- Investigating how to implement SCL through the industry"s cooperation and supporting policy.
- Investigating the viability of existing local supply chain infrastructure and its relevance and evolution over the coming decades.

PLANNING POLICY AND TECHNOLOGY DEVELOPMENT

Although SCL due to its strong dependence on the study of logistics and transport, appears to be an operational issue for the management of sustainable supply chains, instead of a strategic one (Srivastava, 2007), it actually finds its place in the heart of "the problematic bifurcation of sustainable construction into two exclusive agendas: the construction technology agenda and the urban sustainability agenda" (Moore & Rydin, 2008, pg 233). Moore‟s & Rydin‟s (2008) paper raises the issue of lack of integration between the two agendas, how it leads one agenda to be odds with the other and the detrimental effects on delivering mechanisms for sustainable construction that satisfy the technological imperative as well as the goal of sustainable urban development. Rydin (2010) raises the issue that „the planning system is facing new challenges in which the nature of its engagement with technology is a driving force" (Rydin, 2010, pg 256). This is based on the observation that the sustainability agenda has created a shift in the society that puts technology at the centre and planning debates are evolving around the need to focus on technological issues.
SCL has undoubtedly planning implications and requires supporting policy for its implementation. Its scope, however, appears to depend on the technological advancements available. Investigating any potential benefit that SCL might bring is expected to also inform the problem between the technology and urban development agendas.

CONCLUSION

The main objective of this paper is to highlight that the issue of localisation appears to have been neglected in the discussion of sustainable supply chains. Starting from questioning the impact of transport in the total energy consumption of supply chains, and by attempting to impose those concerns on the management of sustainable supply chains the notion of localisation presents two dimensions; geographical and procedural. It is advocated here that both dimensions should be considered for successfully SCL and its scope in construction is briefly presented.
Localising the supply chain is being introduced as potentially an effective approach to achieving a sustainable reduction to the energy demand levels required by construction projects. Emissions from transporting construction materials and labour appear to be overlooked in the study of sustainable construction despite the fact that they are arguably more important than many of the factors currently regarded as central. They could be a reflection of the construction sector‟s reliance on energy, which in turn leads to increasing costs and contributes to greenhouse emissions. Questions centred on transport and logistics management, which are considered as processes that are heavily energy demanding, provide a starting point for a discussion on the definition of SCL and its scope for development and implementation.

Abstract

Although a substantial amount of literature advocates the integrated collaborative design processes for construction projects, very little explicit knowledge exists about the impact of the integrated processes on project uncertainty. In contrast with construction site processes, which can in most cases be organized as a sequence of tasks mutually interlinked by technological interconnections, design is a highly interdependent and iterative process that needs different management approaches. To manage the complex interdependencies of design, managers need to make sense of how far-reaching the impact of addressing a particular requirement will be on project outcomes.

By using the theoretical dichotomy of wicked and tame problems, this paper conducts a study on a design and engineering mega-project to induce the shortcomings of traditional project management applied to complex design problems. This study develops a cognitive map of how a requirement propagates through the entire scope of an ill-structured design problem and contends that the traditional design management techniques do not capture the ill-structure of the design sufficiently. The paper finally develops a list of theoretical propositions and an accompanying set of practical recommendations that are based on the notion that design should be managed on the basis of distinguishing between wicked and tame parts of the problem. The study contributes to design management literature with an early normative framework for managing complex construction design.

Keywords: construction design, requirements management, systems thinking, uncertainty, sensemaking.

INTRODUCTION

During the last two decades, the Architecture, Engineering, and Construction (AEC) sector has witnessed the emergence of a number of management concepts with the sole aim of reducing the fragmentation for which the sector has traditionally been considered notorious. More specifically, the fragmentation within the industry comes not only at the traditional boundaries of architecture, engineering, and construction; it is also a matter of internal fragmentation within each of the disciplines (see, for instance, Latham 1994; Egan 1998). *Integrated project delivery* is a common methodological umbrella to cover different approaches if reducing this fragmentation to make the industry more efficient (AIA 2007). One of the most popular approaches of integrating project delivery is to use the design/build method where the contractor assumes responsibility for the entire scope of work starting with client's project requirements (e.g., Anumba and Evbuomwan 1997). The focus of this type of integration is, however, limited to constructability of the design and does not encompass integration within each of the included disciplines extensively enough. Furthermore, design/build contractors tend to be organizations specializing in construction because the total costs of construction significantly exceed those of design activities (see, for example, Eldin 1991). As a consequence, what is considered integrated at the design/build interface, as a rule, can be oftentimes considered relatively disintegrated within the boundaries of design and engineering.

The most common approach to designing complex systems is by using systems engineering reasoning, where the total system is subdivided into hierarchies of subsystems (NASA 1995). The main assumption of systems engineering is that by managing the parts, one is also managing the whole. Indeed, the only way to manage a project of any scope is by using a subdivision-based reasoning and organizing the dependent units into separate tasks to be assigned to different project teams for execution. However, the resulting interdependency is a source of great complexity that needs to be addressed in the subsequent execution of the project. This complexity underlies every project decision in the form of uncertainty that accompanies project decisions. The essential problem is, therefore, to identify such interdependencies between parts of the design, which will enable the process to be organized as a set of independent tasks and tasks that need continuous process-level integration (see, for example, Thompson 2003).

This paper is an attempt of early inductive theorizing to present the interdependence and complexity in construction design. The main aim of the paper is to argue that organizational integration at the level of processes, not contracts, is the key characteristic of integrated delivery approaches. To accomplish its aim, the paper begins with a theoretical overview of design management concepts and techniques in the AEC context. After the theoretical overview, the paper continues with presenting a case study of an integrated engineering design from which it extracts a series of issues in the form of a cognitive map. From the case study findings, the paper finally induces a set of theoretical propositions and practical recommendations.

BACKGROUND THEORY

Designing a new product (or artifact) with an engineering content is normally defined as the activity of producing information about the system that embodies the functions necessary for fulfilling the set of requirements set forth by the client (e.g., Pahl et al. 1996; Cross and Knovel 2000). In the case of facility design, these requirements need to be mutually negotiated between the stakeholders and the project coalition (Winch 2010). This significantly complicates the design decision-making process as interests of the client, the stakeholders, and the project coalition diverge. Additionally, the elicitation of requirements for the designed system is a tremendously challenging task because the requirements are often changing through time. For all these reasons, the process of facility design is *ill-structured*.

The dichotomy between the *ill-structured* or *wicked* problems in contrast to *well-structured* or *tame* problems was first introduced by Rittel and Webber (1973) who argued that design problems are impossible to define and therefore no optimization in the traditional mathematical sense is possible for such problems. Some of the most obvious differences between tame and wicked problems are that the former are describable and determinate, whilst the in the latter, problem definition incorporates solution and only indeterminate solutions can be achieved (see, for instance, Winch 2010)

Wickedness and ill-structure have, to date, remained considered the fundamental property of design. In a more recent discussion about the subject, Coyne (2005) corroborates evidence for the ill-structured nature of design and extends the debate by stating that:

> *"Wickedness is the norm. It is tame formulations of professional analysis that stand out as a deviation."*

In contrast with the theoretical discussions about design, most known techniques used in design are by and large deterministic in that they disregard the wickedness of the design problem. Some of the most famous of such methods in the AEC sector include the likes of: *Quality Function Deployment*, *Design Structure Matrix, and Process Models* (e.g., Austin et al. 2000; Ahmed et al. 2003; Tzortzopoulos et al. 2005). In Coyne's terms, all of these methods are tame formulations of the wicked problem and, therefore, have a limited value.

To come up with more realistic representations of the wicked problem and to develop better methods for managing it, first the traditional positivist paradigm of :the rational man" needs to be replaced with an interpretive paradigm that acknowledges the subjective and relative nature of decision-making (Simon 1955). Following this cognitive concept, contemporary scholars in construction project management (Winch and Maytorena 2009) contend that decision making in such highly-uncertain conditions, as the ones that appear in design, can be classified more reliably as *sensemaking* under bounded rationality than as rational economizing as advocated by hierarchical breakdown structures from traditional project management literature. Sensemaking is the process of retrospectively assigning meaning to past events and thereby shaping the organizational context for present and future events (Weick et al. 2009).
Using the cognitive concept of sensemaking, we will argue, is a step forward towards describing the decision making process in complex problems of integrated construction design.

RESEARCH DESIGN

To learn more about interdependencies in the complex design project, we chose to conduct a retrospective study because the decisions that affected the project events can only be evaluated *ex post*. The traditional project setting for decision making relies on management procedures that only deal with identifiable contingencies, thus, they belong into the realm of tame problem solving and hard systems thinking. The project normally deals with uncertainty only through risk management procedures that are, again, limited in their predictive potential. We, therefore, chose to trace the processes resulting from decisions in a fast-paced and complex design-build railway engineering project. In a retrospective process-tracing setting, we hoped to encapsulate the uncertainty that would have not been possible to address with ongoing project events.

There are several additional reasons why we chose a large contractor-led design and build engineering project for analyzing interdependency in construction design. Firstly, most design and build projects are characterized with a relatively fast pace with a possibility of overlapping design with construction. Due to the pace of such projects, many design activities are planned in parallel rather than sequentially, which causes additional fragmentation and complexity of the design process. Secondly, because design and build contracts are undertaken relatively early and they are based only on the clients' requirements; there is an inherent uncertainty concerning the scope of the project. The deliverable dates, however, often do not change in such projects, which calls for a robust organization that is capable to adapt to sudden changes in scope and still deliver the job on time. Thirdly, the geometry and size of the constructed facility, along with the multidisciplinary contributions, accentuates the importance of design integration across numerous project interfaces. All these project properties highlight the need for tracing the interdependence in the design system to reduce consequences of uncertainty. Finally, since we wanted to make generalizations from this study at the project level, we chose a project that we believe makes a suitable unit of analysis for an exploratory study.

During a one-week stay in the project offices, the first author used extensively interviewed five representatives of the owner's project management and the contractor engineering organization using ethnographic techniques (Spradley 1979). For the purpose of this study, only accounts by the contractor's engineering organization were further analyzed, thus setting the level of analysis to the contractor's system sensemaking. The aim of the data collection by interviews was to uncover the managerial sensemaking process retrospectively, by having all the relevant data after the project had finished (Weick et al. 2009; Winch and Maytorena 2009). In contrast with the process maps as the result of the ongoing project, here our aim was to develop a cognitive map of the traced processes according to the managers' sensemaking and, finally, induce conclusions of theoretical validity from the single-case study (Eisenhardt 1989; Yin 2003).

Apart from fixing the interview framework to issues in the design management processes, the interviews were open-ended, allowing the subcategories of the topic to naturally emerge during the one-hour long interview interactions with each informant. This unstructured interview setting enabled us to better understand the scope of the complex inter-organizational arrangements in the supply chain and their influence on design. We triangulated the data obtained from the interviews with relevant internal project documentation (project reports, schedules, organizational diagrams, etc.) and with publicly available material from press coverage of this public-funded project. After having analyzed the data from open-ended ethnographic interviews and project documentation,

we then carried out two follow-up telephone interviews that were structured around several topics identified in the initial research session. The aim of the follow up interviews was to get more in-depth information about specific instances of design issues. Following the open ended and structured interview sessions, we tried to induce theory by tracing the processes of how the project design was unfolding in an attempt to establish causal relationships between the events and their consequences occurring in the project (George and Bennett 2005). We finally coded the structured follow-up interviews with all instances of unforeseen uncertainty cause by complex interdependence.

CASE CONTEXT

The case project involved extending a section of a rapid transit urban railway system and incorporating it into the suburban rail system of a congested European metropolitan area. The scope of works comprised partial extension of tracks, replacement of track and signaling equipment, construction of four new stations and refurbishment of five old stations. The project was particularly demanding in civil works as 3.5 km of track is on viaduct and another 3 km is in tunnel. Besides the construction of a new section, the complete section needed to be upgraded to meet the national mainline standards. The design and construction were completed in two and a half years and the schedule itself consisted of roughly 16000 design and construction activities.

The public agency project owner undertook the contract under a contractor-led design and build scheme. The main reason for choosing this delivery method was that the project owner expected a single point of responsibility to better integrate the design, construction, and operation stages of the project. An additional reason for choosing a fast track delivery approach was the political significance of the completion date (public opening). Therefore, owner-perceived advantages of a fast-track delivery method were the integration and collaboration between project contributors. The core project organization included the public agency owner and the contractor. Because the owner organization did not have substantial experience in railway construction, they appointed a project management organization to manage the project on their behalf. Concurrently, the contractor's organization mobilized an engineering department for the project with the aim of coordinating design and construction. The project also had three major external stakeholders, being representatives of the urban and the suburban rail systems as well as the operating company. The former two had the role of ensuring that the newly built section complied with the existing standards of both networks and the latter had the role to ensure that the delivered facility complied with their train operating procedures.

The design scope was organized in disciplinary *work packages* and geographic *design areas.* The disciplinary work packages comprised civil design, structures, buildings and services, mechanical and electrical systems in buildings, and design of accompanying rail systems (Fig 1). Each work package was further broken down into *design areas* defined as "geographical groups of neighboring work packages or a logical system comprising a number of subsystem work packages". Because of its fragmentation, the project developed an *Interface Management Plan* to identify and manage issues that would occur between work packages, design areas and organizations in the design supply chain. As the design evolved, the identified project interfaces were planned to be translated into requirements for each of the design contributors.

The flow of the design was planned as a two stage process: conceptual design and detailed design for the owner's construction approval. The project further fragmented the design process along those stages because the project management organization was supposed to produce the conceptual design work packages and design areas for the contractor's design team. The transfer of knowledge and assumptions made in the conceptual design stage would be transferred to the contractor's engineering organization before the detailed design production. During the detailed design production the lead designer and the contractor's engineering organization needed to ensure coordination via interdisciplinary design review meetings as the principal method of design integration.

The contractor had a web-based collaboration system in place to manage the requirements across different project levels. The high-level requirements would emerge from any of the project stakeholders, the contract, or other obligations with respect to technical standards and legislation. The contractor would then translate those high-level requirements into system-level requirements with such attributes as object type, work package, design area, and contract (see Fig 1). This structure should have ensured traceability of the requirements between the design team level and the project owner.

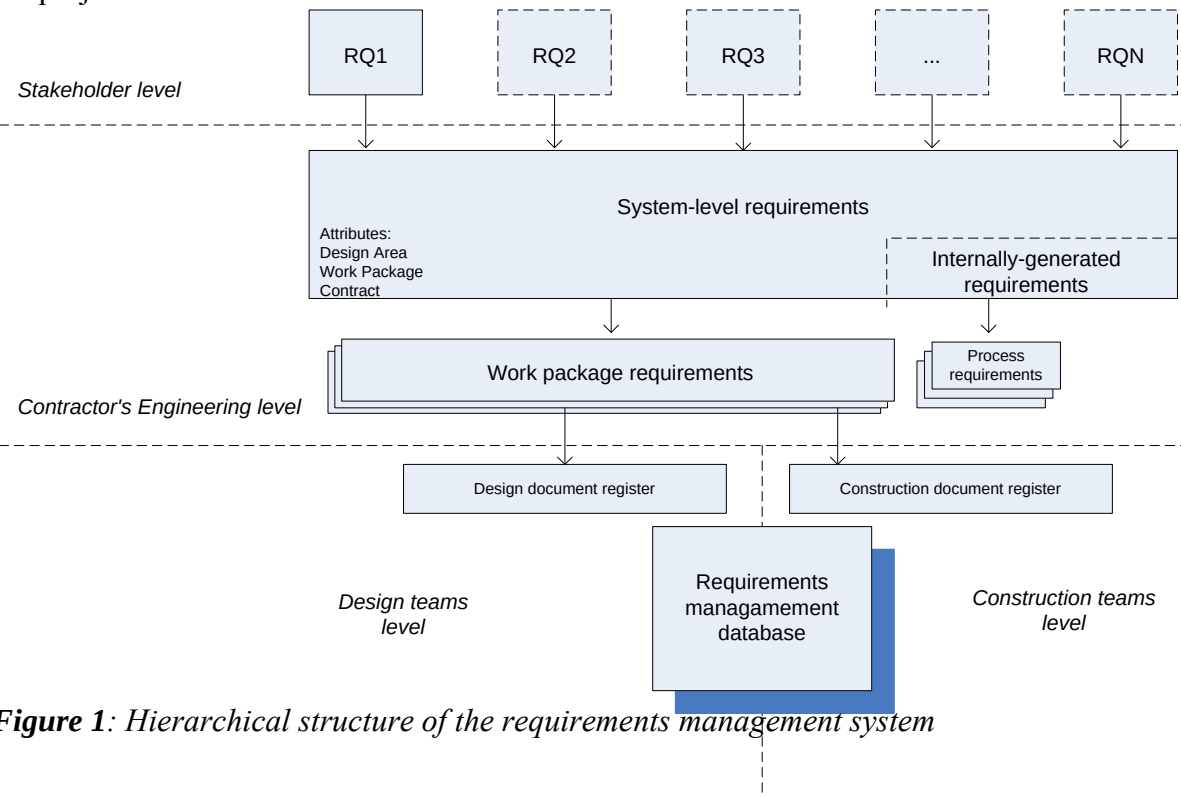

***Figure 1**: Hierarchical structure of the requirements management system*

DISCUSSION OF THE FINDINGS

In reconstructing the design management story from the perspective of the contractor's engineering organization, we immediately noticed the complexity that resulted from interdependence between the design tasks. This complexity was not included in the project management procedures that only described the hierarchical decomposition of project structure. Therefore, at the outset of the project, the design process was structured in an overly simplified way that did not predict well the implications of changes on the entire design process. We

continue with a more detailed description of how the above introduced seemingly small project requirements played out a significant role in the project. Figure 2 below depicts the traced process of a situation, in which a seemingly simple requirement amplifies and propagates through the project due to complex interdependence and sensitive dependence on initial conditions in a wicked problem-solving context.

The traced process begins with two requirements simultaneously being introduced by the client and internally within the project team. The client's requirement was that design team provides a possibility for subsequent installation of an external escalator in one of the stations. The passive provision for an external escalator, however, required that additional power be supplied to the stations and, in turn, the entire section. More power meant that thicker cables had to be arranged for its supply. Thicker cables meant a higher volt-drop and, consequently, further increased the demand for power in an interdependent loop that caused a substantial amount of the power systems to be redesigned for this sole purpose. Redesigning the power systems caused a requirement for additional space to accommodate the newly designed systems. This space, however, was not available neither in the station that had already been designed by that time (and, in other instances, also built), nor in the form of land along the tracks. Therefore, additional land had to be acquired to run the cables along the section, and the buildings had to be redesigned with the new space requirements. It caused another iteration loop in the building design that led to subsequent design integration problems due to geographically-distributed organization of the design process that was the main designer's choice.

Roughly at the same time, a second requirement emerged that needed to be implemented. It related to fire-safety as a consequence of implementing the fire-safety regulation into the design. The implementation of this requirement, in turn, caused an even greater demand for power and, consequently, more land to be acquired to run the additional cables along the tracks. When combined, the total amount of power that was now required for the section became so large that not even the local power supplier was capable of supplying it. Therefore, it wasn't until very late into the design process that the design team and the project owner decided that implementing one of the requirements is not possible and that it had to be relinquished.

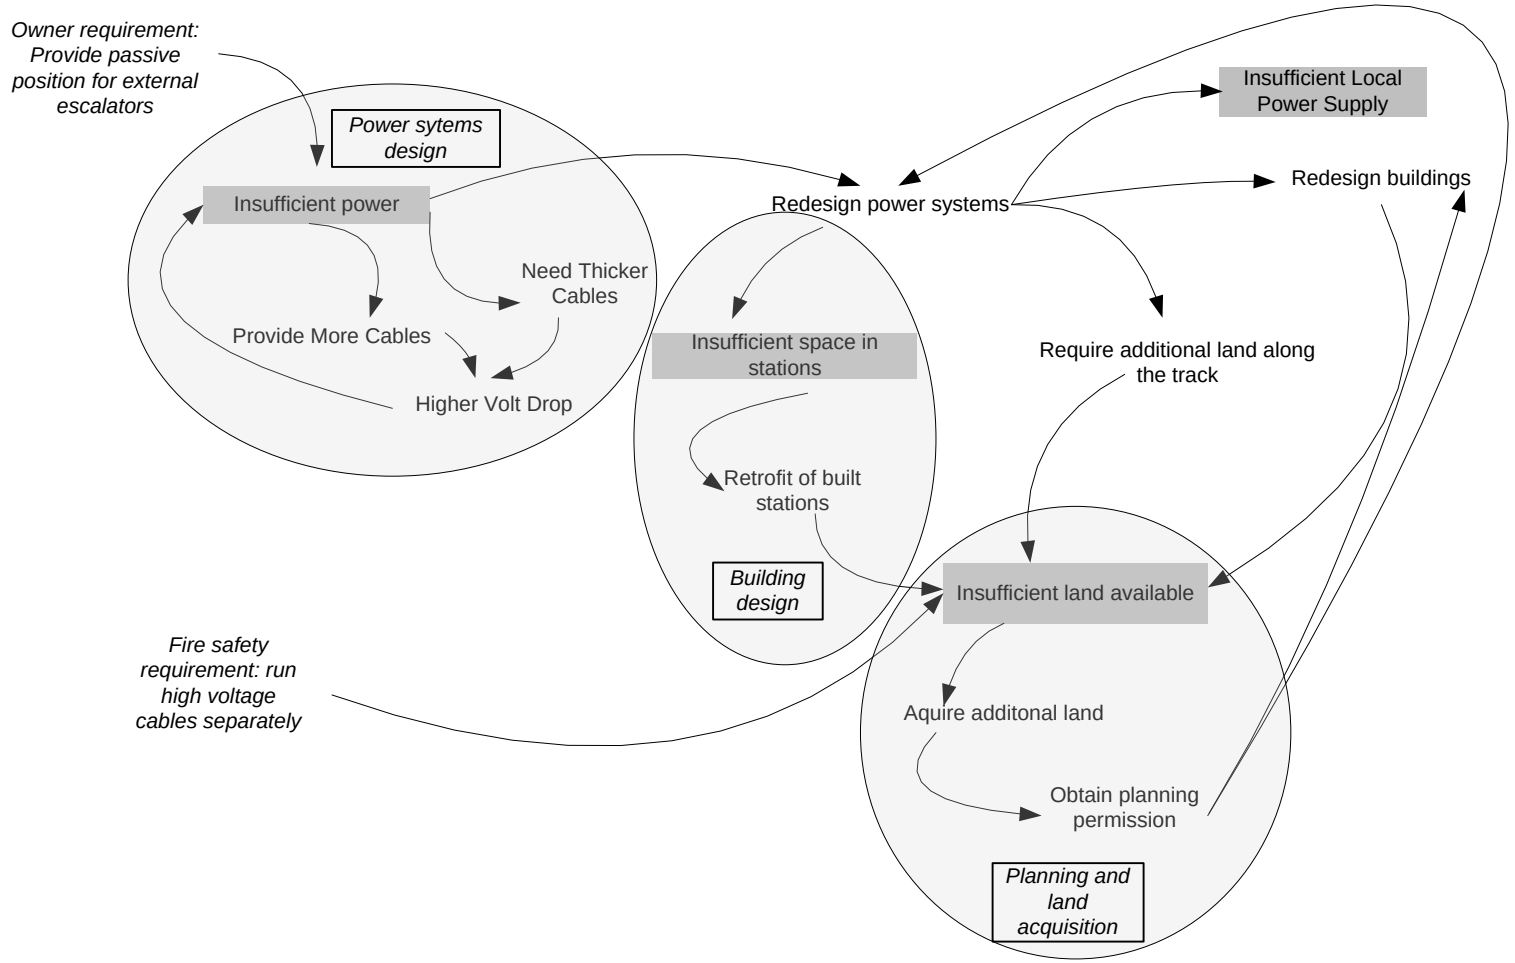

Figure 2*: The process-tracing map of sensemaking in complex interdependence of infrastructure design.*

This example demonstrates that requirements, however insignificant they may have seemed at the time when their implementation was decided upon, cause significant consequences for the project. In the case of insufficient local power supply, these difficulties were insurmountable and resulted with rejection of the requirement. The subdivision of the project linked requirements to discrete and abstract entities such as work packages, design areas, and contracts. In practice, however, parts of the system have not proven to be manageable in discrete pieces. Instead, they acted as an interconnected system of events that needs to be analyzed in the cause-effect context.

Having such a project representation would have facilitated managers' understanding of intricate interdependencies between the tasks captured within the design subsystems. The cognitive process-tracing map shows three distinct design subsystems: power systems, buildings, and planning with land acquisition. Besides the overall design iteration loop, these design subsystems performed additional iteration loops within themselves. The subdivision logic that was employed in the project did not follow these loops. Suboptimal design decomposition exacerbated fragmentation of the overall design scope with the result of unforeseen delays and costs on the project resulting from rework and problems with design integration.

PROPOSITIONS AND RECCOMENDATIONS

Based on combination of the above introduced theory and the findings from the traced process in the case study, we induce several theoretical propositions. From them, we derive the corresponding practical recommendations for managing complex engineering projects.

Proposition I: A wicked problem is characterized by reciprocal interdependence between its constituent parts.

Although it may seem tautological, this theoretical proposition argues that wicked parts of the design are also ones that are reciprocally interdependent. Their main characteristic is that a change in any one part of the system will cause changes on all the other parts of the system. As originally argued by Thompson (2003), such tasks need to be managed by the process of mutual adjustment instead of by standards and plans.

Recommendation 1.1: Differentiate the wicked from the tame parts of the design process.

Before starting to organize the design process, design managers should try to analyze the design problem and divide it into a group of tasks that result in a concept solution and a group of tasks that result in a detailed elaboration of the design concept. The former will form the wicked group and the latter, the tame group of tasks. This will be the first step towards the decomposition and management process.

Recommendation 1.2: Define success and failure criteria for the wicked group of tasks.

Since solving a wicked problem is a cognitive process of socially constructing project information, the key issue is to negotiate the goals of the project and metrics of success. Aligning the stakeholders' interests into a congruent set of project criteria will help lead the design process and reduce organizational friction between members of the project coalition.

Recommendation 1.3: Include buffer time in the project schedule.

