3).

PeBBu Final Report (2005) stresses two main characteristics of performance concept application:

• Use of two languages, one to the demand and another to the supplier of the solution for the expected performance. It reflects the change in roles played by consumers and suppliers. In a performance based context, consumers use their voice (VoC) to express WHY and WHAT the building solution must attend/perform while suppliers will offer HOW this performance/goal will be achieved, in other words, the development of the solution goes from the consumer to the supplier. This is the greatest breakthrough in the building sector, although it is not new (there are register of performance based demands in Hamurabi´s time), performance based approach in the building sector is not frequently used (PeBBu, 2005, CHONG et al., 2007, KASHIWAGI et al., 2010).

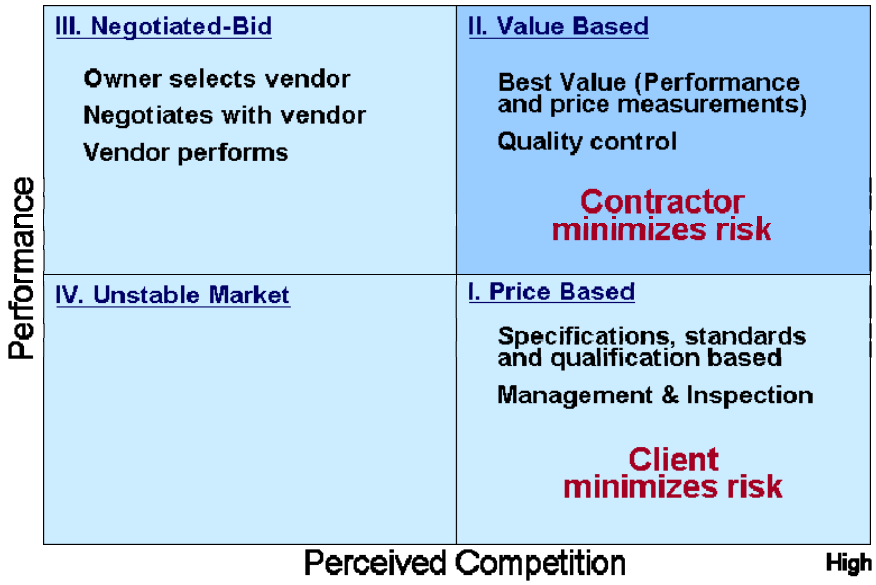
• Need to validate and verify the results achieved compared to the expected performance. It is necessary from the selection of the building solution to the assessment of the performance during the effective building operation. Several methodologies were developed to help this assessment such as Serviceability Tools & Methods®(ST&M®) by Internation Centre for Facilities, a KPI list by the US Federal Facilities Council and the Construction Product Directive by the European Union (PeBBu, 2005).

There is not enough experience in performance based procurement that enables a building to be entirely planned, procured, delivered, maintened and used based on performance documents, so a blend of the two models (performance and prescription) is still needed, however it is important to keep in mind the shift in the role of consumers and suppliers/contractors, where the first says WHAT they want and the sencond present HOW they will fulfill it. Despite the challenges in implementing this structural change, countries like Australia, Canada, Finland, the European Community as a whole, Hong Kong, the Nordic Countries, Singapore, South Africa, Spain, The Netherlands and the United Kingdom have been testing PBP where clients understand this approach serves their purposes better (PeBBu, 2005).

In this paper research it was adopted a 17-year tested methodology called Performance Information Procurement System (PIPS), created by professor Dean Kashiwagi at Arizona State University in 1991. This system is based in the Information Measurement Theory (IMT), Kashiwagi Solution Model (KSM) and the Construction Industry Structure (CIS). All these components are continually followed, assessed and updated in order to strengthen the proposed model and simplify it (KASHIWAGI, 2010).

IMT concepts basically show that: decision making brings risk and demands ones subjective bias and experience to make it; the use of dominant information – clearly identifiable and understood data – is the main resource to minimize decision making; the past performance and future capability enables one to predict future performance and; experts can identify risks before they happen and they can simplify complex information into simple explanations to non-experts (CHONG, 2007).

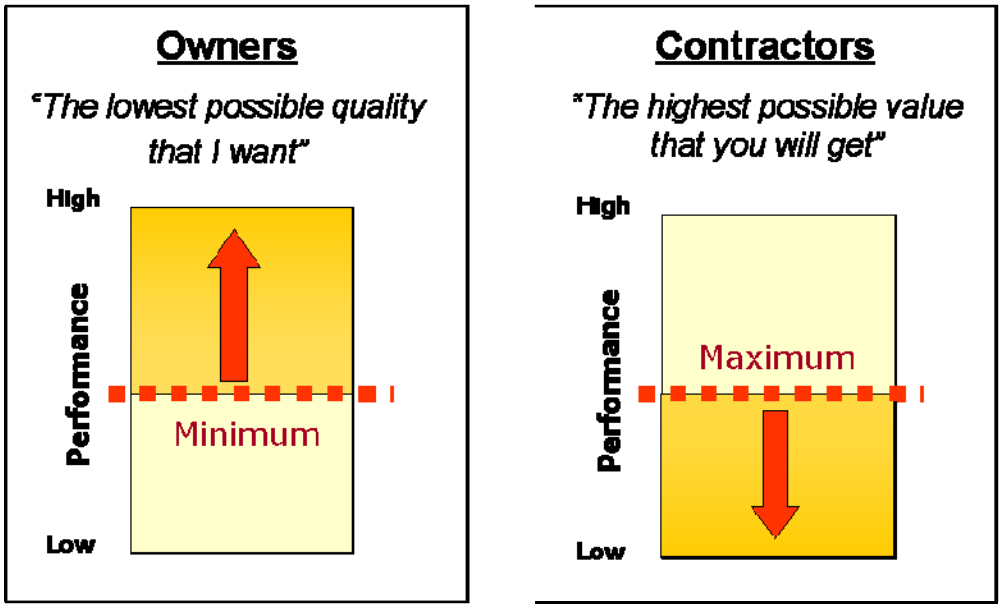
PIPS have been tested over 700 times, for over 17 years, projects worth more than 2 billion dollars. The results show an average of 98% customer satisfaction (projects delivered on time, within budget and according to expectations), reductions of 90% in project management transactions and less than 1% “surprise factor” of nonperformance (KASHIWAGI, 2009, 2010).



Duren and Dorée (2008) make a critical assessment of Kashiwagi´s declared results and identified that even some numbers are overestimated, the average results found are higher than the ones from traditional low-bid contracts. The authors also use the New Institutional Economics (NIE) to explain these results instead of Kashiwagi´s IMT, KSM and CIS and found PIPS has a great potential in reducing uncertainty, opportunism and transaction costs.

The KSM aims to identify if a person has more of visionary characteristics (called Type A) or management/control characteristics (called Type C) in an extreme characteristics model. The most indicated type to support and implement PIPS is Type A, because of it´s characteristics these kind of people use more logic than personal bias and experiences to choose experts, delegate responsibility and release control, minimizing risks as show in the IMT concepts (SULLIVAN et al., 2007).

The CIS classifies an industry into four quadrants according to the perceived competition and the performance factors (Figure 1). Nowadays construction industry all around the world is in the first quadrant – price based – where the clients minimizes risks they identify by managing and controlling all contractors actions (ADEYEMYI et al., 2009, KASHIWAGI et al., 2009).



This price-based model not only reduces contractor´s perfomance but also stimulates a reactive behavior where contractor will do exactly what the client specifies, instead of analyzing all the risks the client may not have identified that would impact on performance (Figures 2 and 3), that´s why this delivery system (based on client´s control over contractors and price based selection) is considered the main source of the problems identified in the delivery of construction (not in time, out of budget and not satisfying consumer´s expectations) and not the lack of technical expertise of players as it was thought (ADEYEMYI et al., 2009; DUREN & DORÉE, 2008; KASHIWAGI et al., 2009, 2010).

Figure 1: *Construction Industry Structure (CIS)*

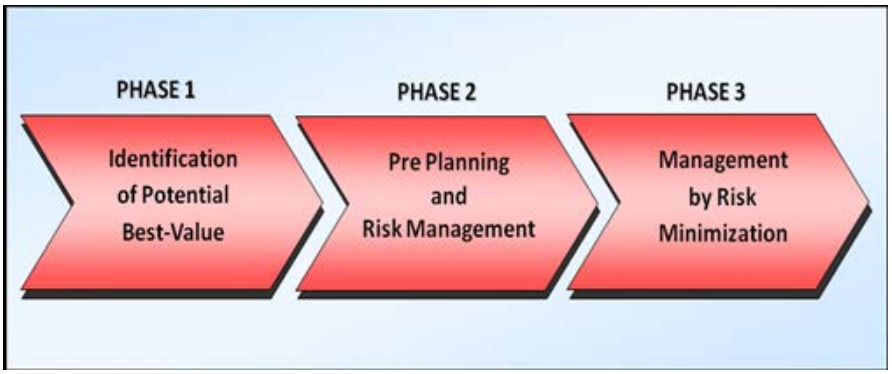
Figure 2*: Problem with Price Based Procurement*

Source: KASHIWAGI et al., 2009.

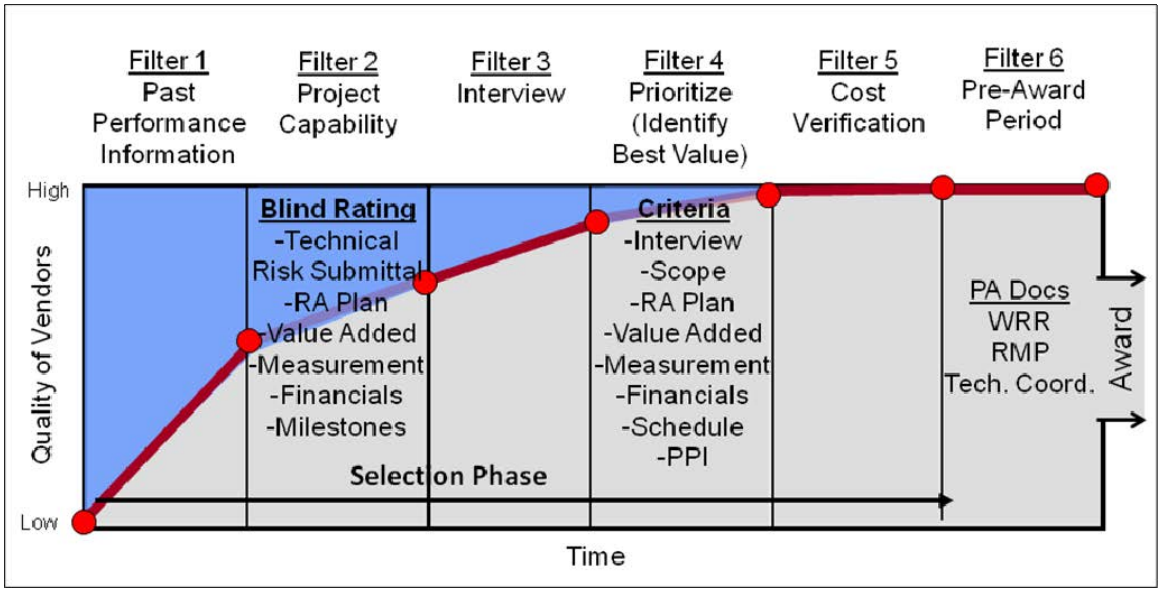
***Figure 3**: Price Based Award*



Source: KASHIWAGI et al., 2009.

PIPS proposition is to reduce as much as possible all decision making based on subjectivity and increase the use of dominant information (clearly identified and understood by anyone) to identify the best perfomer, the best constructor that will be selected to present the best solution (HOW) to the customer´s needs and expectations (WHY and WHAT) based on it´s past performance and it´s proved capacity of risk management and customer orientation.

PIPS – as well as other perfomance based procurement methods – will foster a transition from quadrant I to quadrant II: best value quadrant in the CIS represent a context where contractors have high performance in a competitive context, clients are satisfied once they choose the best value contractor, in other words, best performance (project on time and within budget) for the lowest cost (ADEYEMYI et al., 2009).
PIPS structure is briefly presented by Kashiwagi (2011):



> "The BVP/PIPS has three phases: selection, pre-award, and management of the project risk.
> The selection phase has five filters: past performance information, competitive ability to manage and minimize project risk, interview of key personnel, prioritizing the vendors and doing a dominance check to ensure that the best value vendor is the best value.
> The client's representatives assume the vendors are experts through the selection process then assume the best value vendor is not an expert in the pre-award phase to minimize the risk of the vendor. The paradigm is to minimize the need for technical decision making in the selection process, and maximizing the need for the best value vendor to prove they are an expert in the pre-award phase.
> The previous paradigm also forces vendors to show dominant differential in performance that minimizes the need for any technical decision making by the client.
> The risk is shifted to the vendors to show value through dominant expertise, knowing that experts minimize both risk and cost, thus providing the best value for the lowest cost" (KASHIWAGI, 2011: 36).

The proposition of PIPS adoption in the implementation of the Brazilian public housing policy incorporates ten points that we consider essential to promote sustainable construction using the public investment in the sector:

1) Stimulate cooperation among participants of the sector;
2) Stimulate construction companies to understand and attend dwellers needs and expectations;
3) Promote the building integration in the urban tissue, fostering socioeconomic integration of it´s dwellers;
4) Promote the search for sustainable solutions in all building phases, specially during it´s operation period;
5) Stimulate creativity during the building project, fostering innovation;
6) Focus on the building expected performance not on specifications and standards;
7) Stimulate continuous search for quality and development;
8) Promote building solutions compatible to regional specificities;
9) Stimulate social participation in the building selection phase and;

10) Foster human resources´ development throughout construction value chain.

The flexibility found in the PIPS guidelines allows all points to be incorporated in the public housing policy implementation. One important change proposed is to use the statement of objectives instead of specified models for popular houses – the current practice adopted in the public housing policy.

A request for proposals (RFP) must be done in a way that lets the market (building companies) free to create new solutions that attend the expectations and objectives declared in the RFP. That is the first condition to promote innovation according to the theory presented.

Demanding solutions that take into consideration local specificities and the needs of dwellers, plan the integration of the building – and it´s people – in the urban tissue and fostering economic opportunities for these people are the main drivers to find real sustainable construction proposals.

The maintenance of the requirement for companies to be certified by the Brazilian national program of quality and productivity in habitat fosters the continuous search for development and quality and strengthen the relationship among players across the building sector and use the State power to facilitate the market development and proactiveness not just reactiveness and compliance.

A selection committee can be made with representatives of several professionals of CAIXA (the responsible operator of the public housing policy). This multidisciplinary group has a very important role in the blind assessment and interview phases and during the pre-award meetings where the project risks can be discussed as well as the assessed capacity of the contractor to perfom according to what was asked.

The focus on the capacity of the contractor to perform according to what was asked and manage the project risks not the focus on the compliance of this contractor to the standardized house presented by CAIXA is a great step towards the transition to a participative, sustainable model of promoting the public housing policy.

Once the contractor is selected according to it´s evident capacity to perform successfully, the project is presented to the committee and can be discussed based on it´s attendance to the objectives requested by CAIXA as well as the effectiveness of the innovative solutions presented. All explanations must be based on dominant information and technical certification of the solutions capacity to perform according to what was asked.

Despite the need of technical certifications, according to IMT findings, any expert – in this case, the contractor – can explain the complex details of it´s expertise knowledge in a simple way anyone can understand, so, we believe technical explanations and discussions won´t be a problem to keep the participative structure of the process, in other words, committee members don´t have to be experts in engineering or achitechture to know whether a contractor is capable or not to perfom and solve any risk identified in a project.

After all discussion on project risks (mainly of non-performance) are over, the contract is signed based on the risk management documents, the project developed along with the informations provided during the selection and pre-award process. CAIXA must follow the

building phase according to the risk management plan (assessing if the contractor is managing the risks identified and what it is doing to mitigate any risk that might happen) and contractor must do what they know how to do best: build and deliver according to the customer´s expectations on time and within budget.

To conclude, we can say the main achievements of the exploratory study summarized in this paper are: • the use of PBP to implement the Brazilian public housing policy, which means basically select contractors that will have their projects financed, enables a wider range of project options that incorporate both regional and sustainable aspects as well as develop regional economic agents in the building value chain like material suppliers and local maintenance companies; • a faster approval process; • a cheaper and faster conflict resolution actions in very common problems identified in the existing buildings such as painting and lighting maintenance and security; • a more participative and transparent process; • innovation, the most important builiding block of competitive advantage, is also stimulated by this performance-based model of implementing the national housing policy that promotes also sustainability and competitiveness in the whole construction value chain. In other words, the use of a performance-based approach in the public housing policy has great potential to promote sustainable construction in it´s holistic concept previously presented.

FINAL CONSIDERATIONS

This paper summarizes the main achievements of an exploratory study on the impact the use of performance-based procurement in the implementation of the Brazilian public housing policy has on innovation and sustainability in the building sector.

Although the study was focused on popular housing that is financed by governmental policies and is, nowadays, the most attractive niche in the building sector, the discussion about sustainability transcends this niche. Sustainability has been a market strategy to differentiation and that is, by definition, not sustainable. The responsible use of resources and universal access to houses are fundamental to build a truly sustainable society where everyone has a decent place to live and has support to develop their capabilities to contribute to the whole society improvement.

The achievements shown in the exploratory study, although based on Brazilian experience on public housing policy, are based on international theory of innovation, sustainability, performance based procurement and sustainable construction, therefore, it can be extended to other countries. We must be aware, however, that the implementation, or even a proposition of implementation as the one made to Brazil, must be adapted to the countries´ reality: social and environmental demands, public policy characteristics and current position of Construction Industry Structure and industry level of development.

We believe the intent of the paper was achieved and some opportunites for future research in this area are: the acceptance of this new procurement system by the main actors responsible for this policy implementation; the level of development of each agent identified in the Agenda 21 – how commited to these strategies are they? –; the development of an educational program to train all actors participating in this procurement process and; the development of mathematical methods to assess reputation and a selection score to determine whether companies will or will not have their projects financed.

NEW OUPUT QUALITY INDICATORS IN CONSTRUCTION PRODUCTIVITY MEASUREMENT

JAN BRÖCHNER
Department of Technology Management and Economics, Chalmers University of Technology
Sweden
jan.brochner@chalmers.se

Abstract
Productivity increase in the construction industry is often seen as low. Construction innovation projects could be prioritized partly based on expected contribution to industry productivity. Quality change in construction outputs and inputs is crucial. The purpose is to explore new output quality indicators. The analysis draws upon life cycle analyses for facilities, project benchmarking schemes and environmental assessment systems. Disruption of client core activities due to technology and method choice in construction projects should be taken into account, and also the willingness of clients to pay for risk reduction. The result is a set of output measures. Primary output is identified as 'useful area'. Secondary output measures, with estimates provided by expert panels, would include effects on future energy consumption, effects on other future operations and maintenance resource needs, effects on client/user disruption, reduction of client/user risk during operation and maintenance, user comfort, architectural quality, and external societal effects. However, it would not be feasible or even desirable to collect a wider range of data routinely for the production of official statistics at the industry level.

Keywords: productivity, life cycle analysis, benchmarking, services, innovation

INTRODUCTION

Official statistics in OECD countries usually indicate that the annual rate of productivity increase in the construction industry is low. Earlier research has identified several reasons, including quality measurement errors (Crawford and Vogl, 2006; overview by Huang et al., 2009). As a consequence, international comparisons of construction productivity growth at the industry level, including the partial measure of labour productivity, are difficult to perform and to interpret (Ive et al., 2004). More recently, comparative analyses across industries and countries within the European Union and in relation to the US, relying on the EU KLEMS database, have been made available for the 1980 to 2005 period (Timmer et al., 2010).

Despite the problems associated with productivity measurement for the construction industry, it can be argued that construction innovation projects could be prioritized partly based on their expected contribution to industry productivity. This assumption has been made in the Swedish *Bygginnovationen* (The Construction Innovation, www.bygginnovationen.se) project, operational in its first phase since 2009. How to measure quality change in construction outputs is a crucial question, although there is also a problem with input qualities that change, such as educational heterogeneity in labour inputs. Developing productivity measures for the purpose of selecting innovation projects requires that the quality measurement issues are penetrated. As with the approach chosen by Goodrum et al.

(forthcoming), the ambition has not been to devise new metrics that could be applied throughout the industry for the production of national statistics. However, the exercise might give rise to new ideas for routine collection of productivity data.

The purpose of this paper is to explore the possibility to introduce new output quality indicators in construction productivity measurement. Construction productivity can be analysed at the industry, firm, project and activity/task level (Huang et al. 2009), and there are complicated relations between measures for aggregate and activity levels (Goodrum et al., 2002). For the assessment of innovations, higher levels than the construction project seldom appear to be useful, and there are lower levels such as technologies and components that may be relevant. Both contributions to total (multifactor) and to partial (usually = labour) productivity should be possible to measure, while output and input definitions should be as far as possible consistent with the OECD (2001) recommendations for industry level productivity measurement. This suggests an ambition to measure outputs according to market prices for construction projects, which means a client-oriented view of the value of innovations.

As the construction industry (NACE 41-43) includes both new construction and repairs, and also the whole range from housing to heavy civil engineering, it was decided to attempt the identification of a single set of measures that could be applied to proposed innovation projects of all types and not only for new construction. There will then be a need for estimating different weights for quality measures when applied to different types of construction: assessing a refurbishment innovation project that claims reduced disruption of building user activities is obviously different from assessing a new greenfield construction technology. It should be pointed out that an assessment of contribution to productivity is only one of several tests that an innovation proposal must pass in order to be supported by the *Bygginnovationen* project in its second phase, beginning in 2011; the commercial viability of an innovation project has to be analysed separately.

QUALITY CHANGE IN PRODUCTIVITY MEASUREMENT

Recent developments in service productivity measurement (Djellal and Gallouj, 2008) show that many issues encountered in the service sector are of relevance when analysing productivity growth in the construction industry. One relevant example of new approaches to the measurement of quality change in service outputs include the recognition of how the productivity of professional services is related to the productivity of whatever these services are intended to support as intermediate inputs, although this insight is hard to translate into data collection. Hitherto, the concept of ‘client productivity’ has only been used in the context of management consulting services (Martin et al., 2001), but it could equally well be applied to construction.

Another possible extension of traditional data sources is when data from customer satisfaction surveys are brought into the analysis (Färe et al., 2002). Just as in many services, there is the added complication of the customer participating in the production process of construction, e.g. when approving technical and schedule changes at construction site meetings. Co-production easily leads to the question of how co-productivity can be measured.

Although there remains a potential for the hedonic approach to qualities associated with built facilities, the estimation of implicit prices for housing attributes (Zabel, 1999; Leishman,

2001) is subject to severe limitations in the number of attributes that can be included, and for other types of facilities, even if omitting refurbishment projects, the unique features of each facility are clear obstacles. However, there are other sources of inspiration for better measures of construction output qualities, and the analysis presented below draws upon elements of life cycle analyses for facilities, project benchmarking schemes and environmental assessment systems. Furthermore, successive changes in government regulations for construction appear to offer clues.

Life cycle analyses

Many clients are thought to take the life cycle consequences of choice of materials, technologies and design more seriously than they used to do. Since the 1970s, client concern with energy cost for the operation of facilities has increased the demand for construction output qualities that raise the need for a range of inputs, and the more recent policy interest in construction sustainability emphasizes the relevance of life cycle assessments (Ortiz et al., 2009). Among public infrastructure clients, there is a growing awareness of future costs of maintenance and operations, as for steel bridges (Lee et al., 2004). If more clients are to be understood as basing their decisions on an investment view of the facility to be built, there is a number of issues to be resolved before we know the effect (as implicit prices for construction output qualities that correspond to facility features that lower future costs). One of these issues is fundamental: estimating the implicit discount rates that various categories of clients in various regions could be said to apply in their investment decisions.

Client concern with the life cycle aspects of facilities would be reflected primarily in design specifications and thus influence contract sums. The rise in long-term qualities is unlikely to be registered in traditional measures of construction outputs.

Project benchmarking

Since the UK Egan report in the mid-1990s, inspired by survey practices in the car industry, schemes for benchmarking performance in construction projects have gained widespread popularity (Costa et al., 2006; Rankin et al., 2008). In what ways do these mostly client-oriented schemes point to new output quality measures?

Construction project benchmarking can be seen as the outcome of a combination of ideas taken from customer satisfaction surveys and the project success literature. As yet, we are unable to impute what the actual client demand levels are for project attributes currently used in project benchmarking schemes. Applying the Just-in-Time principle is a good example of how a supplier might exhibit lower productivity and the customer firm a higher productivity, unless there is a compensating price premium paid by the customer. Traditional measures of construction productivity obviously fail to reflect whether contractual time schedules are met. On the contrary, for the customer who is unable to open a new production line because the built shell is not ready, there will be a measurable loss of productivity. Time precision, probably like cost precision and quality precision, is a service process quality that has not been thought about in the context of construction productivity, although it is likely that there is an implicit price for such qualities.

For the purpose of selecting innovation projects, it seems necessary to take into account the disruption of client core activities due to technology and method choice in construction projects, not least in the context of repairs and refurbishment. In general, the experiences from project benchmarking indicate that the willingness of clients to pay for risk reduction in construction projects might need adequate measurement as one or more output qualities. Now

it can be argued that there will only be weak reflections of service process qualities, as well as attitudes to risk, in construction contract sums, because clients tend to select as contractors those who have submitted the lowest tenders. However, there are signs that even public clients, whose freedom of choice is more restricted by procurement legislation, increasingly rely on non-price criteria for the award of contracts and that soft qualities such as ability to work in partnering relationships can be recognized by procurement officials and affect the ranking of submitted tenders in a way that corresponds to a set of implicit prices.

Environmental assessment schemes

The ongoing diffusion of environmental assessment systems such as LEED, BREEAM and CASBEE gives rise to the question of to what extent environmental ratings are associated with output quality changes. Eichholtz et al. (2010) have provided evidence of the economic value of 'green buildings', which should be possible to interpret as affecting construction productivity. One aspect is that clients might show willingness to pay for the image effect of owning a certified building, but this may be nothing but a transitory phenomenon.

These assessment systems offer numerous ideas for measures of environmental qualities. This is also the case with current European standardization efforts, primarily the EN 15643 series Sustainability of Construction Works - Sustainability Assessment of Buildings, which is intended to cover more than environmental sustainability, for which there is already the draft standard EN 15978 Sustainability of construction works - Assessment of environmental performance of buildings - Calculation method. It remains to be seen whether there will be a similar degree of consensus for measuring social and economic performance.

Construction regulations

In the context of selecting innovation projects, one reason why trends in the development of construction regulations are a potential source of relevant measures for construction output qualities is that in the future, existing technologies and designs may become obsolete due to government decisions. Additionally, an increased reliance on market pricing of public services that are currently offered free or at subsidized prices may in time make construction firms internalize effects that currently are external to the market mechanism. Prescient firms might recognize this and direct their demand for construction qualities accordingly, perhaps also influenced by assessment systems such as those mentioned above.

Returning to the idea of considering effects on client productivity, fire regulations for commercial buildings can be chosen as an example. Here there are three effects of regulations to be considered: (i) on client productivity, (ii) on third party (= neighbour, e.g.) productivity and (iii) on public services (= firefighting, e.g.) productivity. As to client productivity, the first of the three effects, a paternalistic view is that clients are subject to search costs for information, or that they suffer from bounded rationality so that they are unable to act fully in their own best interest.

SUGGESTED OUTPUT MEASURES

The result of this analysis is a set of output measures, where the primary output is identified as 'useful area', subject to a set of correction factors. Secondary output measures would include effects on future energy consumption, effects on other future operations and maintenance resource needs, effects on client/user disruption, reduction of client/user risk during operation and maintenance, user comfort, architectural quality, and external societal

effects. However, for a given proposal for a construction innovation project, most of the secondary output values would have to be estimated by expert panels according to simple scales in relation to defined reference buildings and reference technologies, which would represent a typical current base level in the domestic market for new construction or refurbishment.

The examples of related terms in Table 1 have been collected from Gilchrist and Allouche (2005), Hawk (2003), Lee et al. (2004), Rankin et al. (2008), REHABCON (2004), Rouse and Chiu (2009), and proposed European standards for Sustainability of Construction Works.

Table 1: *Suggested output measures.*

Output	Explanation	Examples of related terms
Useful length/area/volume	A user-oriented measure of capacity. Can be modified with a 'future capacity for flexibility' coefficient and coefficients for site-specific factors	urban/rural, geological and climatic factors
Energy	Discounted future reduction for the facility in use [kWh]	fuel consumption
Other operations and maintenance	Discounted future reduction of non-energy operations and maintenance resources for the facility in use	routine maintenance/rehabilitation; feasibility of post-repair monitoring, normal service life of repair
Disruption	Reduction of disruption of user activities	quality issues – available for use; user costs; traffic delay cost, noise/dust/vibration; repair time, cost of business disruption
Risk	Reduction of non-deterministic effects for the customer, within the contractual period and during the subsequent life of the facility (discounted, probability weighted)	time, cost, quality deviation; highway vehicle damage, vulnerability costs; fire safety; security
User comfort	Discounted future user comfort in excess of reference comfort levels	user costs; indoor air quality, acoustic performance, accessibility, smooth travel exposure; comfort and convenience, safety of users; traffic accidents
Architectural quality	Discounted future owner and user architectural experience in excess of a reference level	aesthetic contribution
Social effects	Discounted future reduction of negative external (non-market) effects	environmental damage, business effects; sustainability – design; indirect socio-economic losses; effects on third parties, environmental costs; property damage, noise, emissions, vibrations

A note on inputs

To obtain partial measures of productivity, the ratio between selected output measures and input measures can be estimated. The main input categories chosen here are Labour, Materials, Energy, Services and Environmental externalities. These categories can be divided into subcategories; 'waste' can appear both under (bought) Services and under Environmental externalities. Also with inputs, there is a problem with quality changes that are ignored or underestimated traditionally, such as heterogeneity of labour input, where shifts in educational level should be taken into account (Jorgenson et al. 2003). If wages or salaries reflect educational levels and skills, they would be better measures than number of manhours worked, used indiscriminately for the calculation of labour productivity.

CONCLUSIONS

Over the years, an increasing part of the value of construction outputs in typical OECD countries appears to have shifted towards qualities that are difficult to measure directly when applying conventional methods for calculating industry productivity. When selecting innovation projects according to their expected effects on construction productivity, it is important to devise a wide set of output measures that reflect a broader view of qualities, although it would not be feasible or even desirable to collect a wider range of data routinely for the production of official statistics at the industry level. For the purpose of international comparisons of productivity data, it is necessary to retain classifications and methods of measuring outputs and inputs that minimize the need for subjective assessments of intangible qualities. Unfortunately, this also reduces the usefulness of productivity data aggregated the industry level in many countries; analysis of these data can no longer be reliable guides to the development of either government policies or corporate strategies in regions where construction demand has shifted towards a wider set of qualities that are difficult to measure.

SOME LEGAL ASPECTS OF BIM IN ESTABLISHING A COLLABORATIVE RELATIONSHIP

Prof. dr. M.A.B. CHAO-DUIVIS
Technical University of Delft and Dutch Institute for Construction Law
The Netherlands

Abstract
Working with BIM will have legal consequences. In the Netherlands these consequences are feared by some and seen as an obstacle to wide spread use of BIM techniques. Unnecessarily so. In the paper it will be shown that according to Dutch law liability issues nor copyright issues nor issues of procurement law should be seen as an obstacle. What is needed however is a proper set of general conditions, which are broadly accepted by both employers and designers and contractors.

Keywords: Legal aspects. Construction contract law. Copyright law. Procurement law.

INTRODUCTION

Construction projects involve the work of many different parties. It is widely acknowledged that communication problems are an important source of budget and time excesses as well as errors in design activities and execution. One new exciting way of communication is working with a Building Information Modelling. Working with BIM has many different legal aspects: The contractual relationship between parties will need to be adjusted. The usual general conditions have not taken into account the aspects of working at the same time in one model by different parties. Nor can they. Therefore new contractual documents need to be developed which cover the relationship between the parties working the BIM team as well as between the parties and the owner. The aspect to be highlighted in this paper is the liability question. Than there are aspects concerning procurement law: is it possible to demand that tenderers work with BIM? What does this mean for tenderers who don't work with BIM? Can they be excluded? In this paper these aspects will be dealt with from a Dutch point of view. There are more legal issues to be dealt with for example on the validity of the electronic signature, the obligations to retain information electronically etc.

In this paper BIM is understood as: 'digital technology to establish a computable representation of all the physical and functional characteristics of a facility and its related project/life-cycle information, [that] is intended to be a repository of information for the facility owner/operator to use and maintain throughout the life-cycle of the facility'. This definition comes from US National Institute of Building Sciences (NIBS) and seems to be widely acceptable, in any case by lawyers given the fact it is used in the paper published in 2008 by the UK Society for Construction Law Contract issues in the use of construction building information modelling (the paper is written by Kimberly A. Hurtado and Patrick J O'Connor Jr, and can be obtained from the website from the UKSCL, and was published in 2008 in the International Construction Law Review, p. 262-272). This definition contains two important characteristics of BIM: the computable representation of a facility and the life-cycle approach. What is lacking in the definition is the fact that BIM makes it possible that several people can work at the same time in the computable representation. It is this aspect that basically causes most legal questions. I deliberately use the word questions and not problems, because there are legal questions to be faced, but, as will be shown in this paper, these answers can more or less be given easily.

THE NEED FOR NEW GENERAL CONDITIONS

Introduction

The relationship between the employer and the designers and contractors is governed in most countries by general conditions. In the Netherlands the most used general conditions are: The New Rules 2005
Legal relationship client–architect, engineer and consultant DNR 2005, the Uniform Administrative Conditions 1989 (it is expected that in 2011 a new version of these conditions will be published, an English translation is available at www.ibr.nl.) concerning the relationship between employer and contractor in the traditional model and the Uniform Administrative Conditions for Integrated Contracts 2005 for the design and build model (available in English via www.bna.nl and www.nlingenieurs.nl). None of these conditions have any specific clauses on working with BIM. Earlier research has shown that the content of these general conditions forms no obstacle to working with BIM. From a contractual point of view the main issues are the ownership of the intellectual property rights to the design, the liability for mistakes made in the BIM design and the matter of organizing the actual working in BIM by several people. How to deal with these matters?

Intellectual property

In the non Dutch literature the question concerning who owns the intellectual property rights during and after working in BIM does not seem to cause many legal concerns (H.W. Ashcraft, Building Information Modelling: A Framework for Collaboration, in The Construction Lawyer, 2008, nr 3). That is not the case in the Netherlands. Architects especially have made clear that they are reluctant to work with BIM, because they see their intellectual rights threatened by it. Since the intellectual property rights of architects, notwithstanding their mandatory legal protection as well as protection in the general conditions, are often violated (there is a considerable amount of case law proving this point), this fear is well understandable. But it must be remembered that this violation is due to the behavior of powerful employers and not due to the legal system. The working with BIM does not make it easier to violate the property rights of the architects, but does raise question on ownership caused partly by matters of the law of evidence.

Who is the owner of the design that came into being in a cooperation facilitated by BIM? The starting point according to the Dutch law on intellectual property is that the maker of a design is the owner of it. It should be noted that the terminology (maker of the design) is neutrally formulated and is not limited to only architects. Anybody can have an idea that is worthy of the protection of the Law on Copyright. So it is mistaken to say, that architects who are attached to their legal protection should not be part of a BIM team, because the protection is relevant for all members of the BIM team, which is clear when looking at the Dutch copyright law article 6. But who owns the copyright if there is teamwork? The law does not answer this question just like that. According to Dutch law one has to distinguish between a ‘communal work’ (gemeenschappelijk werk) and a ‘combination of works’. An example of a communal work is the work of an opera writer and the writer of the libretto if both writers worked together on a specific opera. The idea is that the contributions cannot be subject of an independent judgment. If an independent judgment is possible, like with an illustrated book and indeed in many cases of music and words than the Dutch law determines these works to be a combination of works. The determinant factor is: can the contributions be identified and separated. The distinction is of importance because of the legal consequences attached to it. In

case of a communal work the right to exploit the work accrue to all the authors jointly and acts of exploitation need the consent of all the authors as well (art. 26 Auteurswet and article 3:166 Civil Code). In case the work is not deemed to be communal every author can independently of the other ones exploit his rights. It needs to be mentioned however that the law in this case is not mandatory, so other agreements can be made. And a second point is that reasonableness and fairness can be of influence on particular acts. Reasonableness and fairness are also applicable in case of a communal right, art. 26 Auteurswet. One question that is not dealt with in Dutch (case) law is if it is of importance what the size is of the share of one author. It is feasible to argue that if one author had a share of 70% in a design this might influence the way he excersises his rights.

So how are we to qualifiy the design activities when working in BIM? The answer to this question is dependant upon the way the architect, the consulting engineer and the contractor worked together. Is their working to be compared to the opera writer who writes in close cooperation with the libretto writer, than the Dutch law will qualify the result of this cooperation as a 'communal work'. However this way of closely operating together will not often take place. More often it will be so that the architect makes the general design, after which the consulting engineers and the contractor appear to make the 'technical and execution' designs adding their design parts in the BIM model independently of the architect and independent from each other. Architect, engineer and contractor all use the same technique and work in the same virtual surroundings but the results of their activities can be identified from one another and separated intellectually. The fear of many architects that someone else will illegally use and claim their design is this way of working less realistic than in the traditional way of working, because electronically every 'entry' is registered with time and name. The Dutch copy right law considers the result of this way of working as a combination of works provided of course that these works are eligible for being qualified as a work to be protected by the copyright law (only original works are to be protected, see article 10 of the Auteurswet). The fact that certain works are not protected by the copyright law because they lack a certain originality does not mean the law does not offer other ways of protection. Possibly the law of tort offers protection against violation of certain ideas being used in this way of working.

In conclusion: in principle there is no legal difference when parties work in the traditional way or when they work in BIM. The difference is formed only by the 'more primitive' means used to design with in the traditional way not by new legal consequences of working with this new technology.
What is important is that the persons working together in a BIM surroundings make clear arrangements concerning the qualification of their work and the legal consequences. The law allows parties to make their own agreements and since they know best what suits their particular work they should formulate these legal consequences themselves before starting their activities in BIM.

Liability

Since a few years the English speaking world has become acquainted with the model of Early Contractor Involvement. It came into use because of the underlying assumption that if use was made of the execution knowledge of the contractor in the design phase the execution could take place faster. Because of the shortage of houses after the war, caused by the baby boom, speed was of the utmost importance. A special feature of this model (called in Holland: the building team) is the allocation of the liability for design errors. Liability lies not with the

party who suggested a certain idea leading to damages, but with the party in whose specific field of professional knowledge the idea lies and who has accepted this idea. Thus if the contractor suggests something lying in the field of the consulting engineer and the consulting engineer accepts this idea 'as if it was his' and it turns out to be a wrong suggestion leading to damages, according to the general conditions governing this model, it is the consulting engineer who is liable and not the contractor. This is the model in which the contractor joins the designers before the execution of the design. In the Netherlands this model has been known since the Second World War (Van den Berg, 2007, p. 323).

The question that needs answering looking at the way persons work in a BIM setting is, can their relationship be qualified as a 'building team' in the specific legal meaning of the words in the Dutch general conditions on this model (this is the VGBouw Model Bouwteam-Overeenkomst 1992, published in 1992 by the organization of contractors Vereniging Grootbedrijf Bouwnijverheid)? The answer is to be denied. The reasoning is that although contracts in Dutch law have in general no set form and the formation of a contract can take place in any form, the construing of a building team from the sole fact that parties work at the same time in a BIM needs too much to be assumed that this consequence is actually wanted by the parties. More information on the intentions of the parties is needed to draw the legal consequence, that although a specific agreement establishing a building team in the legal sense of the general conditions is lacking, nevertheless such an agreement can assumed on the basis of the way parties behave. So that means that while working in a BIM team the contractor suggests a modification in the work of the consulting engineer, it all depends on whether or not the agreement of the consulting engineer with this suggestion can be seen as he wanting to take over the liability for the suggestion of the contractor. In other words the sole working in BIM creates no new or different law of liability.

So how is the liability allocated in the case of a mistake made in a BIM team not being a building team?
Once again a distinction has to be made, somewhat comparable to the distinction between the communal work and the combination of works in the copyright law. How is the BIM team to be qualified? Is the BIM team to be qualified as a form of coordinated design activity or as a form of an integrated design activity?

In the Dutch legal literature (Van den Berg, 2007, p. 329) the coordinated design activity is described as a form of cooperation by designers individually contracted by the employer. These designers have their own obligations arising from their contracts with the employer, they consult one another on a regular basis in order to make the design parts fit. Cooperation is not the main theme of this 'team'. It fits with this way of working, that each party is liable for his own work. This is not the whole story however, because according to most contracts (and if this obligation cannot be based on the contracts it will follow from the law) between employer and designer there will be a duty to warn against mistakes made by the other members of the 'team'. If that duty was breached liability might shift partly or completely to the person who should have warned. In any case the liability will be joint and several and leave the sorting out of the exact parts to the designers and not to the employer.
It is to be understood that this theoretical model might not be realised in practice. The temptation will be great when working like this, to cooperate more closely than the model allows for. If that is the case, the other model, the integrated team, comes into view.

In the integrated team the cooperation is far closer: two or more parties have accepted an assignment to be fulfilled collectively. The participants in this model will constantly look at

the work from the other members of the team, comment on that, alter it, correct it etc. If this happens it might be argued because it is impossible to distinguish who has made which suggestion, that the result of their activity is one work and with this qualification goes collective liability. This is argued by Van den Berg (Van den Berg, 2007, p. 330). But is this situation the situation of the BIM designers? Van den Berg did not take into consideration one of the typical features of working with BIM: the additions made to the model, the changes and corrections etc. are exactly traceable. So an essential part of his reasoning leading to collective liability seems to be not applicable in the BIM situation. But that is not quit correct: because in a BIM model we know exactly who added something to the model, but we do not know whose idea this was. So the argument for collective liability still stands. But is this liability to be preferred? And what about the division of the liability between the parties of the team?

My suggestion would be the following: in the relationship BIM team and employer collective liability is indeed to be preferred. In the relationship between the members of the team the liability should ideally be allocated according to the Dutch general conditions for the building team.

I would therefore like to argue as follows by starting from the viewpoint: what fits with the idea of working in BIM. To use BIM optimally cooperation between all workers in the BIM team is to be stimulated to the utmost. Allocation of liability to the person to whom a mistake can be traced will per definition lead to discussions between the team members being held liable and the employer that party A who was held liable is not liable but that party B was liable or that party C should have warned against the mistake, so he is liable as well, which party C will of course deny. This kind of arguments are not attractive for the employer. BIM is supposed to make his life easier, by using a technique that is superior to the present techniques, but faced with this allocation of risks, the employer might want to stick to other techniques. So the allocation of the risk must be attractive to the employer and not be more of a burden than necessary. This brings me to the idea of collective liability as suggested by Van den Berg for the integrated building team, because this fits with the nature of the way one works in BIM, or should work in BIM: as a real team.

Being liable to the employer collectively does not mean however that at the end of the day all members have to bear a part of the financial burden of a mistake of one of them. It only means that the employer can choose any one from the team members for the total amount of the damages. But after having paid these damages, the paying member of the team turns around and asks the other members to contribute. How much each member has to contribute, is dependent upon the agreement the team made: possibly only the member who is responsible for the mistake has to pay for the mistake (perhaps together with the member of the team who should have warned against this mistake); possibly all members bear the costs of the mistake in equal amounts or in an amount in accordance with their share of the work in the team. This is an issue the parties of the BIM team have to decide upon in advance.

My suggestion concerning the division of the obligation to contribute at the end of the day (so among the members of the team) would be to follow the allocation of liability according to the Dutch general conditions for the building team: liability should be borne by the party in whose specific field of professional expertise the suggestion lies and who has accepted that idea. This way we stimulate legally what might be a very good side effect of the BIM way of working: to stimulate all parties of the team to come with creative ideas from; but because not every idea is per se a good idea the party most suited to do so, should be obliged to check this

idea and ‘put his money where his mouth is’ by accepting legal responsibility for it. This way we combine creativity with guarding the soundness of ideas. Thus the contractor suggests something in the field of the construction engineer; the consulting engineer looks at the idea and accepts it as a sound idea and adds it to ‘his part’ of the BIM model assuming that the members of the team have designated who takes care of what and who is authorised to add what to the model. This is something parties working in the BIM have to agree upon explicitly and clearly in advance as well. Assuming that the consulting engineer is the only one who can add the idea (because it is in his field and that is the way parties agreed upon in advance), we can assume that the act of adding the idea to the BIM model is prove of his accepting the liability for the idea. BIM makes problems of proof less of a problem. There is hardly any case law on building teams notwithstanding its broad use in the Netherlands. The problem of proving that a party made an idea his own in the building team has never been in a problem in case law as far as I know. All in all the questions on liability in the BIM team are not leading us to a very different approach in comparison to existing ways of working. This conclusion is somewhat similar to what is to be read in Consensusdocs 301, Building Information Modeling (BIM) Protocol Addendum ,1.1. General Principles: ‘This Protocol Addendum does not effectuate or require a restructuring of contractual relationships or shifting of risks between nor among the Project Participants other than as specifcally required per the Protocol Addendum and its Attachments.’ We can use existing examples and apply them to working in BIM.

In conclusion it might be hoped due to the fact that mistakes become visible in an earlier and virtual phase, that damages will decrease.

What does the owner get?

Another question to be answered regarding working with BIM is: what rights does the employer get when the model is handed over to him? The owner wants at least the right to realise the design like with any other design he contracted for. But does he also get the right to alter the design? And if he has that right: does that mean he is entitled to work in the BIM model to design the alterations before executing them or does he have to ask the original designers to change the model such that execution can take place safely? In a recent discussion I heard someone draw the comparison between the rights of the builder of a website and the rights of the employer for whose organisation the website was built. It is possible to make the website in such a way that the employer can change anything, but it is also possible to limit the rights to do so and make the owner only licensed to a ‘limited use of the website’. These are also issues that need a legal strategy before rights are turned over.

Organisation of the BIM team

In the Dutch general conditions for both the relationship employer and contractor and the relationship employer and designer the question of coordination in case the contractor or the designer is faced with other parties working at the same project is dealt with. In the first relationship the obligation to coordinate the works lies with the supervisor on the side of the employer (clause 31 Uniform Administrative Conditions). In the relationship employer and designer the general conditions (The New Rules 2005, clause 6.2)) the employer is obliged to point out a party who will be responsible for ‘the tuning in of the activities of the different consultants and which participant is responsible for steering the process of the activities of the different consultants’.

If an employer wants a design to be made in a BIM team which forms, he will be obliged to take care the leadership of this team or the coordination in this team is properly organised. Failing to do so will give the members of the team claims for loss of time and or claims for damages. Basically the situation in a BIM team is not different from the situation in which in the traditional models parties have to work together. In the Dutch general conditions for the building team it is the employer as well who has to deal with the coordination of the team. Of course he can delegate this task to another member of the team, or he can let the work be done by a third party. Obviously that last choice will not change the liability of the employer to the members of the team.

ASPECTS OF PROCUREMENT LAW

One of the issues raised in the Netherlands is if procuring agencies can demand the use of BIM technology by tenderers knowing that this technology is not widespread yet and actually only used by a very few tenderers. Would this not favour these companies in a way unacceptable from the viewpoint of equality and guarding against favouritism?

I would like to argue as follows. In the Consideration on Directive 2004/18 one can read:

‘(29) The technical specifications drawn up by public purchasers need to allow public procurement to be opened up to competition. To this end, it must be possible to submit tenders which reflect the diversity of technical solutions. Accordingly, it must be possible to draw up the technical specifications in terms of functional performance and requirements, and, where reference is made to the European standard or, in the absence thereof, to the national standard, tenders based on equivalent arrangements must be considered by contracting authorities. To demonstrate equivalence, tenderers should be permitted to use any form of evidence. Contracting authorities must be able to provide a reason for any decision that equivalence does not exist in a given case. Contracting authorities that wish to define environmental requirements for the technical specifications of a given contract may lay down the environmental characteristics, such as a given production method, and/or specific environmental effects of product groups or services. They can use, but are not obliged to use appropriate specifications that are defined in eco-labels, such as the European Eco-label, (multi-)national eco-labels or any other eco-label providing the requirements for the label are drawn up and adopted on the basis of scientific information using a procedure in which stakeholders, such as government bodies, consumers, manufacturers, distributors and environmental organisations can participate, and providing the label is accessible and available to all interested parties. Contracting authorities should, whenever possible, lay down technical specifications so as to take into account accessibility criteria for people with disabilities or design for all users. The technical specifications should be clearly indicated, so that all tenderers know what the requirements established by the contracting authority cover.’

In the Annex VI, belonging to this Directive the definition of certain technical specifications is described as:

‘For the purposes of this Directive:
1. (a) "technical specification", in the case of public works contracts, means the totality of the technical prescriptions contained in particular in the tender documents, defining the characteristics required of a material, product or supply, which permits a material, a product or a supply to be described in a manner such that it fulfils the use for which it is intended by the contracting authority. These characteristics shall include levels of environmental

performance, design for all requirements (including accessibility for disabled persons) and conformity assessment, performance, safety or dimensions, including the procedures concerning quality assurance, terminology, symbols, testing and test methods, packaging, marking and labelling and production processes and methods. They shall also include rules relating to design and costing, the test, inspection and acceptance conditions for works and methods or techniques of construction and all other technical conditions which the contracting authority is in a position to prescribe, under general or specific regulations, in relation to the finished works and to the materials or parts which they involve;
(b) "technical specification", in the case of public supply or service contracts, means a specification in a document defining the required characteristics of a product or a service, such as quality levels, environmental performance levels, design for all requirements (including accessibility for disabled persons) and conformity assessment, performance, use of the product, safety or dimensions, including requirements relevant to the product as regards the name under which the product is sold, terminology, symbols, testing and test methods, packaging, marking and labelling, user instructions, production processes and methods and conformity assessment procedures;'.

From these citations one can conclude that specifications not only are important for the result of the activities of the tenderer but possibly also for the way this result is reached, in our case while working with BIM. If the contracting agency wants the tenderers to work with BIM the agency must be prepared to answer the question calling into doubt that an equivalent of this way of working does not exist. If it can answer this question proving that that this way of working is new and unique and no other way of working can reach an equivalent than the law of procurement does not seem to be a obstacle for requiring the tenderers to work with BIM.

For Holland the relevant legislation, article 23.2 BAO forbids the contracting agency to use unjustified obstacles. Meaning: obstacles as such are not forbidden, which makes sense, because the superior capacity of one party over another in for example technical ability will always be an obstacle for the other party, and it is not forbidden to prefer the tenderer with the highest level of ability as long assuming the criteria are proportionate and aimed at favouring one particular party (the text of this article in Dutch: De technische specificaties bieden de inschrijvers gelijke toegang en leiden niet tot ongerechtvaardigde belemmeringen in de mededinging voor de openstelling van overheidsopdrachten). Important are also clauses 23.11 en 23.12 BAO (the text in Dutch: BAO art. 23.11. Een aanbestedende dienst maakt in de technische specificaties geen melding van een bepaald fabrikaat, een bepaalde herkomst of een bijzondere werkwijze, noch van een verwijzing naar een merk, een octrooi of een type, een bepaalde oorsprong of een bepaalde productie, waardoor bepaalde ondernemingen of bepaalde producten worden bevoordeeld of geëlimineerd, tenzij dit door het voorwerp van de overheidsopdracht gerechtvaardigd wordt. Art 23.12. Een aanbestedende dienst mag de melding of verwijzing, bedoeld in het elfde lid, opnemen in de technische specificatie wanneer: a. een voldoende nauwkeurige en begrijpelijke beschrijving van het voorwerp van de overheidsopdracht niet mogelijk is door toepassing van het derde en vijfde lid, en b. deze melding of verwijzing vergezeld gaat van de woorden «of gelijkwaardig». These clauses forbid among other things the contracting agency to point to specific ways of working except when this is justified by the subject of the contract. Arguments to be used to show that there is a justification to demand that the work is done with BIM are that this way of working is a modern way of working which is comparable to working with a computer, so this might well be the normal way of working in the near future, that mistakes will be avoided, that it will lead to better relationships between all concerned, that the government by stimulating this use will make use of it more wide spread which is beneficial for the whole sector (including the

private market) etc. It seems to me arguments can be used very easily to justify this new and promising technique.

So in answer to the question on procurement: an optimistic viewpoint can be taken here as well: once again the law is no obstacle for the use of BIM.

CONCLUDING REMARKS

Liability, copyright and procurement law are legal issues are often called upon as standing in the way of widespread use of the BIM. I hope I have shown in this article that this is non issue. Certainly these issues have to be dealt with, and preferably in general conditions acceptable to all parties concerned. But they can easily dealt with. An example might be taken from the models used in the USA: ConsensusDOCS ,an Electronic Communications Protocol Protocol Addendum 200.2 and from the AIA: Building Information Modeling Protocol Exhibit, Document E202-2008. More information can be found by using the term IPD (integrated project delivery). It is important however to do this soon, because BIM is becoming fast the way to design.

THE USE OF THE UK BENCHMARK MODEL TO DEVELOP A STANDARD GLOBAL APPROACH TO CONSTRUCTION DATA

STEPHEN GRUNEBERG
University of Westminster
35 Marylebone Road
London NW1 5LS
s.gruneberg@westminster.ac.uk

Abstract

The human population of the world has grown rapidly in the last fifty years. The impact of the population explosion has also had a dramatic effect on the built environment. Yet it is difficult to find a source of statistical information on a global scale that combines the data that is available. Unless there is a measure of construction activity throughout the world there is no way of gauging the scale of the issues involved.

There is a need to know the location of activity, the types and quality of output, and the numbers and skills employed in the construction workforce. Only when these measures of the construction industry are found, policies to deal with construction problems, such as homelessness, migration, health and safety, training and skills, trade in materials, carbon emissions and many other issues can be assessed by the international community.

Setting these issues to one side, a benchmark model of construction based on the UK construction industry is considered. Such a model might be used to calculate the size and growth rate of the global construction industry and this can be used to compare to other estimates of global construction. It is suggested that the global construction industry, using the benchmark model as an international standard, can itself then be used as a benchmark to compare more detailed national construction statistics.

The benchmark model uses Gross Fixed Capital Formation (GFCF) taken from National Accounts. This is then applied to a breakdown of construction using UK Construction Statistics Annual (CSA). The model establishes the breakdown of construction for any country on the assumption that the breakdown in any country will be approximately similar to the breakdown in the UK and the UK breakdown represents a typical national construction industry.

In particular this paper deals with the issue of the most appropriate variable to use to relate GFCF available in every country's national income data to the detailed analysis of UK construction data for the sake of building the benchmark model. There are three options, namely: total GFCF, the total construction element in GFCF or all new work in the CSA. No statistically significant differences are found between any of the variables but for theoretical and operational reasons the preferred option is the total construction element in GFCF.

Keywords: global construction data, UK benchmark model, gross fixed capital formation, all new work.

INTRODUCTION

Construction appears in the Nomenclature Générale des Activités Économiques dans les Communautés Européennes (NACE), which is the agreed statistical classification of economic activities used by the EU. The UK version is the Standard Industrial Classification system, (currently SIC 2007). Both NACE and the SIC are consistent with ISIC, which is the International Standard Industrial Classification agreed at the United Nations for the purposes of global comparisons. In the SIC 92 (Office for National Statistics, 2011b) all activities were divided into sections and Section F covered construction, which appeared as a 2-digit classification: 45 Construction. In both NACE and the SIC, construction was further divided into 4 main 3-digit categories, namely 45.1 Site preparation, 45.2 Building of complete constructions or parts thereof; civil engineering, 45.3 Building installation, 45.4 Building completion, and 45.5 Renting of construction or demolition equipment with operator. Unfortunately, these categories are not particularly useful for the analysis of construction activities in terms of types of output, types of firms, and market sizes. The SIC 92 has been replaced by the SIC 2007 (Office for National Statistics, 2009) together with new 3 and 4-digit codes and descriptors. The 2 and 3-digit codes are shown in Table 1.

Table 1 *UK Standard Industrial Classification of UK Construction*

Section F Construction
41 Construction of buildings
41.1 Development of building projects
41.2 Construction of residential and non-residential buildings
42 Civil engineering
42.1 Construction of roads and railways
42.2 Construction of utility projects
42.9 Construction of other civil engineering projects
43 Specialised construction activities
43.1 Demolition and site preparation
43.2 Electrical, plumbing and other construction installation activities
43.9 Other specialised construction activities n.e.c.

In section F of the ISIC, (United Nations, 2008) there are only three main 2-digit codes within construction. They are 41 for the construction of buildings, 42 for civil engineering and 43 for specialized construction activities. Construction of buildings, which is also given a 4-digit classification, 4100, includes complete residential or non-residential buildings. Civil engineering is divided into three classifications, namely 421, the building of roads and railways, 422 the construction of utility projects, such as pipelines, communications, reservoirs, pumping stations and power plants and 429 which covers all other civil engineering projects, including refineries, harbours and outdoor sports facilities other than buildings.

Not only are definitions and classifications highly complex and variable even between the SIC, NACE and ISIC, they also change over time to reflect changes in technologies and output. There is no agreed method for estimating the size of construction industries in different parts of the world apart from the NACE and ISIC definitions given above. In any case construction data is not always available. As a result there is a need to estimate likely construction output in different countries. As Gruneberg (2008) has pointed out the OECD has modelled global infrastructure construction output using a top down approach based on

an estimate of the value of existing structures, national income and the size of the global population. This data set can be used to assess the growth and size of construction markets throughout the world and gain a view of the scale of the challenge facing national and global organisations such as international development banks, the United Nations, the Organisation for Economic Co-operation and Development, the World Bank and the International Monetary Fund. However, it is not the only approach that can be adopted.

An alternative bottom up approach, devised by Gruneberg (2008), makes use of construction data and estimates construction output as a ratio of construction to gross fixed capital formation (GFCF). To begin the discussion of appropriate statistics for construction, the UK database of construction is used and the ratio of UK construction to UK GFCF can then be applied to other economies. Clearly, where this fails to produce data that resembles available construction data and information, modifications can be made to the results for any given country.

Of course the estimates will vary depending on the method used and the appropriateness of the model, when it is applied to particular countries. Nevertheless, it is important to begin the process of assessing economic activities that have an impact on the environment. Few activities can have the effect both locally and globally that the construction sector has on the environment.

Indeed, the capacity of the global construction industry is challenged by the growth of the world population and expectations regarding standards of living in different countries. Thus, as the population of the world approaches 7bn people, according to the US Census Bureau (2011), it is expected to continue growing to over 9bn by 2050, albeit at a declining rate of increase. Indeed the rate of growth in population is on a downward path from a high of 2.2 per cent per annum in the 1960s to less than 0.5 per cent by 2050. It is currently estimated by the Bureau to be growing at just over 1 per cent.

Not only are the absolute numbers of people increasing but at the same time the expectations of the populations in many ountries appear to be rising, as the so-called BRIC countries, (Brazil, Russia, India and China), increase their domestic consumption, making further demands on the environment and resources in line with their growing levels of income. The question then arises as to whether or not construction has the capacity to deliver and what effect delivering sufficient buildings and infrastructure will have on global resources and the environment.

In looking at national income data the construction industry is often seen as being approximately 5 to 8 per cent of the economy. This, however, only estimates the value added activities on site. Taken as a final good, including all the material and labour inputs, construction activity contributes between 15 to 20 per cent of the annual output of economies. As a consequence of using value added by industrial sector as the basis for aggregating national data, the impact of construction activity is often undervalued and overlooked.

DEFINITIONS AND PROCEDURES USED IN THE BENCHMARK MODEL

It is therefore important to discuss ways of deriving reasonable estimates of construction outputs. The most readily available international economic data is provided by the United Nations and other international organisations. This data includes the National Income accounts of all members of the UN, given in a common format agreed globally. In these sets

of national income accounts is a chapter headed gross fixed capital formation (GFCF). Within the CFCF is construction output. This component of GFCF is itself broken down into two components and these can be used to model a breakdown of construction data into different categories based on the pattern of output in a benchmark country or international average. In the absence of an international average breakdown of construction output by type, it is suggested that the UK construction data be used as a benchmark until a more appropriate standard is found. Of course any country might be used as a standard for this purpose until work can be carried out to find a more suitable international norm, if such as thing could be arrived at.

The actual method involves taking UK construction output data as an example. Each category of output in the data, such as housing, infrastructure, commercial and repair and maintenance are used to establish its percentage of total output by using the mean ratio for a given number of years. Table 2.8 in Construction Statistics Annual provides new build construction output only. Thus infrastructure forms a percentage of UK construction output and within infrastructure the different components can be estimated. Using UK Construction Statistics Annual the average distribution of unfrastructure can be calulated as illustrated in Table 2.

Table 2 *Average UK Infrastructure by Type of Infrastructure 1997-2008*

Type of infrastructure	***Percentage of infrastructure***
Water	15.50
Sewerage	10.82
Electricity	8.39
Gas	4.00
Communications	6.62
Air	4.83
Railways	15.93
Harbours	5.36
Roads	28.54
Total infrastructure	100.00

Based on data taken from Table 2.8d, Construction Statistics Annual, ONS (2010)

Table 2.8 in Construction Statistics Annual provides new build construction output only. The estimates for new build therefore need to be grossed up to find the total value of construction output or an estimate of the total value of all output including repair and maintenance for any given component of construction output where this is not given in the data. This is done using Table 2.2 to find the average ratio of new build to total output. For example, between 1997 and 2008 this was 0.56 of total construction output. The inverse of 0.56 is 1.79 and this inverse can be used to estimate total construction output or the total including repair and maintenance for any element within the data set.

.

This percentage of total construction output is then used as the coefficient of the value of the construction element in annual GFCF to estimate the value of housing or infrastructure or other component in any given country. The same method is used to establish coefficients for all components of construction output for each year.

DISCUSSION

This modelling of the construction industry based, as it is, on existing international data and the UK is of course to some extent an arbitrary method based on a number of assumption. However, it is invariably necessary to make a number of assumptions in order to make an operational assessment to form the basis of rational decision making at an international level. The assumptions are that the same pattern of construction output exists in every country, when clearly it does not. One obvious case would be where the UK as an island, depends on ports and harbours for much of its trade. Ports and harbours do not feature as highly in land locked countries or countries with land borders with its neighbours.