Based on the level of complexity of the project, rework is likely to occur. Due to reciprocal interdependency in engineering design, deterministic planning is not likely to yield accurate forecasts. Including a substantial buffer time in schedules will help initially address the emergent complexity of the wicked tasks.

Recommendation 1.4: Be prepared to reiterate the entire process when new requirements arise.

Due to reciprocal interdependencies that are characteristic for design, there is high possibility of iteration to implement a requirement into the overall design. Given that any design problem is by definition wicked, taming it is only possible with limited results. Depending on how well the internal design interdependencies are assumed, managers can try to predict the impact of a requirement on the project. In certain cases, iterative loops of rework can become so frequent that project teams need significant mutual trust to avoid the failure of the project due to what Weick (1993) calls the collapse of sensemaking. In such instances, subcontracting or geographically distributing work across different offices is not advisable.

Proposition II: The better the organizational design follows the combination of tame and wicked tasks within the overall design scope, the lower the resulting fragmentation of the process.

Recommendation 2.1: Develop work breakdown structures based on the level of interdependence between the packages.

Although it is the basis of every project management system, work breakdown structures based on simple hierarchies of dependency are not sufficient to subdivide a complex design problem. Such problems should be subdivided based on interdependencies between the systems that often go beyond the classical space-discipline logic and also include relations with, for instance, external stakeholders or the overall need for communication between members of design teams.

Recommendation 2.2: Only subcontract tame tasks.

When decomposing the overall scope, it is important to create such design modules that are relatively independent of each other so that the amount of communication between the modules is reduced. The most obvious way of weakening the interdependence between the modules is overdesigning to account for possible future changes. Therefore, only tasks that are identified as tame are appropriate for subcontracting to third parties.

Recommendation 2.3: Wicked tasks should be integrated at the process level.

Although the advantages of contractually-integrated project approaches clearly exist, such approaches do not guarantee integration at the design process level. In fact, when contractors take responsibility for the entire project delivery, there is a realistic possibility of introducing an additional level of subcontracting that can be difficult to integrate into the project. Therefore, a design task that is identified as wicked should be executed by a collocated and socially-coherent

design team. Although team collocation is not the sufficient condition for efficient team performance, the authors' experience indicates that mutual adaptation, which is necessary for executing reciprocally interdependent wicked tasks, is most likely to occur in a collocated social context.

CONCLUSIONS

This study presented an early stage of inductive theorizing about the design complexity. This theorizing developed a cognitive map based on making sense of how requirements impact the overall design. This cognitive map of sensemaking indicates that reciprocal interdependency causes a requirement to amplify and propagate within the boundaries of the integrated project, thus making the problem wicked and ill-structured. The study further developed a list of theoretical propositions coupled with practical recommendations that managers should use to reduce the unforeseen uncertainty on their future projects. These recommendations advocate the need to distinguish tame from wicked parts in the design scope and accommodate the decomposition and integration strategies to the corresponding characteristics of interdependency.

The results of this study contribute to theory on several levels. The sensemaking example of design complexity, we believe, unifies two prevalent high-level approaches of construction project management: the objectivist school of systems engineering (see, for instance, Walker 2007) and the cognitive view of information processing (see, for instance, Winch 2010). More specifically, we believe that the results of this study also contribute to the toolbox of integrated project delivery (AIA 2007) and concurrent engineering (Anumba and Evbuomwan 1997) with a normative set of recommendations that can be used for organizing the integrated delivery process. Finally, we believe that the results of this study complement the standard construction design management toolbox (e.g., Austin et al. 2000; Kagioglou et al. 2000; Ahmed et al. 2003) with a view on the ill-structured problems than can complement the existing methods.

We are aware of several limitations of this study that future studies should address. Namely, generalizations drawn from a single-case study are not at the level of a particular population, but at the level of replicating causal relationships for the given sensemaking context. Gaining insight at the level of particular project characteristics would require a larger sample and a different approach. Methodologically, a continuation of this study should extend this descriptive and qualitative theorizing into further normative and predictive models. We are also aware of the need to extend the normative decision making framework based on its applicability to different procurement routes and organization structures in the construction design field. Moreover, this paper advocates neither the integrated design-build nor the traditional design-bid-build contractual arrangements. It solely attempts to offer a way of thinking in ill-structured problem solving that can occur in either of the contractual approaches. Integration, therefore, is a process-level, not contract-level concept. Finally, this paper does not attempt to give answers to aspects of the project that are beyond the decision-makers' comprehension (i.e. wicked aspects). It aims to bring about awareness of the existence of unforeseen problems and the need for their ad-hoc resolution. This is, we believe, the main practical idea from this study.

ACKNOWLEDGEMENTS

We would like to thank the management team of the case project who supported this study by hosting the first author in their company office and by providing him with informants' time that

was necessary for conducting the interviews. Although all the informants chose to remain anonymous, we acknowledge that without their support this study would not have been possible. This paper is based on a case study whose initial elaboration the first two authors submitted to the 2011 European Academy of Management Conference in Tallinn, Estonia. While the first paper elaborates the case study from the general management perspective on project complexity, this paper, by contrast, focuses on the findings' implications from the perspective of design approaches within the construction sector and continues to develop the list of practical recommendations from the case findings.

ABSTRACT
This paper introduces results of three case-studies of large-scale housing estates situated in Nantes (France): Dervallières (1952/1965), Breil Malville (1955/1967) and Malakoff (1967/1971). The main objective of this "grands ensembles" study is to produce knowledge about their architectural and urban atmosphere characteristic. The atmosphere concept is defined as interaction between some physical phenomenons like: sound, light, wind with urban environment as perceived by the space occupant [Augoyard J-F, 1998]. This paper is organized globally in two parts, the first part presents brief synthesis of history and current context of these areas, second part gives idea about atmosphere's characteristic for three cases-studies. This consists in clarifying and analyzing complex relationships between urban, social and physical (sound, light, sunshine, wind, etc.) environment, taking into account user's perceptions and urban renewal.

Keywords: "grands ensembles", atmosphere, renewal, perception, characterization.

INTRODUCTION

In reference to current stake related to "the town of tomorrow", the residential zones type grands ensembles are the subject of multiple and pressing requests. These blocks constitute by their large free spaces attractive areas for dense city concepts, responding to suburban expansion and its harmful effects on the environment. The stake is also to assure harmonious social and economical development between town center and its periphery. Questions that arise about these stakes concern living conditions and atmosphere quality in these areas: is this quality taken into account in their refitting? If yes how? Are the errors made during the time of massive construction of these social housing in France avoided in their rehabilitation? These questions pin up an important aspect of urban design, which is inhabitant's practices and feelings. As you know, their requirements for comfort and wellbeing are increasingly

important, not only about functional aspects but also about environment, esthetics, and safet aspects. Therefore, renovation project can't be done without a "diagnosis" relating both material components with practices/feelings in these spaces (public and private space).

In this research, we characterize the atmosphere quality in three case-studies of large-scale housing estates situated in Nantes (France): Dervallières (1952/1965), Breil Malville (1955/1967) and Malakoff (1967/1971). Our method consists to use three separate and complementary approaches: observation approach, sensitive and physical approaches. The first two approaches are questioning true-life of the inhabitants: how do they perceive their living environment? What do they think of the social life in their district? And what are the renewal operations contributions? The last approach allows us to explain some micro-climatic phenomenon (sun, wind and temperature) by using simulation tools.

To answer previous questions, the characterization method consists initially of an "exploring" approach of urban spaces using observation (continuous and punctual) in order to discover how the inhabitants appropriate their urban spaces by identifying different types of interactions *individual-individual, individual-space and individual-microclimate*. This first approach also enables us to prepare "sensitive" approach, which consists to collect information about inhabitant's perception from surveys (questionnaire, interview). It allowed us to explain and understand some observation "scenes" noted in the first step of characterization approach with observation. Microclimatic environments described by the inhabitants are crossed thereafter with third approach called "physical" so as to determinate their emergence conditions, by using digital modeling and simulation. Finally, this multidisciplinary approach allows to establishing knowledge of architectural and urban atmosphere, which characterize large-scale housing studied, taking into account the renewal operation and the atmosphere as imagined by architect-designer.

"GRANDS ENSEMBLES" IN FRANCE FROM SUCCESS TO FAILURE

Massive construction of these housing areas in France is not only a quick and economical solution for the housing crisis after the second World-War, but also a response to the unsanitary lodgings. A census conducted in 1940 showed that only 8% of French houses had bathtubs and toilets, hot water, few windows, a minimum area ... [Comité des Grands Prix Nationaux de l'Architecture, 2007, p33]. While these estates have brought more comfort with spacious, airy and sunny apartments surrounded by green spaces, an occupant says: *"...I immediately had "love at first sight" for our new apartment. It was luminous, spacious and had the central heating; it offered fabulous view on the countryside and the greenery"* [Giovanna Francavilla testimony]. The official start construction of these housing was in 1953, when the Minister of Reconstruction and Housing Pierre Courant, carried out a series of interventions named "Courant plane" consisting in facilitating housing construction with land and financial supports, giving priority to the large-scale housing estates. In order to meet the growing demand of housing, other programs were conducted like: "ZUP, Zone à Urbaniser en Priorité" (Priority Development Zone) in 1957 replaced by "ZAC, Zone d'Aménagement Concerté" (Concerted Development Zone) in 1967. Certainly this policy had allowed massive construction of social housing but it didn't create dynamic and attractive districts. In fact, a few years after their construction, first sign of degradation appeared (in the late 1950s)

revealed by social and urban surveys. Social contexts characterized by juvenile delinquency, an enrollment rate of adults who never attended school that exceed 10%, higher unemployment, and degradation for framework built. Finally these areas were associated with segregation, nuisances and danger zones, reason why Olivier Guichard Minister of Construction, decided in 1973 to stop the housing construction exceeding 500 units.

How can be explained this degradation and this change from modern living condition to degraded and unhealthy habitat? When looking back at "grands ensembles" history one can observe that majority of these housing are assimilated to concentration camp cities, housing exiguity, proximity, noise… boredom. Overall, these areas are characterized by spatial and social relegation, with lack of transportation and leisure area, and with difficulty to create a social life and to adapt to these new conditions (to have 200 to 500 neighbors from different backgrounds and cultures). So people still feel some kind of social relegation in comparison to the people living in the city center, and this social segregation was accentuated when middle class leaves to detached houses, knowing that 80% of French people at that time desired to live in detached house. The accumulation of problems inside and outside house has made life very difficult in these housing, that's why these urban housing were a priority for urban political, in order to improve their living conditions through urban renovation and social actions. The main principle of these operations is to take into account inhabitants by creating social office council, so as to centralize the problems and inhabitants demands for giving immediate solutions.

DIVERSITY, DENSITY, COMFORT...: THE RENEWAL OF "GRANDS ENSEMBLES"

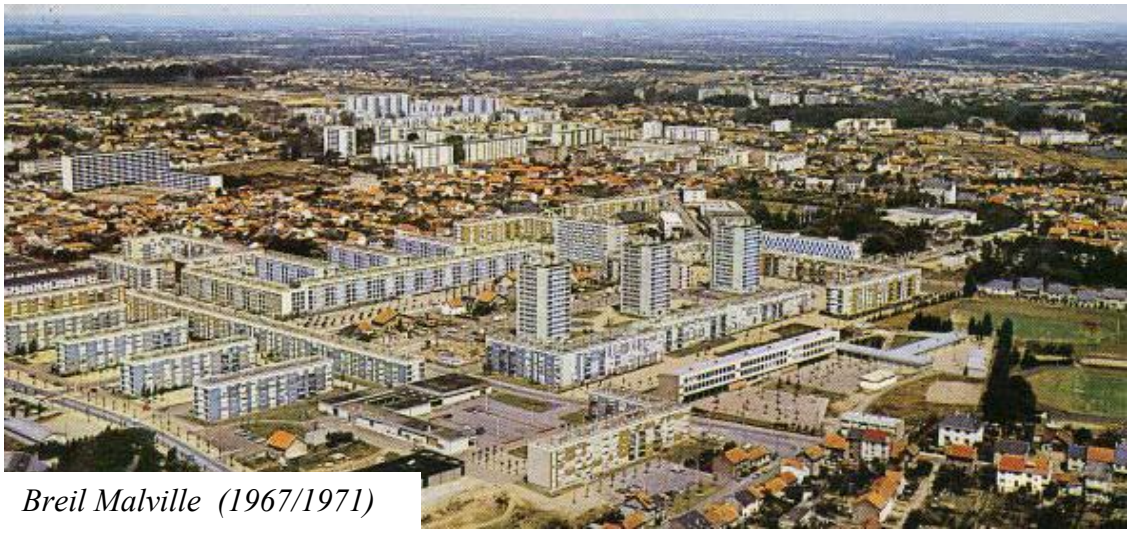
Demolish, convert or renew? Such are the questions which arise since 1980s for the future of these urban areas. Since, measures are presented in diverse actions: social (example: National Commission for the Social Development of the Districts), urban and environmental (example: Great Urban Project become Great Project of City) in order to improve the life quality in these districts. For the professional of building, the partial or total demolitions of these buildings are essential to fight against them insalubrities and enclosure, in spite some inhabitant's refusal to see their housings disappearing. First restoration operations described as "classical" (building front renovating, change of the windows, refitting of public spaces), have been carried out, with mitigate results. But the present renewal programs are deeper, diverse and more effective, consisting in complex programs, conceived on a large territorial scale with a long-term thinking on the future vocation of the district. This policy takes into account sustainable development criteria in all steps of restorations, from construction waste recycling to the improvement of the energy performances.

In a comparative study between large-open spaces of the "grands ensembles" and those of the traditional city Hatzfeld and Moutton [2006], highlights capacity of areas to adapt to urban transformations contrary to traditional centers. These open spaces have a great potential for an equal development between center city and its periphery. Successful densifications of these open spaces should allow creating social and functional diversity awaited in these districts, and reduce periphery-center displacements. If urban renewal seems to satisfy inhabitants, the important transformation must to be in apartments, because inhabitants estimate that changes

inside apartments are insufficient (handing-over in standard of electricity, change of the windows), adding the renovation defects.

Malakoff case in Nantes (1967/1971) seems a good example of this new urban policy. As part of a “Grand Projet de Ville” (Great Project of City) launched in 2004, thought was developed on Malakoff district and neighboring areas. This project was carried by social landlords, the National Agency for the Urban Restoration (ANRU) and the community of agglomeration (Nantes Metropolis) with participation of inhabitants. Budgets inequalities set up by each landlord gave interesting results to analyze. First public landlord had opted for a “classical” rehabilitation with budget of € 25 000 by apartment, the second private landlord had opted for a radical change with € 60 000 by apartment, which has enabled to improve energy performance of buildings. Indeed, energy consumption was reduced by 80kWh.ep / m² / year, saving load about 70 € / year by home [Barthel P, 2008], with double-insulation of the buildings (inside and outside) by semi-rigid 10 cm thick rockwool panels. The building architecture is also revised: apartments became more spacious, with original architecture and diversity of functions. On an urban scale, ensure house diversity and the reinforcement of the connections to city center are the priorities of this project.

STUDIES CASES SITUATED IN NANTES



The three large scale-housing [Fig. 1] choices were built between 1953 and 1973. The first case study is “Dervallières”, first “grand ensemble” built in Nantes (1957-1965) in an old park, building implementation is done in away to preserve the natural framework, and to adapt to the climatic conditions, in order to have better quality of sunning and a protection of the dominant winds. This neighbored is situated in town periphery and contain 2600 housings. The second case is “Breil Malville” designed by the same architect than the first one. It is featured in the presence of different housing type (detached, semi-collective and collective housing) and contains 1600 housing built in 1961-1967. The last case is “Malakoff” situated close to town center, with exceptional natural framework (Loire River and “Amazonie” preserved park). Built in 1967-1971 Malakoff contains 1658 housing. The three selected districts are the subject of many restoration projects, differing in level quality, progress report and budget.

Dervallières (1967/1971)

Malakoff (1967/1971)

Breil Malville (1967/1971)

Figure 1: *the three studies cases.*

SOCIAL DIMENSION AND ITS IMPACT ON PEOPLE PERCEPTION

Interrelations between a social dimension of the district and a sensitive atmosphere are strongly present. The feature of social life in these urban areas: delinquency, poverty, unemployed and unoccupied, drug users with low education and a difficult social condition, insecurity is a major preoccupation of the inhabitants in their life environment. This report is pointed by inhabitant testimony, one of Dervallières occupant says: *"... you know, the morning when I go out from my home, I do not really pay attention to the sun, wind. I think especially to my work, my children, and to not be burgled"* [testimony taken 15/07/2009]. This mistrust feeling concerns most of "grands ensembles" inhabitants, especially the women. That's why these persons not invest in social life of district and stand apart from the others inhabitants. Hence some spaces judged dangerous and bad reputation areas are not used. For middle class family which lives in these areas a departure is a priority especially for the victims of these conditions: *"I made burgle my apartment twice, each time I go out with baggage's they steal me, fine, I can't take it anymore"* [testimony taken 15/07/2009] for the poorest class their socio-economic level not allow them to hope to leave the district, so they seek to adapt by trivialized the bad social life aspect. An inhabitant of Dervallières told us: *"Yes, these are young people, they like to have fun, and they do nothing wrong"* [testimony taken 23/07/2009].

This category of people is able to create his ideal world of sociability. What they often call for solidarity, good neighborhood, is a feeling shared by a group of people or even families who can provide some protection from outside world, seen also as a means of mutual help, mainly present between families of same origin and culture, the old neighbors and neighbors simply. This solidarity can also be found inside blocks; it concerns the cleanliness of common places as stairwells, elevator, landing of floor and also the limitation of noise at certain hours considering the bad soundproofing of apartments. On the contrary, other neighbors distinguish them by their lack of civism and the lack of respect for the community life: trash front of doors, strong music…

PRESENCE AND BEHAVIOUR IN THE PUBLIC'S AREAS FOR "GRANDS ENSEMBLES"

This paragraph presents observation results of public's areas in three cases studies, recalling that objective for this step is to identify inhabitant presence and behavior in these spaces. Observations realised during winter and summer days (day of week or weekend) in the three districts show that urban activities take place mostly in the following areas: square, playing and green areas. Other frequent activities occur in entrance hall of buildings, cellars, parking's, and stairwell. We notice that square is the most used space in these districts [Fig. 2]; the inhabitants justify it by the presence of equipments and services necessary to the everyday life. We can find in this space different activity like: purchases, meeting and discussion. By its central and strategic situation in the district, it is considered as the favorite place where young people grouping and activity, so that it experiences motorcycles and cars races, quarrels, business.

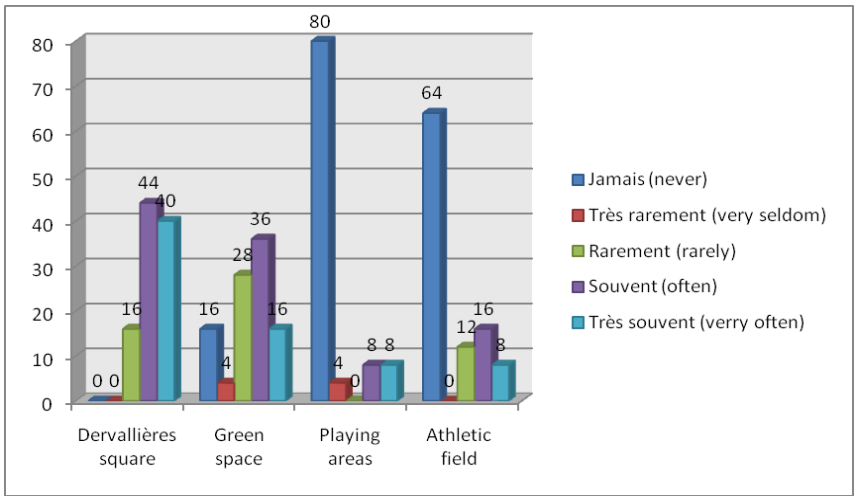


Figure 2: *use frequency of Dervallières public's space*

That is why some inhabitants prefer not to frequent this place. The city planning (street furniture, green area) and configuration of these spaces plays an important role that determinates people practices and urban dynamic. For example, Breil Malville square is not used by people because of its poorest urban arrangement, contrary to the Malakoff and Dervallieres square where inhabitants take advantage of the presence of terrace (bar and restaurant) and of the benches, to create convivial meeting moments for woman and man. In the Malakoff square, women say that they don't like to go to this place, because the glance of the person's occupation of this space is concentrated and oriented to the persons arriving at the place, which is inconvenient for them. This situation is resulting from the square configuration. If squares are the most frequented space in the three districts, the green spaces (with or without pond) are the favorite spaces of the inhabitants. In Dervallières, inhabitants display particular attachment to green space called "pond", which know another dimension after its renovation. Inhabitants appreciate this space natural landscape (vegetation, pond and ducks) that they qualify as "exceptional", "quiet", and "pleasant".

Before its renovation, space was given up by inhabitants for its dirt and for offensive odor emitted by water. Another example related to Malakoff, is the "rock" park, a green space very appreciated in spite of its bas urban arrangement. Rest areas situated in front of buildings are practically unused in three districts, while these areas are well equipped. According to the inhabitants, they prefer isolated spaces sheltered from view coming from buildings.

Atmosphere quality in large-scale housing studies

It consists to give an overview of inhabitant's perception. This was collected by surveys where thirty people by district were participating; responses were given in home or in public space, the questionnaire being completed by the investigator. Generally, the perception of architectural and social framework is rather positive, more particularly in renovated districts. According to inhabitants, this report is justified by improvement of the residences quality of many people that were living before unhealthy houses of old centers and left them to live in these "grands ensembles" (like Malakoff people). They so accessed to spacious apartment, with better sunshine and natural lighting. Of course, many inhabitants are dissatisfied about

the degradation of the built and social framework, but they remain overall satisfied of their life framework.

One of the first questions asked to the inhabitants was: do you live in your district by choice or constraint? Their answers [Fig. 3]; reveal that for 46% to 59% of the inhabitants (according to the district) it was constraint. One can distinguish in this category of inhabitant people that have become accustomed to life in these districts with time, whereas others consider that their presence is temporary, especially persons whose residency duration varied for six months to six years (young household). In the category of people having freely chosen to live in these areas, choice is generally justified by: natural and social framework of the district (like in Dervallières), proximity of worksite and town centre (the case of Malakoff), equipment and the services presence, family reunification. This people invest more in district life compared to the people forced to live there.

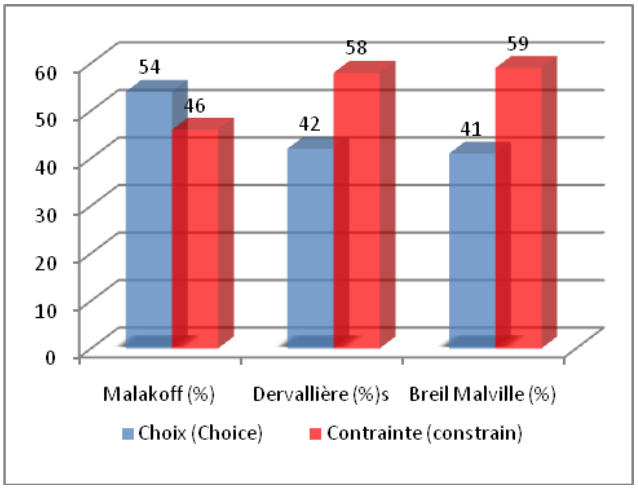

Figure 3: *live you in your district by choice or constraint?*

Evoking the natural and built framework, most of inhabitants interviewed say that architecture which characterizes blocks is banal and old [Fig. 4], consisting of standard buildings dating from the fifties years. Note that this observation is more presents in degrading and not renovating districts like Dervallières. In Breil Malville and Malakoff, renovation of some buildings is well perceived by inhabitants who found it current and original, as well as facades refitting, terrace extensions, with using of some noble materials into facades such as wood, and ceramics (thermal and aesthetic roles), very appreciated by inhabitant. For renovation called “classic” (refitting facade, change of windows), often conducted with some budget constraints, people consider them like a "mask of misery". The outside image of clean and nice building does not reflect true-life of people inside building, this judgment is justified by the bad sound and heat insulation, lack of space, defect, mediocre maintenance and degradation of commonplaces.

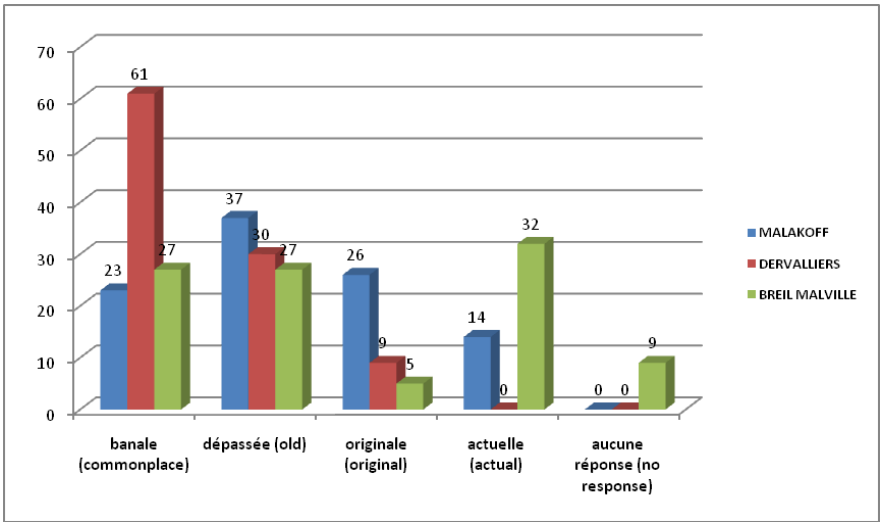

Figure 4: *How do you find the architecture of your neighborhood?*

The will of first architects to develop healthy and pleasant districts away from center town and their pollution (noise and others), has not always been respected in construction of these large-scale housing. Indeed, the choose of implantation sites depends to some land and financial constraints (a property at a lower price). For example Malakoff area built on a site near center town, bounded in the north by a railway that inhabitants see as a major source of noise in district. Contrary Dervallières is built on the site of an old park, near the town center but with more relaxed and calmer landscape. According to surveys conducted in these areas, one can observe that the urban context is not the only determining factor of the sound environment, but the social life and especially social practices are also determining for this atmosphere. In Malakoff and Dervallières, the inhabitants say that district are quite noisy (on a semantic scale of seven levels from very loud to very noiseless), noise sources are mainly associated with racing motorcycles and cars, grouping and discussions at feet of buildings (children and young people), neighborhood noise, young people conflict, renovations noise. Square is a noisiest place in these areas, before children's playing and green areas. Inside buildings, the bad soundproofing gives rise to a less intimate soundscape, as described by an inhabitant [testimony taken 27/07/2009] of Dervallières *"we hear everything in apartments, the neighbouring who walk or who speak, even when they go into WC we know it"*.