A second assumption is that buildings in one country are equivalent to buildings in another. For example, residential buildings in the UK need to withstand weather conditions ranging from relatively mild winters to relatively mild summers compared to seasonal variations in Russia. Buildings therefore need to be constructed to withstand greater or lesser variations in climate in different countries and need to be built to different standards to meet those requirements. Similarly North African countries do not require buildings to withstand the winter conditions experienced by those of Northern Europe.

Gruneberg's benchmark model is based on the combination of the GFCF of the national income accounts of each country and the ratios of construction to GFCF in the UK. In this model Equation 1 shows construction new build (NB) and repair and maintenance (R&M) as a ratio of GFCF, based on the ratio of new build to GFCF and repair and maintenance to GFCF in the UK. The data is taken from the UK National Income Accounts and the Construction Statistics Annual.

$$I = (\Sigma\{RNB/GFCF\}/n)(GFCF + [\Sigma\{R\&M/NB\}/n]GFCF) \quad \text{(Equation 1)}$$

where I = total new build and repair and maintenance
n = number of years

Having established the ratio of total construction output to GFCF, it is then possible to estimate the component parts of the output of construction in terms of the different types of buildings and output of construction, such as housing, commercial and infrastructure. For example,

let INB = infrastructure new build, and
IR&M = infrastructure repair and maintenance = (R&M/NB).INB

Then,

$$I = aGFCF + abGFCF \quad \text{(Equation 2)}$$

where a = Σ{INB/GFCF}/n, that is the average annual ratio of INB/GFCF
and b = Σ{R&M/NB}/n, that is the average annual ratio of R&M/NB.

The reduced version of the equation for infrastructure becomes:

$$I = a(GFCF + bGFCF) \quad \text{(Equation 3)}$$

Using this method, Gruneberg (2008) found the average ratio of infrastructure to GFCF from 1998 to 2005 was 4.08 per cent.

In order to improve on the model given in Gruneberg (2008) a modification of the model involves replacing GFCF with one of three options, namely the construction element of

GFCF alone or all new work as given in Table 2.1, Construction Statistics Annual (Office for National Statistics, 2011a). The original benchmark model used total GFCF but GFCF includes non-construction investment, namely plant and machinery. A revised version of the UK benchmark model should therefore be based on the built element only of GFCF.

Revised version of the benchmark model

In order to demonstrate that this produces a significantly different result, it would be necessary to show that annual changes in the built component of GFCF are significantly differently from annual changes in GFCF as a whole.

When this test was carried out on UK national income accounts data, the following results were found, using Excel:

Table 3 *New construction as a component of GFCF and total GFCF***.**

From Table 4 the differences in the two variables GFCF and the total construction element were found to be significantly different (t = 18.8, with 14df). This would indicate a preference for the construction element of GFCF rather than total GFCF.

Turning now to the first differences of these two time series, given in Table 5, namely the construction element in GFCF and GFCF itself, a similar result is found in Table 6. Even

when comparing annual changes in these variables, significant difference between the behaviour of the two variables can be identified (t = 6.63 with 13df).

Turning to the use of construction output data rather than the value of construction in the GFCF, Table 7 gives the indices of the current values of UK annual total construction new build and GFCF respectively. Again, from Table 8, these two time series are significantly different (t = 7.35 with 14df). Therefore the output of the model will depend to some extent on which of these two time series is selected in the model.

Finally, the difference between the first differences of the indices of new work and the construction component in GFCF in Table 10 are also significant with t = 7.44 with 13df. Again this reinforces the need to select the time series rationally.

The rationale for selecting the construction component of GFCF is that it appears in the national income accounts of all countries. As it appears in all national income accounts, it can be most easily applied to any country in the world and combined with UK construction data using coefficients to represent the proportion of total annual output in any one year attributable to any particular variable. In this way national construction data can be estimated to find output and other aspects of the construction sector within each country. This would only provide an approximate model of any country or region's construction sector. Local knowledge and contingent factors would also need to be taken into account.

CONCLUSION

We reject the null hypotheses that there are no significant differences between the GFCF and the construction component of GFCF and construction output all new work in the Construction Statistics Annual. We also reject the null hypotheses that there is no significant difference between annual changes in total GFCF, the annual changes in the construction component of GFCF and indeed the total new work found in Construction Statistics Annual.

The use of the construction component of GFCF is suggested as the most practical time series to use in the benchmark model to link with national accounts data and this should be used in conjunction with the construction data found in Construction Statistics Annual to form the benchmark model. This method for establishing the link between individual countries and the benchmark model could be applied to any country.

SUPPLY CHAIN PARTNERSHIP WITHIN HOUSING RENOVATION – APPROACHES AND EXPECTATIONS IN THE DUTCH HOUSING ASSOCIATION SECTOR

VINCENT GRUIS
Utrecht University of Applied Sciences and Delft University of Technology
v.h.gruis@tudelft.nl

MARTIN RODERS AND AD STRAUB
OTB Research Institute for the Built Environment, Delft University of Technology

Abstract
Supply chain partnerships within housing refurbishment have not been given much specific attention which may be found surprising because the refurbishment market is becoming of increasing importance compared to new construction and has specific characteristics that require adapted approaches to supply chain integration. In this paper approaches, expected benefits and challenges of supply chain partnerships within housing renovation are explored. From general literature on building process innovation, dimensions of supply chain integration and potential advantages and challenges of have been derived and employed in a preliminary inquiry among Dutch housing associations and their partners that are experimenting with supply chain partnering in housing refurbishment projects. The results indicate that approaches are in a relatively early stage of development towards 'mature' supply chain partnerships. Furthermore, many of the general expectations also apply to the Dutch housing refurbishment sector, but at a more detailed level, refurbishment may require specific attention for the division of tasks and risks between the partners, particularly regarding communication with tenants.

Keywords
Supply chain partnership, housing associations, refurbishment

INTRODUCTION

Supply chain partnering and integration has become a prominent topic of research and debate within the building sector. Several advantages have been attached to building processes that emphasize partnerships between clients, contractors and suppliers in the construction industry, such as decreasing the waste and improving value to the client (e.g. Black et. al., 2000; Bresnan and Marshall, 2000). Nevertheless, most studies have focused on supply chains within new building projects, with some having a specific focus on the housing sector (e.g. Barker and Naim, 2008; Hong-Minh et al., 2001). Publications on supply chain integration in housing refurbishment are scarce. This may be found remarkable, since investment in refurbishment has become increasingly important. As for example Thomsen and Van der Flier (2009) show, the number of new housing construction in Europe constitutes only about 1 percent of the number of existing dwellings, which indicates the importance of maintenance and refurbishment of the existing housing stock to keep housing supply in line with changing demands. Within the current economic climate, the pressure on the existing housing stock to accommodate changing needs, has even further increased, due to the decline in new housing construction in Europe in recent years. According to Mulder (2010) housing construction in Europe, excluding Spain and Ireland, decreased by 10% in

2008, 15% in 2009 and 4% in 2010 compared to the previous year. Housing refurbishment is often a more complicated task than new construction, certainly in cases in which refurbishment encompasses substantial functional and technical improvements to improve the economic and environmental sustainability of the dwellings. Compared to new construction, it is often less easy to develop a more or less continuous production flow, because each dwelling has its own specific challenges. Moreover, refurbishment has to take into account the current tenants, which may create additional socio-economic problems, but also opportunities by knowing the preferences of end-users. At the same time, this complexity may increase the need for supply chain partnerships, in which knowledge of clients, contractors, sub-contractors and supply industry is used efficiently in an early stage of the redesign process. Therefore, combined with the increasing market share for housing refurbishment, there is a (potentially) large opportunity to increase supply chain partnership in housing refurbishment as well.

The market for housing refurbishment is highly fragmented. The existing stock encompasses a wide variety of dwellings and tenures. This paper is focused on the social rented stock, employing recent, innovative practices that are applied by Dutch housing associations and their contractors. There are several reasons why this sector is of particular interest. In contrast to private (owner-occupied) housing, the social rented stock is generally operated by professional management (although to different extents), which enables the development of professional partnerships. Furthermore, throughout Europe, a substantial share of the social housing stock has been built in the (early) post-war period. This part of the housing stock is often encountering a range of physical as well as socio-economic problems and has increasingly been considered to be out-of-date, which increases the need for refurbishment. Moreover, a large part of this stock consists of (large) housing estates that have been constructed in a highly repetitive manner, which potentially enables the introduction of a ‘reconstruction flow’, project learning and strategic supply chain partnering.

In the Netherlands there may be relatively large opportunities for increasing supply chain partnerships in the social rented sector. The Dutch social rented sector stands out internationally due to its large share in the housing stock; in 2009 2.3 mln dwellings out of a total stock of 7.2 mln, approximately 32%, (www.cfv.nl). This stock is operated by housing associations, which are private organizations that have the public task of providing housing to households who have difficulties to obtain a dwelling on the housing market on their own. On average, a housing association owned 5,800 dwellings in 2009 (www.cfv.nl) which are operated by a professional management. In the Netherlands, there has been an increasing interest in supply chain partnership in the construction sector in general and in the social rented sector as well. A survey by EIB (2007) indicated that the clients’ preferences have shifted towards building processes that are based on increased partnership. Furthermore, several Dutch housing associations have begun to experiment with supply chain partnership in new construction, maintenance and refurbishment (e.g. Straub, 2007 and 2009; Van der Brug (ed.), 2009; Vernieuwing Bouw, 2010).

Linking the reducing opportunities for demolition and replacement strategies with continuing challenges to improve the socio-economic and environmental sustainability of the housing stock, it can be expected that housing associations will place more emphasis on management and refurbishment. The financial pressure also stimulates housing associations to increase the efficiency of their organization and building processes, which in turn stimulates their interest in the opportunities that supply chain partnership generates for cost reduction. In addition, many housing associations encounter a shortage in professional skills among their staff

(FLOW, 2007), which is likely to increase in the future due the ageing and retirement of experienced staff with technical skills, thus increasing the need for more efficient sharing of knowledge and staff with their contractors.

This paper aims to contribute to filling the apparent gap in research on supply chain partnerships in housing refurbishment. Specific opportunities of increasing supply chain partnerships in housing refurbishment are discussed as well as various shapes of supply chain integration that are applied by Dutch housing associations, employing literature on the (housing) construction sector. Data was used from 9 housing associations and their partner-contractors that are experimenting with supply chain partnering in housing refurbishment within a knowledge exchange project initiated by the authors.

Section two discusses the dimensions that can be used to typify the approach towards supply chain partnerships. Section three gives an overview of the potential advantages and challenges that have been subscribed to supply chain management in literature. Section four discusses the approaches and expectations of the housing associations and contractors involved in our exchange project. Section five sums up the conclusions.

DIMENSIONS OF SUPPLY CHAIN PARTNERSHIPS

Numerous definitions of supply chain partnerships and related concepts can be found in literature. Table 1 contains a selection of these definitions which can be used to identify key characteristics of supply chain partnership.

Almost all definitions emphasize supply chain partnership is based on transparency, trust and mutual interests. This approach is usually stated as being opposing to traditional procurement approaches, which are characterized by hierarchical relations between functional and organizational divided units within the production chain. Some definitions also emphasize the importance of long-term relationships that enable continuous improvement in the supply chain. This implicates that the partnership should exceed individual building projects. Risk and profit sharing has also been mentioned as an essential component and could be a key characteristic to create the equality and common interests that may be necessary for successful partnerships in the construction industry as well. Another feature of supply chain partnership is that it involves the whole production chain and not just the client and the principal contractor, ideally involving the end-users and supply industry as well. Perhaps more specific for the construction industry, supply chain partnering implicates that contractors and other parties are involved in a much earlier stage in the building process. Within traditional procurement approaches, the contractor is involved after the design has been fully completed. In a building team, the contractor is involved in the elaboration of the design as well, but within (full) supply chain partnership contractors will be involved from an early stage in the design process and will continue to be involvement in the management of the buildings.

In construction practice, supply chain partnership occurs to varying extents. From the characteristics of supply chain partnerships dimensions according to which the extent of supply chain management can be derived. These dimensions are summarized in Table 2.

Table 1: *Some definitions of supply chain partnerships and related concepts*

Source	Definition
Kim e.a., 2010, p. 188	A supply chain partnership is a strategic alliance to achieve business advantage and exclusive goals by paying attention to critical success factors such as organizational commitment, co-ordination, leadership, trust, communication, conflict resolution, techniques and resources.
CIIPTF (1991) and NEDC (1991) in Hong-Minh e.a. 2001, p. 50. Cox en Townsend, 1998 in Khalfan en McDermott, 2006, p. 145	Partnering is a long term commitment between two or more organizations for the purpose of achieving specific business objectives by maximizing the effectiveness of each participant's resources (…).The relationship is based on trust, dedication to common goals and an understanding of each other's individual expectations and values. Expected benefits include improved efficiency and cost effectiveness, increased opportunity for innovation and the continuous improvement of quality products and service.
Ellram en Krause in Minh e.a. 2001, p.50	Supply partnering is an ongoing relationship between firms which involves a commitment over an extended time period, and a mutual sharing of information and the risks and rewards of the relationship.
Lambert e.a., 2004 in Kim e.a., 2010, p. 188	A supply chain partnership is a tailored business relationship based on mutual trust, openness, shared risk, and rewards to create business performance.
Coopers en Ellram, 1993 in Vrijhoeff en Koskela, 2000, p. 170	Supply chain management views the entire supply chain, rather than just the next part or level, and aims to increase transparency and alignment of the supply chain's co-ordination and configuration, regardless of functional or corporate boundaries.
National Agency for Enterprise and Construction, 2004 (Denmark)	Partnering is a type of collaboration in a construction project based on dialogue, trust, openness an with early participation from all actors. The project is carried out under a mutual agreement expressed by mutual activities and based on mutual economic interests.

Table 2: *Dimensions of the extent of supply chain partnerships in building processes*

Dimension	Full supply chain partnership according to this dimension occurs when:
Building life cycle	Partners are involved from initiative till management phase.
Production chain	All parties in the production chain are involved, including subcontractors, suppliers and end-users.
Continuity	Partners are involved in a series of projects.
Risk and profit sharing	Risks and profits are divided between the partners in a balanced and transparent manner.

In addition to the dimensions to assess the extent of supply chain partnership, different approaches can also be found towards the (initial) selection of partners by the clients. In Dutch housing associations' practice (European legislation for public tendering is not mandatory for Dutch housing associations) three different approaches can be found (e.g. Straub and Van Mossel, 2007; Vernieuwing Bouw, 2010). A first approach is that partners are selected on the basis of past experiences. Some housing associations that have begun to experiment with supply chain partnership have selected contractors with whom they already had a satisfying relationship. The level of partnership is increased by having the partners involved in a much earlier stage in the design process and giving them much more responsibility in working out of the design and building plans on the basis of budget restrictions and general performance criteria set by the housing association. Sometimes framework agreements are set up between the housing association and the contractors for continuity in the relationship. In a second approach, partners are selected on the basis of their competences for partnership rather than on the basis of a bid for realizing a concrete design,

after which the housing association forms a design and construct team with the selected contractor(s). In a third approach, a housing association invites consortia of contractors and subcontractors to bid for a building project with a concrete plan on the basis of only some general performance criteria and budget restrictions. The best plan and therefore partner consortium is then selected in a transparent setting after which the selected consortium can further develop and build their plan.

OPPORTUNITIES AND CHALLENGES OF SUPPLY CHAIN PARTNERSHIP

Several (potential) advantages are attributed to supply chain partnership. Hong-Minh et al. (2001, p. 51) summarize the "principal benefits that can be achieved by entering into a partnership…as; on-time delivery (hand-over), on-budget completion, value for money, end-consumer satisfaction, improved quality, improved working relations (team-work spirit) and reduced conflicts (Lamming, 1993; Cooper et al., 1996)". Many of these advantages have also been recognized in practice, as can be derived for example from a survey by Akintoye et al. (2000) in which contractors from the UK state similar reasons for entering into partnerships (see Table 3).

Perhaps the most frequently stated advantage of supply chain partnership within the construction industry is that it can reduce waste. According to a survey conducted by USP Marketing Consultancy (2008) costs as a result of waste in the Dutch construction sector have been estimated to be over 11% of the total turnover, with one of the most frequently mentioned reasons being a lack of cooperation with regular partners in the construction supply chain. But supply chain integration could lead to additional cost savings as well, due to a reduction of the costs of the procurement process itself as well as the avoidance of overlap in the work of the supply chain partners. Straub (2009) concluded an average cost reduction of 20% due to performance-based contracting in housing maintenance compared with traditional contracting. Vrijhoef (2009) states that supply chain management in a new housing construction project, conducted in partnership between housing association Com.wonen and contractor Dura Vermeer, has led to a cost reduction of 8%. Similar effects have been found in studies from the UK (e.g. Hong-Minh, 2001; Khalfan and McDermott, 2006). In addition to cost savings and the other factors already mentioned above, supply chain partnership has been stated to contribute to innovation (e.g. Spekman et al., 2002; Soosay et al., 2008, Khalfan and McDermott, 2006). This could be of particular relevance for developing and implementing the necessary innovations for improving the sustainability of the housing stock.

Next to the advantages, (successful) supply chain partnership also generates challenges for the organizations involved. In this respect, the results of a study by Briscoe et al. (2001) among smaller and middle-sized contractors are of specific interest for the refurbishment market in which such parties are often a logical partner for the housing associations (see Table 4). Briscoe et al. mention as important skills to be developed: ICT skills, communication, marketing, client-oriented behavior, being able to deal with academics, architects and clients, as well as leadership skills aimed at cooperation and innovation. Many studies emphasize the importance of soft skills, such as trust, leadership and commitment (e.g. Kim et al., 2010; Table 5).

Table 3: *Principal objectives in developing construction supply chain collaboration*

Principal objectives	Overall
Benefits to the client	4.53
Improved customer service	4.50
Reducing bureaucracy/ paperwor	4.50
Increased profitability	4.48
Cost reductions within organisation	4.38
Increased market competitiveness	4.35
Benefits to the supplier	4.03
Improved quality assurance	3.93
Overall supply chain reduction	3.70

Approaches and expectations in Dutch housing associations' refurbishment

As stated in the introduction, pairs of housing associations and their (principal) contractors that have begun to work on the basis of supply chain partnership in refurbishment are participating in a two year project, initiated by the authors, to exchange knowledge and experience. Five housing associations are really partnering, another 4 have shown interest in the project and started participating although they did not have a partner at the moment of writing. They are to find a partner during the first months of 2011 in order to continue participation. The project has started in January 2011. The participating organizations were selected on the basis of their willingness to participate and co-finance the project. They were required to bring in a concrete refurbishment project in which they have begun to, or will begin to within a short period, to develop, employing principles of supply chain management. At the start of the project, the organizations have been asked to typify their partnership on the basis of the dimensions and approach towards partner selection as have been described in section 3. Furthermore, they were asked to state their expectations about the opportunities and challenges that supply chain partnership will generate for them within the selected project. The results of these inquiries have been discussed in a workshop with the involved parties in order to validate and complement the outcome. In this section we will summarize the findings of the first stage of this project.

Approaches according to the dimensions of partnership

In order to classify the approaches of the participants, each couple was asked to fill in an inquiry where they could express their used approach, if already decided. If they did not decide yet, they were asked to state their preference. Five inquiries were returned before the completion of this paper. In a plenary session the results were discussed and a common conclusion was derived as well as its advantages and disadvantages.

Building life cycle

The following 6 phases were distinguished:

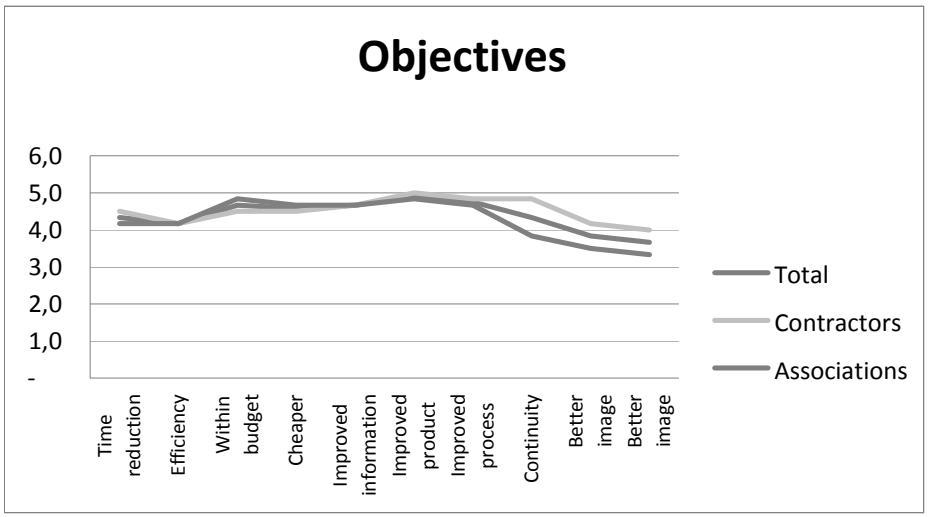
1. Initiative and feasibility study
2. Project definition
3. Design phase
4. Execution
5. Evaluation and transfer to maintenance department
6. Maintenance phase

Three of the couples have started their partnership in phase 1 of the project, whereas one couple started in phase 2 and the last couple started during phase 4. In the plenary session the general opinion was that the best moment to start was during the first phase, however right after the first initiative, as the initiative is a matter of corporate strategy of the housing association. The main benefit of an early involvement was stated to be the optimal use of knowledge, to improve the process and outcome of the design and execution phase. The main disadvantage of early involvement was stated to be the lack of competition and possible resulting uncertainties about the market conformity of the price level.

Production Chain

The number and nature of partners involved in the production chain are quite different. In all cases the involved parties are at least the housing association together with the general contractor. Two respondents stated to involve parties such as sub contractors for electrical equipment and HVAC-systems, consultants for building physics or construction and local authorities as supply chain partners as well. The other three have one or two other parties

involved as supply chain partner. In the plenary session it was concluded that the potential advantages of supply chain partnering would benefit from involvement of partners as soon as it is clear that their expertise is necessary. This implies that particularly in more complex refurbishment projects, a wider range of parties should be included in the partnership in an early stage of the redevelopment, of course also depending on the available expertise within the housing association and general contractor.



Continuity
Four of the five couples had selected their partner with the intention to maintain the partnership for a long term, although no specific agreements had been made about future projects. The benefits of a longer term relationship were confirmed in the plenary session. Benefits of a long term relationship were stated to be among others: more efficiency (‘learning opportunities resulting in a lower price and faster process) and working satisfaction, as people grow used to working together as a team, with common objectives.

Risk and benefit sharing
At this stage in the exchange project, the partners have not made agreements on risk and benefit sharing yet. During the plenary session it became clear that the most important condition for effective risk sharing is to create as much as transparency as possible. When all parties express their possible risks, a comprehensive risk management can be set up and agreements can be made on how to deal with each risk. However, some associations also stressed that the risks of the actual building process should remain with the contractor, since otherwise, the housing association would take on risks outside its core business and contractors might have less incentive to remain within the budget.

At the plenary session it was concluded that all cases involved in the exchange project have explicit elements of increased supply chain partnering, but it was also acknowledged that these were just the first step of growing towards mature partnerships, which require much more explicit and further reaching choices about the involvement of more parties in an early stage of the redevelopment project, the responsibility for maintenance after the refurbishment, the application of ‘framework’ agreements that involve partnership over a number of projects and much more explicit agreements on sharing and division of benefits and risks.

Expected advantages
From the 16 inquiries, 12 were returned in time for inclusion in this paper (75%), equally divided between general contractors (6) and housing associations (6). During the plenary project session the results have been discussed and complemented. The evaluation scale rated from 1 (very unimportant) till 5 (very important). Figure 1 depicts the average results for the importance of the objectives of supply chain partnering in the housing refurbishment projects. As can be seen, most of the objectives are ranked as important or very important bv both housing associations and contractors. Of relatively less importance for housing associations are the possibly positive effects on the company’s image as well as the continuity of the company and the workflow, which is not remarkable, since these factors are mainly of importance for the contractors, because these factors help them to maintain or improve their market position.

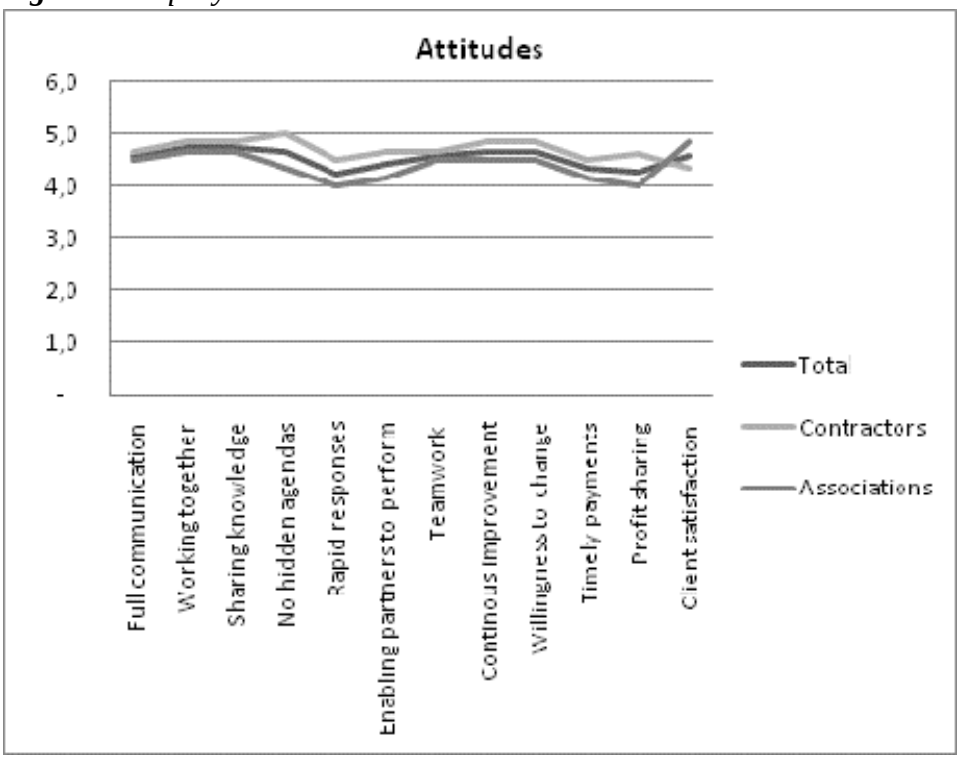


Figure 1: *Inquiry results on objectives*

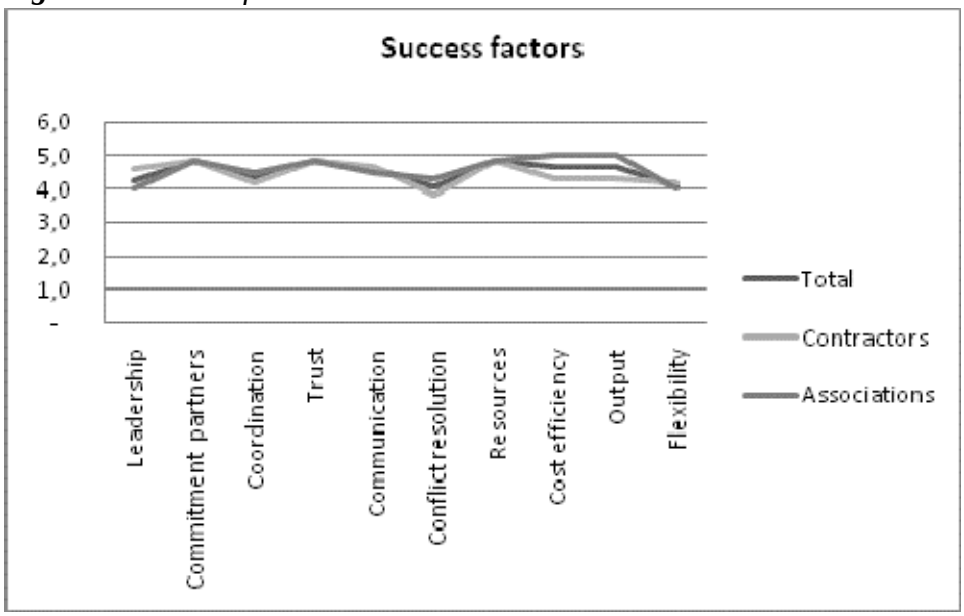
Expected challenges

The participants were also asked to address their expectations about the challenges for successful supply chain integration. These challenges were divided into attitudes of the partners and (other) success factors.

Figure 2: *Inquiry results on Attitudes*



The participants were asked to express their sense of importance of the attitudes as found of major interest for successful partnering by Briscoe et al. (2001), shown in table 4 in the previous section. In general Briscoe's attitudes are considered of high importance, as the average results are rated between 4 (important) and 5 (very important) (see Figure 2). Although the small number of inquiries makes it impossible to make any statistically sound comparison, some of the topics to which the housing associations and contractors responded

differently were discussed in the plenary session to test if there was any significance to the differences and if so, what the background of these differences were. 'Straight talking with no hidden agendas' was evaluated of relatively high importance by the general contractors. At the plenary session the contractors stated that this could be because they sometimes feel accused of working with hidden agendas by their principals, while this is not the case. 'Rapid responses to queries and requests for help' scored relatively low among the housing associations while one could expect that associations find this topic more important than contractors, because any delay is in the associations' disadvantage. The workshop participants stated that, when working as partners, the roles and responsibilities are more clear and the contractor can take more decisions, without referring to the responsible person(s) in the housing association first and thus they expected it to be less of a challenge within supply chain partnerships.

The success factors of partnering according to literature were also evaluated by the participants of our project. Again, they were asked to rate the factors on a scale from 1 (very unimportant) to 5 (very important) (see Figure 3). The average scores are between 4,0 and 5,0, which confirms the expected importance of the success factors derived from previous studies for the Dutch housing associations' refurbishment practice as well. The topic 'Conflict resolution techniques' is scored relatively low by both contractors and associations, which may be found remarkable in an environment known for its conflicts. According to the participants, the explanation for this low score is that working as partners results in clearer and/or shared responsibilities and a focus on common interest. Thus, they expect that conflicts will be reduced or even avoided as a result of supply chain partnering.

Figure 3: *Success factors*

This emphasis on 'soft skills' needed for successful partnering as stressed in previous studies was confirmed in the exchange project as we asked the participants to give their 'top 3' challenges for the project. Among the top 3 of challenges, 2 topics relate to the necessary soft skills and attitudes:

1. How to change competences and mentality and how to create sense of common responsibility?
2. How to create trust among partners?

3. How to share risks and profits among all partners and which (legal) contracting options are appropriate to formalize the partnerships?

Overall it was concluded that many of the expected advantages and challenges of supply chain partnership within housing refurbishment concur with the generally expectations about supply chain management in construction. At the plenary session, the most specific challenge for the application of supply chain partnership within housing refurbishment was stated to be the communication with the tenants. Since tenants are a natural part of refurbishment projects, choices have to be made about who communicates with the tenants, which may also differ from phase to phase in the redevelopment process. Some housing associations stated that supply chain partnering generates specific opportunities for communication with the tenants, since the contractors are sometimes taken more seriously by the tenants if they say that some refurbishment options are not feasible, while the tenants may sometimes suspect the housing association of having a hidden agenda. Other housing associations stated that there could also be a pitfall in involving the contractor in communication with the tenants, since the contractor might promise some things which may eventually be outside the association's budget restrictions. Furthermore, and perhaps specifically for the social rented sector, it was questioned if and how the tenants should be involved as a 'full' partner in the refurbishment process. Although, perhaps ideally, mature supply chain partnership would imply that the tenants as end-users are involved as partners throughout the process, this might not be preferable in the social rented sector since tenants usually pay a rent under the market price and therefore do nut fully bear the financial consequences of the decisions made in the redevelopment process. Furthermore, may tenants do not aspire an active role in building processes.

CONCLUSION

Linking the reducing opportunities for demolition and replacement strategies with continuing challenges to improve the socio-economic and environmental sustainability of the housing stock, it can be expected that housing associations will place more emphasis on management and refurbishment. Financial pressure also stimulates housing associations to increase the efficiency of their organization and building processes, which in turn stimulates their interest in the opportunities that supply chain partnership generates for cost reduction and other potential advantages. In this paper we have explored what the approaches and expectations of Dutch housing associations and contractors in refurbishment projects are on the basis of an inquiry among participants in a knowledge exchange project. It is concluded that all cases involved in the exchange project have explicit elements of increased supply chain partnering, but it was also acknowledged that these are just first steps towards mature partnerships, which require much more explicit and further reaching choices about the involvement of more parties in an early stage of the redevelopment project, the responsibility for maintenance after the refurbishment, the application of 'framework' agreements that involve partnership over a number of projects and much more explicit agreements on sharing and division of benefits and risks. It is also concluded that many of the expected advantages and challenges of supply chain partnership within housing refurbishment concur with the generally expectations about supply chain management in construction. The most specific challenge for the application of supply chain partnership within housing refurbishment relates to the communication with the tenants: if, how, when and by whom tenants should be involved in the redevelopment process is a specific question that requires much attention in supply chain partnerships for housing refurbishment.

Abstract
New buildings are designed for first users. For a sustainable approach there are many advantages in designing in flexibility and adjustability in order to enable and facilitate the other sequential users. For the first investor this flexibility is translated into improved exit values due to increased potential. The second investor is acquiring a building with multi-functional opportunities.
The politically stimulated combination of schools with day care is generating several new design commissions in the Netherlands lately. These projects are characterised by a high level of user related features. At the same time these kinds of buildings are confronted with an additional need for flexibility due to (demographic) developments in the neighbourhood. There are some good examples of such projects, but there is a distinguished need for additional workable solutions. One of the design projects of the faculty of Architecture started a research by design project to establish an architectural approach for the combination of elementary schools with after-school child care in different scenarios: transformation of an existing building in a shrinking village, as a replacement in a urban setting and as a new addition to an existing school in an area with growing potential. The combination of scenarios strongly suggests a focus on flexibility during the building's life time. The growing area will create a peak demand, so even if it does not become a shrinking city after a while, the combined school will still have a fluctuating capacity need. However in this research by design course, accomplished by architectural students, it can be observed that not the life time flexibility, but the daily flexibility, needed by the combination, takes all the creativity. It is already almost too complex to create multifunctional spaces to be used for learning zones in day time and play area and child care zones afterwards. Compared to other types of projects, the first user approach related to architectural design is in this function mix getting even more attention with the specific requirements, up to the level of dedicated furniture.
The solutions provided by practice for the life time flexibility are in many cases related to an even more complex function mix. If a new neighbourhood first can be characterised by a peak in delivery, followed by baby care, elementary school and child care, higher education and taking care of the elderly people afterwards, the relation with different care functions becomes more obvious and time related. The synergy between those functions can be very promising in the right combination. Such a view on the neighbourhood suggests social centres developing and changing over time together with their servicing area. The context will lead to certain investors willing to fulfil their social and sustainable ambitions.
The research by design itself will have a satisfactory result for the institutions dealing with the implementation of after-school child care if the proper selection of design suggestions is

produced. These institutions will represent the first users. The scientific and social significance will be in the developments clearing the conflict by giving an answer to both the daily as well as the life time flexibility.

Keywords Flexibility, elementary schools, after-school child care, mixed function, multifunctional accommodations

INTRODUCTION

The building sector shows rather specific settings of partners around specific types of projects. This paper will discuss the agenda of flexibility for future demands along the developments of elementary schools in combination with after-school child care and additional communal functions. In order to be able to break through the tradition of these typical setting a more abstract view is required. Solutions rising from this view are suspect by default, since the abstraction itself, the alterations and possible extension of the scope, in this case to the communal functions are not proven. The proof of the pudding is in the eating? At least for sure there is the need for change. (1) There is a need for improved daily flexibility in the way limited space is used by different functions. (2) There is a need over time in the way (public) buildings are used with changing quantitative requirements to the functions. Probably the same for commercial buildings but in such a setting the drivers are more clearly. (3) An additional need over time in changing of qualitative requirements. The community will have other demands in future for the public buildings based on demographic changes but also due to a different (and at this point in time unknown) vision.
However, first a sketch of the actual situation must be drawn.

AUSTERELY BUT EFFICIENT

For those not of Dutch origin it is important to understand the Calvinist background of Dutch society, leading to a rather strict and ascetic political demarcation (“sober maar doelmatig”) of the way we deal with our elementary schools. The expression “austerely but efficient” has a boarding-house smell. The current situation is very well described by Jeroen in ’t Veld, Yasmine Hamdan and Emile Barendregt (2010). They have started their analysis from three aspects: the quality of the current buildings for schools, the quality of the process of establishing new schools and the quality of the organizing context (jurisdiction and legislation, financing and budgets and policy) the following conclusions are drawn up.
A key problem in the provision of buildings for primary education as well as the after-school child care is the lack of information. This is not only a huge hurdle while researching the subject, but most of all for a proper development process. Even very basic figures like numbers of buildings and their age are missing.

Based upon the information which is available most buildings do meet the basic requirements. However these requirements are shaped as utterly minimum. For e.g. inner climate, cleaning and maintenance even these very basic requirements are not always met. The requirements as a set do not lead to buildings meeting the expectation of the people of the sector.
The processes for establishing the buildings are inefficient and not productive. The omission of the obvious party taking the lead, especially where multifunctional accommodations are concerned, is disruptive.

The actual legislation and financial system is outdated and designed for a situation with only educational buildings. Act on primary education (WPO) declares the responsibility of the municipality towards realization and building maintenance on a global level. The actual detailed instructions are given in the model by-laws of the Association of Netherlands Municipalities (VNG). Municipalities are not obliged to use the by-law but usually do treat them as law. All the directives to m^2 and budget become rules. Separately there is a Act on Child-Care with additional directives of the Ministry of Social Affairs. Rules for buildings are laid down in the Building Decree with reference to standards. The municipality is responsible for permits of use, all of course fit to the Act on Spatial Planning.

Although the political ambitions may be clear, and again changing with new rounds of elections, the legal and organizational system below is very layered and diverged. It takes more to work out completely the consequences of policy adjustments then to take new directives. The result is a rather unstable complexity in which participants hardly dare to move. The financial component is even more interwoven. On top of the pyramid both the Ministries of the Interior and Education, Culture and Science) are providing funds for realization and maintenance of buildings for primary education and after-school child care. The first cash flow goes through the Fund of the Municipality towards this municipality and the second by lump sum financing to the school. At that point a 'dialogue' is foreseen between the school and municipality if there is a need for an addition to the school stock. The traditional way is along the act on primary education in which the municipality is responsible and using the by-law for the appropriate instructions. The municipality builds. However there is an alternative by which the school can get a yearly amount for realisation and maintenance of the building. The municipality will keep its ultimate responsibility for the provision of education and care.

Probably this diversion of financing is done for historically well thought arguments, but the result is a focus on investment costs for the municipality and cleaning costs and other maintenance for the schools. The value of the investment is hardly steered by the process while all insights on the need to steer on life cycle costs in order to work on more sustainable solutions is basically neglected due to the way the process is set up.

Even more alarming is the fact that during the years a clear demand can be established, the administration and bureaucracy takes a very long time, in which a whole range of temporarily measurements has to be taken, rather often resulting in a situation in which temporarily buildings become definitive solutions, due to the fact the system cannot provide the right terms the system need to move from a temporarily status to a definitive status. Where the important values of these school buildings are missed, municipalities do react heavily on vacancies; schools have to cooperate on sharing (building) resources, logically argued on 'societal costs'. Also in the presented alternative (Veld, Hamdan et al. 2010) this obsolescence is used as an argument for new approaches into the direction of the combination of primary education and after-school child care.

The budget for both primary education and after-school child care is above all a political choice. Therefore it is worrying that although in the different political programs the essential benefits of collaboration between primary education and after-school child care are widely spelled, the whole idea is presented too as a way of economising within the system itself. The loss of the current system is quantified to € 55.000,- per school on simplifying the preparation process, € 16.500,- per school per annum on additional occupation (and removing redundancy and obsolescence) and € 4.000,- per school per annum on life cycle optimisation.

These numbers can be related to 150 new projects and 100 renovations on a yearly base for the preparation costs and about 7.500 schools for the per annum figures.

As acknowledged by In het Veld (2010) it is in this perspective very positive that even with the given bureaucracy the involved people and parties, including the municipalities, are succeeding in the establishment of reasonable buildings after all. The response of the bureaucracy, the Association of Netherlands Municipalities (www.vng.nl) is rather conservative with the proposition a change of system in order to prevent bureaucracy will create additional bureaucracy.

STUDENT RESEARCH

Figure 1: *The Hague (above), Biggekerke (below left) and Amsterdam (below right)*

The first case is a new development in The Hague on a VINEX-location (Leidschenveen). A VINEX-location is an area designated in the Supplement to the Fourth National Policy Document on Spatial Planning as large-scale housing development area, and therefore an example of monoculture development. The second case is almost the opposite, a redevelopment in a small village in the more rural parts of the Netherlands which areas are confronted with shrinkage. Although the demand on pupil places is getting smaller, the integration with after-school child care requires adjustment of the building. The third case is a new development in a brown field area in a larger city. Due to its size there is a large variation in population.

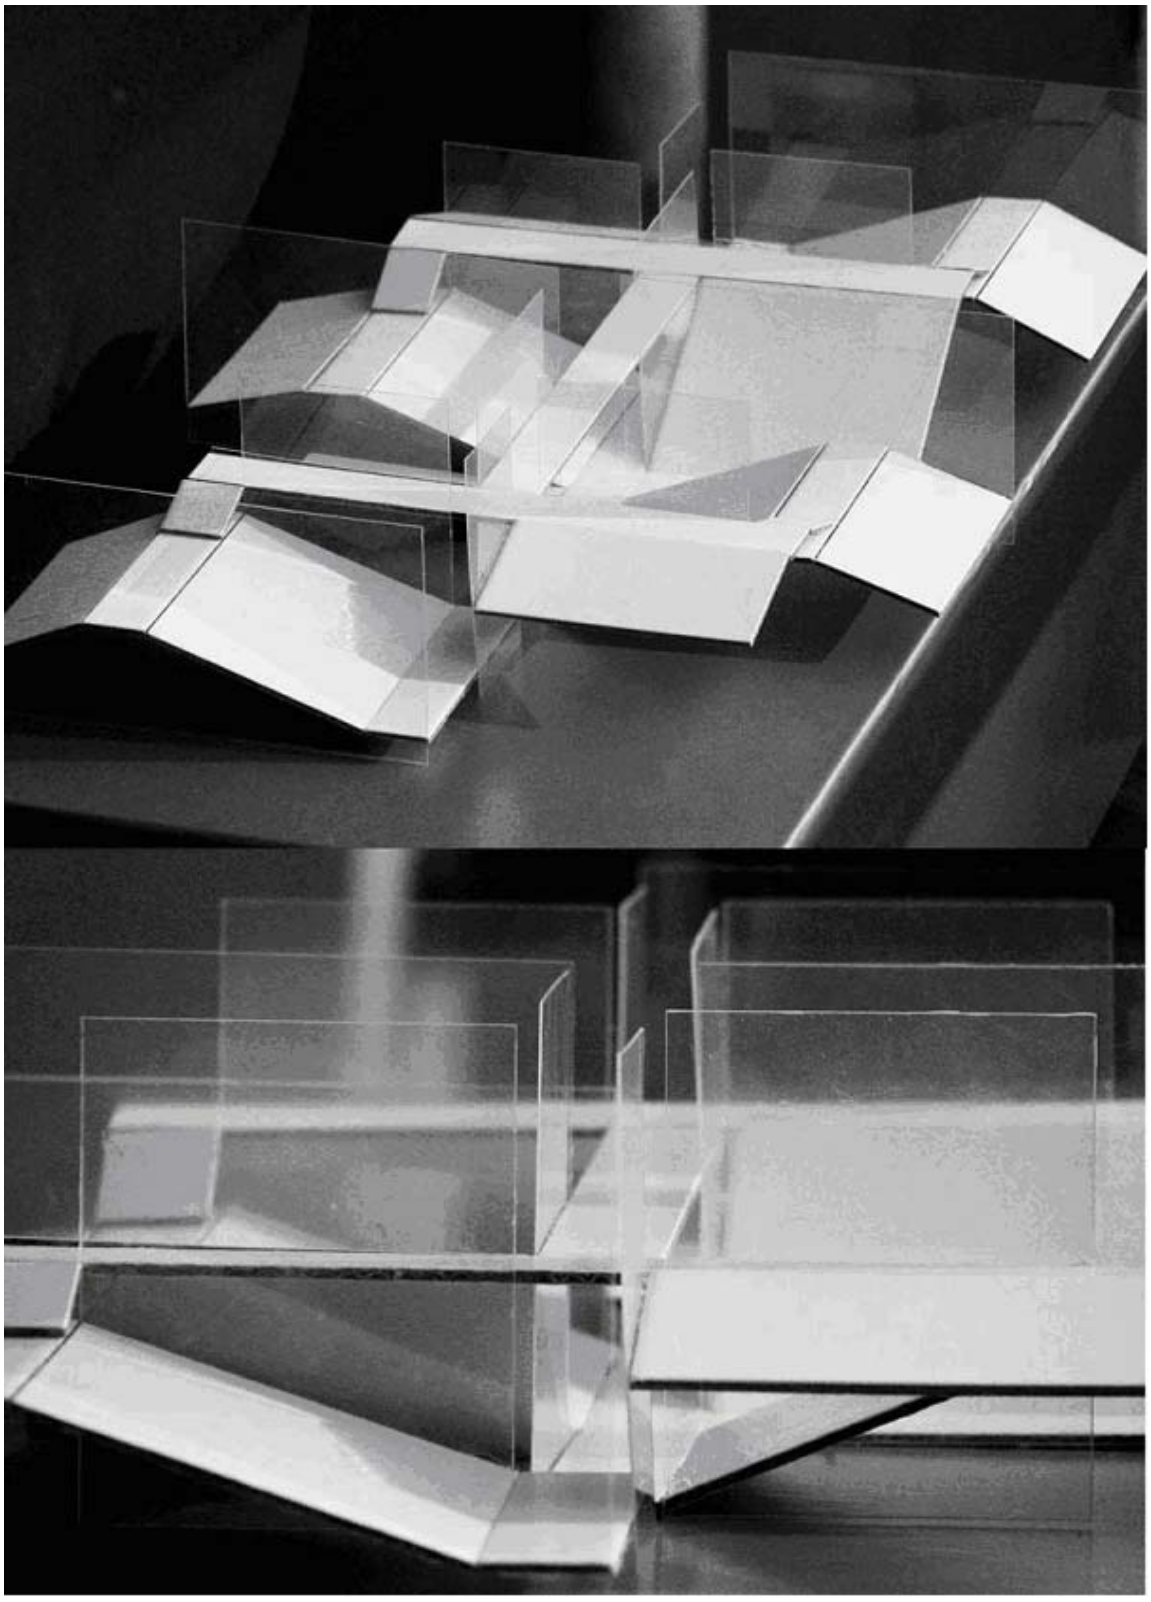

Figure 2: *Transport between rooms is always done through another room since all the horizontal transport area is skipped. Bram van Hemmen Group 1 – Growth and transformation.*

Figure 3: *Considering the use of the building during the day. Jeannette Bisseling Group 2 – New town and transformation.*

Figure 4: *Central hall as meeting place Bob van Rooijen Group 3 – Shrinking city and transformation*

When grouped together like this, it becomes clear the neighbourhood development starting as a VINEX will end someday as a shrinking village. The relation with urban dimensions can give some relieve, depending on the regional impact of such facilities. The answer to these kind of adjustments over time is hardly researched by this research approach. As can be drawn of the examples below, in case of architectural research by design, the complexity of the daily flexibility takes already all the focus of the researcher – designer - student.

The PO-council, a sector organisation concerned with financing, employment and policy for elementary education asked for new ideas from an architectural perspective. The basic

question for the research by design assignment was to give solutions for the combination of elementary schools and after-school child care in case of shrinking cities, new towns and reuse in inner cities.

The student research fulfilled its primary goal. The students did have a steep learning curve on the complexity and possible architectural solutions. However the way this research by design is shaped, students are only confronted with the first flexibility requirement: to find solutions for the optimal use of space during the day by giving room to the primary school with their class rooms in which learning is the issue and the after-school care with places for playing, food and resting in which caring is the matter.

In this research approach the outcome is not to find solutions for primary schools in combination after-school child care in a new town, transformed after some time and again two decades later when the town is shrinking again. So it is not about the need for flexibility over time due to changing quantitative requirements. It is also completely not about variations in qualitative requirements.

Figure 5: *Same project, after care playing options in zones between functions*

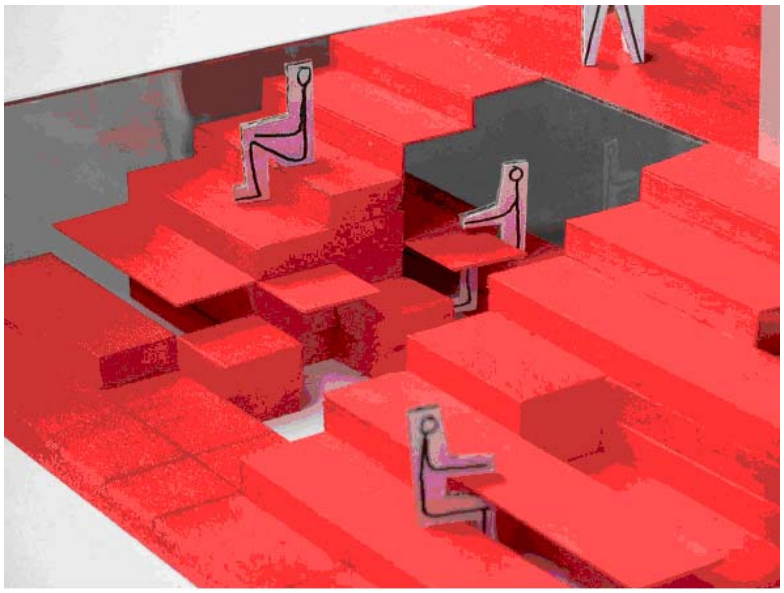

Figure 6: *Soft gradient zoning (from creative to playing), stairs as presentation platform Martijn Aling Group 4 – Growth and transformation.*

INSIDE OUT OR OUTSIDE IN

Both the discussion on the running operations and the research by design are illuminating that it is only very partial an architectural solution. As far as school buildings can contribute to the system, and the idea is of course the appropriate buildings do, the process of establishing these buildings can make the difference, both for the build result as for the process which has to take place in the building.

The solution is to be found in a demand driven system in which the user is holding the central focal point (Veld, Hamdan et al. 2010), a flexible model taking care of the utmost efficient investment of means. Without calling it by its name, the report gives a continuation of what is embraced in the current political climate as the agreeable free market processes. The same privatizing causes besides benefits also plenty disadvantages. Like similar discussions in health and public transport it is disputable if and until which extent such central elements in the society are save in the hands of the market, or depending on someone's stand, to be trusted to the authorities. At least it is clear such processes go in fits and starts.
Several conditions are elaborated, which are probably rather essential, like a guarantee fund in order to keep financing within limits. The necessary knowledge has to be mobilised in this field to keep control over the quality level, support of users and schools has to be developed and maintained, and sufficient consideration has to be given to implementation of such a system modification.
So the free market is not seen as an universal remedy in advance. Nevertheless a small excursion outside the discipline to the office market is needed. Offices are built for centuries, like schools. Take the prototype in Florence in 1580 as an example to see its history. Nowadays it is rather obvious offices are established by developers, whenever possible in close consultation with future tenants, after which the buildings becomes the property of an investor and is rented by the final users. But for the larger part of the previous period between 1580 and today it was rather standard for end users to be the owners. These owner-occupiers took the initiative and were responsible for repair and maintenance. It took a long time before

the insight was gained by these companies to acknowledge the specialism of the specialists, and to see the benefit of stalling risk by those who can deal with it.
Decisive response on market changes is more difficult for companies if they have to maintain accommodation in the ancient way. In the end accommodation is not the only thing you rent but also the service around it. For those reasons the majority opts for rent.
It may seem less logical to take offices as an example in the Netherlands, since there is a good deal of obsolescence, created by this free market (2011). It is to be expected most of this obsolescence will be seen again in societal costs. The public demand for measurements on a national level is increasing, since it is still an option for developers to add to the stock of vacant office buildings while earning a personal profit. This kind of arrangements are declined by the developers but more and more embraced by the investors. At the same time these investors are searching for new forms of real estate investments. Dwellings are becoming a more interesting market. Indeed the possible yields seems substantially lower, yet the risks are within limits too. An investor is looking for the appropriate balance between the return and the risk, where at the moment the risk is playing a slightly more important part. Along this renewed focus on dwellings also other categories become of interest for investors, of which societal real estate is the most promising. New companies and forms of participation are evolving, leading to new sustainable answers.

The previously observed obsolescence in the schools and the supposed benefits additional occupation are missing the awareness of office developers, knowing a certain minimal of vacancy needed for a working market (Remøy 2010). Just like the demand for office space is not changing in building volumes and some small change is needed for dealing on such a market, these types of additional occupation will not work on the single square meters. Aiming at a zero vacancy rate is not realistic.

The need for accommodation in elementary schools in combination with after-school child care can be solved by the market. Unlike complicated Public Private Partnership constructions, in which the authorities are basically coping with risk-avoiding behaviour while trying to keep full control, a more laid back approach of the municipalities seems needed to see what the developing parties are offering. The risk the market is not establishing the kind of building the schools are needing is in this perspective the risk of this market, and they will mature quickly enough to make what is wanted. At the same time the municipality can, as sketched by In ‘t Veld (2010), organise a guarantee fund in order to create the right balance between risk and return, in order to enable this market for investors and developers.
Today it takes years (12 year on average) after the acknowledgement of the need and initiative for a new school. Assuming the market can respond much quicker, the best gain is to be found in these first years, where the demand is best known and the ‘new’ school will fit the original requirements. This can be seen as the best years, which can make the difference between austerely development and quality development.

However the flexibility in the long term still suggest a wider scope on the elementary schools in combination with after-school child care. In order to cope with the demands over time additional functions seem to be the solution, especially in case of shrinking societies.

Analysis of the required space of four programs of demand of multifunctional accommodations did show that almost every combined use of area is related to similar functions and activities. This multifunctional use does not allow any change in use of rooms in order to fulfil different functional needs. As one can learn from the chapter ‘Student Research’ such frequent adjustment are not helping the process.

This observation is confirmed by initiators of multifunctional accommodations (e.g. municipalities), giving ‘tips and tricks’ for improved multifunctional accommodations (2010). “Main points with respect to flexibility, multi-purpose nature and standardisation, are essential to achieve long-lasting, durable and payable housing concepts. These main points stand however in many cases perpendicular on user expectations and wishes; for users a tailor-made approach and identity strengthening services and facilities are important”. This quote and the remaining `tips and tricks' indicates that initiators and users are more concerned with the performance at this instant, instead of future use. Even though motivations for multifunctional accommodations are (cost) efficiency and social appreciation.

With an experimental fictive model we like to show the advantage of considering a multifunctional approach (including a perspective beyond the first user). The experimental fictive model shows not an financial truth nor punctuality, but a thought. We do this by combining two social topics: Shrinking and including-education. Including-education as a second-user can use the without relative large adaptations (care-spaces and extra bathrooms) this second-user can fit in the vacancy of primary and secondary education, as an result of shrinking (notice: the conclusion of student work, page x and program of demands, page x).
The experimental fictive model contains data collected of four municipalities in shrinking area’s (schools and cost indicators) and cost-indicators from a including-education foundation.

This content creates a fictive real estate-file, which contains:
- Around 5.100 students in 2010;
- A reduction of 1.275 to 1.350 students in 2040;
- 23 Primary educations (circa 22.000 m²);
- 6 (secondary) special educations (circa 12.000 m²);
- 5 secondary educations (circa 12.000 m²);
- Estimated building operation cost: €58 per m²
- Estimated taxi-cost special education: €2.500 (cost indicator)
- Reconstruction each 40 years (instead of 60 years ordered by VNG)

Introducing (secondary) special education to primary and secondary education leads in the model to a reduction of 50% vacancy (€0,4 million building cost each year for municipality and school boards). Current ground attitude of special education with became unnecessary can be solved (€P.M). In contrast with primary and secondary education were selling half buildings and ground is much less attractive. An assumption is made that there is 10% less taxi-use can be realised for children in special education, because they can join education in their hometown. This leads to a reduction of €0,2 million taxi-cost each year for municipalities. When these numbers are capitalise, it is possible to purchase an credit around 10 to 14 million + P.M income of ground attitude (note: a part of this funds are needed to realise the integration of special education).

In comparison the scheduled investment cost in this real estate-file is circa 5 to 6 million. Although there are a lot of practical and ideological comments on this experimental fictive model. The comparison shows that financial and social advantage can be realised when the correct social themes are combined with the second of third user.

CONCLUSION

Reviewing the references will show a 100%-Dutch research on a 100%-Dutch case. The Dutch Calvinism is unique in the world, and so will be every idea coming out of it. However neighbouring countries have to deal with similar economic restrictions. Maybe for different reasons elementary schools are lacking the same quality. And above all economising is the main argument for after-school child care. At the same time it is clear this article is not dealing with big time shrinkage like e.g. Detroit is confronted with.

Although the student research did generate plenty ideas on how to combine elementary schools with after-school child care, it has to be acknowledged these ideas are not mature enough yet for being a response to the first flexibility. There is still a lot to improve on these designs where there is hardly a budget to do this professionally. Renewal of the way these kind of projects could be developed using new market mechanisms seems to be an answer to the second flexibility but very depending on the context in which still a lot of hurdles have to be taken. The third kind of flexibility discussed here, involving additional communal functions to create durable 'multifunctional community centres on care and education', resistant to obsolescence is with the increasing complexity far from being guaranteed. If the proof of the pudding is in the eating, it is advisable to start with a small portion. Still there are mountains to climb already to enable experiments into this direction, since many rules in school development are preventing experimental approaches. Probably the appropriate start for any renewal is to deal first with the 'austerely but efficient' directive. These schools are the place where our children do have to spend an important part of their youth, so 'ideally' should be the objective instead of 'ascetically'.

It is the observation of the average quality in office buildings feeding the believe in the free market to be able to create the schools we want and the schools we need. Given the right balance between risk and return, todays developers and investors are not only equipped for such developments, it also fits in their schemes of changing focus to other non-office markets. The suggestion by some of the market parties towards the development of multifunctional accommodations is both promising and still rather unsecure. Thinking on the sequential users of accommodations is new and like many aspects of sustainability, the proof of the pudding takes time, since such projects depend on a long term approach and the results are only to be seen after the first satisfied user has left the building.

Abstract
Over the past decade, the UK construction industry has sought to exploit the rewards of supply chain management practice. This paper explores construction industry capability to implement an extended construction supply chain culture. Where commercial solidarity prevails and integrated supply chains, including small and mediums sized enterprises (SME's) vie for construction projects and economic advantage.
Despite recent advancements in construction supply chain management many barriers continue to inhibit the realisation of fully extended construction supply chains. Economic, social and cultural conventions require to be investigated to appreciate the complexity associated with the strategic alignment of extended supply chain stakeholders' interests.
Drawing on a model of supply chain maturity, the practicalities of extended construction supply chain relationships, rewards and risks are reviewed. Given the current structure of the construction industry, it is proposed that the attainment of extended construction supply chain management practice will require key industry stakeholders to develop innovative collaborative policies that will be progressive, organisationally supportive and commercially attractive to SME's.

Keywords: Supply Chain Management, Maturity, Integration, Relationships, Construction Industry.

INTRODUCTION

Supply chain management is an emerging theme within construction management theory and practice (O'Brien et al., 2009). Advocates of supply chain management now suggest that enlightened organisations within the UK construction sector may seek to take advantage of improved supply chain solidarity. Envisaging a scenario where extended supply chains, rather than discrete companies, compete and tender for future building projects (Tan, 2001). However, considerable critical debate has been directed at the apparent hesitancy of the construction industry to capture the opportunities afforded by supply chain management principles (Akintoye et al., 2000, Dainty et al., 2001a). Proponents are quick to suggest construction has failed to keep pace with contemporary management of supply chain practice, learning and innovation (Bankvall et al., 2010, Lonngren et al., 2010, King and Pitt, 2009). Many reasons for the lack of progress have been expressed. The most common criticisms include fragmentation (Saad et al., 2002), SME scepticism (Briscoe and Dainty, 2005), temporary relationships, short-term projections (London and Kenley, 2001), opportunism, an

infrequent client-base and particularly pertinent in a difficult financial climate, economic uncertainty. All of which individually and collectively conspire to undermine the efficacy of construction supply chain management when contrasted with the highly controlled environments of the automotive and retail sectors (Cooper and Ellram, 1993). It is, however not unexpected that the utility of construction supply chain management is benchmarked against the successes charted in the institutional homelands of supply chain management. In common with most key performance indicators, assessment requires careful interpretation. For some scholars, industrial context is crucial (Green et al., 2005). Context creates a spatial awareness (Jepperson, 1991) that formulates and frames our understanding of the developing situation.

The supply chain maturity model proposed by Lockamy III and McCormack (2004) offers a generic performance criteria against which current practice and future aspirations of construction supply chain management may be evaluated and discussed. Five stages of supply chain maturity are depicted, ranging from stage 1: immature (ad-hoc) to stage 5: mature (extended). Its usefulness is not necessarily comparison with other sectors per se, but a contextually rooted appraisal of what may or may not be realistically 'achievable' within the strict confines of UK construction supply chain management practice.

It is in this area of supply chain maturity and extended supply chain management practice in particular that the paper wishes to make a positive contribution and stimulate constructive debate. The discussion is arranged as follows. The supply chain maturity model is introduced with consideration given to the positive attributes as well as some inherent limitations and assumptions. The following section outlines the importance of the construction industry to the economic and social well-being of the UK. This is supported in the subsequent section with an overview of contemporary supply chain management practice within a construction context. The discussion concentrates on apparent levels of construction supply chain maturity with particular reference to the notion of an extended supply chain as depicted in the supply chain maturity model. Three key themes are identified and debated; relationships, rewards and risks. Finally, the conclusion comments on the likelihood of extended construction supply chain management practice as defined by Lockamy III and McCormack (2004).