Our surveys contain questions about sunshine quality and winds sensation. In three districts, 80 % of the inhabitants say that their apartments are sunny. Indeed, the double orientation of housing allows benefiting from a maximum sunshine hours in different periods during the day. In these three districts, different built forms and orientations can be distinguished. In Dervallières, for example one can find especially low blocks (with an average of 9 floors), so the shadows caused by buildings to others are very low. On the contrary, in Malakoff, buildings are composed of low- and high- rise buildings. The last ones, with their important height (18 floors) and their respective nearness often create extended shadows with consequences on sunshine quality. In Dervallières and in Breil Maville, architect Marcel Favraud privileged an orientation on a diagonal axis (45°), what makes that buildings have a north-west south-est and south-west north-est orientation, which allows an equitable distribution of sunshine on facades. Effectively, 80 % of inhabitants questioned in

Dervallières says that their housing is well sunny, but there are particular cases where some spaces are bad sunny, because of north orientation or plants shading.

Some inhabitants have talked about overheating phenomenon in summer, localized specially in space where openings sizes are large; this finding is verified by simulation of sunshine duration [Fig.5], with the “Solène” software. The simulation affirms an overexposure of some facades. For a maximal duration equal to 12 hours (for a clear sky, and 21 June day) Mean sunshine duration by facade and for day are: 6h58 for North-West, 6h20 for South-East, 9h00 for South-West and 3h25 for North-East. Concerning Malakoff, the architects Evano, Cormier, Choisel and Leroux have opted for North-North West and South-South East facades orientations. 78 % of the inhabitants of this district say that their housing are well sunny, but others find also some spaces especially a rooms with bad orientation (North-North West). We notice that the sunshine duration of this facade is null.

Besides the sunshine quality, wind flow in these areas is also analyzed through inhabitant’s perception and simulation (Saturne software), in order to evaluate the impact of built form. In regards to this climatic factor, inhabitants mainly express discomfort situations. One can notice numerous “corner effects” in studies cases. They consist in wind accelerations at buildings angles, which can reach speed of 5m/s according to simulations made in Malakoff [Fig.6] and Dervallières with a reference wind speed equal to 3 m/s. All the identified effects have been listed in the Beaufort evaluation grid for wind speed [Gandemer G, 1976], that allows considering the impact of wind on the built space in function of categories of wind speed. As example: A speed equal to 5m/s is situated in the category 4 (hair is shaken, leaves and small branch are in permanent movement).

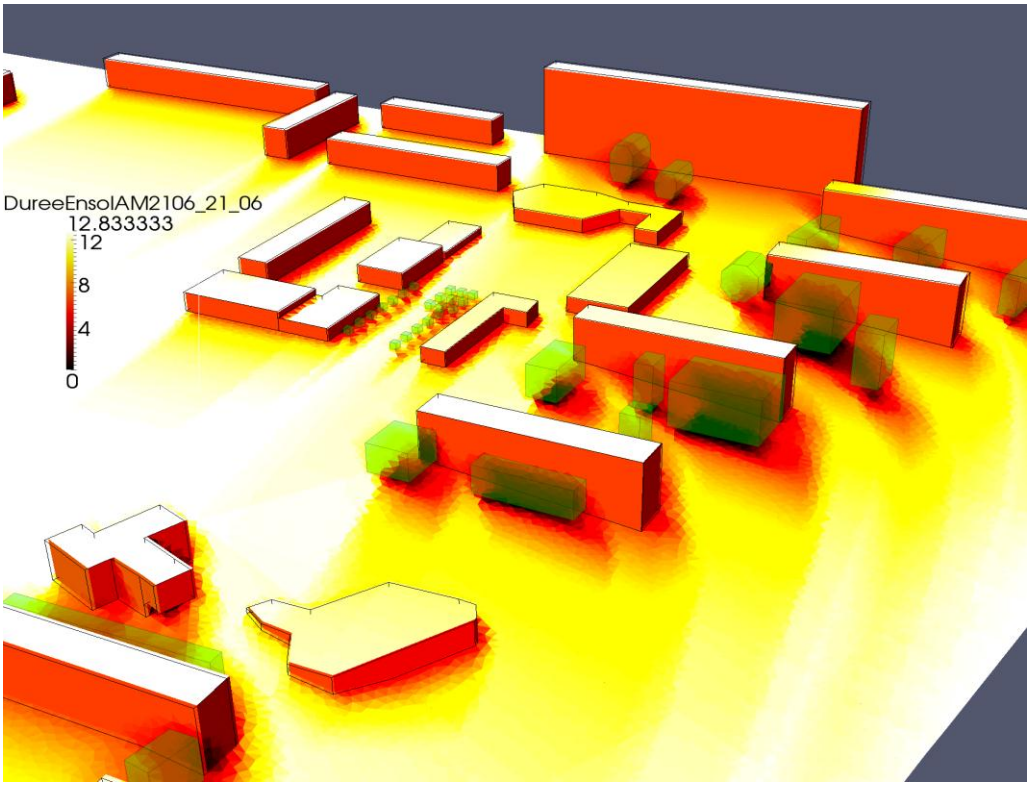

Figure 5: *sunshine duration in Dervallières simulated with Solène software, for summer day 21/06 including the simulation of vegetation*

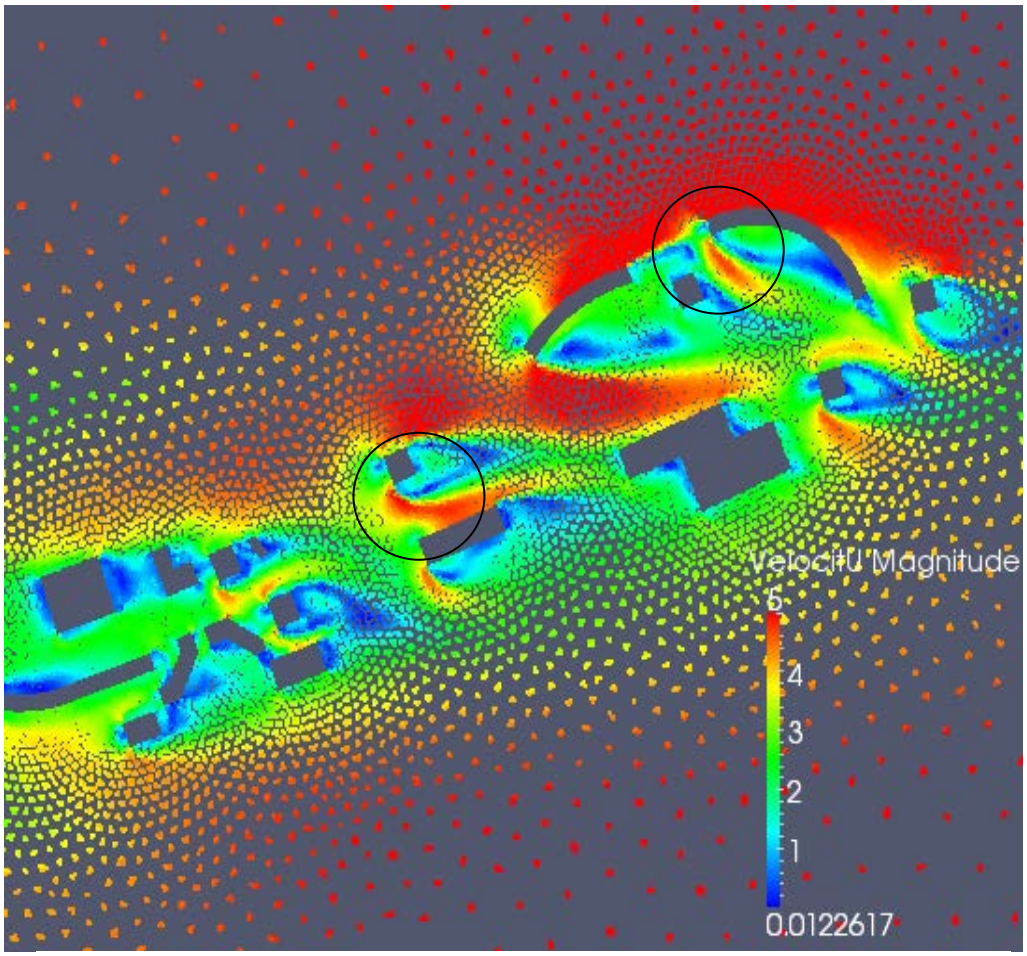

Figure 6: *flow velocity of the wind (m/s) in Malakoff, for west winds. The reference speed is 3 m/s.*

CONCLUSION

Historical and current framework of “grands ensembles” exposed briefly in the beginning of this article indicates that these blocks are French peculiarity because of their construction process and their evolution. However, they have features in common with other models of social housing developed in other countries (Holland, Germany, Spain), in terms of architecture or of their living condition often considered as rough. This study focusing on French cases allowed us to demonstrate that life quality in these districts does not only concern some difficulties that need to be surmounted, but also some qualities that should be highlighted like some inhabitants who manage to ignore negative aspects of their district and to estimate positive aspects, their life spaces become an integral part of their history and their culture. Paul Chemetov says “*ce qui est positif, c’est l’air, la lumière; ce qui est négatif c’est l’enfermement. Comment met-on en relation dans le réseau de la ville, les services, les espaces?* ” (The positive in these areas, is the air, the light; and what is negative? it is the confinement. How can we put in relation the network of the city, the services, and spaces?) [Committee of national Grand Prix, 2007, p35], this architect-planner underlined the quality potential, which still exists in these blocks, namely the natural living environment (aeration, light, sunshine, vegetation).

We notice that low use of their publics areas is justified by social life difficulties (violence, traffic, crime), creating an atmosphere of fear and mistrust among the inhabitants, without forgetting the built degradation. This situation was at the origin of several debates about demolition or conservation of this heritage, where some architects (ex: Claude Vasconi, Lacaton and Vassal) were against the idea to remove these districts knowing that the crisis of housing is still current in France, while others persons estimate that partial and/or total demolition is indispensable. If the inhabitants are globally satisfied by the restructuring of public places in these districts, the most important remains to improve inside buildings quality (insulation, exiguity) where degradation is harder to live and to bear. It is what the three architects Frederick Druot, Anne and Jean Philippe Vassal Lacaton have tried to do in a research paper "Plus" (More) on “grands ensembles”. They proposed to adapt these blocks to the current lifestyle: expansion of livable space, sun lounge with full height, garden terrace, but just one (the tower Bois-le-Prêtre in Paris) of those proposed projects in their research is under realization.

For renovation, we think that architectural and urban atmosphere can be considered as most suitable tool for urban diagnosis in these areas. Because classic sociological surveys not give precise idea of real people expectation in terms of atmosphere quality and wellbeing in their district. Solution can be consisting in organizing some “commented walk” with inhabitants; so as to enable them to describe their perception of district spaces (house and public space). These sensitive experiences can be afterward crossed with physical data (microclimatic, sound and other), what allows designers to clarify some discomfort situations raised by the inhabitants and thus to bring an improvement, or simply to ameliorate atmosphere.

MARGINAL ABATEMENT COST CURVE FOR CO_2 EMISSIONS IN THE MULTY-FAMILY HOUSING SECTOR WITHOUT OR WITH ENERGY EFFICIENY BARRIERS

SYLVAIN LAURENCEAU
researcher, CSTB. French.

CÉLINE VARENIO
PhD student, LEPII-EDDEN and CSTB. French.

Abstract:

First aim of this article is to estimate the CO_2 emissions cuts available in a given building stock. According to our methodology based on a sharp segmentation of the park and a close estimate of refurbishment actions' price and impact on the energy consumption we were able to assess the Marginal Abatement Cost Curve of CO_2 emissions reduction for multi-family building stock in the local area of Grenoble. CO_2 emissions from this stock can be reduced by 72% with casual refurbishment actions. The potential decrease in annual CO_2 emissions reaches300 000 tons. Surprisingly, 92% of the potential decrease is hold by actions that are profitable for a purely rational inhabitant.

Based on those results the second aim of this article is therefore to understand the barriers that prevent housing from implementing refurbishment actions. A case study based on 40 multi-family housings points out liquidity constraints, poor share of homeowners, decision-making in co-ownership and inconvenience as the four main barriers. To integrate those barriers to our model we reduced inhabitants' time horizon and add a fix cost to each refurbishment action. If a reduction in inhabitants' time horizon is not sufficient to explain the poor rate of refurbishment actions observed in the area adding a fix cost of € 15 000 per building is enough to explain them.

Keywords: thermal rehabilitation, local climate plan, barriers to energy efficiency, Marginal Abatement Cost Curve

ACKNOWLEDGEMENTS

This work was done in the frame of the ITEAC project (.i.e. "Integrated Territorial Economic Appraoch for Climate") which aims at gathering methods, data and thinking in order to build a local climate plan. The purpose is to assess, in a bottom-up perspective, the potential and the cost for the reduction of CO_2 emissions for three sectors: transport, building and energy production and supply. A large part of our work relates the first results for the building sector, made in collaboration with ENERDATA. So, we would like to thank Brieuc Bougnoux (Enerdata) and all the researchers linked up with the ITEAC project: LEPII-EDDEN, IDDRI, ENERDATA, VEOLIA, PACTE.

We are especially grateful to Aurélie Tricoire (CSTB) for her helpful comments and discussion.

INTRODUCTION

Since the implementation of the first measures for energy saving and climate preservation, the building's energy efficiency is becoming a core issue in the climate and energy policy

orientations, at the worldwide, European, national or local level. Indeed, this sector represents a large potential for energy savings and CO_2 emissions in the perspective of the implementation of cost effective measures (Price *et al*, 1998, OECD, 2003, De la Rue du Can and Price, 2007, Levine *et al.,* 2007, Ürge-Vorsatz and Novikova, 2008, IEA 2008).

The European Union set up three major directives during the last twenty years aiming at encouraging the Member States to apply minimal requirements on energy performance for the new and existing buildings. The Member States transposed these directives in national law by setting up action plans in order to achieve reducing targets in energy consumptions and GHG emissions.

In France, within the framework of environmental regulation (called the "Grenelle for environment"), a "Grenelle Building Plan" was created with the goal to cut down by 38% the energy consumption to 2020 in existing buildings and by 50% the GHG emission to 2050. It aims in particular at Renovating 400,000 housings each year from 2013 to 2020.

In this context, the forecasting models at national level provide key elements for reaching goals such as the "Grenelle Building Plan" ones (Traisnel *et al*., 2010) as they allow analyzing/testing the public incentives (Giraudet *et al*., 2011). However, the mobilization of local authorities on the energy savings issue in housing is getting stronger (Bailey 2007, Wheeler, 2008). The built up area, which get involved in the Territorial Climate Plan implementation, also enclosed the Grenelle targets regarding this sector in their area. To reach this targets, they use their competences (Housing, town planning etc) to move their territory toward energy efficiency and also provide incentives (financial and non-financial) (IAE-OCDE, 2005, Mckinsey 2008, Criqui *et al*. 2010). Indeed, the mobilization of local authorities on this issue is fundamental because the localization and the context in which buildings were built play a role on there energy efficiency.

That is why our work aims at assessing, at a territory scale, with a bottom-up approach, the environmental and economic impact of technical solutions for rehabilitation and at evaluating the cost of reduction of CO_2 volume. We focus on CO_2 because in the household building sector, this gas represents almost the whole of direct emission of GHG. We produce a marginal abatement cost curve that shows a lot of cost-effective thermal refurbishment measures.

We deal also with the issue of barriers to energy efficiency, in going by an empirical study of multi-family buildings in Grenoble area. We modify our initials assumptions to take into account the two mains barriers identified in this study and produce a new abatement cost curve.

In a first section (§ 0, p.3), we present the main criteria to carry out a relevant segmentation in order to study, from a technical point of view, the building refurbishment, i.e. the type of housing (multifamily apartments), the year of building's construction and the energy source used for the heating system. The criteria selected to carry out a segmentation of the park determine the business as usual scenario of the energy consumption and CO_2 emissions of the existing housing.

In a second section (§ 0, p.5), we come back on the principal technical solutions currently available to reduce building energy consumptions. We observe, for a standard case, the impact of these various solutions on energy consumption and CO_2 emissions.

In a third section (§ 0, p.7), we show the economic impact of these various solutions by analyzing their profitability, through indicators such as payback period, net present value and cost of an avoided CO_2ton. These estimates allow treating on a hierarchical basis the solutions according to their technico-economic effectiveness.

In the fourth and last section (§ 0, p.10), we deal with the issue of the barriers to energy efficiency, by identifying them, starting from an empirical study. We observe then the impact of the modification of the assumptions concerning present preference of the households (by reducing the payback time) on the profitability and on the cost of the CO_2 avoided of the technical solutions.

THE SEGMENTATION OF THE HOUSING PARK

We deal only with multifamily apartments and we hold two main criteria: the year of construction of the buildings and the energy source used for the heating system. We also take into account climatic data, characteristic of the studied zone.

The building's age

The date of construction makes possible to provide key information on materials used for the construction and the thermal characteristics of the building (Table). The delimitation of each period can be done according to:

- Great historical periods marking the urban history such as the Revolution, wars, the Thirty Glorious Years (i.e. the French economic welfare between 1945 and 1975), the oil crisis, etc.
- Modifications of urban policy such as the policy of the post-war period, the stop of the construction of towers blocks etc
- Changes of constructions regulation and standards which followed since 1975.

Period of construction	Context	Building materials	Energy performances
Before 1945	Period "Haussmannienne", no thermal regulation (RT)	Depend on the areas (local materials) Mainly stone and brick	Weak
1945-1974	Post-war period, lot of construction. no RT	Thin walls, in concrete without insulation, no double glazing	Very weak
1975-1981	Oil crisis which induces the 1st RT (1974)	Emergence of prefabricated systems, beginning of walls insulation, ventilation system etc.	Weak_average
1982-1999	2nd RT (1982)	Smaller buildings, generalization of double glazing and wall insulation, beginning of materials certification, beginning of old building's refurbishment	Average
After 2000	3rd and 4th RT (2000 and 2005), (RT 2012 forthcoming).	Reinforcement of wall insulation, reduction of heating needs, increase of the equipments' energy performances ; creation of new labels for buildings' certification	strong

Table 1: *Thermal characteristics of the buildings per period of construction*

The information provided by the last census of the French national institute of statistic and economics studies (INSEE), makes possible to carry out a segmentation of the housing stock on the Grenoble area according to the period of buildings construction. It appears that among the 166,311 housing in this area (including 82% of multifamily apartments), 101,744 housings (61%) were built before 1975 and 76,553 (46%) between 1945 and 1975 (information collected by Enerdata, in the framework of ITEAC project).

The large part of old housings, built with materials and techniques used between 1945 and 1974, shows an important potential for energy savings on this territory.

Heating system

The energy source (gas, fuel, heating network, electricity) and the mode used for heating (central or individual) have an impact on energy consumption. The gap between energy consumption generated by gas and the one generated by electricity is explained mainly by the fact they are expressed in primary energy (ep) which includes the energy lost between the energy production and the supply of energy in the buildings (energy actually used by consumption). The conversion factor from final energy to primary energy is 1 for all fuels (here, fuel and natural gas) and 2.58 for electricity, in order to take into account the output of electricity production and transmission. This factor of 2.58 corresponds to an international convention. It aims to compare energy consumptions according to the various sources used. In France, a controversy exists about this factor because electricity is produced mainly with nuclear power plants (between 70% and 90%) and with hydroelectricity and this factor is thus suspected not to reflect reality by exaggerating the losses related to the production and transport. However when demand peak occurs, the production is done starting from fossil energy (either in France by historical producer EDF, or in another country like Germany which exports it in France). By convention, we preserve this factor of 2.58 and tackle the question of the energy consumption of the residences in primary energy by preoccupations with coherence with the thermal regulation.

Expressed in final energy, the residences heated with electricity are less energy consuming than those heated with other energetic sources. We chose to express consumption in primary energy because the electricity production and transmission are directly related to the demand. On the other hand, expressed in CO_2 emitted, emissions are more “favorable” to electricity, at least in France, because of the large share of the nuclear power in the electrical production.

Assessment of consumption by segment: example of the Grenoble area

In crossing energy consumption by segments resulting from theoretical simulation, with the number of multifamily apartments per segment in the Grenoble area we can (i) estimate energy consumptions and the total CO_2 emissions of the multifamily housing park and (ii) identify the segments which represent the main potential of reductions.

On the figure above, it clearly appears that the buildings from 1945 to 1974 produce the most significant share of energy consumptions and CO_2 emissions.

This is explained on the one hand because this segment represents the largest number of housing in this area but also because, as we explained in section 1, building from this period have bad thermal characteristics and thus large energy loss.

But, the high share of building built in this period (46 % of the total park of multifamily apartments) can’t by itself explain the 63% of CO_2 emissions. Indeed the gap between CO_2 emissions (63%) and energy consumption (56%) is explained by the energetic mix in each period. For instance, the buildings build before 1945 are more heated with electricity (approximately 43%) than those of 1945-1974 (approximately 14%) which are mainly heated with gas (57%).

The segmentation per construction and heating energy mode enables us to draw a representation of multifamily park and to identify the segments on which it is necessary to first operate for

thermal refurbishment. It appears that buildings built between 1945 and 1974 are those on which it is most relevant to act because they have a large potential of reduction.
The determination of the energy consumptions and CO_2 emissions and the identification of the segments which have an important potential for reduction are only the starting point of our study. The final objective of this part is to evaluate the economic impact and environmental various technical solutions.

TECHNICAL SOLUTIONS FOR THERMAL RENOVATION

A broad panel of current technologies exists to carry out energy savings allowing smaller energy consumption than standard practice (Novikova, 2010). These technologies relate to various solutions such as insulation (of walls, roofs, floors etc), improvement of heating system performance, ventilation system. Technical solutions identified here only deal with the reduction of heating consumption. Moreover, we chose "ambitious" measures because of the long lifespan of the equipment in the building, and when heavy work is undertaken (like external wall insulation or boiler replacement), it is unlikely that they are reiterated quickly. This works are called "no regret measures" because it is more efficient to implement them in one time and if retrofit measures are coupled with general refurbishment, it represents a win-win opportunity (Petersdorff *et al*., 2004)

Insulation
The energy losses due to bad walls and windows insulation affect the thermal characteristics of building. If the shares vary according to the date of construction, the main loosing area is often the same: walls, windows and joineries.

- External walls Insulation: it is still poorly developed in France (Orselli, 2008). However, the restoration of the external wall is the good opportunity to add insulation (the repair of the sealing must be carried out every 20 years. This operation can be the occasion to complete work with thermal insulation). Unlike interior insulation, it makes possible to treat a greater number of thermal bridges, without provoking a lost of living space and without decreasing the building inertia. It involves also less nuisances for the occupant during the works and protects the walls against climatic risks. Several techniques of insulation exist, the main one being the installation of an insulating material covered with a coating. The insulators can be alveolar plastics or mineral wool. The effectiveness of the insulation depends on thermal resistance (R) of material used.
- Roofs insulation: they are subjected to the climatic variations (such as thermal freezing, rain, shocks etc.) which deteriorate the roofing and the tightness. The roof thermal losses account for 9 to 11%. The roofs insulation has an important potential for energy saving and its implementation is less heavy than wall insulation. It allows to reduce energy consumption and to improve comfort for the inhabitants in the top floor.
- Low floors insulation: floor lead to losses from 5 to 7% for the independent buildings and up to 9% for the joint buildings. For the apartments located at the ground floor, the floor insulation is a source of energy savings and comfort improvement. It is possible to insulate over or under the concrete flagstone. The choice of one or the other technique will depend on the accessibility of the lower part of the flagstone.

- Windows: thermal losses coming from windows can represent up to 50% of the total thermal losses of a building. In housing, window has several functionalities: it allows improving air quality by natural ventilation and it offers a natural lighting and source of heat by the recovery of thermal contributions of the sun. To reduce the losses, it is

possible either to improve existing windows, or to entirely change them. First solution is possible if original joineries are still in good condition. The second solution is recommended when original windows are in bad conditions. The replacement can be done either by preserving the door frame, or by replacing the complete door frame. Joineries can be out of wood, PVC or metal. PVC framing is most widespread because it resists the bad weather and does not require maintenance unlike joineries in wood. Metal fixed frame (aluminum) is generally reserved for large surfaces windows.

The heating system

According to the French thermal regulation for existing building (RT ex 2005), the electric radiators installed or replaced must be controlled by a powerful integrated electronic device, with at least four operating process (comfort, reduced, no-freezing, stop) and must have timer if they have other functions (blower, towels warmer etc). The standard convectors present very high electricity consumptions. Electrics radiators (with radiant source of energy) offer more homogeneous with low consumption. When the change of radiator is done at the same time or after the insulation of the building, the power necessary will be lower.

Regulation and programming allow regulated heating temperature according to external conditions and free energy contributions. A powerful electric radiator, equipped with a thermostat, can reduce from 5 to 15% the energy consumption compared to an old convector without thermostat.

For the boilers (individual or collective system), considerable progresses were made during the last years. They offer a better output and thus allow reducing energy consumptions. The two principal innovations for boiler are:

- Low temperature boilers: they have an output from 80 to 90%. They allow carrying out 12 to 15% of profits compared to traditional ones,
- Condensing boilers: they reach an output higher than the low temperature boilers thanks to the recovery of the after-heat contained in the steam of the gases combustion which are evacuated by the chimney. They make it possible to carry out from 15 to 20% of profits compared to a traditional boiler. By condensing the steam of combustion gases, they recover energy, allowing a reduction in the fuels needs. Because of their low level of CO_2 and nitrogen oxides, these boilers are also less emitting in GHG.

Ventilation system

The improvement of the ventilation system must be taken into account as soon as people want to optimize the energy performances of the ventilation system (it is a measurement of full-fledged energy saving, because air renewal generates a reducing in energy losses of around 30%), but also as soon as the thermal insulation of housing is improved (in complement of the insulation). Thus, the mechanical ventilation (MV) becomes essential to control air flows necessary to the sanitary arrangements for households.

A system of MV makes it possible to removal the inside air of the buildings while controlling the necessary flow. The air is introduced in frontage, circulates in the buildings then is included in the wet parts (kitchen, bathroom) before being rejected.

With heat recovery ventilation, the extraction and the air intake are mechanized and controlled. With heat exchanger, 90% of the evacuated hot air calories can be potentially recovered. But this technique is less cost effective than MV, because it requires more maintenance and has an electric consumption 2.5 times superior.

The Table 2 sums up the technical solutions that we integrate in our model for assessing reduction potential.

Solutions	Effectiveness	Example of technique
Wall insulation	R = 5	Polystyrene plates (15 cm, λ = 0.03)
Roof insulation	R = 5	Polyurethane plates (14 cm, λ = 0.028)
Floor insulation	R = 2,6	Glass wool (10 cm, λ = 0.039)
Windows	Uw = 1.2	Double glazing, high quality joint, PVC framings
Electric radiator	High efficiency	News radiators with integrated thermostat
boiler	High efficiency	Condensing boilers
Ventilation system	Controlling flow	Mechanical ventilation

Table 2: *Technical solutions used in the model*

We choose these main options for our assessment, but several others solutions exist (technological and non-technological), that will be integrate in our research.

ASSESSMENT OF THE TECHNICAL-ECONOMIC REDUCTION POTENTIAL

Methodology and assumptions

The aim of this section is to assess the marginal abatement cost of CO_2 emissions in the multi-family building stock in a given area (the Grenoble area) according to the cost of the CO_2 ton. The main target is to identify the refurbishment actions considering the price of the CO_2ton which make the investment profitable for society.

For every type of technical solution described in the previous section we calculate the Net Present Value (NPV) with a discount rate of 4%. This rate is used by governmental organizations to assess the efficiency of public investments since 2005 (revision of the actualization rate of public investments, chaired by Daniel Lebègue, Commissariat Général au Plan, January, the 21st 2005). We assume an increase of energy prices of 3% a year (this increase rate corresponds to the projection of IAE in 2008 and is usually used in forecasting models).

The assumption about the technical solutions' life time is based professional building field. We assumed that equipments –heating and ventilation systems- have to be changed after twenty years and the other refurbishment works have a life period of forty years.

Price of refurbishment works are based on a professional database used in building sector (the *Batiprix* database), enlightened with our expertise. We decided to assess the price of refurbishment works on marginal costs instead of total cost for wall and roof insulation. This means that we only took into account the cost of insulator equipment and not the cost of front refurbishment or roof waterproofing. For the other kind of work the cost of the full operation is taken.

To assess the impact of refurbishment actions on the energy bill we used thermal simulation software ("BAO Promodul tertiaire et collectif"), requiring an exhaustive description of the building. This software provides two different ways to evaluate the energy consumption. The first one is the calculus process used in the French regulation (called "TH-c-ex") and the second one, called below the behavioral calculus process, is closer to the German PHPP calculus process. To get more consistent results and to have elements of comparison between those two processes we made the estimation with both of them. After assessment, we chose to use the behavioral calculus process, because the results are closer to the real consumptions according to the developer of the thermal program and empirical verification. Results using THC-ex are not presented in this paper but were done to validate the results presented below.

To describe the buildings we chose between an isolated and an adjacent configuration. We decided to consider every building to be all adjacent both because buildings in the area studied are predominantly adjacent and because it tends to offset the overestimation of refurbishment actions stemming from the additive assumption described in point 0 (p.8).

Besides we assess the CO_2 emission cuts stemming from the refurbishment work over the life period. Based on the spare amount of CO_2 we then evaluate the price of the CO_2 ton that nullify the NPV. This price indicates the cost of CO_2 ton that would make the investment cost effective. For example a cost of CO_2 ton of €48 indicates that a household will not implement the refurbishment measures unless he is forced to pay a fictive tax of at least €48 for every ton of CO_2 they produce.
At this point we have, for every type of refurbishment work in every segment of building, the volume and the cost of CO_2 ton avoided that make the refurbishment work profitable.
In crossing this assessment with INSEE data presented in point 0 (p.4), we can calculate the marginal abatement cost for each segment and classify the different refurbishment work and their global impact according to the price of ton of CO_2 in order to build Marginal Abatement Cost Curve (MACC).
In order to take into account different refurbishment packages, i.e. the combination of various refurbishment actions on the same building, we tested two different hypotheses, one additive and the other cumulative:

- The additive hypothesis assumes that the effects of refurbishment actions are identical in all refurbishment packages. For example, if wall insulation reduces energy consumption by 20% and roof insulation reduces energy consumption by 10% the package would reduce energy consumption by 20% + 10% = 30%.
- The cumulative hypothesis assumes that the relative impact of a refurbishment action remains constant. For example, if wall insulation reduces energy consumption by 20% and roof insulation reduces energy consumption by 10% the cumulative effect would reduce the consumption by 1 – (1-20%)*(1-10%) = 28%.

We tested both assumptions on a couple of cases and finally opted for the additive assumption as it was closer to the software results for the whole package, although the impact was slightly overestimated. The additive assumption is closer than the cumulative one as some refurbishment actions have a synergetic effect. For example, the implementation of a sophisticated controlled mechanical ventilation system is useless if there are high air leakages by the windows. Mechanical ventilation and window change are therefore working in synergy. And if the complete insulation of the building is made the power of the heating system can be lowered.

Results
According to our model, the overall CO_2 emissions of multi-family housings' heating system in an urban area reach the level of 40,414 tons each year. To control our assessment, we compare the initial overall CO_2 emissions stemming from our model to a previous estimate made by the center which made the emission inventory in this area (In Grenoble urban area an inventory of energy consumption and CO_2 emission is conduct by ASCOPARG. This kind of inventory is conducted in almost all urban areas in France). With an estimated level of emissions of 370,000 tons each year for collective housings' heating system emission our results are closed to this estimation.
This level of emissions corresponds to a level of energy consumption of 2,469 GWh of primary energy, about 229 kWh per net floor area square meter.

Figure 1 presents the marginal abatement cost curve taking into account energy gains over the entire life of refurbishment actions.

As we also took into account energy consumption for domestic hot water in collective housings with individual gas boiler, the overall CO_2 emissions are a bit higher than in the previous part. Indeed, annual CO_2 emissions level including domestic hot water in collective housings with individual gas boiler reaches 447,254 tons.
The implementation of all refurbishment actions taken into account can reduce annual CO_2 emissions in the multi-family building sector by 300,000 tons. If we focus on heating system emissions, the potential cutbacks reach 290,000 tons, representing 72% of CO_2. The curve can be broken into three distinct parts:

- The first 20% of CO_2 potential cutbacks have a carbon price below €-200s
- The 72% followed lies in the €[-200; 0] range
- The last 8% have a positive price.

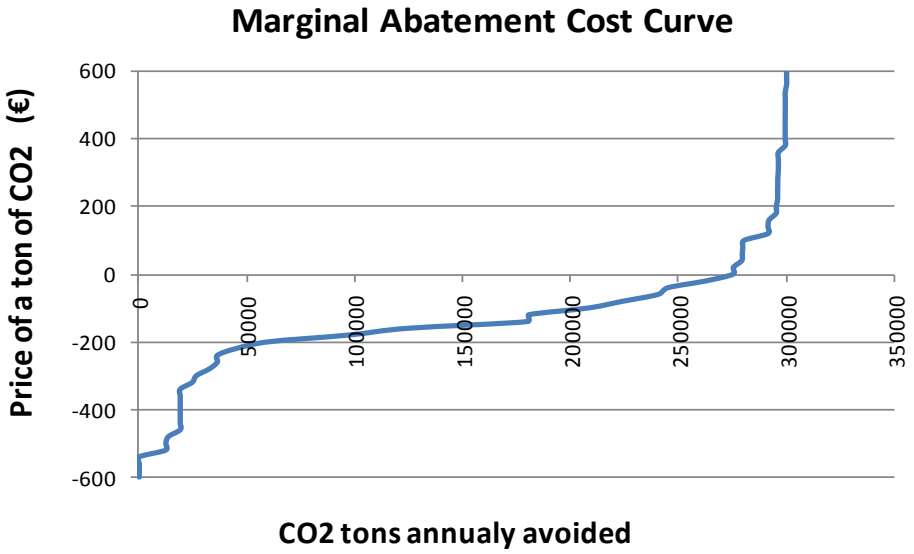

Figure 1: *Marginal abatement cost curve with life cycle analysis*

The reduction potential is different according to the period of construction and the technical solutions:

- Potential CO_2 cutbacks vary greatly with the period of construction: 1945-1975 buildings account for 59%; ante – 1945 buildings account for 27% and post 1975 buildings only account for 11%. As shown on the **Error! Reference source not found.**, the MACC is highly sensitive to the cost of the CO_2ton when its price varies between €-200 and €-20. 48 of the 115 actions are profitable on this price range. Besides, those actions stand for 68% of the potential CO_2 emissions cutback. Multi-family apartments built between 1945 and 1974 account for 44% of total collective housings in the urban area but stand for 60% of the potential of CO_2 reductions. Ante-1975 multi-family housings represent 68% of the overall housings but account for almost 87% of the potential CO_2 cutbacks. Those buildings should clearly be the heart of a low carbon refurbishment plan.
- Refurbishment actions taken into account also have different potentialities. Equipments renewal or installations stand for almost half of the potential, with change of boiler accounting for 26% of the CO_2 decrease and the ventilation system accounting for 20%. Insulation accounts for the other half of the potential, divided between wall insulation -24%-, window replacement -14%, roof insulation -9% and floor insulation -7%. Roof insulation does not account for a large share of potential reduction because of French regulations forced to isolate the roof since 1974. The impact of equipments might be overestimated as some collective buildings might have already replaced their boilers and

as the impact of ventilation system is very difficult to assess. Impact of floor insulation might as well be overestimated as we assume this action to be possible in every situation.

Finally we find four main categories of buildings after our assessment of cost effective measures: untouched (14%), poorly refurbished (i.e. with one or two actions (23%)), well refurbished (i.e. between three and five actions (47%)) and totally refurbished (16%).

The cost of those actions is M€1,793. This gives an average price of CO_2 ton avoided of €3,900.

Implication for energy policy
In France, the 2009 "Grenelle" legislation as the Grenoble Climate Plan, stands that CO_2 emissions in existing buildings have to be cut by 50% until 2050. According to the results presented in Figure 1, this goal should be achieved with a negative carbon cost of -€156 per ton.
Looking closer at refurbishment actions with the national target provides a different perspective concerning their distribution and impact.
At this cost of the CO_2 ton for ante – 1975 buildings stands for 93% of the CO_2 cutbacks, divided almost equally between the ante – 1945 and the 1945 – 1975 periods. Ante 1945 buildings now account for 48% of the potential while they only account for 27% of the overall CO_2 potential decrease, while the impact of buildings built in the 1945-1975 period is lowered.
The price of reaching the policy target is about €375,000,000. This gives a global price of the CO_2 ton avoided of about €2,150 euro. In integrating the reduction of energy bill, the weighted price of the CO_2 ton is -€227.
The main result of this graph is that 92% of CO_2 cutbacks are due to refurbishment measures with negative CO_2 cost, which means that those actions are actually profitable for society and should be naturally implemented. Therefore there are huge lacks in our model, especially in the description of the inhabitant behavior, we can wonder why those refurbishment actions have not in fact been implemented for the overwhelming majority. Understanding those lacks will be the aim of the last part of our article.

ENERGY EFFICIENCY BARRIERS

In spite of many opportunities to reduce energy consumption and CO_2 emissions at low cost, energy efficiency actions are realized at a slower rate than expected (Novikova, 2010). This is due to various barriers such as technological, informational, market-based and behavioral (as bounded rationality) characteristics (Jaffe and Stavins, 1994, Golove and Eto, 1996, de T'Seclaes, 2007, Gillingham *et al.,* 2008).

A case study: a Policy for thermal rehabilitation of 40 multifamily building in Grenoble
A thermal rehabilitation plan in a district of Grenoble was launched by the city. Among the whole technical solutions suggested, all were profitable maximum in 20 years. Moreover, in addition to the national aids (tax credit, loan without discount rate), the city brought a help in order to reduce the payback period. However, among the 43 buildings which had to make a renovation (for aesthetic reasons), which could receive financial aids and which received an energy survey financed by the city, only 22 decided to do energy efficiency works and only 2 did ambitious works (replace the boiler, walls insulation, installation of ventilation system). The others undertook between 1 and 3 operations.
This shows that even if some barriers are reduced, some of household do not invest in energy efficiency.

We carried out interviews with the agents charged to contact the households and to incite them to carry out refurbishment works, the syndics who represent 150 households and some households. From these talks, we identified the following barriers:

- Liquidity constraints: the households do not have the possibility of releasing the funds necessary for work or, when they have savings, they prefer to preserve them for other uses. This shows that the households associate works to an opportunity. Among the owners, the greatest part of them is represented either by old people or by young first-time buyers. According to the syndics, liquidity constraint is the main barrier to invest.
- The weak share of homeowners: for the buildings we studied, less than 50% of the household are owners of their housing. This element strongly reduces the will for an owner to complete work because it is not him which will recover energy saving.
- The decision-making in co-ownership: the decision to complete works, in the case of the condominiums needs a vote in general assembly. This step requires time, implication and negotiations of the whole owners which can cause discouragement. Besides some actions, e.g. roof or floor insulation, have different impacts depending on the location of the flat inside the building. Splitting the cost can be very difficult in some assemblies.
- The inconvenience of the works: this barrier depends on the kind of works, but a part of respondents pointed it out.

The difficulty is to estimate the cost of these barriers in order to determine their impact on the potential and to see how the public authority can face them.

News assumptions and perspectives

The results we presented in the previous section are obtained by assuming no other cost than refurbishment actions and with long term anticipation. This is the reason why the main part of refurbishment actions is implemented with a negative CO_2 price.

To take into account barriers like lack of information, short term view or liquidity constraints, we tested two new assumptions.

First, we reduce the decision maker's time horizon. Reducing the time horizon is a way to account for inhabitant's short term vision but it can also be the consequence of other transaction costs. This modification is equal to an increasing of discount rate. Indeed, we increase the consumer discount rate to reduce the payback period. From a social perspective a low discount rate must be used to identify the economic potential, but from a household perspective, this rate can represent the more or less "short-sightedness" (Frederick *et al*. 2002).

We find a new marginal abatement cost curve with a five year horizon in the inhabitant estimation of the NPV (Figure 2).

Even with a five year time horizon, 43% of the CO_2 potential cutbacks should be implemented with negative cost, but potential decreases with highly CO_2 price sensitive between –100 and 0. 15% of the potential cutbacks have a price below -€100 and only 6% have a price below -€140.

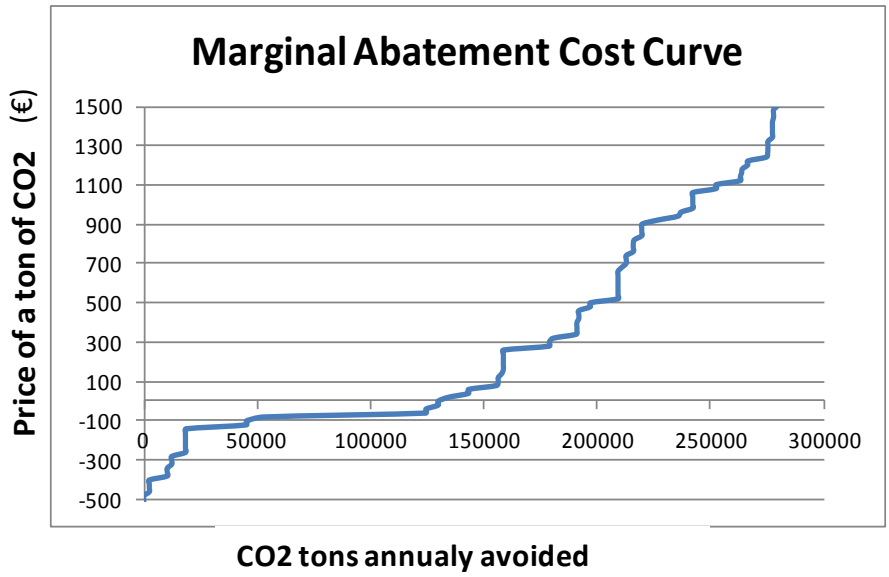

Figure 2: *Marginal abatement cost curve with a five year horizon*

Second, to take into account the inconvenience of such refurbishment actions we added a fix cost to all actions. In our model the fix cost for the building is the same for every type of action, although inconveniences stemming from refurbishment works can vary greatly. In fact, the aim of this part is to assess the sensitivity of the MACC to the fix cost rather than trying to properly estimate those costs.

With a fix cost for the building of €15 000 per action – being €1 071 for ante 1945 buildings and €536 for the rest of them- only 3% of CO_2 cuts are profitable for the inhabitants with a five years' time horizon. The MACC is therefore highly sensitive to the existence of a fix cost. On the contrary, with a fix cost of €20 000 per action for a whole building 75% of CO_2 cuts remains profitable.

A public action targeting the lengthening of inhabitants' time horizon should therefore be very efficient for the barriers that could be model by a fix cost. With the five year horizon and with a fix cost of €15 000 per action, any actions nullifying this cost would lead to an annual decrease in CO_2 emissions of 130 000 tons.

CONCLUSION AND OPPORTUNITIES FOR FURTHER RESEARCH

The methodology developed to estimate initial CO_2 emissions and potential decrease can be implemented for other building stock and should be used by any authority involved in a Territorial Climate Plan.

The first part confirms that the building sector holds a vast potential of CO_2 emissions cuts and that a large part of this potential should be reachable with no expenses from public authorities.

The originality and the main contribution of this article are to bring elements to develop a methodology to understand why those refurbishment actions are not implemented in the real world. The shortening of inhabitants' horizon or the introduction of a fix cost reflecting the inconveniences stemming from refurbishment actions are the two options explored in this paper but other barriers could be questioned in a later work. In particular, liquidity constraint and fix cost dependent from the type or the number of actions are possible assumptions to test. Besides, another development of this work could be the calibration of those barriers based on case study results.

Finally, the households support their decision to invest in energy efficiency measures on a discriminating criteria (improvement of comfort, reduction of noisy, improvement of the inside air quality etc) which decreased the only weight of economic criterion. In such a context, the use of cost effective analysis is relevant to include/understand the policy guidelines and particularly the choice of incentive tools, but it can be interesting to couple it with a multicriteria analysis in order to better comprehend the gap between the theoretical results and the choices of households.

Abstract
As in many industrialized countries, the population of Germany is constantly getting older and smaller nowadays. These demographic changes cause adaptations of technical and social infrastructure in both quality and quantity, to ensure their aspects of economy and usability at long term. Therefore, urban development planning and municipal infrastructure planning have to work closely together. Decisions like expansion, renovation, re-dimensioning or even closing of municipal infrastructure should be based on long term strategies of urban development, in order to meet the budget of future remaining costs. For this reason, development strategies and important new projects have to be evaluated within their infrastructural running and life cycle costs.
A current research project in cooperation with a German Municipality will enable the involved planning teams to systematically integrate the consequences of demographic changes in their infrastructural projects in terms of supply quality and cost efficiency. As part of the project, this first study prepares the database of cost indicators and their drivers for municipal infrastructural project cost estimation in early project phases.

Keywords: Urban Infrastructure, Costs Planning, Demography

INTRODUCTION

As in many industrialized countries, the population of Germany is constantly getting older and smaller nowadays. These demographic changes cause adaptations of technical and social infrastructure in both quality and quantity, to ensure their aspects of economy and usability at long term. Therefore, settlement development planning and municipal infrastructure planning have to work closely together. Decisions like expansion, renovation, re-dimensioning or even closing of municipal infrastructure should be based on long term strategies of settlement development, in order to meet the budget of future remaining costs. As well as development strategies and large new projects have to be evaluated within their infrastructural running costs.
In 2009, two Institutes within the University of Stuttgart started a research project together with the City Administration of Stuttgart (Department for Urbanism and Urban Redevelopment) that will enable municipal planning teams to systematically integrate the consequences of demographic changes in their infrastructural projects in terms of supply quality and cost efficiency.

If for example urban planners have the opportunity to (re-)develop two different industrial wastelands (brownfields A and B) as well as one greenfield (C) within the city limits by installing residential wards, the tool to be developed at the end of this project will help to understand the specific financial input in the case of developing each area. These investment and occupancy costs include all necessary social and technical infrastructure by taking into account possible capacities of existing surrounding infrastructure, as long as these assets are integrated into a Geographic Information System (GIS) database. On the other hand, planners will get information on financial output from these new developments, based on e.g. real estate sales and future tax incomes.
These estimations demonstrate financial input and output of possible infrastructure investments over a timeframe up to 20 years and thus represent an adequate planning tool for variations within a single project as well as being a helpful tool for decision making when comparing two or more alternative developments. It might even allow them to fit the financial characteristics of a certain project into the complex municipal budget by finding the right schedule for project start.

The first idea of the proposed tool is based in on a series of precedent research projects in Germany [Preuß et al. 2009], [BMVBS 2011], [Planersocietät 2011]. And the aim of this study is to contribute to this special kind of research while developing a specific and localised tool ready to use together with and for our public partner.

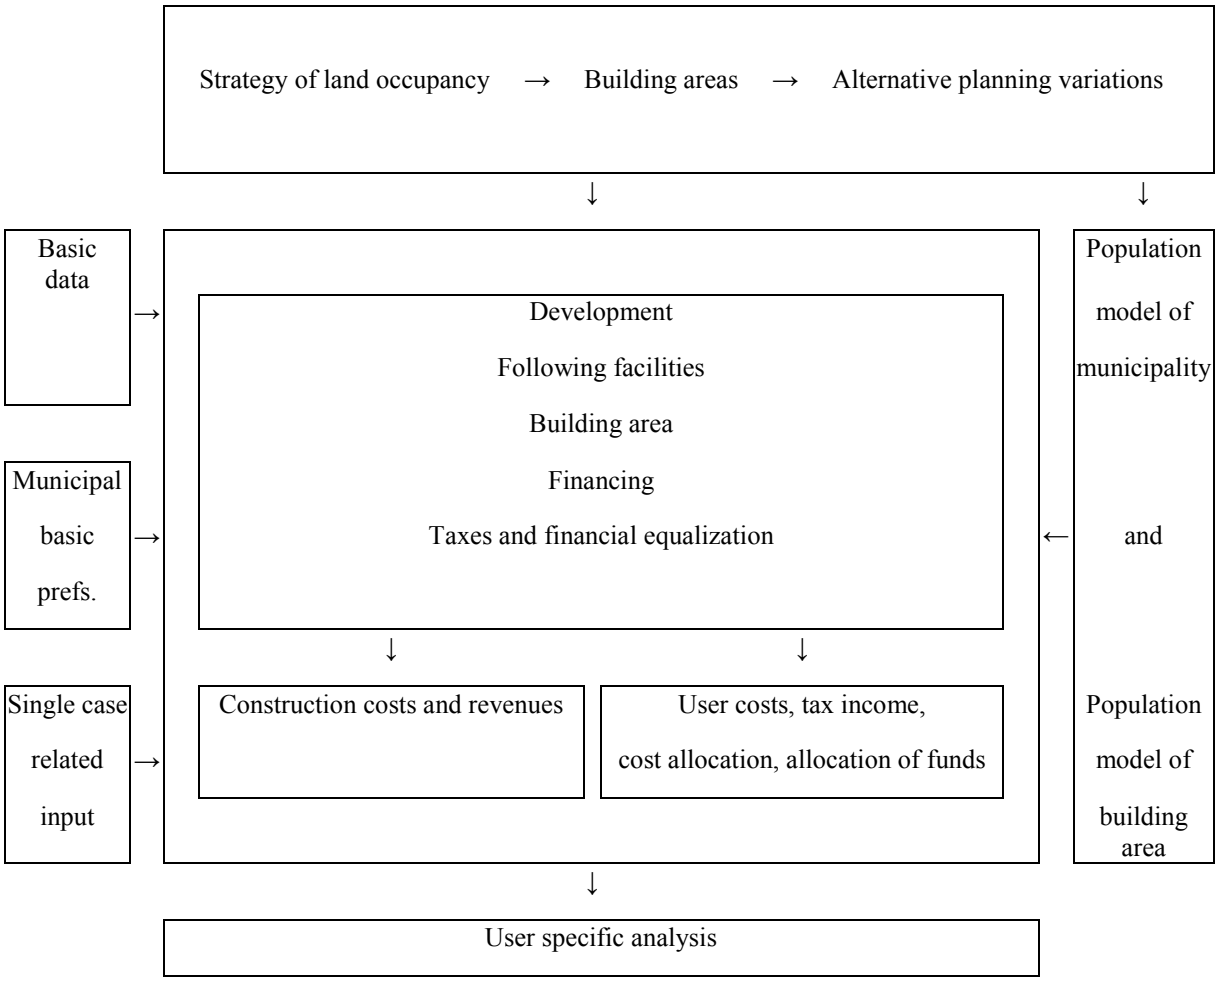

Figure 1 : *System concept and modules; example based on LEANkom [Planersocietät 2011]*

As part of the larger project (compare figure 1), this first study prepares the database of construction cost indicators as well as user cost indicators and their drivers for municipal infrastructural project cost estimation in early project phases.

PROBLEM STATEMENT

Municipal infrastructure in Germany consists mainly of two main types called social infrastructure and technical infrastructure, subdivided in their subtypes as shown in table 1.

	Type	Subtype	Example
Infrastructure	Social Infrastructure	Institution for Education	Kindergarten, School, University, etc.
		Institution for Health Care	Hospital, Rescue Institution, etc.
		Institution for Culture	Museum, Library, etc.
		Institution for Public Administration	Governmental /Municipal Administration, etc.
		Institution for Public Security	Police, Fire Department, etc.
	Technical Infrastructure	Transportation	Public Transport, Facilities for Private Transport
		Communication	Telephone, Internet, Broadcast, etc.
		Supply and Disposal	Water / Sewage, Energy, Waste, etc.