SUPPLY CHAIN MATURITY

According to Lockamy III and McCormack (2004), the extent of supply chain management development, integration and experience may be evaluated and expressed in terms of a numerical grading by applying their supply chain maturity model. The model defines five stages of supply chain maturity;

Stage 1 - Ad-hoc: An unstructured and ill-defined approach to supply chain management. If the term supply chain management is employed it is highly likely in response to management practice witnessed elsewhere and in this context represents mere tokenism.

Stage 2 - Defined: Whilst the implementation supply chain management has structure and key supply chain facilitators are in place, working practices remain largely unchallenged and resolutely traditional.

Stage 3 - Linked: Supply chain management takes on a strategic orientation, focusing on business objectives and customer satisfaction. Collaboration between supply chain stakeholders begins to cultivate an atmosphere of trust and 'budding' team spirit.

Stage 4 - Integrated: Supply chain management principles become embedded in the commercial process, over-riding traditional practices in favour of

greater inter-dependency and commercial solidarity. Corporate investment in supply chain management principles begin to benefit from increasing levels of efficiency and effectiveness.

Stage 5 - Extended: Supply chains compete against other supply chains. Asset specificity is likely to be high and commercial interests are inextricably extended to the success of the collective supply chain participants.

A maturity classification of supply chain adaptation and application draws specific attention to key characteristics associated with various incarnations of supply chain management in practice (Morledge et al., 2009). Explicit within Lockamy III and McCormacks' (2004) interpretation is that ever-greater displays of maturity will generate superior levels of commercial performance. For example, as companies gradually pass through predetermined 'staging-posts' on a supply chain maturity continuum, organisational experience, trust, confidence and predictability in supply chain stakeholder behaviour will evolve.

Whilst a continuum may be well suited to charting key developmental stages of supply chain maturity, the exploitation of the continuum concept exhibits a number of intrinsic limitations and assumptions. A continuum, defined as continuous array of barely discernable points located in succession between two bipolar extremes (Pearsall, 2002) often fails to adequately capture economic, social and cultural idiosyncrasies (Boisot and Child, 1996). Thus a continuum may be perceived as *"too quiescent and mechanical"* (Powell, 1990). This limitation is compounded by an underlying assumption of continuous improvement regardless of context. Yet as stated earlier, context is increasingly recognised by critics as a central tenet to the efficacy of construction industry adaptation of supply chain management principles. Construction industry context will constrain supply chain management ideology with a fit-for-purpose pragmatism. It is therefore not necessarily automatic or 'natural' that supply chain participants would wish to progress to the next stage, even if their experience, learning and supply chain know-how is ideologically sound.

Limitations aside, simple classification of supply chain maturity may be useful as a barometer of stakeholder commitment to supply chain management policy, structure and custom. For some industry commentators the key to successful construction supply chain management is appropriateness (Cox, 2004, Cox et al., 2004); appropriateness to the commercial exchange, appropriateness to the parties involved and appropriateness to the cultural context in which it is enacted. A 'horses-for-courses' contention augments a pluralist supply chain management interpretation of the supply chain maturity model. For example, contingent upon the situation encountered; stage 1: ad hoc supply chain maturity may be wholly appropriate, conversely; stage 3: linked supply chain maturity may be best suited to a contrasting set of circumstances. Either way the policies, systems and procedures can be evaluated against the five distinctive criteria disclosed by the supply chain maturity model.

CONSTRUCTION INDUSTRY BACKGROUND

The importance and complexity of the UK construction industry cannot be underestimated (Thompson et al., 1998, Cox and Ireland, 2002, Ireland, 2004). Both a vibrant and volatile sector, the construction industry is defined by the Department for Business Innovations and Skills (BIS) as an eclectic assortment of construction service and product providers (BIS, 2010a). The economic and organisational structure of the construction sector has some distinguishing features. Construction output, in terms of monetary value is dominated by relatively few very large construction companies. In stark contrast, construction output measured in terms of volume is carried out by a considerably larger number of small and medium (SME's) sized specialist and general contractors (Cox and Thompson, 1997, Morton,

2002). Over the past three years construction activity across all but a few sub-sectors has declined at an unprecedented rate. Down from £110 billion in 2007 to an estimated £95 billion for 2010, representing a 14% downturn in construction output (Experian, 2009b) While construction output had grown steadily in the period up to 2009, the rate of growth failed to match the corresponding increase in UK GDP, indicating that construction industry share of the UK economy as a whole had been contracting (Experian, 2010).

Post second world war, the construction industry has been the subject of numerous Government sponsored reports (Murray and Langford, 2003). To a greater or less extent the consensus of opinion is that the UK construction industry requires reformation in the way in which it conducts business (Latham, 1994, Egan, 1998, Strategic_Forum, 2002, BIS, 2010b). In the wake of the 'Egan Change Agenda' the latest Government review, 'Never Waste a Good Crisis' remains somewhat under whelmed by industry achievement. Whilst acknowledging limited progress, Wolstenholme (2009) pinpoints a lack of supplier integration in the supply chain as an ongoing barrier to continuous improvement in the construction delivery process (Wolstenholme, 2009). In a challenging economic environment, construction service and product providers are looking towards their pre-selected network of supply chain companies to deliver ever greater levels of efficiency (Knutt, 2010).

SUPPLY CHAIN MANAGEMENT IN CONSTRUCTION

With dedicated journal publications and professional recognition of supply chain practitioners, supply chain management has made a notable impact on contemporary management theory and practice. Central Government have endorsed supply chain management as a vehicle designed to deliver enhanced quality of construction services and products (Latham, 1994, Egan, 1998, Strategic_Forum, 2002). As a consequence, the term supply chain management is now commonplace within construction management jargon. Despite increasing popularity, a universally agreed definition of supply chain management remains shrouded in a fog of semantic ambiguity. The complexity of the debate is compounded by confusion over its suitability and utility to a construction sector that exhibits quite unique characteristics when directly compared with the manufacturing heritage of supply chain management theory and practice.

Some commentators refer to an abstract interpretation citing the need for an "integrative philosophy" (Cooper and Ellram, 1993). Other supply chain management experts adopt a more corporate perspective, using terms such as supply chain strategy and structure (Alder, 2009). The Council for Supply Chain Management Professionals (CSCMP), the pre-eminent institute for supply chain practitioners, offer a long drawn-out definition capturing a wide-range of management functions associated with the provision of service and product not only across organisational boundaries but also internally between organisational subsidiaries (CSCMP, 2009). The subsequent lack of universal exactness may be perceived as a both a hindrance and an opportunity. A hindrance with regard to potential misunderstandings with other management fashions of the day such as, partnering and lean manufacturing (Gruneberg and Hughes, 2004). On the contrary, the lack of terminological precision presents an opportunity to root a definition of construction supply chain management within the strict context in which it is being enacted.

To date, much of the practice in construction supply chain management has focused on two distinct supply chain configurations; project and organisational supply chains (King and Pitt, 2009). Both of which are short, bilateral arrangements. The project supply chain relationship is the dyadic relationship between the client and first tier main construction contractors. This configuration has a patently client centric focus and is typified by contemporary procurement

arrangements such as partnering and framework agreements. Driven by the construction client, a project coalition is established with a few pre-selected principal supply chain partners (PSCP) for a predetermined duration. Although there are few restrictions within the private sector, public sector clients must adhere to EU and UK procurement legislation. Typically four years with the option of a further two years (4 + 2) for framework agreements (OGC, 2008).

The organisational supply chain is a bilateral relationship between the main contractors and second tier service and product providers. Driven by the main contractor, the relationship has a distinct business orientation and usually manifests itself as a list of preferred sub-contractors and suppliers. The main contractor would audit prospective sub-contractors and suppliers and grade them against a business criteria sympathetic to their own corporate values, such as predictability, financial security, health and safety, sustainability and in light of the recent investigation by the OFT, ethics.

Drawing on Lockamy III and McCormack's (2004) supply chain maturity model to review construction supply chain management practice, it may be contested that performance levels equate to stage 1, 2 and 3. Stage 1 (adhoc) is representative of traditional contracting practice whereas stage 2 (defined) and 3 (linked) illustrate working practices commonly encountered via contemporary procurement routes such as partnering and framework agreements. Stage 4 (integrated) and 5 (extended) remain at present largely hypothetical.

DISCUSSION: RELATIONSHIPS, REWARDS & RISKS

Analysis of extended construction supply chain relations with second, third and fourth tier suppliers and manufacturers have been comparatively limited. Many economic, social and cultural conventions require careful exploration to comprehend the inherent complexity associated with the strategic alignment of multifarious supply chain stakeholders. Sponsors of supply chain management contend that the construction industry must modify its default cultural disposition. Only by addressing deep-rooted traditions and customs can construction take advantage of the economic opportunities afforded by greater integration and commercial solidarity (Latham, 1994, Egan, 1998). However, it is essential that the adoption and adaptation of construction supply chain management respects the professionalism and intuitive observations of experienced industry practitioners. Environmental agencies will invariability fashion stakeholder perception and construction management enactment of the transactional arena. The following discussion highlights three avenues of supply chain interest integral to the concept of extended supply chain management, namely; relationships, rewards and risks.

Relationships

The dynamic contribution of the UK economic climate to the ongoing construction supply chain management debate needs to be readily acknowledged. It is widely conceded that commercial behaviour in the UK construction sector is largely driven by economic forces (Wolstenholme, 2009). In terms of business and commerce, neoclassical interpretation of transactional exchange remains the dominant economic model in Western society (Biggart and Hamilton, 1998). Broadly perceived as an asocial and largely autonomous interpretation of the marketplace (Biggart and Castanias, 2001, Hirschman, 1970), neoclassical economics promotes a lowest-cost mind-set amongst consumers. The core values of an orthodox economic policy and the fierce competition promoted by free-market values is believed to be both pro-market and pro-consumer (OFT, 2001). However, it is generally recognised even among advocates of neoclassical doctrine that neoclassical economics is an

oversimplification of trading relations (Granovetter, 1985, Uzzi, 1997). In other words, despite a dogged adherence to neoclassical values it is illogical to wholly exclude social reasoning from the economic calculus.

The challenge for the construction stakeholders is to craft the correct balance of economic and social interplay appropriate for the optimal exchange of goods or services. In relation to the bilateral arrangement between construction client and main contractor (Project Supply Chain) the procurement selection by the client is pivotal to the ongoing construction relationship. Hitherto, the Joint Contracts Tribunal (JCT), the construction industry's foremost suite of contractual governance has exploited the values of an orthodox, asocial, autonomous, fiercely competitive marketplace. Although traditional contracting remains the most popular procurement route in UK construction (RICS, 2006, RICS, 2010), the practice has been repeatedly censured for being adversarial, fragmented and short-term (Briscoe and Dainty, 2005). Over the past decade alternative procurement routes have become more commonplace (RICS, 2010). Contemporary procurement routes such as partnering, framework agreements and more recently the Scottish Futures Trust (SFT) initiative have sought to instil a greater emphasis on relations contracting between construction client and first tier service and product providers. Contractual agreements popular with contemporary procurement such as Project Partnering Contract 2000 (PPC2000) and the New Engineering Contract 3 (NEC3) are calculated to engender values of trust and mutual respect in accordance with industry best practice initiatives (NEC, 2005). That said, uptake in contemporary procurement practices is unlikely to result in a cultural sea-change however it is anticipated to induce behaviour modification.

Recent examples of public sector framework procurement in conjunction with NEC3 contracting have created an alternative project environment conducive to greater integration of the supply chain. Whilst the Health Frameworks in England (Procure 21+), Wales (Design for Life, Building for Wales) and Scotland (Framework Scotland) conform to the requirements of EU and UK procurement legislation, each framework agreement differs slightly to accommodate characteristics unique to national circumstances. Arguably, in terms of Lockamy III and McCormacks' (2004) supply chain maturity model and within the context of the NHS procurement, the Welsh NHS framework agreement presents the most advanced example of construction supply chain integration. It is mandatory for NHS Trusts in Wales to procure major capital construction projects (total costs exceeding £6 million) via the framework agreement (WHE, 2010). Three principal supply chain partners (PSCP) have an integrated supply chain that includes architects, health planners, cost managers, building services engineers, civil and structural engineers, building services installers, FM advisors and CDM Consultants (WHE, 2005). All participants have exclusivity within their integrated supply chain, creating a 'squad' of service and product providers with 'teams' selected for each project (WHE, 2010). As a result, 'squad members' are wholly dependent on the success of their PSCP for future workload. It may be contended that the Welsh Health Estates pro-active management of the NHS framework agreement have initiated 'project' supply chain characteristics representative of a stage 4 (integrated) classification on Lockamy III and McCormacks' (2004) maturity model.

A key feature of construction activity is the high level of subcontracting (Hartmann and Caerteling, 2010). A typical construction project may witness up to 90% of its total value outsourced to an array of specialist and general subcontractors (Dubois and Gadde, 2000, BERR, 2004). A statistic that may suggest construction stakeholders are ideally placed to benefit from greater integration of the supply chain. At present the main contractor driven organisational supply chain remains short. Corporate preoccupation is typically focused on the development of a second tier preferred suppliers list. Second tier subcontractor and supplier information is centralised on a company database and formal auditing procedures are

put in place to evaluate the strategic nature of the ongoing commercial ties. From the resultant inquiry the main contractor will establish an inventory of validated subcontractors and suppliers within key construction disciplines. Subcontractors and suppliers cannot tender for work unless 'validated' via corporate supply chain protocol. Preferred suppliers will be continuously monitored on a criterion of predetermined key performance indicators (KPI's) complete with feedback loop. Whilst it remains rare for main contractors to proactively manage relations with third and fourth tier members of the supply chain, 'pinch-points' could on occasion jeopardise project deadlines. Consequently, the main contractor may be required to adopt a more 'hands-on' approach to 'downstream' supply chain management to protect their business interests.

Rewards

The benefits of supply chain management have been extensively extolled in management literature. Commercial solidarity has potential benefits for all the participants. The client secures a reliable and trustworthy construction provider who understands and appreciates the trials and demands of the client business. During period of economic growth the client has also insulated the provision of major construction services and products from inflationary price hikes due to demand outstripping supply. The client also benefits from project learning and information sharing throughout the supply chain. Challenging entrenched practices where organisational learning is usually at the expense of the client without either the client or the main contractor benefiting from the project experience (Strategic_Forum, 2002).

Industry ingenuity may also have an opportunity to thrive in an extended supply chain environment. Modern methods of construction (MMC) may be prototyped, developed and refined via supply chain collaboration. Minimising the financial risk of implementation and increasing the rewards for successful innovation. For example, off-site building techniques challenge the predominately craft approach to the traditional building processes. Although MMC are widely believed to improve construction productivity (Goodier and Gibb, 2007), it requires considerable capital and human investment plus economies of production to justify a business case. From a supply chain management perspective, the advancement in industrialisation and assembly processes will also begin to mirror the applications used in manufacturing supply chain management. Second, third and fourth tier construction providers will benefit from a near continuous stream of work. Alleviating excessive fluctuations in demand and supply that construction companies often find difficult to adequately manage (Hartmann and Caerteling, 2010).

Other rewards are less obvious. Health and safety, for example is a prime concern for all parties engaged in the building process. Off site working coupled with increased assembly processes and strong supply chain leadership can help facilitate an incident and injury free working environment (Doherty, 2008). Reducing near misses and accidents not only reduce otherwise hidden costs but also sets a standard of working and performance that transgresses from the exceptional to the norm. Sustainable working practices will also reap benefits from MMC. Embedding working relationship within the supply chain increases both formal and informal communications channels. Efficient dialogue among stakeholders will mitigate project risks via comprehensive risk register, especially in high profile, complex construction projects. Integral to the communication and information sharing is the development of ICT channels. This will not only improve communication but depending on the sophistication of the communication and information exchange systems the prerequisite for capital investment may act as a barrier to market entry for those organisations outside the supply chain coalition (Powell, 1990).

Risks

Engaging in extended supply chain management within a construction context is not without risk. Inextricably linking business interests with the success or possible failure of other discrete organisations may mitigate risks on the one hand but on the other if the failure is catastrophic then there will undoubtedly be collateral consequences for the extended supply chain participants. It is possible that due to the fragmentation of the industry and high incidence of insolvency (Chevin, 2010) within the construction sector that construction firms remain wary of high levels of interdependency. A narrow relationship portfolio may be detrimental to their self-interest over the longer-term. Over embeddedness within a supply chain may also be accompanied by corporate lethargy. The competitive edge may be compromised by an over-reliance on collaborative arrangements that insulate the organisation from the competitive pressures of the free market. There is an inherent risk, as with most administrative tasks that supply chain management practice and procedures become victim of increasingly bureaucratic processes, the sharpness of the supply chain enterprise blunted by an administrative encumbrance.

Whilst relationships are stable and the informal social contract remains intact, the efficiency of the commercial solidarity is likely to mitigate corporate tendencies to merge. However, there remains an ever-present operational and commercial risk that irreconcilable differences between supply chain partners may trigger dysfunctional behavioural patterns and a return to adversarial relations. Consequently, a breakdown in trust and mutual respect will necessitate that economic and social ties are either; relinquished or alternatively, contingent upon ongoing commercial commitments an acquisition may be appropriate (Granovetter, 1985).

The potential futility of engendering social relationships within a construction project environment should also be carefully measured. The transient nature of production (Akintoye et al., 2000) necessitates a nomadic construction workforce (Trajkovski and Loosemore, 2006). Therefore building personal relationships over many years of social networking may be unexpectedly dissolved due to company or individual circumstances. Investing considerable time developing social capital may create business opportunities mutually conducive to the participating parties but within the context of construction, ties remain tenuous and the terms of social contract ill-defined.

Within the construction contracting community, subcontractors and suppliers remain sceptical of main contractors' motives for developing alliances (Dainty et al., 2001b). Small and medium sized enterprises (SME's) in particular continue to question the value of strategic alliances. Often believing that strong business ties with one or a few main contractors may endanger business opportunities with other construction providers. Even industries with a history of successful supply chain management it is somewhat inevitable that during periods of economic hardship the suppliers are subjected to cost cutting measures, commonly referred to as the *'squeeze'* (Blake et al., 2003). Construction clients and main contractors are unlikely to behave any differently. Evidence from the private sector already suggest that blue chip construction clients are turning their back on framework agreements (Wright, 2010). Consequently any ambition of 'extended' relations within construction supply chain management is likely to be compromised by an enduring faith in orthodox economic thinking, driven by self-interest, competition and supply and demand.

CONCLUSION

This paper has shown that the concept of extended supply chain management (stage 5) as illustrated by Lockamy III and McCormack's (2004) supply chain maturity model remains an aspiration within the context of the UK construction industry. Exemplars of extended supply

chain management witnessed in the manufacturing sector bear little semblance to the highly institutionalized setting of a project-based, craft orientated, geographical dispersed construction industry. Construction supply chain management, like the construction industry is unique. Ingrained construction operating practices (Dainty et al., 2001a) interlaced with complex environmental agency conspire to undermine the innocent ambitions of a manufacturing supply chain management ideology.

The supply chain maturity model does offer a benchmark of adaptation and application against which construction supply chain management may be evaluated and current practice discussed. However, progress on the notion of extended construction supply chain management will require key industry stakeholders to develop innovative collaborative policies that will be progressive, organisationally supportive and commercially attractive to SME's. As with all transactional and social relationships, risk will need to be offset against the rewards. Given the structural characteristics of the construction industry and a preoccupation for competitive tendering procedures it remains fanciful that construction supply chain management will attain a stage 5 (extended supply chain management) category of supply chain maturity.

Abstract
A scarcity of empirical research has been observed on risk mitigation measures for those construction projects procured by guaranteed maximum price contracts (GMP) and target cost contracts (TCC) worldwide. This paper aims to seek and examine the risk mitigation measures associated with GMP and TCC (GMP/TCC) construction projects through an industry-wide empirical questionnaire survey launched in Hong Kong. Survey respondents were invited to delineate their levels of agreement on 18 individual risk mitigation measures identified from reported literature and in-depth interviews, and the views of client group were compared with those of contractor group. The survey results manifested that both the client group and contractor group are in general consistent in their views towards the risk mitigation measures for GMP/TCC contracts. However, the Mann-Whitney U Test revealed that they held different perceptions on 4 out of the 18 risk mitigation measures, and the findings may stem from different roles involved in the projects. The research findings are useful in providing industrial practitioners with valuable pointers towards effective risk mitigation measures of applying GMP/TCC schemes at an early stage of project delivery.

Keywords: Guaranteed maximum price contracts (GMP), Target cost contracts (TCC), Risk mitigation measures, Construction industry, Hong Kong.

INTRODUCTION

Traditional adversarial relationships are often encountered between employers and contractors within the construction market, primarily because various project stakeholders tend to focus mainly on the success of their individual own businesses instead of the overall project itself. By linking the individual own financial goals of the contractors with the overall

project objectives, both the Guaranteed Maximum Price (GMP) and Target Cost Contracting (TCC) schemes are often applied as effective means to motivate contractors in achieving better value for money and more favourable project outcomes (Construction Industry Review Committee, 2001). GMP/TCC schemes can add value to project delivery only if the key risk factors are carefully identified, analysed, shared and managed (Trench, 1991; Walker *et al.*, 2000).

Although both GMP and TCC contracts have been in use for several years, not all of these projects were successfully completed and some of them resulted in a high level of risk or an uneven apportionment of risks. For example, Roja and Kell (2008) found that the final construction cost of 75% of public school projects based in the northwest of the United States cost more than the contract GMP value at completion, while the same phenomenon was observed in about 80% of public non-school projects. Hence, it is essential to seek ways to mitigate the potential risks which may be detrimental to the overall project performance of GMP/TCC contracts. This study serves as an attempt to fill up the gap of research in the area of risk mitigation measures for GMP/TCC schemes.

DEFINITIONS OF GMP/TCC

Carty (1995) defined GMP as "Both the contractor and owner agree that the contractor will perform an agreed scope of works (defined as best as possible) at a price not to exceed an agreed upon amount, the guaranteed maximum price (GMP) …… if these costs and the agreed upon contractor's profit are less than the GMP, the owner and contractor will share the savings in cost based upon an agreed formula. If the costs exceed the GMP without any changes to the defined scope, the contractor must solely bear the additional cost."

The National Economic Development Office (NEDO) (1982) suggested TCC to be "Target cost contracts specify a 'best' estimate of the cost of the works to be carried out. During the course of the works, the initial target cost will be adjusted by agreement between the client or his nominated representative and the contractor to allow for any changes to the original specifications. Any savings or overruns between target cost and actual cost at completion are shared between the parties to the contract."

HIGHLIGHTS OF RESEARCH STUDIES ON GMP/TCC

An extensive review of published literature has sought a bunch of research studies in relation to GMP/TCC schemes over recent years. Matthews and Howell (2005) reported on a case study of a central chilled water plant in Orlando of the United States which was procured with a GMP arrangement and achieved a cost saving of around 10% because of the partnering efforts of the project team. Pryke and Pearson (2006) carried out three European case studies and advocated the application of a GMP arrangement to be an effective means to transfer risks to the employer associated with design development at post-contract award stage. Kaplanogu and Arditi (2009) explored the practice of pre-project peer review process of GMP of contractors in the United States via an empirical questionnaire survey. Puddicombe (2009) established a regression model to explain the variations of project performance of applying different compensation schemes including GMP, cost-plus and lump sum contractual arrangements.

Badenfelt (2008) launched 16 interviews with the Swedish clients and contractors to identify the important factors influencing the selection of sharing ratio under TCC. Another recent study by Badenfelt (2010) revealed that a business relationship solely built on mutual trust appears to be rare in Sweden, and more attention should be placed by contracting parties to trust-nurturing actions to facilitate a smooth delivery of TCC. Lahdenpera (2010) examined the problem with late involvement in design of contractor in TCC, and proposed a two-stage target cost arrangement to combine early contractor's involvement and price containment.

Despite plentiful literature about the application of GMP/TCC contracts in construction, there seems to be a shortage of empirical research looking into the "risk aspect", especially the risk mitigation measures for GMP/TCC schemes which are generally perceived to be applicable to projects with high levels of complexity and risks. This observation has paved the way for conducting this study with the purpose of generating useful insights into risk mitigation strategies under the GMP/TCC umbrella towards industrial practitioners for reference and implementation.

DEVELOPMENT OF SURVEY INSTRUMENT

A comprehensive review of relevant materials from textbooks, academic journals, professional journals, conference proceedings, research reports, previous dissertations and internet information was first undertaken to capture background knowledge about the application and risk mitigation of GMP/TCC contracts worldwide. The literature review helped establish an overall framework for the research study and to prepare for the template of the survey questionnaire.

A total of seven semi-structured face-to-face interviews were carried out between June and July of 2008 with senior industrial practitioners with direct hands-on experience in procuring GMP/TCC construction projects in Hong Kong (Chan *et al.*, 2010a) to glean their opinions on key risk factors, risk allocation and risk mitigation measures for implementing GMP/TCC projects. Then an empirical survey questionnaire was compiled according to the findings from literature review (Chan *et al.*, 2010b) and those in-depth interviews. An industry-wide questionnaire survey was subsequently launched from March to April of 2009 to solicit the opinions and perceptions of relevant industrial practitioners on risk identification, risk assessment, risk allocation and risk mitigation associated with GMP/TCC construction projects in Hong Kong.

The survey form was made up of four major sections. The first section was about the respondents' general personal profiles. The second section was concerned with the risk identification and assessment of 34 listed key risk factors in relation to GMP/TCC construction projects. The third section focused on the risk mitigation measures for GMP/TCC contracts in which respondents were invited to rate the effectiveness of 18 possible risk mitigation measures as postulated by the interviewees with a five-point Likert scale, where 1 indicated "least effective"; 3 "effective" and 5 "most effective". The fourth section was optional and the respondents were requested to show their personal preference on future development and application of GMP/TCC contractual arrangements with their supporting reasons. It should be stressed that only the survey findings in relation to the risk mitigation measures are reported and discussed in this paper due to length limitation. The results of other sections will be duly documented and disseminated in other publications in

near future, for example, on the first section of the development of a fuzzy risk assessment model (Chan *et al.*, 2011).

Altogether, 300 self-administered blank survey forms were delivered to individual construction professionals and project stakeholders in Hong Kong through both postal mail and electronic mail between March and April of 2009. The target survey respondents were first determined from previous research studies on GMP/TCC procurement strategies in Hong Kong undertaken by the authors (Chan *et al.*, 2007). A total of 94 valid and duly completed survey forms were returned in June of 2009 for further statistical analysis. The 94 respondents either have acquired direct hands-on experience in participating GMP/TCC projects or they declared to have basic understanding of the underlying principles of GMP/TCC schemes even though without the direct exposure to GMP/TCC contracts before (Chan *et al.*, 2010b). Since all of the major active practitioners in applying GMP/TCC had been included in the list of target respondents of the questionnaire survey, it was discerned that their opinions and perceptions could substantially represent the GMP/TCC project pool in Hong Kong over the past decade of 1999-2009. Hence, the chosen sample was perceived as representative of the survey population given the limited number of construction projects completed under GMP/TCC schemes in Hong Kong (about 20 as cited by Chan *et al.*, 2007).

Table 1 serves as a summary of the profiles of the 94 respondents. More than 80% of the respondents have already derived working experience of at least 5 years within the construction industry, their opinions and data collected from the survey are regarded as representative and reliable. The collective opinions from all of the survey respondents will be presented in this paper, and the views of client group will also be compared with those of contractor group because they are the key players in driving the GMP/TCC procurement process. A four-level data analysis framework (Chan *et al*., 2010b), including descriptive statistics, Kendall's concordance test, Spearman's rank correlation test and Mann-Whitney U Test, will be applied to investigate the intra-group agreements and inter-group comparisons for this survey.

Table 1: *Personal profiles of survey respondents*

Category	Respondents	
	Frequency	Percentage
Grouping by role in the project		
Client	33	35.1%
Contractor	27	28.7%
Consultant (i.e. architects, engineers, quantity surveyors, project managers, etc)	34	36.2%
TOTAL	94	100%
Experience level in construction		
Below 5 years	17	18.1%
5-10 years	11	11.7%
11-15 years	11	11.7%
16-20 years	12	12.8%
Over 20 years	43	45.7%
TOTAL	94	100%

PRESENTATION OF SURVEY RESULTS

Overall ranking of the risk mitigation measures for GMP/TCC projects

The mean scores of each of the 18 listed risk mitigation measures as rated by all respondents were calculated and they were ranked in descending order of the mean scores as reported in Table 2. The mean values for the 18 measures ranged from 2.60 to 3.90. Since all the mean values are above 2 (fairly effective), the respondents believed the suggested risk mitigation measures to be effective and feasible in general but with different levels of agreement only. Item 16 "Right selection of project team" was ranked as the most effective risk mitigation measure for GMP/TCC construction projects. Chan *et al.* (2010c) advocated that the selection of a competent project team is crucial to overall project success of a target cost contract, as inexperienced or claim-conscious contractors may jeopardise the smooth implementation of the GMP/TCC procurement process. Gander and Hemsley (1997) also concurred the recruitment of an experienced project team as crucial to the success of a GMP/TCC project since an inexperienced one could generate a lack of clarity for his roles and obligations.

The respondents ranked Item 3 "Clearly defined scope of works in client's project brief" as the second most effective risk mitigation measures. Since "change in scope of works" was regarded as the most significant risk in the same survey (Chan *et al.*, 2010b), it is not astonishing that respondents indicated that a clear definition of scope of works at project commencement could effectively mitigate risks inherent with GMP/TCC projects during site construction. This finding is in line with that in a recent study from the United Kingdom (Olawale and Sun, 2010), suggesting that clear distinction between a design change and a design development item well at the outset of a construction project could reduce the potential risks arising from subsequent design changes. Thus, it is essential to define the scope of works as detailed and accurate as possible at the initial project stage and to keep scope changes or necessary variations to a minimum.

The third most effective risk mitigation measure was Item 12 "Mutual trust between the parties to the contract". It is found that partnering concepts were introduced in parallel in a number of GMP/TCC construction projects in Hong Kong (Chan *et al.*, 2007). The methodology of TCC is usually applied in projects with high risks (Wong, 2006), so mutual trust between the employer and the contractor would be necessary to cope with the risks associated with the projects. Moreover, because of the unique arrangement of the target cost contracting approach based on joint determination and agreement between the client and the contractor on the allocation of major risks, the client recognised the essence of realistic target cost estimates, which would include appropriate risk contingencies under the pain-share/gain-share mechanism (Chan *et al.*, 2010c). Mutual trust and close working relationship are thus essential in reducing the possible risks under a teamwork culture.

Table 2: *Rankings and results of Kendall's concordance test of risk mitigation measures for GMP/TCC construction projects*

ID	Risk Mitigation Measures for GMP/TCC	All respondent group			Client group			Contractor group		
		N	Mean	Rank	N	Mean	Rank	N	Mean	Rank
16	Right selection of project team	60	3.90	1	33	4.00	1	27	3.78	1
3	Clearly defined scope of works in client's project brief	60	3.73	2	33	3.79	2	27	3.67	6
12	Mutual trust between the parties to the contract	60	3.70	3	33	3.67	4	27	3.74	3
6	Confirming a contract GMP value or target cost after design documents are substantially completed	60	3.63	4	33	3.70	3	27	3.56	11
4	Prompt valuation and agreement on any variations as they are introduced	60	3.58	5	33	3.52	5	27	3.67	6
14	Proactive participation by the main contractor throughout the GMP/TCC process	60	3.57	6	33	3.48	6	27	3.67	9
15	Reasonable sharing mechanism of cost saving / overrun of budget between client and contractor	60	3.55	7	33	3.42	9	27	3.70	4
8	Early involvement of the main contractor in design development process	60	3.53	8	33	3.39	10	27	3.70	5
17	Tender interviews and tender briefings to ensure tenderers gain a clear understanding of scope of works involved and necessary obligations to be taken in the project	60	3.50	9	33	3.42	7	27	3.59	10
11	Sufficient time given to interested contractors to submit their bids for consideration	60	3.47	10	33	3.24	12	27	3.74	2
2	Clearly stated circumstances in which agreed GMP value or target cost can be adjusted in contracts	60	3.45	11	33	3.27	11	27	3.67	6
18	Establishment of adjudication committee and meetings to resolve potential disputed issues	60	3.39	12	33	3.42	7	27	3.35	13
5	Proper risk register with responsible parties assigned and agreed	60	3.17	13	33	3.24	12	27	3.07	16
7	Development of standard contract clauses in connection with GMP/TCC schemes or methodology	60	3.12	14	33	3.00	15	27	3.26	15
1	Application of price fluctuation clause in the contract	60	3.07	15	33	2.82	16	27	3.37	12
13	Open-book accounting regime provided by main contractors in support of their tender pricing	60	3.03	16	33	3.09	14	27	2.96	17
10	Implementation of relational contracting within project team	60	2.97	17	33	2.69	17	27	3.30	14
9	Employing a third party to review the project design in compliance with prevailing building regulations and buildability at tender stage	60	2.60	18	33	2.36	18	27	2.89	18
	Number (N)		60			33			27	
	Kendall's coefficient of concordance (W)		0.124			0.175			0.109	
	Actual calculated chi-square value		122.149			95.221			48.284	
	Critical value of chi-square from table		28.870			28.870			28.870	
	Degree of freedom (df)		17			17			17	
	Significance level		<0.001			<0.001			<0.001	
	H_0 = Respondents' sets of rankings are unrelated (independent) to each other within each group Reject H_0 if the actual chi-square value is larger than the critical value of chi-square from table									
	Note: Items were rated on a 5-point Likert scale (1 = Least effective; 2 = Fairly effective; 3 = Effective; 4 = Very effective; and 5 = Most effective).									

Results of Kendall's concordance analysis

The second step of data analysis is to perform a Kendall's test of concordance to gauge the agreement of different respondents on their rankings of the risk mitigation measures for GMP/TCC within a particular respondent group (*Chan et al*., 2010b). As the number of

attributes (i.e. risk mitigation measures) considered was larger than seven, the chi-square value would be used as a near approximation instead of the Kendall's coefficient of concordance to measure the agreement of different respondents on their rankings of risk mitigation measures for GMP/TCC as a whole based on the mean scores. According to the degree of freedom (18 - 1 = 17) and the allowable level of significance (5%), the critical value of chi-square from table was found to be 28.87 (Siegel and Castellan, 1988). For all respondents, the actual computed chi-square value of 122.149 was much greater than the critical value of chi-square of 28.87. This result indicates the null hypothesis that "Respondents' sets of rankings are unrelated (independent) to each other" has to be rejected. Consequently, there is sufficient evidence to conclude that there is significant degree of agreement among all respondents on the rankings of the risk mitigation measures for GMP/TCC. The same result (actual calculated value of chi-square larger than critical value of chi-square) is found in both the client group and contractor group. This concordance test ensures the data and opinions collected from the questionnaire survey to be valid and consistent for further analysis.

Results of Spearman's rank correlation test

With the purpose of comparing the perceptions between the client group and contractor group, the next step of data analysis is to conduct a Spearman's rank correlation test. The Spearman's rank correlation coefficient is a statistical tool to test the strength of relationship between the rankings of two respondent groups (Olawale and Sun, 2010). The level of association between the client group and contractor group on their rankings of the 18 risk mitigation measures for GMP/TCC schemes was gauged by the Spearman's Rank Correlation Coefficient (r_s). The coefficient, r_s , ranges between –1 and +1. A value of +1 indicates a perfect positive correlation, while a value of –1 indicates a perfect negative correlation (Fellows and Liu, 2008). If the Spearman's rank correlation coefficient (r_s) was statistically significant at 5% significance level, the null hypothesis that "No significant correlation on the rankings between the two groups" can be rejected. It can then be concluded that there is significant association between the two groups on the ranking exercise.

The level of agreement amongst the respondents on the ranking exercise was tested via the Spearman's rank correlation test as portrayed in Table 3. The results reflected that the null hypothesis that no significant correlation on the ranking between the client group and contractor group is rejected at 1% significance level. This results in significant correlations in general on the rankings of risk mitigation measures between the two respondent groups and they shared similar perceptions on the ranking exercise as a whole (e.g. Item 16 both ranked as the 1st, Item 7 as the 15th and Item 9 as the 18th).

Table 3: *Results of Spearman's rank correlation test on the risk mitigation measures for GMP/TCC construction projects between client group and contractor group*

Comparison of Rankings	r_s	Significance Level	Conclusion
Client's ranking vs Contractor's ranking	0.625	0.006	Reject H_0 at 1% significance level

H_0 = No significant correlation on the rankings between the two groups
H_a = Significant correlation on the rankings between the two groups
Reject H_0 if the actual significance level (p-value) is less than the allowable value of 5%

Results of Mann-Whitney U Test

The final step of data analysis is to detect any differences in perception on individual risk mitigation measures by means of the Mann-Whitney U Test. The Mann-Whitney U Test is a non-parametric statistical test which is applied in hypothesis testing involving two independent variables (Gibbons and Chakraborti, 2003). It is performed to test if there is any statistically significant difference in the median values for each attribute under study between any two respondent groups. This same technique was adopted in a recent research by Wibowo and Mohamed (2010) to test whether there was statistical difference between perception towards criticality of risks of regulators and operator in water supply projects in Indonesia. This test is used because it is distribution free and thus requiring no assumption of normality of data sets (Wibowo and Mohamed, 2010). The Mann-Whitney U Test was applied in this study to test the null hypothesis that "There is no significant difference in the median values of the same risk mitigation measure between the respondents from client group and contractor group" and the medians can be represented by mean ranks (Sheskin, 2007).

Level of significance (α) for testing these hypotheses was set at 5%. The results can be interpreted by the Z-value and p-value. When the actual calculated p-value is less than the pre-defined significance level of 5%, then the null hypothesis (H_0) can be rejected. Thus, it can be concluded that there is a significant difference in the median values of that risk mitigation measure between the two respondent groups (Sheskin, 2007).

The results of Mann-Whitney U Test are shown in Table 4. It can be seen that the two groups of respondents had statistically different perceptions towards 4 out of the 18 risk mitigation measures. The contractor group considered Item 1 "Application of price fluctuation clause in the contract" more important than the client group. This finding may stem from the fact that there was a significant increase in the materials price when the survey was conducted (i.e. first half of 2009). The contractors suffered a lot for such increase in materials price if the price fluctuation clause was not applied. So the contractor group would believe the price fluctuation clause to be very effective in mitigating risks in GMP/TCC schemes.

The two groups of respondents also held different views towards Item 9 "Employing a third party to review the project design in compliance with prevailing building regulations and buildability at tender stage". This risk mitigation measure is similar to that found from those interviews undertaken in the United Kingdom by Olawale and Sun (2010) that employing a design manager to manage the design process and review related information as it comes in. Again, the contractor group perceived this risk mitigation measure as more effective than the client group did. Perhaps, the contractor group may advocate that the lack of buildability of project design would unnecessarily delay the overall project duration and affect the progress of subsequent portions / phasing of works. The contractor's resources may be wasted in preparing for works which is actually difficult to construct, due to the deficient initial project design.

Table 4: *Results of Mann-Whitney U Test between the client group and contractor group on the risk mitigation measures for GMP/TCC construction projects*

Risk Mitigation Measures for GMP/TCC	Respondent Group	Mean Rank	Significance Level
1. Application of price fluctuation clause in the contract	**Client**	**26.42**	**0.036***
	Contractor	**35.48**	
2. Clearly stated circumstances in which agreed GMP value or target cost can be adjusted in contracts	Client	27.59	0.128
	Contractor	34.06	
3. Clearly defined scope of works in client's project brief	Client	31.45	0.622
	Contractor	29.33	
4. Prompt valuation and agreement on any variations as they are introduced	Client	29.73	0.688
	Contractor	31.44	
5. Proper risk register with responsible parties assigned and agreed	Client	31.94	0.457
	Contractor	28.74	
6. Confirming a contract GMP value or target cost after design documents are substantially completed	Client	31.15	0.734
	Contractor	29.70	
7. Development of standard contract clauses in connection with GMP/TCC schemes or methodology	Client	28.58	0.326
	Contractor	32.85	
8. Early involvement of the main contractor in design development process	Client	28.36	0.273
	Contractor	33.11	
9. Employing a third party to review the project design in compliance with prevailing building regulations and buildability at tender stage	**Client**	**26.58**	**0.044***
	Contractor	**35.30**	
10. Implementation of relational contracting within project team	**Client**	**25.16**	**0.013***
	Contractor	**35.74**	
11. Sufficient time given to interested contractors to submit their bids for consideration	**Client**	**26.59**	**0.043***
	Contractor	**35.28**	
12. Mutual trust between the parties to the contract	Client	29.88	0.752
	Contractor	31.26	
13. Open-book accounting regime provided by main contractors in support of their tender pricing	Client	31.52	0.606
	Contractor	29.26	
14. Proactive participation by the main contractor throughout the GMP/TCC process	Client	29.08	0.457
	Contractor	32.24	
15. Reasonable sharing mechanism of cost saving / overrun of budget between client and contractor	Client	28.95	0.429
	Contractor	32.39	
16. Right selection of project team	Client	32.47	0.305
	Contractor	28.09	
17. Tender interviews and tender briefings to ensure tenderers gain a clear understanding of scope of works involved and necessary obligations to be taken in the project	Client	28.95	0.419
	Contractor	32.39	
18. Establishment of adjudication committee and meetings to resolve potential disputed issues	Client	30.80	0.670
	Contractor	28.98	

* Risk mitigation measures with a significance level of less than 0.05 which indicates significant statistical differences

The contractor group also rated Item 10 "Implementation of relational contracting within project team" higher than the client group did. According to Chan *et al*. (2007a), partnering spirit is essential to the overall success of GMP/TCC projects. The partnering spirit incorporated in relational contracting enhances the willingness to achieve co-operation between the contracting parties and ensures a smooth operation of the projects.

Finally, the two respondent groups shared different views on Item 11 "Sufficient time given to interested contractors to submit their bids for consideration". This finding is not surprising since it is the contractor to submit the bids, the client may like to have the overall project duration as short as possible and may be less concerned about the tendering period. A reasonable tendering period would allow interested contractors to gain a basic understanding

of the special features and contractual requirements of the project such as the methodology of GMP/TCC contractual arrangements (Chan *et al*., 2010a). The tenderers would probably recognise potential risks involved in the projects concerned before contract award, and this would certainly reduce the risks such as change in scope of works at the post contract award stage.

CONCLUSIONS

An empirical questionnaire survey was launched on some risk mitigation measures for GMP/TCC schemes which are still at a germinating stage of development in the construction industry of Hong Kong. The three most effective individual risk mitigation measures as perceived by those industrial practitioners are: (1) Right selection of project team; (2) Mutual trust between the parties to the contract; and (3) Clearly defined scope of works in client's project brief.

Following the descriptive analysis of the survey results, the Kendall's concordance test indicates that the responses in both the client group and contractor group are in general consistent within their respective groups. The result of Spearman's rank correlation test further suggests that the rankings of risk mitigation measures between the two groups are also consistent statistically as a whole. The Mann-Whitney U Test shows that the contractor group perceived 4 out of the 18 risk mitigation measures as much more effective than the client group did in the survey.

With the survey results of this study in mind, industry leaders and decision makers have secured sufficient evidence and useful pointers to determine whether to adopt GMP/TCC contracts in future projects or not. It is hoped that this research study could be served as a first step towards generating valuable solutions for mitigating potential risks associated with the GMP/TCC contractual arrangements which are discerned to be suitable for projects with high risks (Wong, 2006). Further research could be undertaken in future via case studies to confirm the applicability and effectiveness of those suggested practical strategies for mitigating the potential risks inherent with GMP/TCC schemes worldwide.

ACKNOWLEDGEMENTS

The authors would like to thank The Hong Kong Polytechnic University for providing financial support to this research endeavour (HK PolyU BRE Departmental General Research Grants Allocation 2006/07 with Project Account Code: BRE-G-U252). The work described in this paper was further supported by a grant from the Research Grants Council (RGC) of the Hong Kong Special Administrative Region, China (RGC Project No. PolyU 5107/07E). This paper forms part of a RGC funded research project entitled "Evaluating the Key Risk Factors and Risk Sharing Mechanisms for Target Cost Contracting (TCC) Schemes in Construction" with several objectives sharing common background of study and research methodology. Special gratitude is also extended to those industrial practitioners for their kind co-operation and generous contributions in completing the empirical survey questionnaires used in this study from March to April of 2009.

Abstract

Due to technological, economic and spatial developments, various inner-city industrial areas have lost their former use and their original economic value. Many of these areas have elements of cultural-historical value. Preserving this cultural heritage means managing it for the benefit of current and future generations, and –by doing so - contributing to a sustainable development. Governments, private parties, citizens and interest groups are often convinced of the desirability of preserving the cultural heritage. However, the presence of cultural heritage entails extra complexity. Hence, public and private parties are searching for new methods, processes and instruments to embed cultural heritage in urban redevelopment projects. In this paper we present a framework to study strategies used and their implications for balancing costs and benefits. To develop this framework, we analyzed five Dutch urban redevelopment projects with cultural heritage and confronted the results with literature. We then argue that value creation, through collaborative efforts in finding new uses, and value claiming, by negotiating on the costs and benefits involved, go hand in hand. From this perspective, value creation and settlements regarding costs and benefits of cultural heritage depend on how stakeholders handle this tension.

Keywords: cultural heritage, urban redevelopment, collaborative strategies, balancing costs and benefits, negotiation

INTRODUCTION

One of the key concepts of sustainability is preserving the environment for future generations (Nijkamp and Riganti, 2008). Developments should meet the needs of the present generation without compromising the ability for future generations (World Commission on Environment and Development, 1987). However, many urban areas were developed in a period when sustainability was not really an issue. In recent decades technological, economic and spatial developments caused that many urban industrial areas lost their original economic value or the use was not considered socially desirable anymore at the specific location. Without a new use, these areas will fall into decline. Buildings will slowly deteriorate and the areas can become a spot for crime. Such areas can cause serious economic, social, political damages to

society (Yousefi et al., 2007). As spatial developments will increasingly consist of inner-city redevelopment projects, a big challenge is to transform these areas. This contributes to a sustainable environment. Re-use of (parts) of buildings saves demolition waste, buildings will become more energetic, and inner-city redevelopment makes greenfield development elsewhere superfluous.

In contradiction to greenfield development, urban redevelopment has to a greater extent take into account its economic, physical, social and environmental context. This includes the context of the surrounding urban area, but also the characteristics of the redevelopment area itself. An important characteristic of these projects is that they often include buildings which are considered to be of cultural-historical value. Although the added value of this cultural heritage for urban redevelopment is generally acknowledged, in practice successful transformation seems hard to attain. Based on an analysis of five Dutch urban redevelopment projects in which transformation of cultural heritage plays a significant role, we will explain the challenges and bottlenecks in more detail. We confronted the findings from the empirical analysis with literature on planning and negotiation. We end this paper by presenting a general framework to study collaborative strategies and the implications of these strategies on settlements regarding the costs and benefits to effectively transform of cultural heritage in urban redevelopment. In the following section, we first pay attention to cultural heritage in an urban redevelopment context.

CULTURAL HERITAGE IN URBAN REDEVELOPMENT

Cultural heritage in urban areas is often seen as the physical representation of the identity of a certain community (Nijkamp and Riganti, 2008). More specific, cultural heritage comprises a whole of various things, like (art) collections, archaeological heritage, individual buildings, city views, landscapes, industrial complexes and waterworks with cultural, social and economical value (Coccossis and Nijkamp, 1995). An area can be appointed as cultural heritage, like UNESCO world heritage sites, or individual buildings can be officially registered (like national protected monuments) or generally be considered as such.

In urban redevelopment, the presence of cultural heritage can offer opportunities for social-economic development, such as the development of tourism, recreation, leisure and other kinds of cultural activities (Bizarro and Nijkamp 1997). Cultural heritage gives an area a specific identity and generally improves the satisfaction of people living in the neighbourhood (Aarsen et al., 2010; Linssen, 2009). Preserving cultural heritage means managing it for the benefit of current and future generations. In this way, preserving and transforming built cultural heritage into new uses, contributes to a sustainable development (Nijkamp en Riganti, 2008).

Governments, private parties, interest groups and citizens are often convinced of the desirability of preserving and re-using the valuable cultural-historical buildings. Besides interests like perception of a certain identity and historical conscience, there are also other material and immaterial considerations to preserve cultural heritage: aesthetical, ecological, social and economical interests. However, urban redevelopment projects tend to be complex in general and even more when cultural heritage is involved. Urban redevelopment projects are characterized by high contextual and organizational complexity; mutual dependencies among actors, as the investments needed are generally too high and the project too complex for a single actor; the need for collaborative interaction between private and public parties;

and a long time frame (Bult-Spiering, et al. 2005). The presence of cultural heritage entails extra complexity. It is often a challenge to find new appropriate uses for these buildings which are also financially feasible.

In this paper we focus on transformation of built cultural heritage as a part of a wider urban area development. These projects often concern former industrial or military complexes.

A well-known example of a successful transformation of a former urban industrial area is the so-called Westergasfabriek in Amsterdam. Constructed in 1883, this factory was once the largest coal plant of the Netherlands (14 ha). The plant closed down in 1967. Most of the remaining buildings were officially acknowledged as cultural heritage 30 years later and became successfully used for temporary creative and cultural activities. This was the start of a redevelopment project in which many of the buildings were renovated. Nowadays, these buildings are used for events, or as a gallery, office, theatre, bar or restaurant. The industrial buildings and surrounding area are transformed into a characteristic place to work and play.

The complexity of the projects implies that straight-forward planning is not possible. The great number of actors and interests in area developments makes planning processes slow and complicated. Especially financial agreement seems hard to attain when plans have to be made effective. Although various studies (Ruijgrok, 2004; ABF Research, 2007; a.o.) show that the presence of cultural heritage adds value to an area, quantifying and allocating the increased value is often very difficult. As a consequence, a number of parties profit from investments to preserve and or transform cultural heritage without contributing in the costs. For collective goods this is known as the problem of free-riders.

In previous years, governments usually subsidized non-commercial elements, like cultural-historical values, as an incentive for urban redevelopment projects (Aarsen, Brons et al. 2010). As government funds are decreasing and more emphasis is put on efficient use of public money, opportunities to capture the increased value are searched for. Governments, market parties, citizens and interest groups have a need to cooperate (Ministries OCW, LNV, VROM, V&W, 1999) to prevent cultural heritage buildings to disintegrate and embed them in the urban redevelopment projects. However, a major bottleneck in the efforts to transform cultural heritage buildings in urban redevelopment projects appears to be the lack of transparent system for balancing the corresponding costs and benefits between actors involved.

BALANCING COSTS AND BENEFITS IN CULTURAL HERITAGE PROJECTS

Balancing of costs and benefits can be seen as acknowledging the fact that additional value of commercial elements, like houses or offices also depends on the granted subsidy for non-commercial elements (Ministry of Finance, 2001). Boeve (2006) defines it as “the transfer of rights, risks, financial or qualitative values, between profit making and non-profit elements in order to make a coherent programme possible".

In recent years a lot of attention is paid to the balancing of costs and benefits in area development projects, both in policy documents (Ministries VROM, V&W, EZ, LNV and Finance, 2003; Ministry of VROM, 2004 en 2001; a.o.), as by interest groups of the private sector. A distinction can be made between voluntary balancing of costs and benefits and the use of governmental instruments to enforce contributions of private parties. Within the

current Dutch institutional context - contrary to some other countries – the legal possibilities to capture the added value due to public investments are very limited. The applicability of a recently introduced law on land exploitation is limited to a contribution in the costs of certain public facilities, instead of focussing on capturing increased value. Besides, investments in preserving cultural heritage or cultural facilities are not listed cost categories of public facilities in this law. As institutional changes go beyond the scope of our research, balancing costs and benefits in transformation projects is primarily based on (voluntary) negotiation. In urban development practice, balancing costs and benefits usually takes place in the context of an agreement between public bodies, property developers and landowners. Therefore, we focus on the collaborative strategies of actors and the implications of these strategies regarding settlements of costs and benefits.

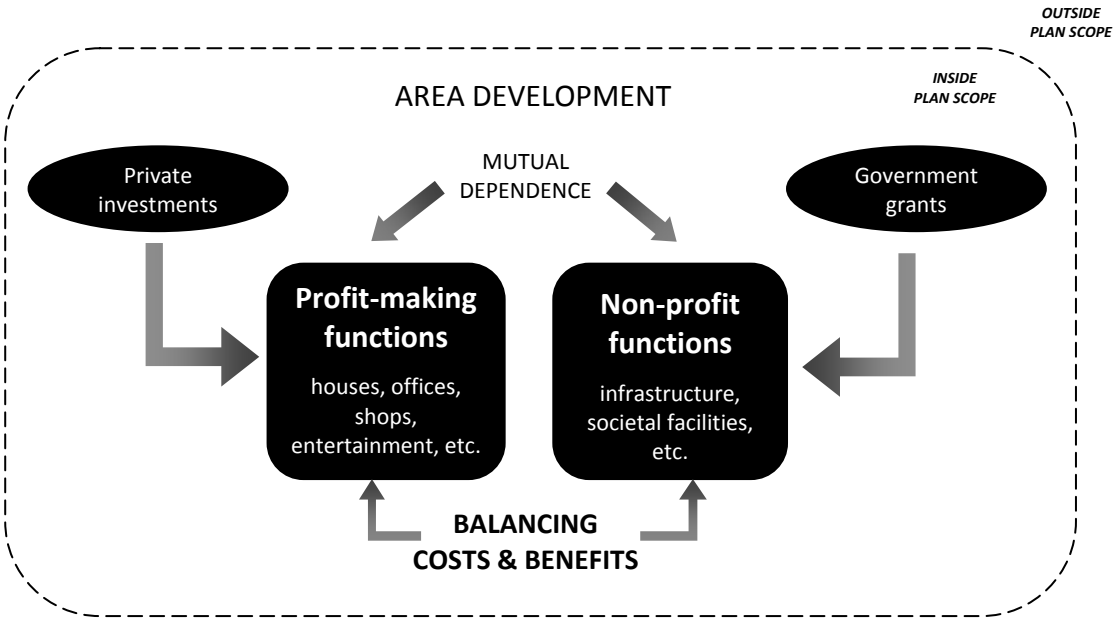

Figure 1: *Balancing costs and benefits*

RESEARCH METHOD

A premise of our research is that there is a strong relation between spatial quality, finances and process. In other words: preservation and re-use of cultural heritage adds quality to urban redevelopment projects, but requires substantial investments. To find the money needed, possibilities to integrate various uses and involve more actors are searched for during the planning process. In that way new value can be created for locations which have lost their old value and costs and benefits can be balanced. The question is then which collaboration between governments, developers, financers, users and people living in the neighbourhood contributes to fair settlements on costs and benefits and how this influences effective transformation of the cultural heritage. Therefore, the emphasis in our research is on the collaborative strategy used.

To develop such strategy we adapt the design oriented- approach, developed by Van Aken (2004). The design approach is pragmatic and the knowledge is to be applied by practitioners (Van Aken, Berends et al. 2007). The results of the design approach are so-called technological rules (van Aken, 2004) *"if you want something like x, in setting z, than do y"*. In our research: 'x' would be the effective transformation of cultural heritage; 'z' is the

network of actors in an urban redevelopment project, and ‘y’ is the collaborative strategy to make financial agreements to balance costs and benefits. To reach greater understanding of the relation between x, z, and y, a first step is to gain insight in the specific characteristics of urban development projects with cultural heritage and the bottlenecks experienced by stakeholders in the process to transformation. For this purpose we analysed five urban redevelopment projects in the Netherlands, in which the re-use of cultural heritage plays an important role.

These projects were selected based on the following criteria: 1) redevelopment of an entire area instead of a single object; 2) multiple functions, the aim is to develop several different new uses (not only housing) in mutual coherence; 3) one or more buildings in the area are considered to be of cultural-historical value and the aim is to re-use these buildings; 4) the area has to be urban, located inner-city or at the border of a city, and 5) the project should be in the planning stage, thus in other words, plans for redevelopment are being made but stakeholders are (for some parts of the project) still searching for appropriate new uses that are financially feasible. Side conditions were access to project documentation and the willingness of the project managers to participate in interviews.

To study how the processes in these projects develop towards settlements on costs and benefits we chose to vary the context as less as possible. Therefore, we only studied projects in the Netherlands. So, in this research institutional factors do not have the status of variables which can be optimized to attain agreements on costs and benefits. The first four criteria are related to the context of the projects. The last criterion is important as we aim to identify the current substantive bottlenecks and interaction processes among actors. The projects we selected are Wagenwerkplaats (Amersfoort), Spoorzone (Tilburg), Hart van Zuid (Hengelo), Hembrugterrein (Zaanstad) and 't Vaneker (Enschede).

For each of these projects, we conducted at least two face-to-face interviews. The interviewees were the project managers of the leading organisation for transformation of the cultural heritage. Besides, four meetings with the project managers were held to discuss the findings. For each project we also carried out a document analysis. Among others, master plans, official decision documents of the city council, studies of the cultural-historical elements, progress reports and (initial) agreements among parties were analyzed. The analysis gave insight in the physical-spatial characteristics of the projects, the stakeholders and organizational setting, and the bottlenecks experienced with transforming cultural heritage. We confronted this data with literature on planning. Together, these provide the building blocks for a framework to be used in a more in-depth analysis of strategies for balancing costs and benefits of cultural heritage.

PROJECT DATA

Project description

The Wagenwerkplaats in the city of Amersfoort (145.000 residents) is a former maintenance area for railway carriages of the Netherlands Railways Company (NS). The area with two maintenance buildings, the boilerhouse and the smithy, was build in 1908. In 2000 NS closed down their maintenance workplace and the area lost its use. NS is now developing and realizing a vision to create an area of commercial cultural activities. Some buildings have already been restored and are currently used by an architect company, the CliniClowns education centre and a theatre.

Spoorzone Tilburg, in the city of Tilburg (205.000 residents), is another former railway workplace. The central area, where various buildings of cultural historical value are located, is part of a large urban restructuring project that is to be realized around the central railway station. The redevelopment should result in a dynamic, playful multifunctional area for arts, theatre, education and living, with an old industrial atmosphere.

Hart van Zuid is a former industrial area just south of the city centre of Hengelo (75.000 residents). In 1854 Stork and Dikkers settled their headquarters in the area and produced, among others, large engines and pumps. In the 1980's the economic growth stopped and the company moved a part of its production processes to other countries. Currently, most of the buildings are not in use anymore and there is a opportunity for the municipality to strengthen this part of Hengelo and create an area of added value to the city. One of the heritage buildings is already in use as a large scale educational centre.

Hembrugterrein is a former military area in Zaanstad (150.000 residents). From 1895 till 1970s the area and the buildings were used for producing, testing and storing ammunition. The area has a green character with 62 registered monuments (of 120 military buildings in total). Besides built heritage, also a stretch of woods to muffle explosions of ammunition tests and former gas pipelines are indicated as monuments. In 2003 all activities stopped and the area was abandoned. Although actors agree that it is a unique area with many opportunities, all planning attempts failed so far. Recently, a start is made by creating opportunities for creative artists and companies to temporarily hire buildings and opening the area for public.

't Vaneker is also a former military area, situated between the Airport of Twente and the city centre of Enschede (157.000 residents). There is an old fenced military complex, called "Het Zuidkamp", which was build in 1940. The municipality is developing this area to a high quality living area in the specific green landscape of Twente.

Not registered as monuments. Main parties signed covenant how to deal with valuable buildings.	62 official registered monuments: buildings, stretch of wood, small elements	Buildings. Not registered as monuments.

***Table 1**: Physical-spatial characteristics*

The cultural heritage - officially registered or considered to be of cultural historical value - gives these areas a unique character and identity. The unique character and the apparent opportunities keep attracting new ideas of governments and developers. However, many

redevelopment attempts fail. Appropriate new uses have to be found for the buildings to be able to preserve them. This requires high investments, while the benefits are difficult to express in financial terms and – due to environmental issues – are often in a far future. Besides, the presence of monuments in most projects entails additional regulations. These characteristics make transformation of cultural heritage in urban redevelopment projects a complex challenge.

Organizational setting

In all projects multiple stakeholders are involved in the planning process. Resources needed to redevelop the areas are divided among various parties. A person or group who has a vested interested in the success of a project and the environment within the project operates is called a project stakeholder (Olander and Landin, 2005). As mentioned before, in urban development practice, balancing of costs and benefits usually takes place in the context of an agreement between public bodies, property developers and landowners. They own, decide, invest and/or have the knowledge and other resources to develop the area. Therefore, we focused primarily on the roles of these parties.

	Wagenwerkplaats	Spoorzone Tilburg	Hart van Zuid	Hembrugterrein	Het Vaneker
Leading role (project management)	Private developer (NS Poort)	Municipality	Municipality & Private developer	Central government	Municipality
Landowner(s)	NS Poort	Municipality	Multiple	Ministry of Defence	Municipality and Province
Public authority	Municipality	Municipality	Municipality	Province and Municipality	Municipality
Property developer	NS Poort	Volker Wessels	Van Wijnen BV	X	X
Cooperation agreement?	No, Informal deliberations between NS Poort, municipality and citizens that live near the plan area	Yes, A Public Private Partnership of the municipality and Volker Wessels	Yes, A Public Private Partnership of the municipality and the Van Wijnen Group	No, Informal steering committee of central government, municipality and the province	No, Municipality prepares and sells the land primarily for housing

Table 2: *Organizational setting*

It appeared that the roles of various types of stakeholders vary substantially. In some projects, the municipality is the leading actor, while in others they are only involved as public authority. Land ownership and the perception of urban development possibilities seem to be the important influential factors for the differences in roles.

Landowners, public bodies and property developers contribute to the costs of transformation in different ways. Their benefits are also quite different. Besides, they have different interests. In general, public bodies strive for societal benefits, while property developers have financial gain as their primary goal. Table 3 provides an overview of the division of costs and benefits among stakeholders.