Table 1: *Types of infrastructure*

In order to enable our model to calculate construction and user cost estimations of social and technical infrastructure elements in the area to be developed, we need the necessary quantities and related cost indicators based on the same unit:

Equation 1: $Ce = q_y \times ci_y$

Ce = Cost estimation (construction costs, user costs at a single point in time)
q_y = quantity (based on unit y)
ci_y = cost indicator (based on unit y)

We will learn in a later part of the project how quantities will be defined and managed by the model, so at this stage the correct value of a quantity is taken as given. But it is important to pay attention to the unit of this quantity, as the cost indicator to be chosen has to be based on the same unit. This might be obvious in theory, but in many cases it happens to be rather difficult in real life.
As far as buildings are concerned, measurement of quantities and the related units are defined in detail in the German standard "DIN 277: Areas and volumes of buildings" [DIN 2005]. The corresponding standard "DIN 276-1: Building costs – building construction" [DIN 2008-12] defines the related cost groups for each quantity based on corresponding units for construction costs. And the standard "DIN 18960: User costs of buildings" [DIN 2008-02] defines cost groups for user costs. In addition, cost indicators for building construction costs are largely known and published, e.g. by Building Cost Information Center of German Architectural Associations [BKI 2011], and BKI just published its first user cost indicators for schools and kindergartens [Stoy et al. 2010]. All of this published data by BKI is based on above mentioned DIN standards. This means that most part of the database of cost indicators

for social infrastructure types (buildings) are well defined by specific standards, already collected or published and ready to use for early phase cost estimation.

But it is obviously different in the case of technical infrastructure. Only since two years now, there exists a German standard named "DIN 276-4: Building costs – Part 4: Civil constructions" [DIN 2009], and its corresponding standard of measurements still is missing totally. And nearly every technical infrastructure project in Germany seems to be calculated in a more or less execution oriented way. In that case, some types of technical infrastructure like roads and bridges may be based on a publication called "Catalogue of Typical Specifications for Road and Bridge Construction (Standardleistungskatalog für den Straßen- und Brückenbau)" [BMVBS 2009], but its execution oriented structure makes it quite difficult to use it for early phase cost estimation. In addition, there is no known published German data yet that might be used as cost indicator, neither for construction nor for user costs of technical infrastructure types. Construction companies seem to keep the data as their secret.
Even the German Sustainable Building Council (Deutsche Gesellschaft für Nachhaltiges Bauen, DGNB) – the institution of the German label for sustainability in building construction – would need a reliable database of technical infrastructure cost indicators when it comes to their new label for sustainable neighbourhood development, especially in terms of life-cycle-cost analysis. But their experts who are just about to finish the development of this special type of DGNB label, can only confirm the lack of this kind of published cost data and structure in Germany.
This means that in order to enable the model to estimate construction and user costs of technical infrastructure projects, we have to provide reliable and publicly available cost indicators as well as define the unit definitions both indicators and quantities are based on.

When looking abroad for existing similar and maybe inspiring equivalents, the Swiss CRB (Center for rationalisation in building construction) seems to have one of the most promising systems. By publishing its eBKP-T (SN 506 512) [CRB 2010a] together with eBKP-T Bezugsgrössen (unit definitions) [CRB 2010b], CRB is offering a system to structure infrastructure cost groups and have their relevant measurements clearly defined. Another quality is its accurate and detailed definition on the level of elements, often with the possibility to sum detailed elements up to a higher level of hierarchy, which can be very useful for early phase cost estimation. However, this Swiss system is quite new and cost indicator based on its new structure are still to be developed.
Concerning our project in Germany, the idea of Swiss definition quality and structure has to be transferred and integrated into the existing German landscape of standards, of course.

PREPARATION OF DATA COLLECTION

In the case of the database for estimating social infrastructure, the large quantity of cost indicators published by BKI had been chosen in addition to the corresponding values based on city administration´s own experiences. So far, both datasets had shown to be quite correlative in first tests. The only remaining tasks concerning the non BKI data are to verify the correct measurements of quantities according to DIN 277, the correct cost grouping according to DIN 276 and DIN 18960, as well as the correct application of the construction price index to projects finished in the past years.

The units for cost indicators of social infrastructure might be described in different ways:

Equation 2: ci (Institution for Education) = EUR / m² GFA (BGF)

ci = cost indicator (unit: EUR per m² of gross floor area GFA (Brutto-Grundfläche BGF))
EUR = capital (VAT excluded)
m² GFA = unit of gross floor area GFA (Brutto-Grundfläche BGF) as defined in DIN 277-1

Nearly the whole BKI cost indicator database supplies at least GFA based construction cost indicators of published projects. But in addition to this equation 2 it would also be possible in some cases it to use another approach, depending on the availability of adequate data:

Equation 3: ci (Institution for Education) = EUR / c

ci = cost indicator (unit: EUR per capita of children visiting this type of institution for education, e.g. kindergarten, school, etc.)
EUR = capital (VAT excluded)
c = unit of the number of children visiting this type of institution in the planned area (possible capacities or existing need of education institutions in the surrounding area have to be taken into account)

Concerning the cost indicator database for estimating all types of technical infrastructure, clearly more research is needed. Because of the lack of published data in Germany, together with municipal representatives we decided to take the existing raw data from the specific city administration departments and transform them into compatible cost indicators for our model. First step: measurement of quantities. Due to governmental regulations, all types of technical infrastructure networks had been integrated into a GIS database only recently. But these real length network measurements sometimes are quite filigree and quite complex structures so that their cost indicators need another unit than "EUR / linear m" in order to be applicable in early project phase cost estimations. This is the case for the subtypes "Communication" as well as "Supply and Disposal". The question remains how to handle a road within an area of a new development that is used by a high percentage of people not living or working in this area, e.g. a thoroughfare. Therefore, as far as "Transportation" is concerned, we decided to execute a test drive with "linear m" as unit to be independent of this kind of interfering effects:

Equation 4: ci (Public Road, Type Z) = EUR / linear m

ci (Public Road, Type Z) = cost indicator valid for construction costs of a certain type of public road (types are still to be defined by section measurements, material qualities and other details)
EUR = capital (VAT excluded)
linear m = unit of the quantity, to be measured as middle axis of road section [CRB 2010]

This means of course that the subtype of "Transportation" has to be planned up to a certain level before we are able to get quantities and apply adequate cost indicators. But maybe we will achieve a good range of per capita cost indicators over time.
When it comes to a special kind of infrastructure as for example "Water Supply" and "Sewage", the idea of "Total Population (TP)" is integrated into the equation in order to understand the real requirements concerning this infrastructure network. Total Population represents the sum of inhabitants and the so called "population equivalents" (Einwohnerwert [DIN 2007]) that might be e.g. industrial companies within the examined area that are

consuming water and / or producing sewage equivalent to a population of x members. This value of total population is used to obtain a base for demand planning of the network layout and its dimensions.

As a result, the equation for water supply cost indicators is the following:

Equation 5: ci (Water Supply) = EUR / c

ci (Water Supply) = cost indicator (unit: EUR per capita)
EUR = capital (VAT excluded)
c = unit of the total population [DIN 2007]

It still has to be defined how to handle special punctual facilities within a certain type of network, for example in the case of sewage. What if a new area will accommodate 400 new households and the clarification plant attached to this network is able to integrate this additional load without extra construction costs. And what if, on the other hand, these 400 new households will cause the decision to build a new clarification plant that has capacities for far more than just the 400 x 4 = 1600 total population units (if the architecture of this area is meant to accommodate families). One possible way would be to divide theoretically the construction costs as well as the user costs of these punctual facilities by all possible users, even if the facilities are not always working to their full capacities.

In summary, table 2 provides an overview of the different proposed units allocated to the different subtypes of infrastructure.

Type	**Subtype**	**Example**	**Unit**
Social Infrastructure	Institution for Education	Kindergarten, School, University, etc.	m² GFA (BGF) [DIN 2005]
	Institution for Health Care	Hospital, Rescue Institution, etc.	m² GFA (BGF) [DIN 2005]
	Institution for Culture	Museum, Library, etc.	m² GFA (BGF) [DIN 2005]
	Institution for Public Administration	Governmental /Municipal Administration, etc.	m² GFA (BGF) [DIN 2005]
	Institution for Public Security	Police, Fire Department, etc.	m² GFA (BGF) [DIN 2005]
Technical Infrastructure	Transportation	Public Transport, Facilities for Private Transport	linear m (meter) [CRB 2010]
	Communication	Telephone, Internet, Broadcast, etc.	per capita
	Supply and Disposal	Water / Sewage, Energy, Waste, etc.	per capita of total population [DIN 2007]

Table 2: *Proposed units for early phase cost estimation*

Second step: creating the cost indicators. Fortunately, nearly all elements of the technical infrastructure GIS database in the Stuttgart Department of Civil Engineering have construction costs allocated to them. So we are able to calculate cost indicators for construction costs as soon as we have the measurements in combination with the specific cost totals of the measured areas.

As far as the user cost indicator is concerned, the Department of Civil Engineering did not yet start to integrate these cost types into their GIS database. It is said to be done only within the next two years. So, in order to be able to run the model soon as a test drive, we decided to take a few but typical examples from the recent years and try to calculate these cost indicators manually.

Finally it should be possible in some of the above mentioned cases and under certain circumstances to change the unit of a cost indicator by applying an adequate coefficient. If for example a new development needs a kindergarten for 80 children, but our cost indicator´s unit is "EUR/m² GFA". In that case, the tool should be able to convert either the 80 children into the adequate value of GFA (200 m² GFA at a ratio of 2.5 m² GFA / child), or to convert the value and unit of the cost indicator to get the same result in the end.

CONCLUSION AND NEXT STEPS

The presented research project in cooperation with the City of Stuttgart will enable the planning teams to systematically integrate the consequences of demographic changes in their infrastructural projects in terms of supply quality and cost efficiency. As part of the larger project, this first study prepares the database of cost indicators for municipal infrastructural project cost estimation in early project phases.
Based on specific German standards for cost estimating of building construction and user costs, as well as the large published database available for construction cost indicators and the coming up data for user cost indicators, the integration of estimation construction and user costs of social infrastructure within the model seems to be unproblematic. Concerning the different types of technical infrastructure, the lack of standards comparable to building construction in terms of measurement, unit definition and cost allocation makes it necessary to develop adequate own definitions. The proposed system will soon be applied in order to produce cost indicators for use in early phases cost estimation. As soon as possible, the results should then be tested in one of the next projects to get real life feedback.
A test drive demonstration of the whole model is planned to start April 2011. And we will be glad to present first results and experiences to CIB in June 2011.

Abstract
Since 2008 new long-term agreements on energy-efficiency have become effective in the Netherlands. Participating organisations of thirty-six sectors have agreed with the Dutch government to make efforts to realise energy-efficiency of 30 percent in the period 2005-2020 and 50 percent - as a guideline - before 2030. Higher education is represented among these sectors. To achieve the energy-efficiency objectives many sectors and associations of organisations have developed sustainable visions and road maps to implement these visions.
This paper will elaborate on the sustainable vision for the sector 'higher education', summarizing the results of a research project, which included an analysis of the higher education sector, scenario studies and strategic choices for the sustainable campus. In the process of developing sustainable campuses energy efficiency is not the only goal, setting a good example for visitors, employees and a new generation of students is another.
The research project consisted of three parts: (part I) the future of the campus, describing the higher education sector, (part II) collecting tools and measures for sustainable development and (part III) combining the components of part I and part II in future models for the sustainable campus. This paper describes the process of developing sustainable visions for the university and campus of the future.

Keywords: energy-efficiency, higher education, university, campus, sustainable development

INTRODUCTION

Background of this research
Research about the sustainable campus starts with more fundamental questions about the future of higher education and the current state of the university campus. The answers are the basis of models for a sustainable campus. Nonetheless, this research project was funded to answer a more practical question, supporting the long-term agreements on energy-efficiency: what measures can be and have already been implemented to achieve sustainability goals? The challenge for the research team was to combine these approaches.

During 2008 new long-term agreements on energy-efficiency have become effective in the Netherlands. These so-called MJA3 agreements replace earlier versions of MJA (an abbreviation for the Dutch "MeerJarenAfspraak"). The current MJA agreement is more

comprehensive than the previous versions and is connected to the Dutch governmental programme on sustainable development ("Schoon en Zuinig" in Dutch, which can be translated in "clean and efficient"). Agentschap NL – an agency of the Dutch Ministry of Economic Affairs and formerly known as SenterNovem – guides all sectors in the process of creating visions and implementing sustainable strategies. MJA agreements have been signed by thirty-six sectors. Higher education represents two of these sectors: universities (academic research institutions) and institutions for higher professional education ("hogescholen" in Dutch).

The participating sectors have agreed to make efforts to realise energy efficiency progress of an average of 30% in the period 2005-2020 and 50% before 2030. For higher education all fourteen (academic research) universities and a group of institutions of higher profession education have signed the agreement. In this paper the term „university" will be used for all higher education institutions (HEIs) in this sector.

Objectives for higher education

The research team believes energy efficiency only makes sense when it is related to a sustainable development in general (as defined by the WCED – Our Common Future 1987). The term "sustainable campus" not only refers to the physical campus, but also to the overall strategy of a university and the individual users of the campus. Higher education is a sector with relatively many people involved: students, employees and visitors. A sustainable campus is dependent on the collaboration of these campus users: are they willing to change their behaviour to achieve energy efficiency goals? At the same time, sustainable solutions on campus can influence the behaviour of these users outside the campus, now and in the future. In time students will be decision-makers themselves, or policy makers on sustainable development. At least, users will take their experiences with sustainable solutions on campus and references of innovative technology to other – working, learning and living – environments. More importantly, many university employees are professors who conduct activities of exemplary nature, like lectures to students, professionals and academic colleagues and articles or interviews for different media. On top of that, visitors expect innovative solutions of universities with world-class reputations on subjects that are related to sustainability. This is all the more reason to aim at „changing the mindset" of the campus users in the process of creating a more sustainable campus.

Changing the mindset of all user groups – students, employees, visitors – by implementing sustainable solutions or by setting a good (visible) example with innovative technology is an extra objective for the sector higher education, apart from the energy efficiency targets. Consequently, this research aimed at two targets: (1) supporting strategies for energy reduction and CO_2 reduction in line with the energy-efficiency goals for 2030 and (2) a mindset change for the users of the campus, both students and employees.

Research methodology in three parts

This research project was conducted in three parts: (part I) the future of the campus, describing the higher education sector, (part II) collecting tools and measures for sustainable development and (part III) combining the components of part I and II in future models for the sustainable campus. For each part a range of sources was used. Part I and II started with literature review and document analysis, exploring the future of higher education and (strategies for) the Dutch campus for part I and the existing sustainability tools and measures for part II. Furthermore, many workshops among campus managers, students and other experts on and user groups of the campus supplied additional ideas or validated the results.

Examples are workshops with campus managers and energy coordinators, online questionnaires among students and employees in higher education and workshops among students. The results of these workshops can be found throughout this paper. Figure 1 shows how all three parts of this research are connected in the research structure.

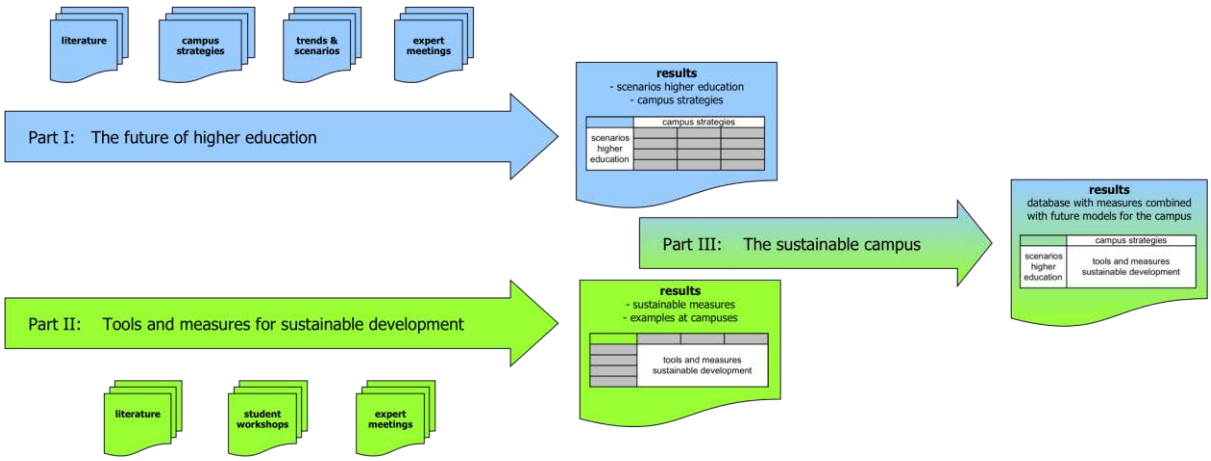

Figure 1: *The research structure in three parts*

The next sections will subsequently elaborate on (part I) the future of higher education, (part II) tools and measures for sustainable development and (part III) the sustainable campus.

PART I - FUTURE OF HIGHER EDUCATION

The future of the higher education sector can be composed by exploring the global developments that (can) influence the university and (can) shape the campus and strategic choices and policies of the universities. Both are described in part I of the research project. Yet, different generations on campus influence decision-making about future models and the support of sustainable solutions. These generations are described below.

Generations on campus

Most students in the higher education are young people in the age group of 18 to 24 years old. The employees, e.g. the scientific staff, the management staff and support services may be of other generations. It is good to realise that there is a visible generation gap between different generations. Generally the following generations are distinguished (e.g. Boschma & Groen 2006; SCUP 2009):

- The Baby Boom Generation follows World War II (1945 – 1955 up to app. 1964). The features are: a demographic bulge, a rejection or redefinition of traditional values, born in large families that they have outgrown, they are raised rigid and authoritarian; they hardly divorce and computers became familiar when they were older: they use them for finding information and surfing the Internet. They do not use chat services or social media.
- Generation X is the generation generally defined as those born after the baby boom ended (1960 - 1985). Children were part of small families - the first divorces also introduced broken families - and they were not raised very strict. As young adults they started to use computers for surfing and information and nowadays you will find them more often on chat services and social media.

- Generation Einstein (also Y or the Millennials) is brought up in the digital information society (1988 – 2000). Children of this generation want their own family, live in different structures and divorces are very common; „love baby" is a keyword in family planning and upbringing is a matter of compromising. Children are raised with computers, which they use as a social machine, chat, self-publishing and sharing, you find them continuously on chat services. This is the current generation of students.
- The next generation Z or I (Internet generation) is characterised as digital natives. These are the students of the future.

Differences between these generations indicate that they will react differently on sustainable measures, also in terms of acceptance. Younger generations will be more inclined to share facilities with other user groups; older generations are used to "unlimited resources", private territory and exclusive use of facilities and will – for instance – not easily accept sharing a workplace with colleagues. The youngest generations have been taught about "the inconvenient truth" of the climate crisis and are more aware of the urge to reduce the footprint, also by sharing floor area and less frequently used facilities with other user groups. Differences between generations might require culture changes to implement some sustainable solutions on campus. For decision-makers it is important to acknowledge that. Nevertheless, the mix of generations at HEIs also offers a challenge to use each other's creativity and ideas and to learn from each other.

Decision-makers on the sustainable campus

While many generation types are present among the users of the campus, it is also important to acknowledge the age profile of decision makers. However relevant sustainability issues are in education and research, it is usually policy makers from the supporting staff that make the decisions on the campus. Facility managers decide on the ecological concepts in the catering and products in the restaurants, energy coordinators are discussing new technologies with their colleagues. Facility manager and campus managers do consult their superiors or colleagues, but they do rarely consult the academic staff about scientific knowledge about state-of-the-art, innovative or even experimental sustainable solutions. For the higher education sector this would be highly recommended, not just to improve the common knowledge about sustainable development, but also to improve the acceptance of sustainable solutions. Academics and students on sustainability could be proud ambassadors of "practicing what they preach" on campus. The age profile of the supporting staff differs from the age profile of the academic staff. Academic staff is relatively young, also because of the PhD students and young researchers. This could lead to a situation in which the traditional policies of a relatively older supporting workforce do not match with the ideas of the younger academic workforce and the students.

These are arguments for the proposition that sustainable campus strategies are most likely to be effective when prepared with members of each user group: students, academic staff and supporting staff. They are not only more likely to be innovative, but also more likely to be accepted on campus.

Scenarios for the future

In 2009 Agentschap NL published a document describing four different scenarios for the future in 2030. With "Agentschap NL" promoting sustainable development and innovation, these scenarios not only describe the future in terms of demography, economy, technology, culture, political choices and sociological developments, but also in terms of sustainability issues or – at least – influences on how sustainable the world will be in each of these futures.

Each of the four scenarios is characterised with many images and with descriptions of economic growth, consumer profiles, state of the world, societal values, population growth in the world (and in the Netherlands), the power of public authorities, the role of the European Union, (environmental) legislation, entrepreneurship, technological developments and innovation, available resources and available human resources.

The main scenario variables that distinguish the four scenarios are (I) globalisation versus regionalisation and (II) individualisation versus social integration. Combining these two variables results in the four scenarios (see Figure 2):

(1) Global market – combining globalisation with individualisation: the world as the playing field for competitive organisations and individuals;
(2) Global solidarity – combining globalisation with social integration: the world as the collective playing field to collaborate for mutual growth;
(3) Transatlantic region – combining regionalisation with individualisation: the region or own country as a habitat to compete with other;
(4) Regional community – combining regionalisation with social integration: the region as a community to collaborate for mutual growth.

Figure 2: *Agentschap NL scenarios (photo sources: Flick.com; Jason Kuffer, Amirjina, Paolo Màrgari and Stephen Poff)*

For higher education, the research team translated these scenarios in five main variables:
(a) The number of Higher Education Institutes, the size and their profile, compared to 2010;
(b) The funding of higher education, both private and public;
(c) The use of ICT, for education, research and valorisation of knowledge;
(d) The type of students;
(e) The type of scientists – professors and researchers.

1. Global market: knowledge for sale	2. Global solidarity: knowledge to share
(a) More universities and schools compete with each other; (b) More private funding, high student fees; (c) Greater use of ICT for distance learning and research; (d) Calculating students: investing in degrees and shopping for qualifications; (e) Competition between schools for the most talented student and professor, teacher and scientist.	(a) Fewer universities, better networks between universities and better cooperation to diversify the profiles; (b) Mix of public and private resources, but emphasis on (effective use of) public resources; (c) More ICT use to maintain the network and for open source knowledge sharing; (d) Travelling students with a home base; (e) Professors are academic gypsies loyal to their home base.
3. Transatlantic region: knowledge for yourself	4. Regional community: knowledge applied locally
(a) Institutions for specific target group, selection on culture, religion, world-view; education in local language; (b) Less public and more private funding from local business community that depend on local employees and regional economic growth; (c) ICT: closed network to use for individual growth; (d) Students: traditional and uniform, enrol at university close to home, majority still lives at home; (e) Academic staff: traditional, hierarchical – lifelong contracts.	(a) Universities focusing on regional economics / demands; (b) Education in local language, in close collaboration with professional and local economic partners; (c) Strong community with a lot of personal contact, mainly using ICT for file sharing; (d) Students: environmentally conscious, socially active, not necessarily born and raised in same community – feeling responsible for community wherever they study; (e) Academic staff: idealistic, maintaining good balance between work and home, feeling responsible for community.

Figure 3: *Table with scenarios for the higher education with different characteristics*

Additional aspects for each of the scenarios are the partners for collaboration, the changing in student population and community, the changing space demand, function mix and quality requirements, the increased demand for related university functions: residential, related businesses, retail & leisure and infrastructure, the feasibility of environmental goals and sustainable ambitions. Detailed information about all scenarios on all aspects can be found in the research reports (TU Delft 2010).

Opportunities and threats for higher education

All the mentioned developments require rethinking opportunities and threats to sustainable development on the campus of the future. Universities and colleges manage a total of approximately 7 million m^2 gross floor area and have considerable (re)investment programs, seizing opportunities for sustainable development or acting against a number of trends in sustainability under the influence of policy choices. The table (figure 4) below shows these opportunities and threats more explicitly.

Opportunities for sustainable development in higher education and on campus	Threats to sustainable development in higher education and on campus
- Smaller budgets (through public funding) provide more support for sharing facilities and services among managers and end users. - Emphasis on cooperation in education and research encourages shared use of facilities and reduces demand for private space by individuals, sections, departments and even colleges and universities (sharing laboratories that require a lot of energy and money). - Increasing student numbers provide opportunities to intensify usage of existing spaces. - ICT developments can partially replace space requirements with digital tools (instead of labs) or collegerama. - Cooperation with the city (council) in providing campus functions: intensification in usage of urban functions, more opportunities for reuse.	- National and international competition among institutions may lead to: → the same laboratories at every university - or even faculty → wanting to "hang on to" talented scientists and students with facilities, requiring (more) energy and money. - Increasing numbers of students may lead to building more m^2, as more intensive space usage may demand a large culture change for the organization or may not be consistent with policy. - ICT developments may reduce campus size, but increase demand for off-campus space and energy supply (more m^2 and higher energy usage working form home and other locations *). * Energy consumption by 300 college students watching online lectures on 300 different workstations compared to the energy consumption of the construction and maintenance of classrooms.

***Figure 4**: Opportunities and threats for higher education.*

Campus strategies

The three campus strategies are based on literature on the future of the campus (Chapman 2006) translated into similar issues - purpose, meters, users and funds - and used as a framework within real estate research strategies of the Dutch universities (Den Heijer 2007). In the table (figure 5) the characteristics of these strategies are illustrated in comparison.

Strategy A “Back to the Future” (traditional campus) is most similar to the present situation or to the past traditional, closed university model. A university wants to keep a relatively large portfolio of university buildings, most of which are exclusively used by the institution itself. The so-called “exclusive campus” can add to the image or identity of the university, but is also quite expensive and has a relatively large footprint per user. However, in this strategy, the campus is exclusively for the university.

Strategy B “Intellectual Agora” (network campus) represents an open market place for the creation and exchange of knowledge, with the campus as an integral component of the city, where many spaces are shared with other users. This strategy can be characterised as a network campus: the campus is shared with partners of the university.