	Wagenwerkplaats	Spoorzone Tilburg	Hart van Zuid	Hembrugterrein	Het Vaneker
Costs of maintaining the cultural heritage (before redevel.)	Private developer (NS Poort)	Municipality	Private owners (Stork e.a.)	Central government	Municipality
Risk-bearing investor in cultural heritage	NS Poort	Municipality VolkerWessels	Municipality VanWijnen	Not yet known	Future buyers

Actors who (financially) benefit	NS Poort and surrounding neighbourhoods (housing corporation)	Municipality, Volker Wessels, surrounding real estate owners	Municipality, Van Wijnen surrounding real estate owners	Not yet known	Unknown
Current balancing costs and benefits	Indirect as NS Poort is both landowner as developer.	Indirect in PPP construction	Indirect in PPP construction	Still too many uncertainties.	No expected free rider behaviour
Perceived bottlenecks for balancing costs and benefits	Environmental regulations; Planning in phases; Accessibility of the plan area	Current market situation; No feasible new uses yet; Ground pollution	Current market situation; No feasible new uses yet	Environmental regulations; Ground pollution; Many cultural heritage buildings in decrepitude; Inflexibility of municipality	No appropriate financially feasible new uses yet

Table 3: *Overview of the division of costs and benefits among stakeholders*

Uncertainties and complexity in transformation

The analysis shows that all projects have to deal with quite similar difficulties in the process towards effective transformation of the cultural heritage. Firstly, although in the long term returns on investments are generally expected to be positive, the initially needed financial investment are often far higher than in a situation without cultural heritage (Saris, Dommelen et al., 2008; Bade and Smid, 2008). The former industrial or military activities frequently caused heavily polluted ground. This pollution needs to be cleaned up to make new use possible. The costs for sanitation are high. Furthermore, there is often substantial uncertainty, as these costs can only be calculated precisely after the sanitation started. This uncertainty makes initial agreements more difficult. One of the involved actors states: *"due to the ground pollution, the project keeps stagnating"*. Costs to make re-use of the cultural heritage buildings possible are also high. For example, only conserving a (large) building costs about a million. This includes as much as repairing the roof so the building will be wind- and waterproof. Even more investments are needed to adjust the buildings to the current standards of working and living.

Secondly, not all possible new uses are considered appropriate and the ones that contribute to the unique character of the areas are often non-commercial. A manager of one of the projects states "*For some parts of the area it is really hard to find a suitable new use, that does justice to the cultural historical character and is, at the same time, financially feasible"*. Regulations for officially registered monuments limit the possibilities for adapting the buildings. Housing

is often excluded due to environmental regulations of noise, air quality, dust, smell and external safety in the specific areas. As housing is one of the most commercial new uses, these limitations make returns on investment uncertain. Furthermore, non-commercial uses contribute positively to the specific character of the industrial heritage buildings. For example, these buildings attract budding artists for a studio but they cannot afford high rents.

Thirdly, the tangible and intangible returns are uncertain as the added value of the transformation of cultural heritage can rarely be expressed in financial terms alone (Linssen, 2009). The interviewees were asked what their perception of success was of the urban redevelopment project. One project manager said: "*You can look at success in such a project in two different ways: as an accountant who will define success as selling the area for a good price. However, you can't run an area like this as an accountant. You need vision and inspiration. It has to become a beautiful urban neighbourhood, where you can feel the former atmosphere, and still see history".* Another project manager described success as: *"the project is a success when my children walk through the developed area and say that they are proud that their dad took care of saving the historical buildings."* All the interviewees stated that preserving gives additional quality to the area. "*Investments in cultural heritage will make the rest of the area attractive and will strengthen the image and identity of the project".* However, the end users determine what "atmosphere", "identity" or "history" is worth. They have to be willing to pay more for the additional quality by preserving the cultural heritage buildings. In most of the projects they do. One interviewee states: *"For example, the prices in the surrounding neighbourhoods are already rising. Before, the municipality did not invest in these areas as it wasn't profitable, but now there are even private development initiatives. The story sells".* However, what future users are willing to pay extra is difficult to determine beforehand. So, the value of cultural heritage is difficult to express in financial terms and 'believing' in the added value of the transformation is vital.

Summarizing, transforming cultural heritage in urban redevelopment project is complex as 1) initial investments needed are far higher than in greenfield development; 2) finding feasible new uses that contribute to the ambition to preserve the unique character is difficult and; 3) the tangible and intangible benefits are uncertain at the start of the process and are hard to express in financial terms. Current economic developments make financing urban redevelopment projects even more complex. Risk adverse behaviour of financial institutions and decreasing government funds especially endanger these projects. Subsidizing non-commercial elements is less an option. The situation is described by one of the interviewees "*the market situation makes development difficult. The budget may not be enough. We ask ourselves, do we need to slow down the project? But this is not desirable. Currently, the municipality is in hard negotiations. Developers knock on our door for subsidies. How can you develop now? […] How can investors have financial returns? If you cannot make benefits because you preserve the cultural heritage, no developer wants to invest."*

TOWARDS AN ANALYTICAL FRAMEWORK

As previously indicated, collaboration resulting in balancing costs and benefits between actors involved helps to preserve and transform cultural heritage in urban redevelopment projects. *"Success of the project depends on the possibilities to balance the costs and benefits of the total urban development project, including the investments needed to transform the cultural heritage".* Balancing of costs and benefits is indicated as a crucial instrument. "*Balancing of costs and benefits is the only option to preserve cultural heritage. It stimulates*

the right development and should be seen as a kind of loan beforehand". However, settlements regarding costs and benefits are not easily to attain. The projects are characterized by many uncertainties in costs, new-uses, and benefits. Hence, a straight forward answer to the question what strategies will realize effective transformation of cultural heritage cannot be given.

The complexity is mainly causes by the mutual dependency of the actors in the urban redevelopment projects. Knowledge, resources and authority are fragmented and dispersed, so planning decisions on what to do with the cultural heritage and how to make arrangements on costs and benefits involved require interaction among multiple actors. They have to make decisions about their abilities to act and their commitment to future actions that will satisfy their (financial) interests (Forester 2006). However, the actors in these projects cannot command other actors whose cooperation is vital, so negotiation to reach decisions regarding the content of the plan and (financial) settlements is needed (Koppenjan and Klijn, 2004). Thus, planning for these projects is essentially joint decision making, which is in turn inherently transactional (negotiated) (Shmueli et al, 2008). In literature four key elements of negotiation are distinguished (Lax and Sebenius, 1986) 1) mutual dependency among actors to realize their objectives; 2) some perceived conflict, as competing claims; 3) opportunistic or strategic behaviour of the actors, and 4) the possibility of agreement which is mutual beneficial. These four conditions are present in urban redevelopment projects in which re-use of cultural heritage is an important component.

In general, negotiation consists of both cooperating and competing elements, which makes it difficult to create mutual gains. At a certain point in the process, created value - for example by redeveloping the cultural heritage for new use - has to be divided and a claim on the increased value by one party implies there will be less for others. This tension between creating and claiming value is called the *negotiators dilemma* (Lax and Sebenius 1986). Value creators are the actors who are inventive and cooperative, in search for a win-win situation. This behaviour is contrary to value claiming behaviour in which actors try to convince the other actor of their own right. Leeuwis (2000) distinguishes two broad categories negotiation processes: distributive and integrative negotiation. In a distributive negotiation process the various stakeholders hold on to their own perceptions and positions, and basically use negotiations to divide the added value. The source of conflict remains intact, which leads to an unstable compromise. The result is a win-lose situation; the gains of one party represents the losses of another. For example, the developer’s goal is to get the highest possible return on his investments in the commercial real estate, while the municipality wants to capture (a part of) this return as their investments in the cultural heritage adds value to the developer’s real estate. If the municipality gives in, they have to fully bear the costs for preservation of the cultural heritage. If they do not give in and the developer is not willing to contribute, the realisation of the complete urban development might be endangered. In case of integrative negotiation, the stakeholders develop new (and often) wider problem definitions. Through interaction the actor learns about the nature of the problem, the possibilities for (joint) problem-solving and about other actors (Koppenjan and Klijn, 2004). They change perceptions on the basis of a creative collective learning process, resulting in the identification of so called win-win solutions. The result is similar as is intended with participatory processes (Leeuwis, 2000). For example, the municipality and the developer learn about the value of cultural heritage from both actors' perspective. Instead of negotiating on who has to contribute what, they search for possibilities to combine functions and for other actors to join the process. Communicative and strategic action is in many ways two sides of the same coin. Learning and negotiation are intertwined "effective social

learning is unlikely to happen if it is not embedded in a well-managed negotiation process. At the same time, effective negotiations are impossible without a properly facilitated social learning process" (Leeuwis, 2000).

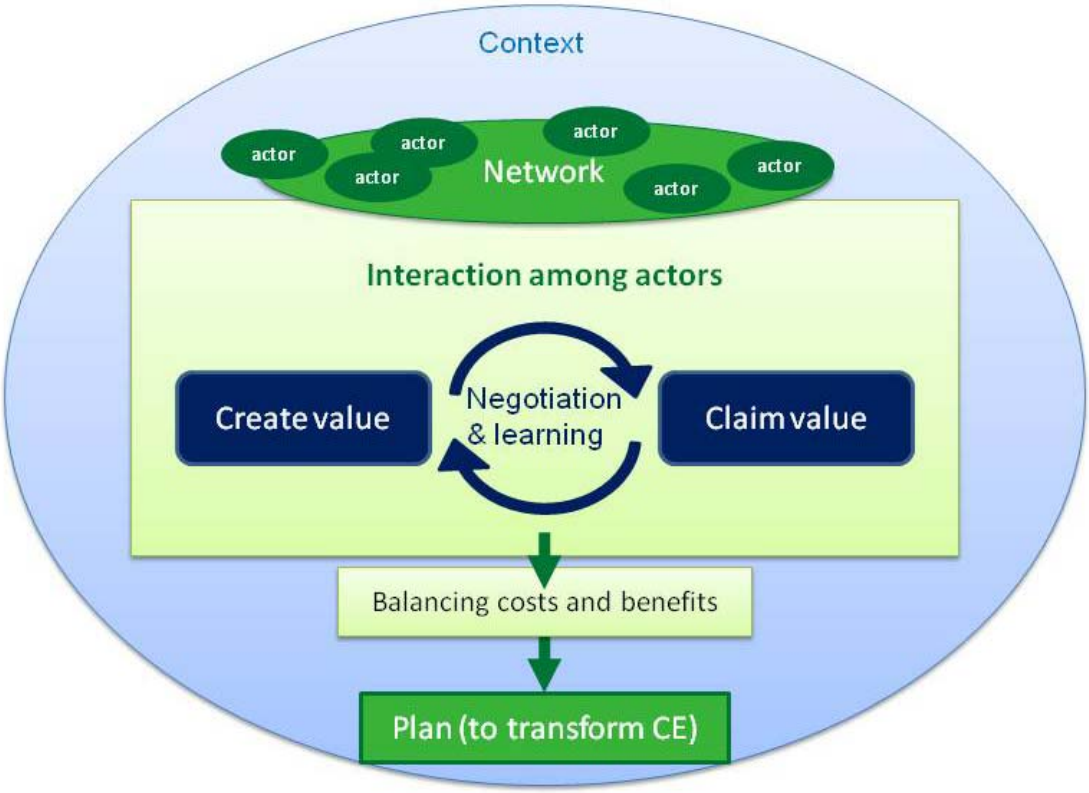

Figure 2: *Framework for analysis of the process to transform cultural heritage*

In conclusion, in order to effectively transform cultural heritage in urban redevelopment, a win-win situation is needed. In cultural heritage projects, a win-win situation can be considered as a mutual beneficially agreement on costs and benefits between actors involved, whereby the cultural heritage is preserved by transforming it for new use. During the planning process, actors will negotiate and learn. We argue that learning and negotiation, or creating and claiming value, go hand in hand, as stakeholders in these projects cooperate and compete with each other at the same time. In this 'game' of interaction actors try to deal with the uncertainties of the project. The context of the project, the network of mutual dependent actors, the actors´ characteristics and the interaction among the actors determine the plan-making process (De Kort, 2009). Together, these elements influence the possibilities to re-use cultural heritage in urban redevelopment project. They form the basic building blocks of a general framework to be used in a more in-depth analysis of strategies used to redevelop cultural heritage.

DISCUSSION

In this paper we presented the characteristics of five urban redevelopment projects with built cultural heritage and the difficulties stakeholders in these projects have to tackle in the plan-making process, in order to achieve effective transformation of the heritage for new use. Based on the empirical data and a study of literature on planning and negotiation we presented a general framework to be used for further analysis. The next phase of our research

will consist of a more in-depth study of the five cases in order to understand the negotiation processes and how these processes develop towards arrangements on costs and benefits. This requires that the building blocks of our framework are further made operational. For that some dilemma's have to be overcome.

Firstly, it is hard to measure performance in urban redevelopment projects in general. Often used performance criteria in planning projects are: efficiency, effectiveness and relevance (Walter and Scholz 2007). Efficiency refers to the relation between means and outcomes. Effectiveness is related to how well the proclaimed objectives of the project are attained. Relevance indicates the accuracy of a solution to the targeted problem. As urban restructuring projects have a long time frame and objectives will change during time, measuring these criteria will be difficult as the projects will not be finished in the next 10 years. Furthermore, proclaimed objectives are abstract and probably there will be no consensus on operational level. In a context of interdependencies, performance partially depends on the perception of actors (De Bruijn and Ten Heuvelhof 2008). Performance indicators that can be used, are: actor satisfaction; solved problems of the actors involved; learning, as the actors were confronted with new issues and information; lasting relations and; a fair process with equal chances and respect to core values (De Bruijn and Ten Heuvelhof, 2008; De Graaf 2005; De Kort 2009). In the projects, the sum of perceived performance of individual actors will not be – by definition - the performance of the total project. Therefore, to evaluate the performance of the transformation projects, we plan to use process (actor satisfaction, solved problem, learning) and project (expected efficiency and effectiveness) criteria.

Secondly, distinguishing creating or claiming behaviour in the process is difficult. We argue that negotiation and learning are intertwined and creating and claiming go hand in hand. However, as we want to gain insight in the relation between the used strategy and the performance, we need to measure these aspects somehow. From literature, we can define conditions which have to be met for creating or claiming value behaviour to occur and then study these conditions in the projects. Another possibility is to use a more grounded approach. In an open interview interviewees describe the main events in the process, their actions and the effects of their action. Afterwards, the data will be analysed and coded to link their stories to creating and claiming value. In this way we will be able to define creating and claiming value.

We hope that this paper contributes to a more profound discussion on the transformation of cultural heritage in urban redevelopment. We welcome feedback on this paper and suggestion to cope with the presented dilemmas for further research.

Abstract
This paper examines published construction data sources available to researchers, construction professionals, clients and government policy makers in South Africa. The paper explores whether the authenticity of these data sources are reliable and accurate because there are assumptions and processes behind the computation of the data sources which are unknown. The rationale for the examination of these documented construction data sources stems from the argument put forth by scholars that a significant number of these data sources have loopholes and black holes and therefore need to be verified. The paper intends to identify authentic South African construction data sources which can be used in construction data analysis and propose possible methods that should be used in preparing valid construction data sources for publication.

Keywords: Construction Data, Data Sources, Cost Indices, and Industry Performance

INTRODUCTION

According to Ofori (1990) construction is considered to be a sector comprising a number of industries. Sawhney, Walsh and Brown IV (2004), opined that the construction industry consists of a vast array of contractors, sub-contractors and suppliers, resulting in a very complex supply chain. According to Sawhney et al (2004), there are no formalized industry structures that represent all of its stakeholders and its primary output is a series of projects, each resulting in a unique constructed facility. The United Nations (1998) in Ruddock (2002) defines construction activity when used in the compilation of construction statistics as an economic activity directed to the creation, renovation, repair or extension of fixed assets in the form of buildings, land improvements of an engineering nature and other such engineering constructions as roads, bridges, dams and so forth. Data is regarded as a measurement scale consisting of information, facts and statistics such as cost information used for reference or analysis (Agresti, 2007 and Ofori, 1990). Construction data can therefore be said to mean the information, facts and statistics used in the industry in which fixed assets are erected, renovated, repaired or extended.

The aim of this paper is to explore whether the assumptions and processes behind the development of the published construction data sources available to researchers, construction professionals, clients and government policy makers in South Africa are authentic, reliable

and accurate because according to Patil (2010) and Mc Cabe (2002), there are assumptions and processes behind the computation construction data sources, which are unknown. Furthermore, Ruddock (2002) opined that the ability to provide full conformity with the International Standard Industry Classification (ISIC) is lacking to varying degrees in different countries.

Ofori (1990) noted that owing to the large number of geographically scattered sites from which data needs to be collected, the multiciplicity of enterprises involved and their often transient nature, the widespread practice of subcontracting and the risks of omission and double counting that that involves, and the difficulty of defining the boundaries of the industry, statistics on the construction industry are seldom accurate. This view is further corroborated by The World Bank (1984) publication cited in Sawhney et al (2004) which observes that the construction industry is typified by temporary, contract-driven relationships between participants of a given project, and this condition makes characterization and collection of national statistics for cross-country comparison very difficult to satisfactorily achieve. While, Lopes (1998) in Ruddock (2002) referred to the inadequacy and rudimentary nature of data on the construction industry in developing countries pointing out the lack of input-output data in such construction sectors. There is also the added problem of several agencies within a country collecting data on the construction industry in different formats and in relation to different criteria, even where the subjects are similar, leading to unnecessary processing problems (Ofori, 1990 and Ruddock, 2002).

In order to examine the assumptions and processes behind the development of the various data sources available to the construction industry in South Africa and to determine their authenticity, reliability and accuracy, this paper firstly presents the holistic methods used in the compilation of construction data – including definitions and descriptions of the data. Secondly, the paper identifies the published construction data sources and information available to users in South Africa. Thirdly, the paper reviews the assumptions and processes used in compiling the construction data in South Africa and the limitations of the data if any in order to establish the authenticity, reliability and accuracy of the available sources. Finally, the paper proposes possible methods that could be used in preparing valid construction data sources.

HOLISTIC METHODS USED IN THE COMPILATION OF CONSTRUCTION DATA

The construction data to be used in the paper will be mainly related to the resource costs, construction cost indices, all in rates of major items of work, labour cost, national statistics such as GDP, income per capita, construction industry performance indices and so forth. The focus on cost (quoting O'Brien and Al-Soufi (1993)) is due to the fact that it continues to be the dominant dimension in construction with its use of competitive tendering, commodity suppliers and sub-contractors.

According to Ofori (1990) there is a wide range of sources used to gather construction data including direct reporting by contractors, federal government regulatory agencies, and federal, state and local government agencies engaged in construction activity. He further stated that construction data can be obtained in surveys, on a sample basis with estimates made for enterprises not responding to the questionnaire and those not surveyed. In some cases, Ofori (ibid) noted that the data relates only to major conurbations and sometimes only to certain category of projects – location e.g. cities, government construction units, new construction,

value, and method of procurement – e.g. traditional, size of establishment by number of employees, licensed and registered construction establishments, tax inclusion or exclusion.

The accuracy of the compiled data has been a topic for consideration before now. Remer and Buchanan (2000) quoted in Sawhney, Walsh and Brown IV (2004) indicated that as much as 50% variation between estimated and actual construction cost has been found to exist depending on the level of effort expended as measured by the cost of the estimation preparation process. As a result, Sawhney et al (2004) observed that wealthier nations are likely to be willing and/or able to devote the effort required to obtain accurate estimates for a standard project and that less wealthy nations may not be willing or able to do so, and as a result, may develop less accurate estimates.

To improve the quality of international (and national) data provision generally, Lievesley (2001) in Ruddock (2002) in his suggestion noted the fact that, although the term 'quality', when applied to official statistics is difficult to define, the following components should apply: (1) validity, (2) reliability, (3) currency, (4) clarity and transparency with respect to known limitations and (5) comparability through adherence to internationally agreed standards.

Construction data according to Sawhney et al (2004) should have the following important characteristics:

- A relatively shortlist of items, in order to minimize the effort required to collect the data
- Incorporation of productivity and the labour/equipment tradeoff into the result
- Items on the list should be representative of construction work performed in each country, meaning that they should be things that actually occur routinely rather than items with artificial pricing due to scarcity of use or lack of demand, and
- Items on the list should be comparable between countries, meaning that they should be as equivalent in objective and perceived value as possible in every country.

Methods used in the compilation of construction data as presented by Sawhney, Walsh and Brown IV (2004) and Mc Cabe, O'Grady and Walker (2002) include: -

- Standard Project Methods which incorporates output indices
- Basket of Goods and Services Approach which incorporates the input indices, and
- Construction component/hybrid based approach

Standards Projects Method (SPM)

According to Sawhney et al (2004), the Standard Projects Method (SPM) was pioneered by Eurostat, and adopted by the United Nations as part of the International Comparison Program (ICP) around 1970. In this method, around 20 standard construction projects are identified for the three basic construction types, i.e. for residential buildings, non-residential buildings and civil engineering works. The projects are documented with a complete set of construction drawings, construction specifications, and bills of quantities for each of the projects. The Bill of Quantities (BoQ) lists basic work items from which the standard project is comprised, and is used in the pricing process (United Nations, 1992 in Sawhney et al, 2004). Pricing of the standard project is done with the help of government and professional quantity surveyors, architects, cost estimators, or civil engineers with some regional modifications. The SPM can be used in gathering output indices. Output indices measure the total cost of construction of a completed structure in each location (Mc Cabe et al, 2002).

The limitations of output indices and the SPM method is that it is a highly complex data collection process and it is extremely difficult to collect the information, usually requiring significant estimating resources (Sawhney et al 2004 and Mc Cabe et al, 2002). Furthermore according to Sawhney et al (2004), it requires specialized knowledge and knowledge of the wide variety of construction tolerances and acceptable quality that exists between nations. The advantage of this approach is that measurement of prices is at the output level and therefore includes productivity differences and the implications of the equipment/labour trade off in its calculation, and the fact that these indices more accurately represent the real costs of construction and reflect local conditions including labour skill, availability and productivity (Mc Cabe et al 2002).

Basket of Goods and Services (BOG) Approach

According to Sawhney et al (2004), the ICP utilizes a basket based on a comprehensive nationwide sample of goods and services on which money is spent in a country. Biru (1998) quoted in Sawhney et al (2004) notes that all expenditure components of GDP including purchases of capital goods and outlays are represented in the basket. The BGS approach is similar in content with the Input method reviewed by and Vermande and Van Mulligen (1999), who stated that the input method is based on the weighting of statistical input data (wages, materials and productivity) that is, a factor cost approach. While Mc Cabe et al (2002) viewed the input indices as representative of the construction process inputs such as common materials, equipment and trade labour hours.

The limitations of the BGS method were noted by Sawhney et al (2004) to include its inability to capture productivity very well and that even in cases where the basket includes labour items in most instances, the cost of a fixed number of hours of labour is reported, as it removes the labour/equipment trade-off from the results because no consideration is given to the degree to which some of the trades performed by labour are simplified by equipment use, and also representativity concerns. They opined that existing baskets in common use seem to concentrate on structural elements (concrete and steel principally), which may be appropriate. However, the advantages of input indices as noted by Mc Cabe et al (2002) include the fact that they are the simplest to produce and contain the least error and are useful if labour productivity can be assumed to be similar between the locations or if a general cost of construction comparison is desired.

Construction-Component Based Approach/Hybrid Index

According to Vermande and Van Mulligen (1999), the component method is applied in Germany, Austria, Luxembourg and Canada. They stated that the components, which constitute the basket for the statistical index, specify similar work operations as the building items of the Eurostat bills of quantities. Mc Cabe (2002) notes that the focus of the Hybrid index is on the smaller, more manageable building elements such as foundation walls, insulation or roof membranes to exploit the ease of input index development and the reliability of output indices.

Sawhney et al (2004) opined that it is important to develop a system that can be used to identify component contributions towards final construction output in the nation's GDP in order to establish weightings for the contents of a conceptual model to be called the basket-of-construction components (BOCC). According to them, the proposed model would require pricing of relatively few construction components, and the labour or equipment required to put them in place. As a result, material, labour and equipment costs could be inherently incorporated to whatever degree in a given nation.

PUBLISHED DATA SOURCES AND INFORMATION AVAILABLE IN THE SOUTH AFRICAN CONSTRUCTION INDUSTRY

The South African construction data sources and information reviewed below were used only because they were readily available to the authors. Most of the data reviewed are easy to access except for Quantec SA where access may need to be negotiated. While every effort has been made to provide a comprehensive study of the available construction data sources in South Africa, it is inevitable that some sources will have been unintentionally left out.

Statistics South Africa (Stats SA)

Statistics South Africa (Stats SA) is the national statistics agency in South Africa and it is mandated by government to undertake surveys, collect and process data and produce official statistics that will provide the private and public sector with reliable and relevant information. According to Barnes et al (2007), Stats SA's mission is to provide relevant, timely, reliable and accurate body of statistics to inform users on the dynamics in the economy and society through the application of internationally acclaimed practices.

From 1998/99, Stats SA has been developing a set of social statistics. Social and population projects such as the annual October Household Survey and the Population Census have been run to provide Government with critical data for planning and monitoring socio-economic development. According to Stats SA (2010), Stats SA has also emphasized improving the work processes, methodologies and technologies for generating key economic statistics by for example ensuring the compliance of statistical series with the International Monetary Fund and the United Nation's Standards.

Stats SA produces a variety of vital construction data including, GDP on both sectors and inflation, Consumer Price Index (CPI), Producer Price Index is calculated using specific formulas to determine the price escalations for the construction industry. Stats SA also gives a holistic overview of Employment Statistics through its published results of the Labour Force Survey. The Labour Force Survey, which was introduced in year 2000 to track poverty and labour market dynamics, are based on representative probability samples drawn from the South African population. Consequently, all estimates are subject to sampling variability.

South African Reserve Bank (SARB)

Through the South African Reserve Bank's (SARB) Quarterly Bulletin; one can access the National Account's Gross Fixed Capital Formation (GFCF) and the infrastructure spend on private and public sector projects on the Residential, Non-Residential, Machinery, Equipment and Construction Works. The economic data collected by Stats SA and SARB are prepared at various levels of aggregation. This may be illustrated using the CPI which is available at the national level as macrodata.

Industry Insight

Industry Insight offers a wide range of construction business intelligence and customized services these include; Project Database, State of industry reports, Statistics, Forecasts, Newsletters, Provincial Reviews, Preferred Supplier Trade Surveys, Price Indices, Electronic library. In partnership with other willing stakeholders; Industry Insight hosts a series of Focus Forums, in these Focus Forums industry players meet and discuss issues that affect the industry and this also serves as a platform to network and explore other industry opportunities that may be available for the stakeholders.

The Bureau for Economic Research (BER) Building Cost Index

According to Cruywagen (2010), the original BER Index was developed in 1966 by Brook, a quantity surveyor who was at the time responsible for research and development in the quantity surveying division of the Department of Public Works in Pretoria. Segalla (1991) cited in Cruwagen (2010) stated that the original Brook index was based on a variation of the cost items of a single storey, 100m^2 quasi-house.

Brooke (1974) cited in Cruywagen (2010) explains that the basic logic to the background of the development of the BER index involves the assumption that the total building cost will move in correspondence with the cost of the specific items selected for the purpose. The accuracy of the index will accordingly, depend on the degree to which the items are representative of the most common, and therefore the most widely used, construction and finishing materials. To this end, he stated that the items have been selected in such a manner that the resulting index will be indicative of relative cost levels not only for various types of buildings but also for various regions in the Republic of South Africa and also South West Africa (now Namibia).

Twenty-two cost components including excavation of footings, mass concrete footings, reinforced concrete in slabs and reinforcement were selected and expressed as quantities. These components are then weighted based on the proportions to the role played by each in the total cost, in which consideration had been given to the incorporation of basic design criteria which vary from the simplest one of the fundamental ratio of light or window area to the more complicated criterion of a predetermined floor loading in respect of the ratio of formwork, steel and concrete floor slab component.

By using the quantities (or weights) assigned to the components, an index is calculated for each specific project by multiplying the applicable weights with a rate supplied on a quarterly basis by quantity surveying firms, who submit BER calculation sheets for completed projects. The total amount obtained for each project is then expressed as a percentage of the amount obtained in the base month (Cruywagen, 2010). According to him, these project indices are then used to calculate the overall building cost index.

Davis Langdon Africa Region Property and Construction Handbook

Davis Langdon Africa Region Property and Construction Handbook (2010) highlighted the fact that construction cost estimation is complex and comprehensive exercises based on detailed accurate information are required to achieve reliable levels of comfort, for various undisclosed reasons however, it was revealed that decisions are often based on inclusive rate estimates i.e. rate per m^2 of construction area or rate per unit in number. It was emphasized that the list of approximate building cost rates for various buildings types in South Africa, which are available in the publication are purely of an indicative nature and should be used with circumspection, as they are dependent on a number of assumptions which were not given. The rates given are said to include the cost of appropriate building services, e.g. air-conditioning, electrical, etc but exclude costs of site infrastructure development, parking, any future escalation, loss of interest, professional fees and VAT. The area of the building expressed in m^2 is said to be equivalent to the 'construction area'.

Building cost for the purpose of the handbook is deemed to mean the tender price (or negotiated price) submitted by the building contractor. The handbook explains that the words building cost depends on the application thereof in context. A building contractor, for

example, may refer to building cost as the cost of labour, material, plant, fuel and supervision while in contrast, a developer may refer to building cost as either the tender price from the contractor or to the ultimate cost of the project, which could include professional fees, plan approval fees, escalation, loss of interest etc.

The Handbook allowed for regional variations. It explains that construction costs normally vary between different provinces of South Africa and that for example, costs in the Western Cape and KwaZulu-Natal, specifically upper class residential, are generally significantly higher than Gauteng due to the demand for this accommodation.

Support Programme for Accelerated Infrastructure Development (SPAID) Infrastructure Expenditure Tracker

Lockwood (2010) explains that in an effort towards the attainment of the public sector infrastructure programme's objectives, the Business Trust – with the Presidency as a strategic partner – established the Support Programme for Accelerated Infrastructure Development (SPAID). SPAID's goal is stated as being to provide focused support to mobilize an increased private sector contribution to meeting the Accelerated Shared Growth for South Africa (ASGISA) infrastructure targets, while its developmental objective is to ensure that underserviced communities have access to infrastructure.

The tracker includes comprehensive data on the level and composition of infrastructure spending in South Africa. Unpublished data was obtained from the South African Reserve Bank that enabled the estimation of the effects of fixed capital spending on the real value of the fixed capital stock, and the quantification of the consumption of fixed capital. Standardized industry data, which was used to assess trends in employment in the construction sector, in terms of both number and skills level was obtained from Quantec (Lockwood, 2010). Multipliers – also obtained from Quantec – were used to estimate the impact of public infrastructure spending on the wider economy in respect of indicators such as value added, remuneration and employment.

Typical information found within the body of the SPAID Infrastructure Expenditure Tracker includes the actual and projected infrastructure spending by the public sector, detailed breakdown of spending on different project types within each province, major projects by types, estimated cost, implementing agent and project completion date, changes in employment in the construction sector among others.

cidb Construction Industry Indicators (CIIs)

Though, the paper will mainly focus on resource costs due to the fact that it continues to be the dominant dimension in construction, mention need to be made about significant construction data being compiled on an annual basis by the cidb.

Construction Industry Indicators (CIIs) were developed by the Department of Public-Works and the cidb with the assistance of the Council for Scientific and Industrial Research (CSIR) in South Africa (Marx, 2009) to play a useful role in developing a sustainable industry and to be adopted as a tool for improving performance in the South African construction industry.