	Back to the Future (A) traditional campus	*Intellectual Agora (B) network campus*	*Clicks & Mortar (C) virtual campus*
			
Purpose	The campus does not change much in comparison with today"s campus The physical campus is gradually adapted to new quality requirements	The campus operates as an open market place for the creation and exchange of knowledge The physical campus increasingly becomes part of the urban fabric, other users are welcome	Much smaller campus due to more working/ learning from home: „dicks" replace some of the square meters (bricks) The physical campus is above all a meeting place: „creative, stimulating and with a focus on intellectual and social exchange"
m^2	Same number of m^2	Same number of m^2 Higher occupancy & usage	Less m^2 Campus is partly virtual
Users	Largely exclusive use of buildings by their own users, also at faculty level	Knowledge institutions make use of each other"s facilities and are no longer the exclusive users of their buildings	Students and lecturers spend less time at the campus, come to the campus to meet others
Euros	Same amount of resources available	More resources due to shared usage – external users pay	Same amount of resources available
Impact on quality	Same money for the same m^2 → Only enough money for "healthy and safe"	More money for the same m^2 → more quality differentiation possible → From "healthy and safe" to „inspiring"	More money for fewer m^2 → higher quality per m^2 → up to "inspiring"

Figure 5*: Strategies for the higher education*

Strategy C "Clicks & Mortar" (virtual campus) assumes there will be a much smaller campus with a great deal of inspiring space for social and intellectual encounters, an important trend in campus design. However, in this last strategy, students and employees will spend most of their time off-campus, while the campus does not supply a fulltime workplace for these user groups. The workplace can be anywhere, but consequently, the workforce is also spread around the world or region. This strategy is also referred at as a virtual campus: part of the university is virtual.

Strategic choices to make are: (1) what do we want to share with others and what do we want to exclusively use ourselves and (2) what part of the floor area can or do we want to we replace with virtual workspace? In essence, these choices have to be made in relation to the strategic vision of the university: what are the university values and how can the campus add to these? Combining these three strategies with the four scenarios creates twelve future models for HEIs, which are illustrated in next table (figure 6).

SCENARIOS STRATEGIES	Global market - Individualisation - Globalisation	Global solidarity - Social integration - Globalisation	Transatlantic region - Individualisation - Regionalisation	Regional community - Social integration - Regionalisation
	Knowledge for sale	Knowledge to share	Knowledge for yourself	Knowledge applied locally
A – "Back to the future" *exclusive campus* - exclusiveness, less sharing of facilities - many m^2 / student and employee - bigger selection, therefore smaller institution(s) - only affordable if higher tuition fees are common	Members Only	New network university	My gated community	Our village
B – "Intellectual agora" *network campus* - more cooperation with others - more frequent sharing facilities - more money / m^2 by renting out - campus = meeting place + workspace	Business & Science Park	Home base for academic gypsies	Campus to share in closed network	Our region
C - "clicks & mortar" *virtual campus* - less m^2 / student and employee - higher quality and more money / existing m^2 - campus only as meeting place - specific demands for workspace at home	Academic internet store	Open source campus	My closed virtual network	Our open virtual community

Figure 6: *Table with future models for HEIs: green indicates a logical scenario-strategy combination, orange is less realistic*

PART II - TOOLS AND MEASURES FOR SUSTAINABLE DEVELOPMENT

Many tools and measures are available to make implement sustainable strategies and to achieve sustainable objectives. In part II of this research project – parallel to part I – data was collected about these tools and measures.

Overview of tools

In the past years several tools have been developed in order (to try) to achieve sustainable ambitions. There are tools that focus on the development of an organisation, on the products or on the physical environment and tools that concentrate on testing the results. In this research the following classification used was: ambition tools, process tools, control tools, design tools, performance tools, prestige tools, user tools, support tools and testing tools. These tools can also be distinguished on the scale size they focus on, the time period during the building process they aim at, the achieved impact on the final results in practise and the effort they demand from the users in order to use the tools. The number of tools is enormous.

Depending on the specific situation, tools are more or less fit for the purpose. The overview of scenarios and strategies shows that the specific situation can differ significantly from campus to campus. This means that for the higher education sector there isn"t just one advise on the usage of tools plausible. The right choice for tools depends on the ambitions, campus culture, the willingness of the users to adapt to measures, the goals and for instance the

current themes. Three general categories of tools exist and can be divided into twelve sub categories (see figure 7): development tools (focussing on organisation and process); development tools (focussing on hardware: the built environment) and testing tools.

In figure 7 the various tools are divided into five categories, also based on prior sustainability research (TU Delft 2010):

1. Achieving a ***sustainable working place / sustainable way of working*** (for both students and staff).
2. ***Make buildings sustainable*** as objects.
3. ***Make the campus sustainable*** as setting or organisation as a whole (including the relationship with external settings).
4. ***Sustainable business process***.
5. Working on a sustainable ***mindset*** (both student and employee) (also visible outside the setting of college or university).

	Development tools 1	Development tools 2	Testing tools
Sustainable workspace	Future studies Vision development System analysis	Ambition tools User tools	
Sustainable buildings		Ambition tools Process tools Design tools Support tools	Performance tools Prestige tools
Sustainable campus	Future studies Vision development System analysis	Ambition tools Process tolls Assessment methods Control tools	
Sustainable (operational) management	Future studies Vision development System analysis	Ambition tools Assessment methods Control tools	
Sustainable mindset	Future studies Vision development		

Figure 7*: Tools for the higher education*

Overview of measures collected by student workshops

To create an overview of possible measures groups of users were asked to give their opinion. Workshops with (international) students were organised to collect information. The students were asked to use the mind mapping method to create an extensive list of measures.

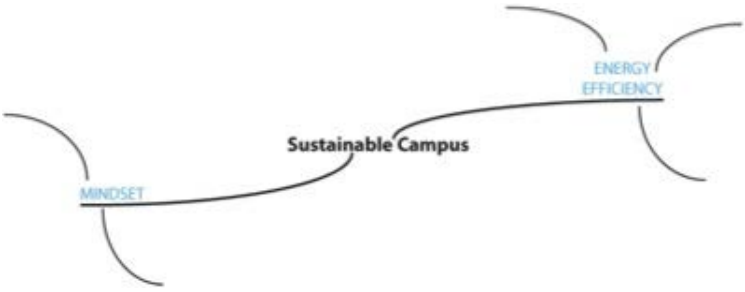

Figure 8: *Mind mapping, a technique used by students during the workshops*

***Figure 9**: Example of mind mapping result of student workshops*

***Figure 10**: Impression of a student workshop*

Notes on the results
The workshops encouraged students to think creatively. The results had some remarkable outcomes. As overall results the students‟ conclusions can be described as:

- Thinking in extreme situations in order to collect a range of measures;
- Ranking the scenarios Global Market or Regional community as their preferences;
- Having a positive approach;
- Thinking in goals and scenarios;
- Finding out that energy efficiency is possible in every scenario;
- Creating a change in mindset depends on the scenario.

The ideas of the students are summarised in a large collection of measurements. The most acceptable ones, that are the ones by the students marked as positive, are used in expert workshop to be ranked by the experts in part III of this research project.

PART III - THE SUSTAINABLE CAMPUS

In order to make future models for the sustainable campus the results of the first two parts of the research has to be combine; to validate the results these were presented for comment by

various groups of expert. These results were very useful to find a way to create a roadmap towards a sustainable campus.

Expert validation

Special expert workshops were organised. The participants were staff members of universities concerned with campus management. Measure lists created during the student workshops were used as input for the expert workshops. The experts were asked to indicate which measures are already being adopted at their organisation, which measures they missed on the list and which measures they did not find fit for their HEI. Through the Internet the questions asked during the workshop were presented in a questionnaire to staff members of other higher education organisations as well. Also members of the DHO platform were questioned: 78 questionnaires were filled out.

All experts during the workshop indicated in the matrix which scenario is the most likely for their specific higher educational organisation. They also indicated the most and least desirable scenario. The figure (11) shows the results of an expert workshop with campus managers and energy coordinators: most respondents expect globalisation; prefer social integration and fear individualization on both global and regional scale.

***Figure 11**: Results of an expert workshop with campus managers and energy coordinators*

The questionnaires contained a long list of measures meant to indicate whether one would like to apply one of these measures or rather not. Also was inventoried which measures are already applied. Most wanted measures were: creating a cold-heat storage (heat pump); possibility to turn all devices off by default (1 button per building), a public display of energy consumption to increase awareness of energy use, more green on the campus, good public transport connections, the use of renewable energy sources, a visible application of sustainability, efficient use of space (more facility sharing), more awareness and applying insulation. Unpopular measures were: the use of greenhouses on buildings for heating, a car-free day, the production of food on the campus, sharing cars, incineration on the campus, a day without printing, the use of recycled toilet paper, fitness as a source of energy and less automatic arrangements.

The measures HEIs already apply are many solutions concerning the organisation and educational courses like competitions, pilot projects, education and symposia to improve awareness of sustainable development among students, staff and guests. Also efficient use of space; insulation; good public transport; separation of waste and turning off the lights (and

computers) at night are commonly use. More ambitious measures are applied, but are not yet common. Nobody applied a day without printing or fitness as a source for sustainable energy.

Conference

On April 27, 2010 sixty to seventy campus users (energy coordinators, campus managers, academics and students) attended a conference about the sustainable campus. However the first two were the largest groups in the audience, influencing the discussion about the propositions. The propositions were supporting by an electronic enquiry system to be able to discuss the collective opinion of the audience immediately and to enable to (anonymously) relate certain answers to the user group, the age or other characteristics of the respondent. Using this technique some of the research results were validated or tested. Some of the conclusions are summarized below.

Conclusions

The audience confirmed that the most probable scenarios are either "Global Market" or "Global solidarity", with the latter being the preferred scenario. The majority of the educational institutions already adopted the measures belonging to the scenarios Global Solidarity (mostly universities) and Regional Community (mostly institutions for higher professional educationally). If they did not adopt those measures yet, those were the most desirable measures. The measures belonging to Transatlantic Region are being judged as least desirable or even negative.

A clear difference is visible between the different goals. The mindset measures are mostly desired, while there is a big difference in the judgement of energy efficient measures.

The majority of the educational institutions will probably focus on the scenario Global Market or Global Solidarity, showing that globalisation is clearly visible in the higher education sector. The experts prefer to focus on social integration. Combining those will lead to Global Solidarity. Most educational institutions fear the Transatlantic Region scenario.

Most respondents are choosing "the network campus" (strategy B "Intellectual Agora") as a preferred strategy and "home base for academic gypsies" as a preferred future model – combining strategy B with scenario "Global Solidarity". However, the audience with mainly supporting staff did acknowledge that the opinions of academic staff could differ a lot.

With various generations in the audience – 67 percent older than 45 years and 33 percent younger – it became obvious that the decision-makers are indeed of a different generation than all students and a large group of academics. Discussions about a question like "Are you willing to share your workplace for a sustainable campus?" illustrated the culture change that such a measure to reduce the footprint would require.

Nonetheless, all respondents confirm that implementing the sustainable campus of the future is a collective task, which requires involving representatives of different target groups.

RESULTS - STARTING POINT FOR THE FUTURE ROADMAP

The research results are merged in a web based tool, which can be used by higher educational institutions in order to create their own future roadmap for 2030.

The vision on the future, based on the choice of strategy and scenario, determines the sustainability factor.

The possible measures are connected on this vision and the educational institution is free to choose a combination of measures to sustain their campus.

The twelve shown visions of the future – combinations of strategies and scenarios – are being arranged in terms of sustainability. Figure 12 shows which visions are most and least sustainable. Three considerations are at the basis:

1. The virtual campus of strategy B is more sustainable than the network campus of strategy B or the exclusive campus of strategy A.
2. Scenarios or strategies (scenario 2 and 4 and strategy B) using collective use of amenities and buildings are more sustainable than the exclusive models such as strategy A and scenario 1 or 3.
3. Due to the transportation aspects the global scenarios 1 en 2 are less sustainable than the regional scenarios 2 and 4. Scenario 2, with its global cooperation, might result in "academic gypsies", and might even result in more travelling in combination with strategy A or B than scenario 1.

A comment on strategy C virtual campus is that the space reduction on the campus will result in space use on other locations, for instance at the private homes of students, teaching staff, due to the fact that a larger workspace might be needed, which has to be heated or cooled down and demands printing facilities (space and energy demand).
Combined with scenario 2 and 4 the virtual campus might need a physical location to meet each other to meet the needs of the social interaction. Should those interactions take place on campus grounds or within the existing structure of the city? Figure 12 shows a sustainability ranking of all future campus models. Again, it should be noted that this is a ranking for the campus. Models C1, C2, C3 and C4 are relatively sustainable campus models, but might cause a larger footprint at the homes of all students and employees at the same time.

	1. Global Market	2. Global Solidarity	3. Transatlantic Region	4. Regional Community
	Knowledge for sale	Knowledge to share	Knowledge for yourself	Knowledge applied locally
A. Back to the future	Members Only	New network university	My gated community	Our village
B. Intellectual agora	Business & Science Park	Home base for academic gypsies	Campus to share in closed network	Our region
C. Clicks & mortar	Academic internet store	Open source campus	My closed virtual network	Our open virtual community

Figure 12: *Sustainable ranking of future models (green to red - from most to least sustainable)*

Web based tool

One of the research results is a web-based tool that combines these models with a database of sustainable measures. This tool is available on the Internet (www.duurzamecampus.nl - currently only in Dutch). With this tool HEIs can share knowledge and experience to work together towards a sustainable campus in 2030. With four scenarios and three campus models as a starting point, the tool leads to twelve possible future models. Based on these, an

impression is given which sustainable measures fit the specific situation of a HEI. While exploring various future models the users of this tool will gradually generate a customised, sustainable vision for their own campuses.

CONCLUSION - COLLECTIVELY CREATING THE SUSTAINABLE CAMPUS

Sustainable campus strategies are most likely to be effective when prepared with members of each user group: students, academic staff and supporting staff. They are more likely to be innovative because of the diversity of user groups on campus – representing different generations. But more importantly, they are also more likely to be accepted on campus, because users have been part of the process and academic staff members can be ambassadors of the practice that they preach. The scenarios, strategies and sustainable measures – also merged in the web-based tool – are a basis for this collective process to create the sustainable campus of the future.

Abstract
The collaborative use of Information and Communication Technology (ICT) and Building Information Modelling (BIM) across a temporary project organisation (TPO) may represent the future of construction project delivery through greater design coordination, reduced conflict, efficiency savings, and a valuable information stream for use throughout the operational life of a building. However the success of BIM in a TPO is dependent upon participant firms that share compatible technologies, business processes and cultures, led by people who hold attitudes and display behaviours conducive to collaboration. Their collective interaction thereafter defines the culture of the TPO, more often than not resulting in differentiation, or fragmentation: true integration is the exception. This paper presents preliminary findings from a case study of a TPO, identifying differentiated cultures within the project, and explains their causes. It suggests that careful selection of trading partners and focused attention to the establishment of a TPO may mitigate many of these negative outcomes.

Keywords: ICT, BIM, TPO, culture

INTRODUCTION
Building Information Models capture the characteristics and relationships between the parts and assemblies of a building in database form, enabling them to be visualised and their behaviour tracked over time under different operating conditions. Weisberg (2000) highlights the potential this technology has to trigger significant changes in the development, design and building process, yet it has still to gain widespread acceptance in the architectural, engineering and construction (AEC) sector, lagging behind other major industries producing 3D products.

ICT provides a range of technological solutions which have the potential to standardise and streamline business processes throughout the design, construction and operational phases of a building. BIM functionality combined with improved business process alignment between trading partners should lead to increased uptake and integration across the AEC sector, providing adopters with increased profitability and value generation that ICT is said to present. However recent research indicates that psychological phenomena observed in individuals (Brewer, Gajendran & Beard, 2009) and across project teams (Gajendran & Brewer, 2009) can be just as important in determining the business outcomes of ICT/BIM adoption. Moreover, whereas literature suggests that ICT/BIM is generally a force for

integration of the TPO previous research (Brewer & Gajendran, 2010) indicates that this isn't necessarily the case, often leading to differentiation within the team, and even fragmentation. This study reports a meta-analysis of case study data of a TPO assembled to complete an iconic civic building in Australasia, focussing on the involvement of a specialist subcontractor to design and construct the engineered façade. This project was deemed suitable for this study as it utilised BIM, web-based information sharing, and a raft of other ICT. The case study data were initially collected as part of a research project funded by the Co-operative Research Centre for Construction Innovation (CRC-CI), and reanalysed using protocols developed subsequently, resulting in it being subjected to multiple forms of qualitative analysis.

LITERATURE REVIEW

It has sometimes been suggested that the low level of innovation is a consequence of a lack of conviction on the part of decision makers in the industry of the benefits - economic return - arising from its use. Classical economic theory indicates that this is a logical consequence of a rational cost benefit analysis undertaken by potential innovators, resulting in widespread rejection of its efficacy, and indeed on one level this appears irrefutable. However, such business decisions are made by humans, often on the basis of incomplete knowledge of the "facts", influenced by prior experience and also frequently emotion, in a boundedly rational way (Simon, 1991). Business decisions made on the basis of bounded rationality are rarely optimal, instead resulting in "satisficing" solutions, outcomes that can be described as being "good enough".

A better understanding of the influences that shape the attitudes of potential innovators and adopters of innovation, and particularly the attitudinal traits (Venkatesh, Morris, Davis, & Davis, 2003) of strategic decision makers who sanction and dictate their deployment within construction firms and construction project organisations would help innovation levels in the construction industry. However, the human dimension has been largely overlooked by construction industry researchers and policy-makers. At present, no research has been undertaken to comprehensively map the attitudinal profile of innovators in the construction industry.

Describing the attitudinal traits or attitudinal profile of a particular population is a technique that is familiar to both market and academic researchers, across multiple fields and disciplines. However in each case the starting point has to be a pre-existing framework of reference such as Ajzen's (1991) model, or multidimensional attitude profiling (Gann & Salter, 2000). This approach underpins the mapping of the attitudinal domain within which ICT/BIM decision-makers for TPOs operate (Brewer, 2009; Brewer & Beard, 2009). Implicit in this is the understanding that a collection of decision-makers within a single TPO will necessarily develop a group culture, be that positive or negative.

Organisational culture has been variously described as a "strong prescription for success" (Martin, Frost & O'Neill, 2004) and "an interpretation for better understanding" (Willmot, 2000). However in both cases the concept of "cultural analysis" has been mooted as an appropriate mechanism to allow its investigation.

Culture is an emergent feature of a group, which springs from the underlying assumptions and beliefs of its members about what they share in common, how the world operates and

consequently, how they should relate to it. This shapes their attitudes and often their consequent behaviour.

Schein (2004) defines culture as:
...a pattern of shared basic assumptions [beliefs] that was learned by a group as it solved its problems of external adoption and internal integration, that has worked well enough to be considered valid and, therefore, to be thought to new members as the correct way to perceive, think, and feel in relating to those problems. (p 17)

Group culture can manifest itself overtly through rituals and other behaviours, although often the most enduring cultural traits are embedded in the underlying beliefs held by its members (Schein, 2004; Rousseau, 1990). These beliefs can take one of two forms: espoused, and actual.

Espoused or claimed (beliefs) are usually those attributes that people want to be seen to possess, or believe they should demonstrate. By contrast actual beliefs are those made manifest through their unconscious behaviour. Literature (Schein, 2004) suggests that that attempting to understand culture through surface level manifestations alone (e.g. overt behaviour) is unreliable. Schein (2004) recommends surfacing deeper psychological manifestations such as underlying assumptions or beliefs as a more reliable approach. Thereafter it is possible to observe "inconsistencies" or "conflicts" between overt behaviours indicative of claimed beliefs, and underlying beliefs.

The learning or transmission of cultural assumptions or beliefs from one person to another within a group is the way in which group cultures form, whether they form spontaneously (e.g. when a group is thrown together unexpectedly) or by design (e.g. through recruitment of like-minded staff). Various metaphors have been developed to explain the cultural development of groups, likening it to engineered control mechanisms (Archer, 2004), infection (Geertz, 1966), or evolution (Sperber, 1996): where the spread or promotion of cultural traits is not actively initiated or managed there has to be an alternative, naturalistic facilitation process, as in the latter two instances. In the context of this paper the development of project team culture and the cultural influence of the industry beyond the focal project are of central importance.

Many authorities regard the integration of ICT/BIM into construction industry supply chain activities as both desirable and imperative (e.g. Department of Trade and Industry, 2001). This runs counter to its cultural norms and project-centric structure. A conceptual model of the TPO is therefore useful to analyse cultural influences on ICT use in this context (Brewer, Gajendran, & Chen, 2006). Derived from concepts originated by the Industrial Networks School of supply chain management (Ford, 1997; Hakansson & Johanson, 1992) it notes that each organisation within the project consists of a network of interacting actors, resources, and activities, all of which are necessary in order for it to function. Crucially this is extended to include the project, which itself becomes an actant. The model therefore posits that a TPO accretes around a project rather than an individual actor (e.g. the client).

There are a number of ways in which TPOs can be influenced by each other, and that these are not always contractual. Indeed they may not be formally recognised at all, rather being the product of a network of informal contacts and communications (Wasserman & Faust, 1994). It follows that whilst the adoption of ICT might facilitate the communication of ideas and information within a TPO this is only one of a number of possible communication

channels (Gajendran & Brewer, 2007). In the context of the current research it is clear that the characteristics of a TPO have the capacity to impinge upon the formation of culture in relation to the adoption and use of ICT/BIM within a project setting, both in a positive and a negative way.

Brewer (2009) develops model of innovation and attitude to explain the influences affecting the behaviour of decision-makers considering the innovative use of ICT across TPOs in the construction industry. Using Ajzen's Theory of Planned Behaviour (1991) as the point of departure it acknowledges that the ideal decision ought to be to integrate ICT throughout the primary participant organisations in a particular TPO, with its ultimate expression in the adoption of web based communication plus online access to BIM information. A meta-analysis of case study data (Brewer, Gajendran & Beard, 2009) confirmed the model's applicability for analysing the decision-making of key individuals operating within BIM-centric contexts.

The collective attitudes and behaviours of a group of people in large part serve to define their group culture (Schein, 2004). Culture has the ability to influence all areas and activities within organisations, and whilst these are usually thought of as being an individual firm, club or institution, cultural concepts can equally be applied to project teams. It has been observed that the culture of a construction project influences its level and quality of ICT uptake and integration.

Previous research identified the Critical Success Factors (CSFs) for integration of ICT as being: Organisational Commitment; Organisational Attitude to Communication; Rights and Duties of Organisations (in relation to ICT-mediated communications); Investment Drive, and; Risks related to ICT Usage (Brewer & Gajendran, 2006). Subsequent cultural analysis of these revealed that the cultural values espoused by the industry were analogous to the desired cultural values for an optimised project environment, which in turn ought to facilitate ICT integration. Unfortunately in practice it has been found that very few real life project cultures fully reflect these cultural ideals, resulting in a wide disparity between the levels of ICT integration experienced by participants in different projects and at different levels within the project supply chain.

It follows that a comparison of the actual culture of a project with the espoused values of the individual participants provides a basis upon which to identify the issues that lead to sub-optimal levels of ICT integration. The Cultural Analysis Framework for ICT integration proposed by Gajendran & Brewer (2007) maps the actual cultural characteristics of the environment into which ICT is deployed, comparing it to the cultural stereotypes first identified in their CSF study (Brewer & Gajendran, 2006).

RESEARCH METHOD

The underlying principle for this research is exploratory, intended to develop theory. However Brewer and Gajendran (2010) established both the theoretical adjacency of attitudes, behaviour, and culture, and the practical fusion of these concepts in the presence of concurrent principles and codes. These were found in independently conducted interview-based studies of the same people, relating to a common project. In preparation for this study comparisons were made of the coding for themes developed during the authors' doctoral work when applied to case study data developed by each other. Over 85% of the thematic codes developed during their doctoral work (Brewer,2009; Gajendran, 2010) could be

usefully applied to each other's interview data, and since this had been confirmed in a subsequent case study (Brewer and Gajendran, 2010) a rigourous re-analysis protocol was developed to enable the study of attitude, behaviour, and team culture based on a single set of case study interviews and supporting data.

Data re-analysis protocol
Interview transcripts originally developed for the CRC-CI project were subjected to multiple pass qualitative analyses. Each stage was designed to elicit deeper levels of understanding of the data whilst concurrently providing a concise and consistent description of the phenomena thus revealed.

The first pass of each transcript generated a memo, which was written as a "sense-making" exercise that captured the researchers understanding of it. No prior assumptions were made as to the ideas that were likely to be found.

The second pass at the data confined itself to interrogating the memos themselves in order to identify recurring themes. Any ideas considered of interest or relevance were coded by the researchers to generate a code list. This list was cross-referenced to those codes originally developed in Brewer and Gajendran (2010) in order to ensure wherever possible a consistency of terminology: where this was not possible new codes were added, thereby adding to the overall library of codes related to the topic.

The third pass of the data reviewed both the original transcripts and the memos associated with them in order to assign detailed "meaning" to relevant passages.

The final process was therefore one of abstraction, designed to explain the codes and their appearance in the transcripts with reference to both the attitude and behaviour matrix (after Brewer, 2009 - see Table 1), and the cultural analysis matrix (after Gajendran, 2010 – see Table 2).

Case study protocol
The case study was completed over several months during the construction phase of the project, and collected interview data, questionnaire data, participant-derived supply chain maps, and other peripheral data offered by the participants. Five representatives from primary stakeholders in the TPO (head contractor, client's in-house project manager, architect, steel fabricator, client's façade consultant) and three representatives from the façade supply chain (specialist subcontractor, steel fabricator, glass supplier) were interviewed. At the interview each was asked about both their firm's stance in relation to the five critical success factors for ICT integration (Brewer & Gajendran, 2006) and their own personal attitude towards them.

The interview was augmented by their completion of a questionnaire that had also been distributed by post as part of a national survey. The interviewees were also helped to sketch a diagram of the TPO supply chain as viewed from their perspective, indicating both the nature of the relationships with their trading partners, and the nature of the ICT mediated interactions with each of them.

CASE STUDY

The case study project came about subsequent to a design competition where the winning architect prepared sketch plans. These were approved by the client (city council), and were then used to prepare the documentation and cost plans. The key feature of the project was the front facade, known as the "Sculpture Wall", which consisted of an extensive glass curtain wall, curved in three planes. Subsequent to an audit of domestic facade engineering expertise and in accordance with the client's wish to minimise contractual risk (i.e. pass on risks/costs associated with design and construction flaws and delays), an overseas facade engineer was appointed as consultant to the client, who then recommended a suitable specialist subcontractor.

The design package was put out to tender ahead of the main contract for the building. Although slightly dearer than the lowest bid, the specialist subcontractor's bid was accepted. There followed a round table meeting to resolve any remaining difficulties at which the specialist subcontractor pointed out that the steel content of the design was 50% higher than they would have expected. They subsequently tabled an alternative design that used cast aluminium elements and over the next seven months this was collaboratively refined to produce significant improvements at lower cost, with most components being sourced in Asia.

The use of diverse ICT was evident in various parts of the TPO at different stages of the project. Various participants professed to have building product model (BPM)/BIM compatible software and the capability to use it collaboratively, though in reality this did not extend beyond the production of 3D CAD models with limited attached attributes. There was no formalised ICT-mediated communication structure for the TPO, though emailed document distribution was the norm, especially during the early stages of the project. Figure 1 illustrates the structural relationships between the various TPO participants.

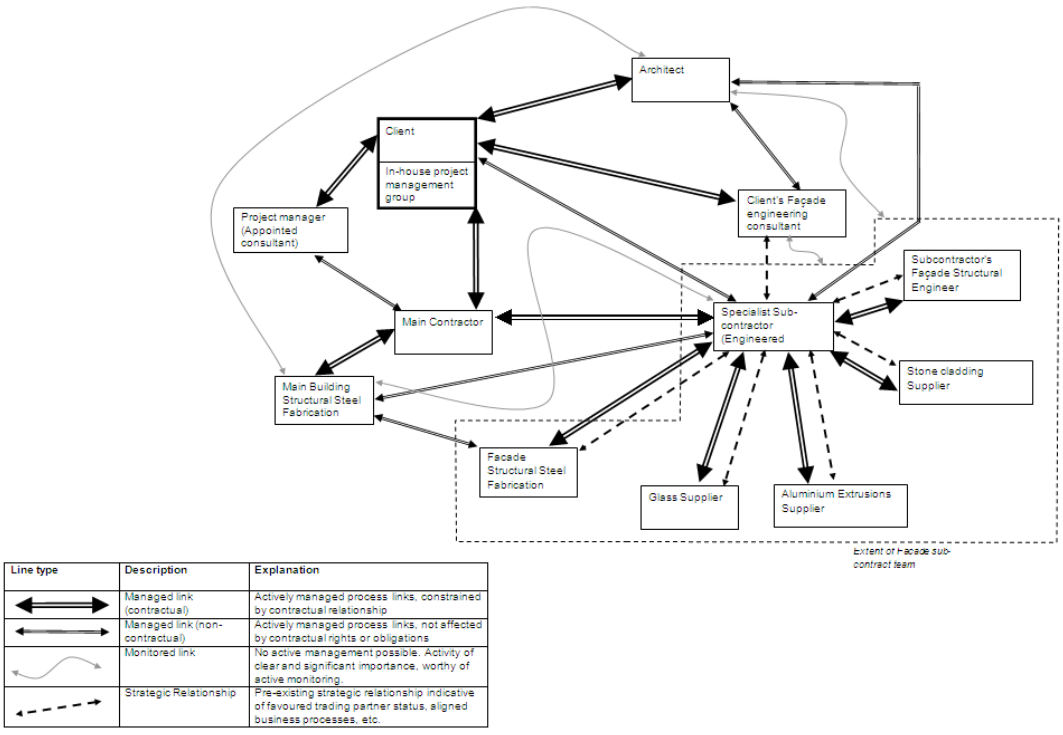

Figure 1. *Supply chain map for the case study project.*

RESULTS AND DISCUSSION

The following sections summarise the outcomes derived from the various analyses/re-analysis of multiple data obtained during the case study. In doing so they reveal the espoused values of the various participants, their true attitudes and beliefs in relation to the use of ICT in the current project, linking them to their subsequent decisions and conduct in the project environment, further linking them to the creation and subsequent development of the project team culture.

When interrogated through the application of a standard questionnaire, originally developed for use in the CRC-CI project (Gajendran, Brewer & Chen, 2005) all of the project participants' responses were found to be within one standard deviation of the sector norms. As a consequence the project participants could be thought of as being a representative sample of industry thought and practice, sharing the espoused attitudes of their colleagues in the industry. Their hopes and concerns in relation to the collaborative use of ICT within project teams therefore centred on issues associated with Organisational Commitment; Organisational Attitude to Communication; Rights and Duties of Organisations (in relation to ICT-mediated communications); Investment Drive, and; Risks related to ICT Usage (Brewer & Gajendran, 2006).

Brewer (2009) revealed that the development of attitudes and subsequent decision-making behaviour in relation to ICT-based innovation was in fact more complex, and reflected a range of boundedly rational influences. These could be summarised in the form of a map, within which the individual attitudinal profile of decision-maker could be located. The attitude and behaviour matrix developed in Brewer & Gajendran (2010) has been populated with data analysis from the study and is shown in Table 1.

Further analysis of the data reveals the aggregated impact that all of the participants' decision-making and conduct within the project team have had on the overall project team culture. The cultural analysis matrix first developed in Gajendran & Brewer (2007) has been used and populated in order to summarise these effects (see table 2). This indicates that out of a potential 17 espoused aspects of ICT integration within the project, only 3 had been integrated on the case study project, with 10 being differentiated and the remaining 4 being fragmented (see table 2, column 3). By contrast the same analysis performed on the specialist subcontractor's own supply chain revealed a very different story, with all but three of the espoused conditions for ICT integration being put into practice, these being inappropriate for a supply chain of that nature (see table 2, column 4).

In many respects this case study is a tale of two supply chains, one associated with the procurement of the building, the other entirely related to the specialist subcontractor. The contrast between the two could not be more stark, with the former being conventionally convened to deliver the bulk of the project, whilst the latter appearing to be bound together strategically in a non-exclusive set of relationships (Blankenburg Holm, Eriksson & Johanson, 1999). It is perhaps telling that the business entre between the two was facilitated by the client's facade engineering consultant, who also had a strategic relationship with the specialist facade subcontractor.

The significance of the strategic relationships in this TPO relate in the first instance to the way in which the specialist facade subcontractor had invested time and resources in establishing stable supply chain relationships with all of its suppliers, particularly in terms of its use of ICT (Blankenburg Holm et al, 1999). This extended to temporarily embedding staff

members in its suppliers firms in a training capacity, to ensure that their use of the available technologies meshed seamlessly with its own. Whilst conventional wisdom seems to indicate that "championing" of ICT innovation is principally the domain of the "informed client" (e.g. NSW Government, 2002) in this case the championing "client" was itself a supplier to the project client, who made no such demands.

Domain	Technological			Human			Business process			Personal		
Participant	Intra	Inter	Term	Intra	Inter	Term	Intra	Inter	Term	Intra	Inter	Term
Client/In-house Project Manager	Commitment to basic ICT infrastructure for common business uses	Little expectation of boundary-spanning ICT but	Long term commitment to intra-organisation integration	Commitment to ongoing staff development Built env. applications low on list of priorities			Tends to be bureaucratic				Appreciative of collaborative ICT use on current project	
Architect	ICT is a mechanism for error reduction in design.		High costs associated with model generation must be sold to client asn		Best to tone down ego when collaborating online. Trust is essential when sharing IP.		Envisages the advent of full virtual prototyping, reflecting the business practices of other industries.	ICT not regarded as a prerequisite during selection of trading partners, however flexibility is required	Essentially an evolutionary process. AEC sector something of a laggard.			
Main Contractor	Commitment to the automation of internal business processes	Disinterested /mistrusting			Tends to cynicism			ICT not regarded as a prerequisite during selection of trading partners			Doesn't believe inter-firm ICT will play a major role during his career	
Client's Façade Engineer	Central to function of business	Regards limited inter-firm interaction as inevitable during the design phase	Long-term, unable to control/limit pace of development					ICT not regarded as a prerequisite during selection of trading partners				
Main Building Fabricator	Commitment to the automation of internal business processes	Little evidence of engagement			Preference for F2F communication/paper esp. during construction phase							
Specialist Façade Subcontractor (SFS)	All staff capable of operating all systems and platforms used in-house	Preference given to trading partners who share similar platforms, but not prerequisite	Serious long term commitment to ICT. Significant portion of annual investment.		Commitment to supporting the training of trading partner staff in required technologies for ICT interaction			Commitment to supporting the training of trading partner staff in required business processed for ICT interaction	ICT compatibility essential prerequisite for doing business	Unwilling to support non-tech savvy staff.	Very aware of the potential for Catastrophe when relying on ICT – inter-personal dimension to be closely monitored	Long-term commitment
Façade Fabricator	Generally supplanting paper-based processes	Happy with interaction with SFS, less so with others in the main building contract	Long-term commitment to ICT for design and fabrication	Staff development to complement and support ICT investment	Able to meet client demand/ willing to adapt to changing client demands			Flexibility required when dealing with clients' requirement for ICT				Long-term commitment
Glass supplier	Undergoing major ICT reinvestment largely in response to client demand	Willing to align with SFS as price for doing business	Long-term commitment to ICT	Staff development to complement and support ICT investment	Willing to accept external input to assist in business process alignment with clients			Flexibility required when dealing with clients' requirement for ICT			Very adaptable, keen to exhibit best practice	Long-term commitment

Table 1. *Attitude and behaviour matrix.*

The contrasting supply chains were populated by individuals whose attitudes mirrored those who were driving the supply chains. On the one hand the client considered itself quite separate from the other participants. On the other hand the specialist facade subcontractor

insisted on high levels of involvement, even in areas of the project where it held no primary responsibility. Throughout the facade supply chain there was never any evidence of resistance to, or resentment of the imposition of specific ICT protocols from its client. All of those who were interviewed from this part of the project expressed appreciation for the streamlined way in which their supply chain relationship operated, leading to improved business outcomes for their respective firms. What cannot be determined from this study is the extent to which the collaborative nature of their relationship with the specialist facade subcontractor was mirrored in their dealings with their customers from other TPOs.

ICT Integration Trait *Successful ICT implementation requires the:*	Organisational trait *For a firm to successful integrate ICT within a TPO:*	Observed culture (TPO) *In this case it was found to be:*	Observed culture (SSC) *In this case it was found to be:*
The commitment of a firm's senior management.	Senior management should embrace ICT and commit to implement ICT in their organisation/when there is potential for ICT to support operations.	Differentiated	Integrated
The commitment of an organisation's employees	Employees need to commit to engage with ICT tools those support/enhance their personal work environment	Differentiated	Integrated
Transparency and trust among project team participants	Members of the team should develop trust and transparency within the project environment	Integrated	Integrated
The identification and sensitive handling of the ownership of the intellectual property generated during a project	Contractual arrangements should encompass safeguard on intellectual property rights.	Differentiated	Integrated
The project team members to acknowledge the sensitivity and confidentiality of other participants' information	Members are guided by explicit codes of practice and informally held ethics and moral values. The source of these value codes may come from the organisation's procedures, personal upbringing or by education.	Integrated	Integrated
A powerful ICT "champion" to support the technologically weaker organisations in project teams	Powerful member should support the weaker members through leadership, collaboration or as a result of their positional power.	Fragmented	Integrated
An organisation's continuous and conspicuous investment in staff development and training	Should continuously invest in their staff ICT development programs and training	Differentiated	Integrated
A "powerful organisation" within the team to impose ICT adoption	Could impose 'power positions' within the project to encourage appropriate level of ICT use in a project environment	Differentiated	Integrated
A "champion" to support all new technology that is to be used across a project team within a firm/Project.	Leadership structure should engage in giving proactive direction in the use of new ICT tools and techniques	Fragmented	Integrated
Standard conditions of contracts that specifically accommodate the issues raised by the use of ICT	Need to maintain contractual clarity in ICT employment through stipulating conditions of contract and adherence to the conditions. This also could be viewed as an industry regulators role.	Fragmented	Differentiated
An organisation to be prepared to engage in long-term collaborative relationships	Preparedness to engage long-term relationships with trading partners.	Differentiated	Integrated
Organisations to commit to ICT as a long-term strategic decision.	Commitment to engage in long term strategic relationships with trading partners to foster return on large ICT investments	Differentiated	Integrated
Organisations to commit to ICT as a project-based tactical decision.	Commitment to engage with ICT in project to project basis in short run in small ICT investments	Differentiated	N/A
The organisations to monitor competitor's ICT adoption.	Need monitor the competitors to gain potential competitive advantage	N/A	N/A
Addressing the fragmentation issues of the project team for improved performance of ICT-enabled operations.	Must engage in procurement methods that minimises fragmentation of project teams.	Fragmented	Differentiated
Organisations try to limit their use of multiple online systems promoted by different project participants.	This factor can be viewed purely as a technical (interoperability) issue, outside of cultural considerations. However, one can relate the espoused values to Item 12 above	Fragmented	Integrated
The security of information is vital in an ICT-enabled project environment.	This can also relate to the espoused values relating to the level of acceptance of ICT security	Differentiated	Integrated

Table 2. *Cultural analysis matrix.*

It is appropriate at this point to remember that the primary stated purpose of technological integration is to reduce the inherent information fragmentation commonly experienced in

industry (Nitithamyong & Skibniewski, 2004), and to look for clues as to why the presence of high-level new technology has apparently failed to achieve its objective in some parts of the industry, whilst proving very successful in others.

In most vital respects the construction project at the centre of this case study was typical of those found in the industry. Many of the key decision-makers who were active in the early stages of the project decided to stick with the tried and tested approaches to project procurement and consequent project team selection. None of these players had sufficient experience with high-level ICT to fully understand its potential or to drive its adoption/integration into the life of the project (NSW Government, 2002). It was therefore purely fortuitous that a project participant chosen because of the technological excellence of its product was in fact the one who eventually championed high-level ICT use across parts of the TPO.

In reality the penetration of high-level ICT/BIM from the specialist subcontractors supply chain into the TPO was quite limited. However the cultural impact of its champion was more profound. Several TPO participants spoke of a change in the culture of the project once the subcontractor became involved. They often cited its willingness to share commercially sensitive information and engage in additional, unrewarded work, thus facilitating speedy problem-solving and improved project performance. This openness and willingness was reported as being infectious, leading others including the head contractor and main building fabricator to reciprocate. No one suggested that this was an act of charity or altruism, but rather a welcome change to the normal expectation that problems in a project necessarily equated to delays, conflict and eventual increased costs. The role of ICT/BIM in facilitating this agreeable flow of information was widely regarded as being incidental, and indeed much of it occurred at a time when all parties had largely moved to an on-site presence, predominantly using paper-based drawings.

A fundamentally different story emerged from the subcontractor's own supply chain where, after a period of experimentation prior to this project a set of fairly stable supply chain relationships had developed. These necessarily spanned international boundaries, were information intensive, and required all parties to invest heavily in them. Their longevity was based in equal measure upon two characteristics: firstly, the ability to deliver quality products, to the right price, at the right time (Blankenburg Holm et al, 1999), and; secondly to engage with the specialist subcontractor using high-level ICT, including BIM-compatible information exchange, in a manner which suited their purposes (Nitithamyong & Skibniewski, 2004). Informal contact with the specialist subcontractor a couple of years later has confirmed the centrality of these principles to their ongoing relationships with supply chain partners:
You know, there are 6 billion people in the world, and it's surprising how difficult it is to find one of them who will reliably supply you with what you need on a regular basis….. When you find someone you can do business with, you cling onto them. They are pure gold. They become family. (CEO, Specialist subcontractor).

The questions remain as to whether the specialist subcontractor's influence on cultural development of the TPO was real or coincidental, and whether the experience for others in the TPO produced a lasting change in their attitude to collaboration or whether it was a purely transient phenomenon. It is unlikely that such complex questions can be satisfactorily answered, and certainly not without a prohibitive amount of forward planning in the design of a longitudinal study that follows the case study participants into further projects. Nevertheless

it is reasonable to speculate that negative attitudes to a variety of issues pertaining to TPO relationships (and the behaviours they trigger) commonly encountered in the industry are in fact cultural artefacts, developed and/or learnt from others over a considerable period of time (Schein, 2004). Such traits are not easy to overcome and yet, as the specialist subcontractor and its trading partners demonstrate, the rewards for doing so can be both enduring and rewarding. It can therefore be further speculated that if the negative cultural traits endemic in the industry have endured because they produce profitable results then positive cultural traits have to produce demonstrably more profitable outcomes in order to supplant them.

Given the foregoing it is perverse that it cannot be assumed that successful ICT/BIM outcomes can, or should be equally attainable by all. In the past ICT/BIM enthusiasts have espoused the notion of ICT integration as a panacea for the industry's ills. In this they have been amply supported, or perhaps even inspired by successive industry reviews (e.g. Egan, 2002), which have promoted industry adoption of the technological and supply chain innovations commonly found in manufacturing. Such playing field-levelling, pain-share/gain-share perspective is inherently egalitarian, and yet modern approaches to the issue such as the American Institute of Architects Integrated Project Delivery system (AIA, 2007) appear to eschew this, preferring a pragmatic technological sectarianism. In accepting the reality of differing levels of technological capability, they also acknowledge differing levels of integration between trading partners, the lowest of which ensures little more than the exchange of CAD data.

CONCLUSIONS

This case study has built upon earlier work by Brewer and Gajendran (2010), which established the theoretical overlap and practical links between the attitude and decision-making behaviour of key individuals within single firms and the resulting culture formed within TPOs. In doing so it has created a reliable methodological framework that can be used for future investigations of ICT/BIM integration within TPOs in the AEC sector.

This paper has presented an example of a highly integrated supply chain and a largely differentiated/fragmented TPO. Earlier studies (e.g. Brewer & Gajendran, 2010; Gajendran, 2009) have suggested that the latter is the industry norm.

These findings raise a number of important questions: Firstly, to what extent is it beneficial or even necessary to integrate the ICT/BIM used in a TPO across all its members? Secondly, what is the nature of the relationship between ICT/BIM integration in a TPO and its culture (i.e. does culture drive integration, does technology shape TPO culture, or is the relationship more complex)? Thirdly, how is ICT/BIM integration experienced and understood by diverse project participants?

ENDOGENOUS RISK IN UNBALANCED BIDDING

Abstract
Models of unbalanced bidding in unit price contracts (UPC) can be categorised into two types. The first category assists clients in detecting and contractors in optimising skew bidding. More theoretical oriented models of the second type focus on bidding behaviour in order to study market efficiency. These models predict corner solutions, i.e. zero prices, for unit prices of expected overestimated quantities. However, anecdotal evidence indicates a lack of zero prices in the actual contracts. A possible explanation for this discrepancy is risk-aversion of the contractor. However, none of the models of the latter category have incorporated risk as an endogenous variable. A model of such is presented in this paper.

Keywords: Unbalanced bidding, risk, modelling

INTRODUCTION

Unit price contacting (UPC) is common in the construction industry throughout the world. This contracting form has the client – often a public entity – preparing and taking juridical responsible for the design. The design consists of a bill of quantities with related descriptions of the work. Contractors then submit bids in forms of price vectors, one price for each quantity. The lowest vector product of prices and quantities, i.e. the lowest total price, is awarded the contract.

The simplicity of this contracting form is appealing, which can be one explanation for its frequent use. There are however problems with this contracting form. UPC has been accused of causing the low productivity in the sector. The logic behind this is that the contractor has low incentives to come up with innovations since the clients to a large extent provide rigid contracts on how the work is to be conducted (see e.g. Mandell and Nilsson, 2010).

Another argument against the use of UPC is that it opens up for unbalanced bidding, i.e., that bidders skew their bids in response to having superior information relative to the procurer. Research regarding this issue includes models for client detection and contractor optimisation of skewed bidding. Such models can provide practical guidance to practitioners but they cannot determine the extent of the problem from an efficiency perspective. Other models focus on predicting bidding behaviour in order to study market efficiency. Intuitively, the contractor's perception of risk may be an important part in unbalancing since the concept is based on uncertainty. However, to the best of our knowledge no model has incorporated the contractor's risk in bidding models.

The paper is further motivated by an apparent miss-match between the theoretical models in the literature and the empirical indications. In short, the existing theoretical models predict corner solutions that entail zero bids for overestimated quantities. However, very few zero bids are observed in data. There are potential explanations for this. An argument is made that the institutional setting in Sweden is such that the primary reason for not seeing zero bids in a Swedish data-set must be due to risk concerns among bidders. Thus, this paper sets out to incorporate the contractor's perception of risk as an endogenous variable in an unbalanced bidding model.

UNBALANCED BIDDING

The idea of unbalanced bidding in UPC contracts is not a new concept in research or practice. Gates (1967) and Stark (1974) made some early and influential work on this phenomenon. Unbalanced bidding is sprung out of the fact that the contactor is better informed than the client. This is based on the contractor finding errors in the ex ante bill of quantities, which can be used to his advantage. In general terms, the best informed contractor can both win the tendering and enhance his profits, despite the fact that he may not the most efficient contractor. Hence, the existence of unbalanced bidding entails an inefficient outcome on the market due to information rents.

There are basically two types of unbalanced bidding discussed in the literature; unbalanced bidding through "front loading" the bids and unbalanced bidding based on information rents regarding quantities. Hughes (1982) distinguished the former type of unbalancing as *finance cost/cash flow unbalancing* in contrast to the *error exploitation unbalancing*, described in the above example. Cash flow unbalancing involves the contractors marking up prices on quantities that are scheduled for early completion trading off quantities for late completion (Arditi and Chotibhongs, 2009; Skitmore and Cattell, 2011).

From an efficiency perspective, the problem with front loaded bids is that the client will make the payment to the client earlier than in a situation with full information about costs. Differences between contractors regarding information about the scheduling of the tasks to front load bids in different ways can however be questioned. Scheduling of a construction project has certain elements that cannot be changed. The pavement cannot be laid out before the construction of the sub base of the road is finalised.
Hence, a rather mild assumption would be that front loading does not differ between the contractors and that it is private information about quantities that will be the base for unbalanced bidding. The remaining paper will not deal further with front loading, but will focus entirely on the first type, i.e., unbalanced bidding following from superior information about quantities actually required.

The inefficiency of this type of unbalanced bidding can be illustrated by a numerical example. Consider a setting where two contractors compete for a road investment contract that requires only two inputs, e.g. paving and provision of gravel. A bill of quantities including estimations for gravel and pavement is announced by the client, 100 m^3 and 150 m^2. The contractors differ in the first being more efficient (i.e. having a lower marginal cost) but being less informed about the quantities actually required, i.e., the *ex post* quantities. Contractor 1 bids his marginal cost at prices 10. Assume that contractor 2 has a higher marginal cost than contractor 1 on both inputs but he has private information about the project and predicts that the gravel is underestimated and the pavement is overestimated by

the client. Given this expectation, contractor 2 raises his price on gravel and reduces the price pavement as seen in figure 1.

Ex ante	Bill of quantities	Contractor 1's bid (Uninformed)	Contractor 2's bid (Informed)
Provision of gravel	100 m^3	10	12
Pavement (paving)	150 m^2	10	8,5
Total bid		**2 500**	**2 475**

Figure 1: *Ex ante bill of quantities and bids*

As depicted in figure 1, contractor 2 submits the lowest total bid and wins the contract.

The project starts and contractor 2's prediction, that the quantities of gravel will be increased and pavement decreased, turns out to be correct. As seen in figure 2, contractor 2's skewing of prices based on his expectation of changing quantities made him win the contract and earn higher revenue.

Ex post	Actual quantities	Contractor 1's revenue	Contractor 2's revenue
Provision of gravel	110 m^3	10	12
Pavement (paving)	145 m^2	10	8,5
Final cost for client		**2 550**	**2 553**

Figure 2: *Ex post actual quantities and revenue*

Hence, due to unbalanced bidding the most efficient contractor did not win the contract. The client ended up paying an information rent to contractor 2 i.e. a higher cost than if the most efficient contractor 1 would have won.

EARLIER WORK ON UNBALANCED BIDDING

This section addresses earlier work targeting unbalanced bidding, which consists both of theoretical modelling and empirical studies.

Theoretical models of unbalanced bidding

There is a lack of exact definition of unbalanced bidding. Models are one way of making concepts more concrete. Two types of models have been developed regarding unbalanced bidding.

A first type focuses on assisting practitioners to detect possibilities for unbalanced bidding in the tendering stage and how to exploit these. The detection models supports clients' interests (see e.g. Arditi and Chotibhongs, 2009) and exploitations models assist contractors in optimising the skew (see e.g. Yizhe and Youjie (1992); Cattell et al (2008); Cattell et al (2010).

The second types of models are not designed to provide direct practical guidance to unbalanced bidding. Rather, they focus on predicting and measuring the extent of the phenomena in order to determine efficiency effects. The present paper belongs to this latter category.

In particular, there are two prominent papers in this category. The first is Ewerhart and Fieseler (2003), who model a UPC contract where two tasks are required in order to complete a project; 1 unit of material and *h* hours of labour. The contractors have private information about their type, i.e. being fast or slow in order to finish the task. This information is not known by the client, hence contractors are better informed than the client. The UPC auction starts by the client announcing his estimate on the number of hours required to complete the project. This estimate will be underestimated for slow types and overestimated for fast types. Based on their type, the contractors submit bids i.e. price vectors of material and labour. Final payment is based on the vector product of prices and quantities, where the latter is actual hours put into the project and 1 unit of material.

The usual prediction of unbalanced bidding applies; the slow types face an underestimated client prediction of hours and will mark up the price for labour and compensating the price for material downwards. This will result in a corner solution i.e. one sided bidding, where null bids will be submitted for labour by fast types and for material by slow types. The model predicts that the most inefficient types i.e. the slowest contractor, will win the bidding process. This is due to the fact that the slowest contractor will be able to exploit the gap between the estimated hours and the actual hours put down. The slow types profit function is increasing in hours. Ewerhart and Fieseler (2003) express this as the slow types are being subsidised. In the extended version of the model, it is shown that the subsidy to inefficient contractors will force the efficient ones to bid more aggressively, having a positive effect on client cost.