The cidb CIIs has been documented since 2003 and the variables used by the cidb to measure performance of the South African Construction Industry include: client satisfaction with project milestone dates achieved, construction costs versus budget, contractors' performance,

consultants' performance and the quality of materials used in construction. Figure 1 shows the Client Satisfaction results of the Construction Industry Indicators (CIIs) survey for 2009.

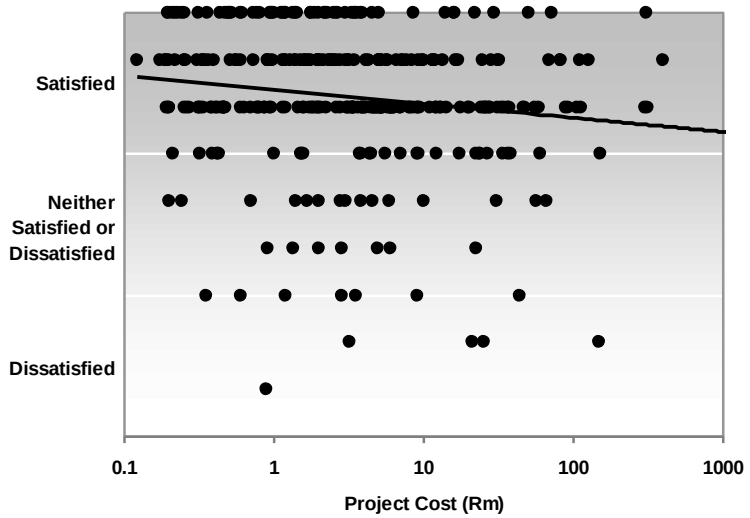

Figure 1: *Client Satisfaction (CIIs, 2009)*

cidb SME Business Conditions Survey

The SME Business Conditions Survey measures contracting business conditions amongst cidb registered contractors in Grades 3 to 7. The Survey measures, amongst others, the business confidence, and construction activity, tendering competition, employment and labour constraints amongst cidb registered contractors at a provincial level and in various contractor grades. The Bureau for Economic Research (BER) undertakes the SME Business Conditions Survey for the cidb.

The cidb has been undertaking Construction Industry Indicator surveys for the past three (3) years. The trends emerging from these surveys are used to initiate interventions in support of contractor development and the improvement of the overall contracting capacity in the country. Recently, the cidb initiated a quarterly registers monitor to study the registration trends across South Africa.

The cidb SME Business Conditions Survey aims to validate the findings of the internal surveys and provide deeper understanding of the business environment and needs of SMME contractors in order to develop responsive interventions. It must also measure access to work opportunities and the types and value of investments emerging contractors are making in their business across the different provinces. Where possible, the business confidence survey should correlate these to the overall economic climate in the provincial building and construction industry.

Fig 2. Below demonstrates the data that is captured on cidb SME Business Confidence.

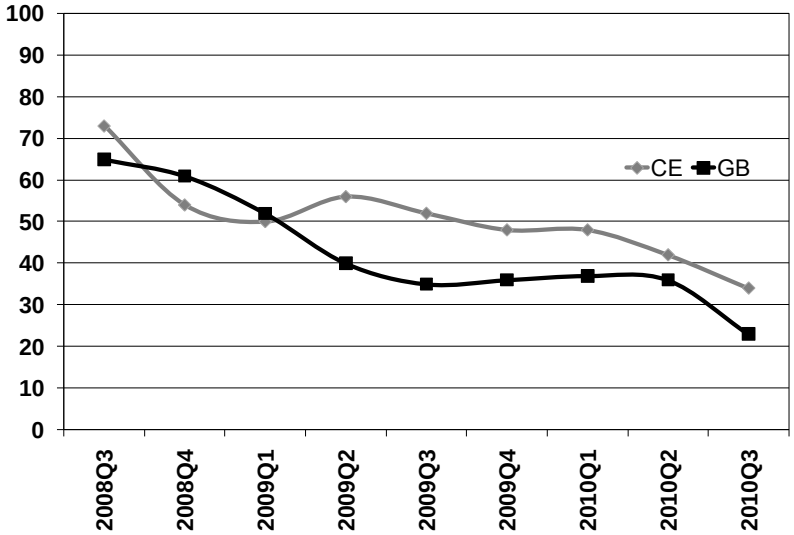

Figure 2: *cidb SME Business Conditions Survey (2010)*

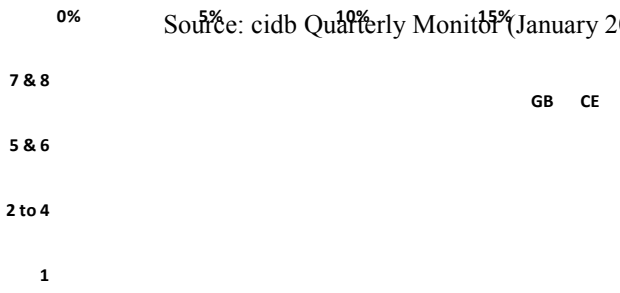
cidb Quarterly Monitor



The cidb Quarterly Monitor provides an overview of the state of contractor development in South Africa as input to developing targeted development intervention strategies in support of the National Contractor Development Programme (NCDP). The Quarterly Monitor focuses on public sector supply and demand at a provincial level, and deals only with the General Building (GB) and Civil Engineering (CE) cidb Class of Works.

Included in the cidb Quartely Monitor is the ratio at which the contractors are Upgrading on the cidb Register of Contractors as shown in Table 1 and Figure 2.

Table 1. Contractors Upgrade on cidb Register of Contractors

Upgrades; 201001 to 201004

Quantec SA

Quantec SA discusses the availability of the South African construction industry indicator time-series database that provides disaggregated and consistent long-term view of South Africa's economic structure by industry. The data is compiled by combining a consistent input-output framework spanning three decades with a comprehensive set of industry and national account indicators. The emphasis of the database is on the input and output indices.

SUMMARY OF DATA SOURCES

Table 2 summarizes the characteristics of the available construction data sources in South Africa. It gives an indication if the data types are input, component/hybrid, output or industry performance indices. It also indicates the level of aggregation of the data sources, and if the data provided can be compared along location indices and regions in South Africa. Other variables tabulated are the source of information whether from private or public agencies and the possibility of expressing the data compiled as a time series with a view to facilitating comparisons.

Data Source	Data Type						Location Indices	Availability of Time Series
	Labour (Input)	Materials (Input)	Equipment (Input)	Components (Hybrid)	Projects (Output)	Industry Performance Index		
BER Cost Index (Govt)				√				√
StatsSA (Govt)	√	√					√	√
SARB (Govt)					√		√	√
Davis Langdon					√		√	√
SPAID (Govt)	√				√		√	√
cidb CIIs (Govt)					√	√		√
cidb Quarterly Monitor (Govt)					√	√		√
cidb SME Business Confidence Survey (Govt)					√	√		√
Quantec SA	√	√	√		√		√	√
Industry Insight	√	√	√	√	√		√	√

Table 2 shows that only three private data sources - Davis Langdon Africa Property and Construction Handbook, Industry Insight construction management services and Quantec SA

are available to the construction industry in South Africa. Davis Langdon handbook, Stats SA, SARB, SPAID, Quantec SA and Industry Insight provide sources of construction data with location indices, though that of Davis Langdon handbook is not comprehensive in nature. It is important to consider location because South Africa covers a very wide expanse of land and that building costs are likely to differ across the republic due to social factors such as population, demand, income levels among others.

LIMITATIONS, AUTHENTICITY, RELIABILITY AND ACCURACY OF THE PUBLISHED DATA

Certain limitations were revealed in the compilation of the readily available construction data sources. For example, although the BER uses the component based hybrid method advocated by Sawhney et al (2004) in the compilation of data, researchers including Martin (2006) quoted in Cruywagen (2010) has expressed concern about the age of the index and that best practice is not followed any more in compiling the index. An indication that the BER is also worried about the correctness of the index is the fact that it commissioned an independent organization in 2005 to investigate whether the index measures changes in the cost of construction in South Africa correctly (Marx, 2005 cited in Cruywagen, 2010). Other major areas of concern regarding the BER index include the current item descriptions and the fact that the items are not in line with the latest version of the Standard System for Measuring Building Work – 6th edition as published by the Association of South African Quantity Surveyors, some of the materials referred to in the descriptions such as Asbestos roof covering and ceiling are outdated and the relative low number of projects sampled (Cruywagen, 2010).

The degree of accuracy of the rates provided in the Davis Langdon Handbook must be considered to be in direct proportion with the amount of research and study undertaken to establish the rate for the building (Sawhney et al, 2004). Furthermore, the publishers of the Davis Langdon Data Source emphasized the fact that the rates presented are purely of an indicative nature and should therefore be used with circumspection, as they are dependent upon a number of assumptions. This statement in itself has cast a doubt on the accuracy, authenticity and reliability of the Davis Langdon Data Source.

Stats SA and SARB make use of reliable methods in the compilation of the construction data sources published. Stats SA specifically makes use of representative probability samples drawn from the whole South African Population and ensures compliance of the statistical series with the IMF and UN Standards. The data presented is representative of all participants in the economy and for all levels of data aggregation

The construction data published by Industry Insight, Quantec SA and SPAID, rely heavily on the primary data obtained from Stats SA and SARB. The only inputs in these documents are the additional reports and insights provided based on further analysis and interpretation of the data obtained. The extent of reliability of their published data will therefore depend to a large extent on the authenticity of the data obtained from primary sources.

Methods used to obtain the data compiled in the cidb publication tend to be reliable and accurate, and based on information from a representative sample of contractors on the cidb Contractor Register and classes of works. The survey carried out by the cidb relates to

contractors who are mainly involved with government projects and it might not entirely represent unregistered contractors who are only involved in private projects.

Limitations identified on a global scale by Vermande and Van Mulligen (1999) is the difficulty with pricing of building specifications. According to them, building cost experts sometimes are not familiar with particular items, work operations or materials specified in the bills of quantities. Prices given can therefore be completely wrong. The case of the Eurostat surveys is considered to be more serious by Vermande and Van Mulligen (1999), due to the hybrid composition of a 'basket of building types' which has to be representative of all EU-countries, and due to the fact that Eurostat statisticians perhaps have too little construction experience.

CONCLUSION

Ruddock (2002) opined that if the national system cannot provide efficient access to micro-data bases, both business and governments will come to depend increasingly on private proprietary databases, and the advantages of an overall integrated system will be lost. The scenario in South Africa is such that a significant number of the available construction data sources are provided by the government and even the private data source obtains a significant part of its information from the government data sources thereby attempting to integrate the public and private sources of construction data suggested by Ruddock.

Seemingly therefore, there appears to be no visible loopholes and black holes in the computation of the investigated data sources in South Africa and all the data sources can be said to be authentic having made use of standard practices, save only for that of Davis Langdon handbook, wherein the fact was emphasized that the rates presented are purely of an indicative nature and should therefore be used with circumspection and the BER index of which scholars have expressed concern about the practice used in its compilation.

As a guide to construction data compilation in South Africa, it is recommended that samples should be used that will reflect the diversity and size of the country using accepted standards such as input, composite/hybrid and output methods.

ACKNOWLEDGEMENTS

The authors would like to acknowledge the support of the Construction Industry Development Board (cidb) and Dr. Rodney Milford, Programme Manager, Construction Industry Performance, cidb, for his guidance and valued contributions.

Abstract
The UK committed in 2008 to reduce its greenhouse gas emission by 80% by 2050. The construction industry is a key contributor to the greenhouse emissions and future legislative adjustments for the built environment are well underway. The industry will face many challenges and it is expected that its profile will be very different by 2050. The scenario that there will be pressure for the supply of labour, materials and components to be much more localised due to increased energy costs is very likely. In turn, supply chains, which currently are becoming increasingly long as the demands of projects become increasingly complex, will inevitably have to face the localisation challenge.
The long supply chains provide the increasingly high levels of technical input relating to design, manufacture, installation and servicing in the context of an industry anxious to maintain flexibility in the face of uncertain levels of workload and investment. These tall contractual hierarchies contain a massive amount of expertise but the contractual hierarchy constrains the effective management of knowledge and innovation through excessively long network paths, containing multiple, perversely incentivised, network bridges and gate keepers. Contractual relationships, knowledge management and information exchange networks define the localised supply chains and important work needs to be done to examine the potential for these networks to be established and be maintained. Social network analysis can be employed to map existing supply chains and to provide predictive models for local supply chains in 2050.
The paper discusses how to best examine what the capabilities of the local supply chains today are and what their capabilities would be if they were specifically enhanced to meet 2050 challenges. These capabilities inform supply chain management targets which mainly focus on continuous improvements of the supply chain increasing value and stimulating knowledge sharing and innovation. Sustainability targets are yet to be fully incorporated in the value equation, which is what the 2050 challenge requires; therefore particular attention is paid to it. It is suggested that exploring the location of intellectual capital in construction supply chains, demonstrating how the use of BIMs and vertical integration of the supply chain might be exploited to provide interfaces between local supply chain actors and end-users, examining the logistics and embedded energy, comparing the today's logistical demands with a 2050 localised supply chain scenario, is a starting point in developing the concept of the localised supply chain as a successful approach to the sustainability problem.

Keywords: Sustainability, Localisation, Supply Chain, Knowledge Management, Information Exchange Networks

INTRODUCTION

The UK‟s commitment to reduce greenhouse emissions by 80% from 1990 levels by 2050 has been the driving force for legislative changes; it has also raised issues associated with sustainable development and its meaning. Sustainable development has three dimensions; economic, environmental and social. Changes to accommodate the demanding environmental targets by 2050 have to deal with the forces opposed to the economic and social dimensions. It is generally perceived that the relationship between the economic and environmental dimensions require the negotiation of trade-offs, which is not always true because many of their objectives can be found to be perfectly aligned creating a win-win relationship (Quariguasi Frota Neto et al., 2010).

Increased public awareness and governmental regulations are imposed on various industries and as result many organisations and brand companies like Xerox, IBM, and Sony have initiated significant reforms in the entire supply chain systems (Lu et al., 2007). Supply chains not only get extended to include the end-of-life phase of products but also Supply Chain Management (SCM) principles are facilitated to improve the environmental performance of the manufacturing processes with suppliers and of products with customers (Lu et al., 2007). This is leading the most recent concept of Sustainable Supply Chain Management (SSCM), which advocates the integration of sustainability within SCM for successfully achieving the implementation of sustainability targets at business strategic level (Adetunji et al., 2008). The construction industry, which encompasses the design, construction and operation of the built environment, plays an important role on both the growth of the economy and the rate at which resources are being used. It is responsible for almost half the UK‟s carbon emissions (HM Government, 2008) and a similar proportion of its energy consumption (Miller, 2001). Legislative adjustments for the built environment are well underway and the industry is expected to face many challenges. Its profile will be very different by 2050. However, SCM‟s appropriateness, scope and ways of implementation in construction is still debated (Pryke , 2009) and only a few major clients and contractors have successfully implemented it in their business strategy for procuring projects (Adetunji et al., 2008; Pryke, 2009). The construction industry is lagging behind in its focus on SSCM because the debate is still on going on about sustainability and SCM as separate concepts and integrating them considerably increases the complexity of any discourse (Adetunji et al., 2008).

Supply Chain Localisation (SCL) could be considered as a bottom-up approach as its starting point is the study of transportation concerns and logistical implications for the greening of supply chains with the ambition to move towards the issue of SCM and SSCM. In other words, starting at an operational level to inform strategy. For that reason, the focus of the research might appear to be limited to solely the environmental implications and some associated economic factors. Construction supply chains might however be regarded as social networks, which affect and are affected by their surrounding environment.

This paper aims to introduce an alternative approach to the problem of making construction supply chains sustainable by advocating the importance of localisation. Presenting the paper in MISBE is considered the first step into refining the research problem posed and the appropriateness of the proposed method for future empirical data collection and analysis. Therefore, no empirical data or results are currently available.

WHY LOCALISATION? BACKGROUND

The consumption of natural recourses is a problem of two dimensions. One is the cost of the resource and the other its efficiency and therefore the price is a primary determinant of behaviour (Barrett et al., 2008). As the price of energy is expected to rise in the future it is highly possible that the supply of labour, materials and components will be significantly affected by it. For construction materials and components, particular attention must be given to the notion of embodied energy - the energy impacts of material and component production. The energy embodied in a material due to its transportation in most cases is small when compared to its total embodied energy and its quantification is typically oversimplified (Miller, 2001). This point is returned to later. It is, however, the transportation of labour that causes greater concerns. Efforts to reduce passenger transport by road have been made through traffic management approaches or land use changes requiring planning policy support (Barrett et al., 2008). Raising urban densities, which would result in shorter journey length and possibly replacing the use of cars with the use of public transport or even the use of non-mechanised transport such as walking and cycling (Barrett et al., 2008), is considered to be a move towards localisation or enhancing the supply of labour at local level.
Interestingly although many efforts are made to enhance the energy performance of operations and products, the demand for energy continues to rise (Barrett et al., 2008) and with it energy emissions. Through SCL, there is a need to consider increasing energy use performance but more so minimising the supply chain‟s dependence on energy. This could be achieved by identifying energy consuming processes and activities that could be omitted or replaced with others that require less energy.

SUSTAINABLE SUPPLY CHAINS AND THEIR MANAGEMENT

Focusing on the supply chain as a vehicle for accumulating value and improving efficiency is becoming increasingly important. Equally, the challenge to incorporate sustainability into business strategy has led many organisations to look at the activities of all supply chain actors in increasing detail (Lu et al., 2007). Therefore, consideration is given to the integration of sustainability and supply chains (Linton et al., 2007; Adetunji et al., 2008) in order to create sustainable supply chains. Sustainable development requires the triple bottom line of economic, environmental and social dimension to be satisfied (Linton et al., 2007; Quariguasi Frota Neto et al., 2010; Adetunji et al., 2008) and when integrating sustainability in supply chains their complexity increases significantly (Adetunji et al., 2008; Quariguasi Frota Neto et al., 2010).
Sustainable supply chains are extended supply chains, which include and integrate issues beyond the ones traditionally considered. These are product design, manufacturing and during product use by-products, product life extension, remanufacturing, products end-of-life and recovery processes at end of life (Linton et al., 2007). Their management moves from being reactive in the sense of monitoring general environmental management programmes to a more proactive direction through the implementation of energy/resource efficiency or reduction, re-use, rework, refurbish, reclaim, recycle, remanufacture and reverse logistics (Quariguasi Frota Neto et al., 2010). The end-of-life phase of the product life cycle has attracted particular attention and interest because this approach not only minimises waste but also captures any remaining value (Linton et al., 2007). This indicates a trend for sustainable supply chains to be „closing the loop" with the introduction of reverse logistics (Figure 1).

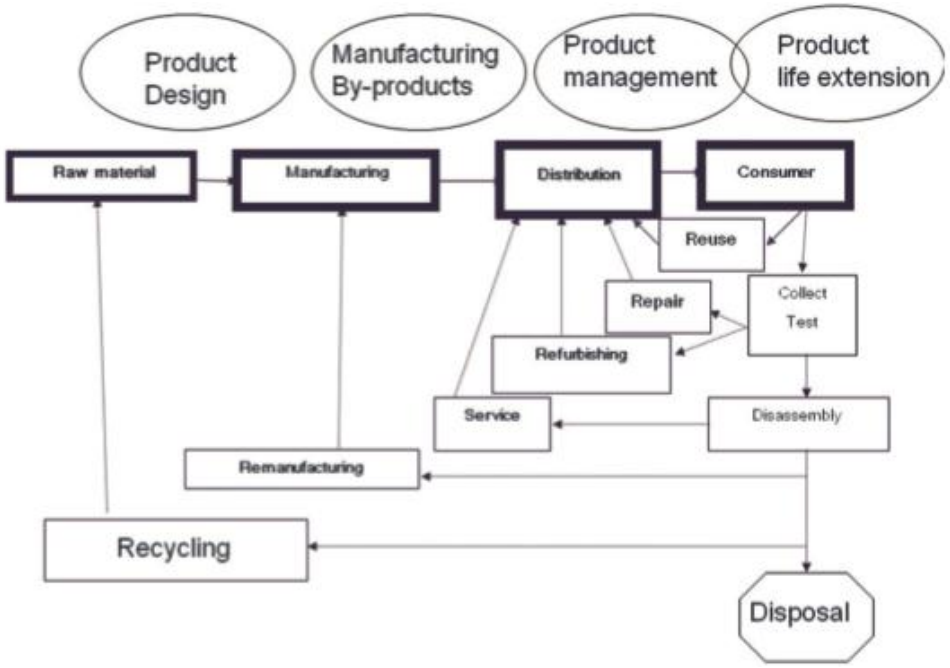

Figure 1: General framework of a closed-loop (sustainable) supply chain.
Source: Quariguasi Forta Neto et al., (2009), pg. 4465

Including the end-of-life phase, recycle and recover larger quantities of material are assumed to be proven measures to reduce the supply chain‟s environmental impact but this does not necessarily make it sustainable (Quariguasi Frota Neto et al., 2010). This is because energy consumption levels are not the same at the various phases of a product‟s life cycle and significant energy emissions do not always occur during the manufacturing process. Quariguasi Frota Neto et al. (2010) debated the sustainability aspect of closed-loop supply chains through the study of different electronic products‟ life cycles. Figure 2 illustrates how different the energy consumption profiles of products in an industry can be.

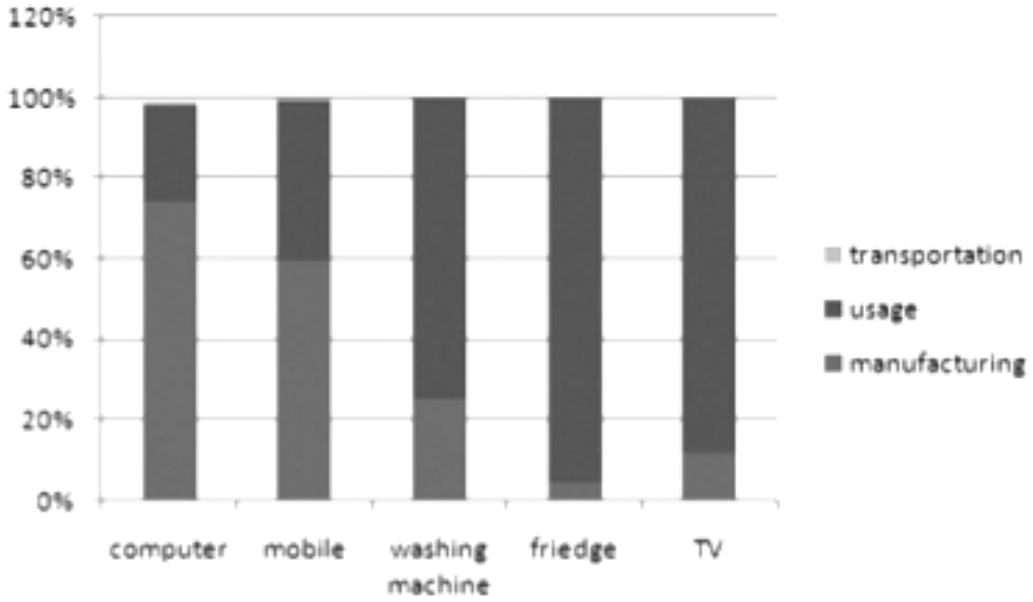

Figure 2: Energy consumption profile for PCs, mobiles, washing machines, fridges and TVs.
Source: Quariguasi Forta Neto et al., (2009), pg. 4470

The different consumption profiles prove that the scope of closing the loop of all supply chains might not be the most effective way of creating a sustainable supply chain. For the products that have high energy consumption levels during manufacture, the scope of closing the loop is very high. However, an alternative would be to extend the product‟s life cycle (Quariguasi Frota Neto et al., 2010), which is a product design consideration. For products with low manufacturing energy consumption, little improvement can be obtained via the adoption of end-of-life decisions (Quariguasi Frota Neto et al., 2010), and the maintenance service supply chains could be the focus for improvement to support the products efficient use of energy during its operation.

Energy consumption due to transportation is treated as negligible when compared to the total energy used for the production and operation of products and buildings. However, it is recognised that it is a significant source of cost in the supply chain and that, in extreme cases it can consume up to 8% of the energy needed over the entire life-cycle of a product (Quariguasi Frota Neto et al., 2010). Transportation is required for both the forward and reverse directions of the supply chain, and although it might be negligible in the forward direction, its energy consumption levels at the reverse direction become critical (Miller, 2001).

Buildings are responsible for almost half the country‟s emissions, about one third of landfill waste and use one quarter of all raw materials (HM Government, 2008). Efficiency in design, managing construction waste through increasing reuse, recycling or incineration, and reducing landfill waste are the main foci of the efforts aimed at making construction supply chains sustainable. The consideration of the energy consumption due to transport is almost non-existent as in common practice the energy embodied in the winning and manufacturing process is considered, which excludes the final delivery to the construction site (Miller, 2001). However, relative proportions of transport energy can vary greatly for different projects, which require different material and supply chains (Miller, 2001). The energy consumed in the delivery of materials can attribute 1.5% of the total embodied energy of materials for a new build project and up to 20% of the total embodied energy of recycled materials (Miller, 2001).

WHAT IS A LOCAL SUPPLY CHAIN?

Localisation in the context of this study is perceived in two dimensions, which should both be considered in the efforts of localising the supply chain. The first is the obvious dimension of geographical/ spatial location, which aims to shorten travel distances and stipulate local sustainable growth. However, this dimension is vulnerable to the energy efficiency of the transport modes available to the geographic area. Transport modes vary in their cost and impact with rail being 3.4 times more efficient than truck, barge 2.5 times more efficient than rail and 8.7 times more efficient than truck (Kendall et al., 2010). The second dimension is when supply chains are viewed as networks of production processes and localisation in this sense refers to the partial supply chains that are part or make-up the whole (global) supply chain (Albino et al, 2002). This dimension is highly relevant to construction because construction projects in addition to the construction (forward) and demolition (reverse) supply chains also require a Facilities Management (FM) supply chain. Also, construction supply chains require technical input of knowledge and expertise. Knowledge and information exchange networks can therefore be considered as partial supply chains. Localisation in that respect, therefore, allows for the efforts to minimise energy consumption at a local/ partial level of the supply chain. The importance lies into establishing localised

boundaries, which would effectively be different for professional services, materials, plant and labour.

THE SCOPE OF LOCALISING CONSTRUCTION SUPPLY CHAINS

As in the case of electrical products (Figure 2), different building types have different emissions profiles during their life cycle. Figure 3 present the percentages of embodied carbon and operational carbon for offices, warehouses, supermarkets and houses.

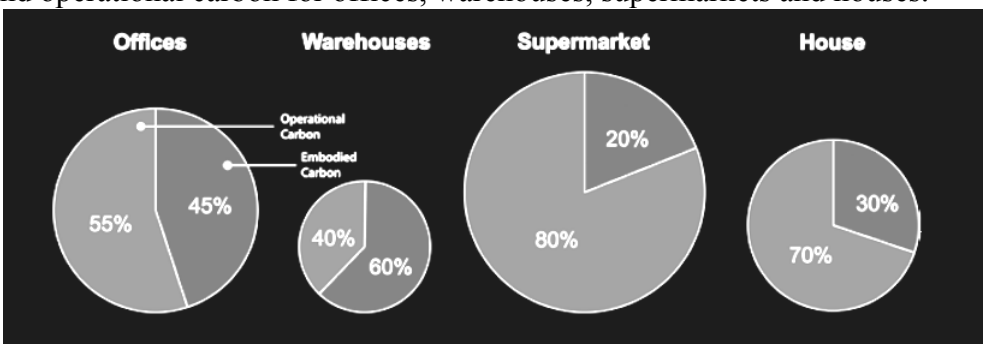

Figure 3: Typical different whole life Carbon splits for different types of buildings
Source: Sturgis & Roberts, (2010), pg 12

This can be treated as a guide on the construction phase‟s impact in comparison to the overall life cycle. It appears that SCL, in both geographical and at the construction/demolition partial supply chain dimensions, has a great scope for industrial buildings, where the embodied carbon percentage is much higher than the other building types. Having material production or recycling units in an industrial area does not raise particular planning implications, which could massively benefit the energy performance of the construction of new warehouses.
There is also scope for FM supply chains to become localised in areas where the demand for their services is high. FM is essential in maintaining the designed levels of energy efficiency of buildings. Therefore, for the building types where energy efficiency during operation is critical and more challenging to be achieved (e.g. offices), FM services, which in turn should minimise energy consumption, are expected to be in demand.

Key Themes	**Principal issues**
Economic sustainability 1.1 Improved project delivery	– Improved productivity
Environmental sustainability 2.3 Transport planning 3.1 Improved energy efficiency 3.2 Efficient use of resources	– Green transport plan of sites and business activities – Use of local suppliers and materials with low embodied energy – Use of recycled/ sustainability sources products
Social sustainability 4.2 Working with local communities & road users	– Contributing to local economy through local employment and procurement – Delivering services that encourage local environment – Building long-term relationships with local suppliers

Table 1: Key sustainability construction themes
Source: Adetunji et al., (2008), pg 166

However, the scope of localising the construction supply chain extends when considering the key sustainable construction themes. Table 1 lists the themes and the principal issues that relate directly to the issues discussed in this paper.

PROPOSED METHOD

Exploring the potential of SCL is extremely challenging due to its scope vagueness and as well as its interdisciplinary nature. This interdisciplinary nature is not only evident at the policy and industry level but also at a theoretical/academic level. The policy level initially requires for the issue to be considered as a critical adjustment in order to minimise energy demand but still maintain growth. However, an adjustment that requires moving away form the principals of globalisation to localisation raises implications of economic nature in addition to planning policy and social implications. The industry level requires cooperation and co-ordinated action by committed clients, design professionals and construction experts within a supporting policy framework. The industry and policy levels paint the picture for the vast number of theoretical/ academic disciplines, which are required to develop in an environment of cooperation. For the construction industry field of research some of those disciplines are planning, design (per design discipline), construction management and supply chain management including waste management, project management, economics of construction, facilities management etc.

Social Network Analysis (SNA) is proposed as a method to investigate the problem of localising the supply chain. Construction projects/ programmes/ enterprises can be seen as Social Networks (SNs). A particular characteristic of SNs is that they not only encompass information exchange networks but also value and resource flow networks. This allows non-social aspect of construction activity (Pryke, 2008) and organisations to be explored in conjunction with social aspects. Although, the use of SNA in the study of construction supply chains is not unknown, its application in the sense of concurrently investigating social and non-social aspects, which is proposed as bridging the economic, environmental and social dimensions of sustainable developments, is innovative.

Resource/value flows and logistics, knowledge management, contractual relationships, performance incentives and information exchange networks define the supply chains that are required to deliver construction services. These networks have a geographical dimension, which is considered in addition to the relationships between the supply chain actors listed above The existing energy demand profile of sustainable developments can be investigated by mapping current supply chains through SNA, starting at project level and expanding at programme or portfolio levels. The size and capacity, technical expertise, the geographical location of the supply chain as well as the location of the intellectual capital in it should be investigated in order to make a viable proposal about SCL. This would involve proposals on which local supply chains need to be enhanced, how best to enhance them and how the use of BIMs and vertical integration of the supply chain might be exploited to provide interfaces between local supply actors and end-users.

In summary, investigating the issue of localising the supply chain involves:

- Defining SCL.
- Investigating SCL"s input in dropping energy demand (define the scope for its adoption as a model).