The second prominent article is Athey and Levin (2001), who model unbalanced bidding in timber auctions. These auctions differ from construction projects as the buyers of timber harvest rights are the bidders, and not the sellers as in a construction project. The model consists of two species of timber and allows the buyers to invest in private information. This is done by the buyers inspecting the tract before the auction in order to estimate the proportion of timber species. The auction starts with the Forest Service (seller) announcing their estimated proportion of timber species and total amount. In reverse order from the above model, the buyers will mark up the price on overestimated timber types and compensate through bidding a lower price on the underestimated type in order to secure a high bid *ex ante* and pay less *ex post*. Payment is made by the actual amount of timber and the ex ante prices. As in the above model, a risk neutral bidder will end up in a corner solution submitting the buyer's reservation price (in the extreme; zero).

The two models differ in respect to what there is asymmetric information about. In Ewerhart and Fieseler (2003) the contractors are better informed about their own ability while in Athey and Levin (2001) they are better informed about the project's characteristics. Even so, both papers predict corner solutions that entail zero price bidding on overestimated quantities.

Empirical studies on unbalanced bidding

The empirical work on unbalanced bidding has focused on capturing the correlation between differences in prices and quantities respectively.

Athey and Levin (2001) have data from both oral (N=697) and sealed (N=63) timber auctions. The study has data on the sellers estimated volume and proportion of timber type, ex ante bids and ex post (actual) volume and proportion of timber type. This data enables the authors to calculate actual payments. Some control variables as number of bidders are also included. The overall conclusion is that private information is used in the bidding by the buyers. However, the information rents are to some extent offset by competition. This empirical result can be related to the theoretical argument put forward in Ewerhart and Fieseler (2003) about the inefficiency of unbalanced bidding being offset by strengthen competition by the efficient contractor.

Regarding sealed bidding, which is the most common auction form used in construction, the study show that 65 percent of the winning bids are skewed in the expected direction. In other words, the direction in which the theory predicts, i.e. raising bids on overestimated type of timber. The empirical models regress the skew parameter, i.e. dollars spent on the overestimated species of wood, on the sellers' misestimate of the tract with some control variables. In accordance with theory the correlation is positive, which the authors interpret as the winning bid incorporating the superior information into the bid.

Bajari et al (2007) test three types of mark-ups in construction auctions, where one is the existence of unbalanced bidding. The data consist of 414 paving contracts from California between the years 1999 and 2000, which contains 1939 bids from 271 contractors. The actual ex post quantities and "Blue book" prices are also available. This data makes it possible to regress quantity overrun on the dependent variable percentage difference between the winning and the blue book price. In accordance to what the theory predicts the correlation is positive, indicating that on average a 10 percentage overrun on quantities will result in a mark-up of approximately 0.27 per cent.

THE LACK OF CORNER SOLUTIONS IN PRACTICE

Both Ewerhart and Fieseler (2003) and Athey and Levin (2001) provide models that theoretically predict corner solutions in the form of bids equal to zero. It is then striking that the empirical studies discussed above, even though they find evidence indicating that unbalanced bidding exist, do not observe zero pricing. The same observation is done in a database under development of UPC for road investments in Sweden.

The lack of zero pricing can be explained by different factors. The most evident ones are

1. That the client or law prohibit zero pricing
2. A reputational mechanism of losing future work
3. That contractors are risk averse

There is however a disagreement regarding the explanatory power of these factors. Bajari et al (2007) argue that that bids with zero unit prices are very likely to be rejected and therefore not very common. Athey and Levin (2001) support the risk-aversion explanation, even though it is not formally modelled in their paper.

The institutional setting in Sweden sheds further light on why there is a lack of zero bids in our Swedish data-set. A recent court order in Sweden challenges the first explanation for the lack of zero pricing. The case regarded a public UPC for road maintenance, which was rejected for being unbalanced with low prices (although separated zero) for one of the tasks (snow ploughing) in the contract. The rejection was appealed by the contractor with the court ruling in favour of the contractor (Förvaltningsrätten i Falun, 2010). There is a paragraph in the Public Procurement act saying that the client can reject a bid if it is too low. The paragraph refers to the overall total bid and not unique unit prices according to the verdict (Förvaltningsrätten i Falun, 2010). This can be interpreted as the law paragraph is not there to secure an efficient use of state funding but to guarantee delivery i.e. not risking standing without a contractor to take care of the state's responsibilities. This court order prevents Swedish clients from rejecting zero unit price bids and moreover inhibits client rejection as an explanatory variable for the lack of such bids on the Swedish market.

Regarding reputational mechanism, there is a law in Sweden (based on an EU directive i.e. this argument should apply to the EU) prohibiting the client to use repeated interaction and self-enforcing contracts (see e.g. Gibbons (2005) for relational contracts) The purpose of the Public Procurement Act is to hinder nepotism of government funded projects with the disadvantage of not being able to use repeated interaction as an incentive. As the law states that every new project should be objectively procured, the contractor cannot take credit for "a job well done" in prior projects. Regarding construction in general and road construction especially, public clients that are subject to this legislation represent a large part of the total amount of clients. The legislation can be used as an argument to downsize the effect that the reputational mechanism has as an explanatory variable for the lack of zero bidding. Even though repeated interaction effect cannot be completely ruled out, as tendering documents can be adjusted for a certain contractor, there is still a law against repeated interaction.

Hence, neither of the first two explanations above have much support in the institutional setting on the Swedish construction market. This leaves risk aversion as a prime candidate to explain the lack of zero pricing in Swedish UPCs.

None of the models above include risk as an endogenous factor in the models. The following section set out to do this.

THE MODEL: RISK AVERSION IN UNBALANCED BIDDING

Assume that two tasks, A and B, are required to produce a product, e.g., a road. As above, we restrict our attention to Unit Price Contract Procurements under which the principal, e.g., the road administrator, specifies quantities for A and B respectively. There are a number of agents bidding in the procurement. Their bids consist of per unit prices on A and B, denoted P_A and P_B. The agent with the lowest total price, $P_AA + P_BB$ wins.

Consider a stylized setting in which there are several agents bidding. These all have the same information as the principal, i.e., they have no reason to suspect that the actual ex post quantities will differ from the specified quantities A and B. We refer to these agents as

"uninformed". We introduce one agent who is better informed about the quantities actually required, A_{true} and B_{true}, than the principal and the uninformed agents. To capture this, we assume that this "informed agent" knows that the *expected* quantities actually required is $A + \alpha$ and $B + \beta$, respectively. It seems plausible that there, ex ante, is some uncertainty surrounding these quantities. Thus, let the required quantities be $A_{true} = A + \alpha + \varepsilon$ and $B_{true} = B + \beta + \eta$, where ε and η are stochastic variables. For simplicity, let $\varepsilon \sim U[\varepsilon_{low}, \varepsilon_{high}]$ *and* $\eta \sim U[\eta_{low}, \eta_{high}]$, where $\varepsilon_{low} = -\varepsilon_{high}$ and $\eta_{low} = -\eta_{high}$ such that the distributions are both symmetrical around zero.

Conducting each task is assumed to be associated with a constant marginal cost. The informed agent's total cost for task A is given by $TC_A^I = C_A^I (A + \alpha + \varepsilon)$ and for B it is $TC_B^I = C_B^I (B + \beta + \eta)$. The net payment received is given by:

$$\pi = (P_A^I - C_A^I)(A + \alpha + \varepsilon) + (P_B^I - C_B^I)(B + \beta + \eta) \quad (1)$$

Where P_A^I and P_B^I denote the informed agent's per unit bid for tasks A and B respectively. As will be shown, the informed agent may let its superior information influence the bid prices P_A and P_B. There are two restrictions limiting the degree to which the bids may be tweaked. Firstly, neither bid must be negative, i.e., $P_A^I \geq 0$ and $P_B^I \geq 0$ Secondly, the total bid, i.e., $P_A A + P_B B$, must be (weakly) lower than the competing bidders' to win. Let us denote the competing bids as P_A^U and P_B^U for task A and B respectively (U denotes that these are the uniform agents' bids). We may then write a "bid restriction" which must be fulfilled for the informed agent to win the procurement as:

$$P_B^I \leq \frac{A(P_A^U - P_A^I)}{B} + P_B^U \quad (2)$$

We will subsequently assume that (2) is binding, as a strict inequality implies leaving unnecessary surplus to the procurer. Thereby, we may use (2) to substitute for the informed agent's bid on B, thus allowing us to optimize over the bid on A only.

The agent may be risk averse. We capture this by letting the agent's expected pay-off be $E\{\pi\} - Rvar\{\pi\}$, where R is a coefficient measuring risk aversion. When $R = 0$ the agent is risk neutral and when $R > 0$ he is risk averse. Using (1) and (a binding) (2) we may express the expected net payment as:

$$E\{\pi\} = (P_A^I - C_A^I)(A + \alpha) + \left(\frac{A(P_A^U - P_A^I)}{B} + P_B^U - C_B^I\right)(B + \beta) \quad (3)$$

and its variance, $var\{\pi\}$, as:

$$var\{\pi\} = \frac{1}{2}\left(\eta_{high}^2\left(\frac{A(P_A^U - P_A^I)}{B} + P_B^U - C_B^I\right)^2 + \epsilon_{high}^2(P_A^I - C_A^I)^2\right) \quad (4)$$

The objective for the informed agent is to choose P_A^I and P_B^I so the expected pay-off is maximized. To facilitate the presentation, let us assume that all agents have the same marginal cost structure and that the competition among the uninformed agent is strong enough to drive their bids down to marginal cost. This assumption allows us to substitute P_A^U and P_B^U in (3) and (4) by C_A^I and C_B^I, respectively, which greatly simplifies the interpretation of the resulting outcome. The expected pay-off is then

$$(A+\alpha)(P_A^I - C_A^I) - \frac{A(B+\beta)(P_A^I - C_A^I)}{B} - \frac{R(C_A^I - P_A^I)^2(A^2\eta_{\text{high}}^2 + B^2\epsilon_{\text{high}}^2)}{3B^2} \quad (5)$$

From (5) we may derive the following first order condition

$$P_A^{I*} = C_A^I + \frac{3B^2\alpha - 3AB\beta}{2R(A^2\eta_{\text{high}}^2 + B^2\epsilon_{\text{high}}^2)} \quad (6)$$

The first term in (6) is the agent's marginal cost. The second is a (possibly negative) mark-up that the agent will apply to his bid on task *A* as a consequence of his superior information. From (6) we can draw a series of conclusions regarding the agent's optimal bidding strategy.

The first observation is that the mark-up increases in α. This is in line with the intuition behind strategic bidding. A positive α implies that the (expected) true quantity is larger than the procured one. Thus, the agent would like to increase the asking price per unit of that quantity and thereby gain from the expected increase in required quantity.

Second, the mark-up decreases in β. This follows from the bid restriction. If the agent increases his bid on task *A*, he must decrease the bid on some other task. As there are only two tasks in this model, this means reducing the bid on task *B*. A positive β implies that also the true task *B* quantity will, in expectation, exceed the procured one. In that case, decreasing the bid for task *B* results in an expected loss on task *B*. Thus, when β increases the bid on task *A* must decrease in optimum, ceteris paribus.

A related observation is found in that if *B*=0, i.e., only task *A* is procured, the second term in (6) is zero. That is, even if α is positive, the agent is unable to bid strategically by increasing P_A^I above marginal cost, as there is no second task with which to compensate the total bid. On the other hand, if *A*=0, which implies that the principal only procures task *B*, but the agent believes that task *A* is needed, i.e., α is positive, he may place a bid above marginal cost for task *A*. In this, somewhat unrealistic case, neither *B* nor β puts any restriction on the bid simply because P_A^I will have no impact on the total bid (as it will be calculated at *A*=0).

Third, and perhaps most interestingly, both the risk aversion coefficient, *R*, and the limits of the probability distributions appear with positive signs in the denominator of (6). The former implies that the optimal bid for P_A^I decreases in risk aversion and the latter that it decreases in the range of the stochastic variables, i.e. the risk. Both these suggest that there is a downside for the agent in bidding strategically following from that this behaviour exposes him to risk. Thus, there is a trade-off between expected net payment and risk exposure. The informed agent may use his superior information to increase the expected net payment by the means of unbalanced bidding, but in so doing the variance of the net payment will increase. The latter refrains a risk averse agent from skewing his bids too aggressively.

That this trade-off is central to the understanding of the agent's behaviour is illustrated by looking at the behaviour of a risk neutral agent. Equation (6) cannot handle risk neutral agents as it would result in a denominator equal to zero. By setting $R = 0$ already in (5) and differentiating the resulting expression with respect to P_A^I yields

$$\frac{\partial E[\pi]|_{R=0}}{\partial P_A^I} = \alpha - \frac{A\beta}{B} \quad (7)$$

Equation (7) shows the extreme incentives involved for an informed risk neutral agent. As long as $\alpha > A\beta / B$, the expected pay-off always increases in P_A^I. That is, we end up in a corner solution stating that P_A^I should be set as high as possible, i.e., a similar outcome as in Ewerhart and Fieseler (2003) and Athey and Levin (2001). The only restriction is through the bid restriction and that we do not allow for negative prices, i.e., what limits P_A^I is that P_B^I must be set to zero. When $\alpha < A\beta / B$, the opposite applies; we will end up in a corner solution only limited by that P_A^I may not be lower than zero. It is only when α exactly equals $A\beta / B$ that a corner solution is avoided. In that case the informed agent will bid his marginal costs.

CONCLUSIONS

Most papers on unbalanced bidding conclude that risk neutral contractors will submit zero unit price bids on overestimated quantities. When making risk aversion endogenous, the model presented in this paper comes up with an internal solution. This result is more in line with the available data.

Apart from risk aversion, the inconsistency between theory and data can also be explained by a reputation mechanism or a ban on zero pricing. The institutional setting of the Swedish construction market gives little or no support to the latter explanations, leaving risk aversion as a prime candidate to explain the inconsistency. This entails that the explanatory value of a model for unbalanced bidding is improved by including the contractor's perception of risk.

The model captures the intuitively appealing characteristics that the contractor's risk perception may affect the extent of unbalanced bidding. It shows that unbalanced bidding increases the expected net payment from the contract. However, it also increases the contractor's risk exposure.

This is captured in the above model through a variable about an informed contractor's level of risk aversion. In line with earlier models in the literature, the model predicts that a risk neutral bidder will maximize skew bidding by submitting zero prices on the overestimated quantities. The model shows that the incentives for such behaviour are very strong. But by allowing the contractors to be risk averse, the model predicts an internal solution without zero pricing which is more in line with the data available.

BUILDING RENOVATION – A NEW INDUSTRY?

TERTTU HILLEVI VAINIO
VTT Technical Research Centre of Finland
www.vtt.fi
terttu.vainio@vtt.fi

Abstract
Based on construction economics, building economics and assessments of building service life, the renovation need of buildings is notably higher than the actual amount of building renovation. As energy saving renovations become more common, the volume of building renovation is forecast to grow even further. Building renovation suffers from both a lack of suppliers and tailored solutions.
This study has searched for a reason for this phenomenon. This is a theoretical study in economics, testing the rationalisation ability of three different economics theories, including the theory of construction economics, evolutionary economic theory and the theory of creating customer value.
In accordance with construction economics theory, renovation construction competes in all owner sectors with other expenditures, and since renovations can be postponed, they often are. Demand is not activated by interesting supply or by supply corresponding to the needs. Renovation projects are implemented with a production-oriented new construction concept. In addition, a user-oriented approach does not produce a good outcome if it does not include catering for the special features of renovation construction.

Keywords: renovation, building stock

INTRODUCTION

In developed countries construction has long been used to respond to a quantitative demand for new buildings. There has been a preference to demolish old properties to make way for new construction rather than renovate them. In the past, fires and wars have destroyed the building stock and thereby removed the need for renovation. As a result of new construction, the building stock has expanded greatly, and the cultural heritage it represents is valued as a part of sustainable development.

The battle against climate change has increased interested in renovation. Significant cuts in greenhouse gas emissions can be achieved by making the building stock more energy-efficient. Because the building stock consumes a great deal of energy, it promises a hefty potential benefit. In contrast with many other consumers of fossil-based energy, the energy requirements of the building stock can be satisfied with low-emission sources of energy or with renewable energy.

As a result of the expansion and ageing of the building stock and new requirements for its energy-efficiency, renovation is seen as a growth sector in developed countries. Renovation has also become a commercially interesting market for businesses, as property owners have relinquished their own maintenance organisations.

Renovation is undergoing a transition, with several development alternatives to choose from. Should the existing building stock be made more energy-efficient through renovation, or should existing buildings be replaced with new and more energy-efficient ones? To what extent will digitally produced services, logistics and new forms of working reduce the need for space?

The building stock and its properties have been widely studied. In contrast, renovation has received much less attention from researchers than has new construction. And when it comes to improving energy-efficiency, the focus has been on technological development, without giving proper consideration to how this technology is to be installed in buildings.

RESEARCH QUESTION

The object of this study is renovation as business. The primary aim of the study is to identify a workable theory to describe the development of renovation. A theoretical basis is needed to enable improvements in renovation and thereby respond to identified challenges.

RENOVATION

The term 'renovation' is used in statistics to distinguish between construction work on existing building stock and new construction; it includes both repair work and work undertaken for other reasons. Sometime the superior term for the concept discussed here is not 'renovation' but 'repair', defined as the altering of a built object towards a desired state, either technologically or functionally. Hierarchically they are an umbrella term for the following:

- 'refurbishment' and 'renewal', where a building or parts thereof are renewed,
- 'modernisation', 'rehabilitation', 'retrofit or refit', 'refresh' and 'upgrading', where the quality of the object is significantly improved, for instance by improving the energy efficiency of a building, linking it to the water and sewer networks, or installing a lift,
- 'rebuilding' and 'reconfigure', where the purpose or manner of use of a building is altered, and
- 'restoration', which aims to preserve or bring back the cultural historical value or architectural value of the object.

'Demolition' is the destruction of a building. Materials can be 'reused' or 'recycled'. If a new building is then built on the same plot, even if it is similar to the previous one, this is 'rebuilding'.

THEORIES

Construction economics, a well-developed theory applied in several studies, links construction to development of the social and economic structure (Ruddock, Lopes 2006). According to the theory (Bon curve), the purpose of construction is to build spaces, areas and connections. When they are taken into productive use, construction's proportion of gross domestic product (GDP) shrinks. The utility of the theory has been demonstrated by comparing economies at different stages of development or comparing regional development (Crosthwaite 2000). These analyses have been achieved by comparing construction investments or profits as a proportion of GDP.

The theory describes the market of quantitative demand. In addition to quantity, demand for construction is affected by changing needs (Gruneberg 2009). Even if the economic structure is stable according to quantitative metrics, changes in content require construction. Internal structures do not assume permanent form, in fact their rate of change accelerates. Old economic sectors become more productive, die out, split or generate new sectors. Growing productivity frees up resources for entirely new sectors. According to **evolutionary economics**, among other theories, this sort of development is a prerequisite for sustained growth (Saviotti, Pyka 2004).

With the development of new technologies, a number of different theories have emerged about the birth of new sectors. Observations to the effect that old sectors can split into new ones or that technology can give birth to an entirely new sector can be seen as falling under the rubric of **business economics** (Hamel 2000). Various sector emergence mechanisms have their advantages and drawbacks. When an old sector is reinvented, the resources of the old sector can be harnessed for new activity. Blue Ocean Strategy (Kim, Mauborgne 2005), for example, puts forward a number of cases to demonstrate that it has been possible to renew traditional and even challenging sectors by reconceiving the market. The strategy places value innovations in a key position.

When a sector is conceived from nothing it does not have an old sector's burdens, such as the need to "unlearn" practices or to unlock potential. This route is defended by the theory of Disruptive Technology (Christensen 1997), which says that improvements alone have never had revolutionary effects. Disruptive technology emphasises renewal by way of technological innovation.

New sector generation is studied with reference to a number of sectors. A model of sector generation has been built by drawing together research from different fields (Gustafsson et al. 2010). Generation of a new sector requires a trigger, an industry identity, an activity network and commercial viability.

EMPIRICAL MATERIAL

The explanatory ability of the theories is tested against Finland's renovation market. Three cross-sectional studies of renovation in Finland were carried out by Pajakkala & Lehtinen (1982); Vainio, Nippala & Lehtinen (1991) and Vainio, Jaakkonen, Nippala, Lehtinen & Isaksson (2002). The studies gathered information both about renovation projects and about business participation in renovation work.

Since 2000, Statistics Finland has compiled information about construction companies' renovation activity (Statistics Finland 2010). At the end of the 2000s, qualitative information about renovation was compiled for the Ministry of the Environment's implementation plan for the Strategy for Renovation 2009–2017 (Ministry of Environment 2007), and for monitoring the measures outlined therein. Pipe repairs are examined as an example from the perspective of value return to the client (Paiho et al. 2009).

DEVELOPMENT OF BUILDING RENOVATION IN FINLAND

Building renovation in the 1980'

Drivers. The primary reason for renovations was to save energy and the secondary reason was related to functionality (spatial reorganisation). Deteriorated condition was only the third reason for renovation because on average age of building stock was only 23 years. Building renovation concentrated on buildings constructed before 1960. (Pajakkala, Lehtinen 1984)

Commercial renovation. Most renovation projects were carried out by building owners or their organisations. Only a quarter of building renovation activity was commercial. That was the reason why developers, designers and the industry did not even consider building renovation a construction activity. Nor did the banks what paralleled loans for building renovation with the consumption credit. (Pajakkala, Lehtinen 1984)

Barriers. The undeveloped technology of the construction industry, the inability to produce tailored solutions and the general lack of know-how became the technical challenges for building renovation. Housing associations were unable to decide whether or not to carry out renovations. (Pajakkala, Lehtinen 1984)

In order to resolve the technical issues, a research programme that examined building renovation from 1986-1990 was started in the middle of 1980s. The research programme concluded that building renovation would develop into a secondary sector of the building industry.

Building renovation in the 1990s

Drivers. Changes in use were the reason for renovating other types of buildings. The study found that the efficient use of square meters in new construction led to an increase in the need to renovate even newer buildings. The interiors and fittings of residential buildings were customised, but the structures were not renovated until the technical life span of the building was reached. Proportionately, buildings constructed prior to 1960 were still renovated most often and most extensively. (Matilainen, Lehtinen & Vainio 1991)

Commercial renovation. Commercial building renovation has increased during the decade before the study and by 1990, it accounted for 40 percent of all renovations. (Kontuniemi, Lehtinen & Vainio 1991)

Barriers. A number of areas needed improvement. Know-how was required for surveying, determining the renovation needs, planning the renovation and for carrying out the actual work. Also issues related to cooperation between the different parties of the project needed improvement. Deficiencies were identified in the availability of services connected with building renovation, model agreements and suitable materials, prefabricated products as well as machinery and equipment. The expertise of designers and builders who worked on new constructions was not applicable to renovation projects. The study recommended expanding training to include building owners. (Matilainen, Lehtinen & Vainio 1991)

The renovation technology for prefabricated buildings, as well as the maintenance know-how of real estate owners and the tools to assist them, was added to the existing list of developmental needs. To address these issues, a research programme called Remontti (Renovation) was carried out from 1992-1996.

Building renovation in the 2000s

Drivers. The average age of the building stock is 30 years, which means that half of the building stock has reached an age at which renovation is increasingly required. The fact that the renovations of older public buildings are being postponed is backfiring – and resulting in more costly renovation projects. Still it was obvious that changes in the content of building renovation as well as higher quality requirements will increase the amount of building renovation more than factors such as escalating building stock or ageing. (Vainio et al. 2002)

Commercial renovation. Seventy percent of building renovations was done commercially and at the same time, both the share of the owner's own work and that of voluntary work in building renovation had reduced. The share of commercial renovations increased due to legal requirements to involve skilled labour in the planning and implementation of any projects that received public funding. Structural changes towards partial renovations have increased the share of specialised contractors that carry out the actual work. (Vainio et al. 2002)

Barriers. The renovation of buildings is often neglected due to problems with financing or the high level of associated costs. Financing is a particular problem when it comes to the renovation of public buildings. For residential buildings, decision-making remains the most problematic issue that slows down the renovation activities. The problems in the renovation work itself are often technical, but they may also be related with the quality or availability of resources. (Vainio et al. 2002)

During 2000-2010 many research programs and campaigns have been carried out. Many of them are focused to solve existing mold and moisture problems. Also energy efficiency has been on the research agenda. The ministry of environment has also launched the strategy for renovation 2017 (Ministry of Environment 2007). One part of it is developing renovation processes. The idea is that demand arouses supply.

According the statistics renovation and new building are today nearly equal size. Building renovation can no longer be seen as merely an activity that balances the economic cycles of new construction. From the beginning of 1980' the share of commercial renovation has grown form quarter to 70 percent (table 1).

Table 1. *The development of renovation markets (Source: Statistics Finland).*

	Building renovation % / new %	**Commercial renovation per total renovation %**
1980'	25% / 75%	25%
1990'	35% / 65%	40%
2000'	40% / 60%	70%
2010'	45% / 55%	70%

The share of renovation activities is in Finland lower than in Europe, where building renovation already receives over half of all the investments in construction (figure 1).

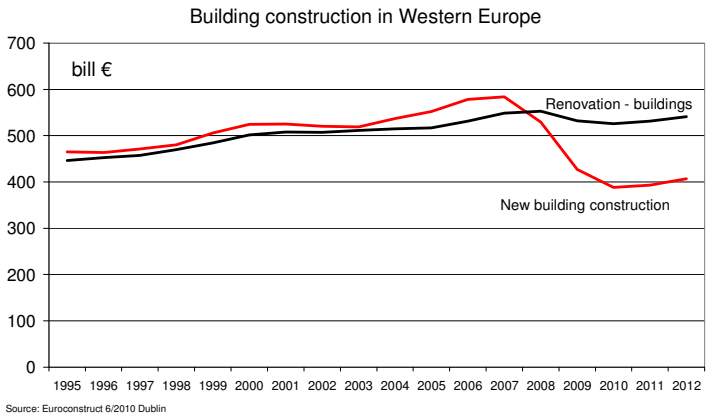

Figure 1. *Building construction in Western Europe, besides European Union member states includes also Norway and Switzersland, but excludes new EU members states*

There is no sign of specialisation in renovation work among companies with payrolls larger than 20 employees (figure 2). Rather the contrary expect HPAC contracting. Companies operating in the expanded renovation market are smaller than this (fewer than 20 employees). Real estate services companies and building materials retailers have also claimed their share of the market. The retail building materials and construction products sectors have developed a range of products for DIY renovation and also provide installation services. Increased demand has been met with technology developed in new construction.

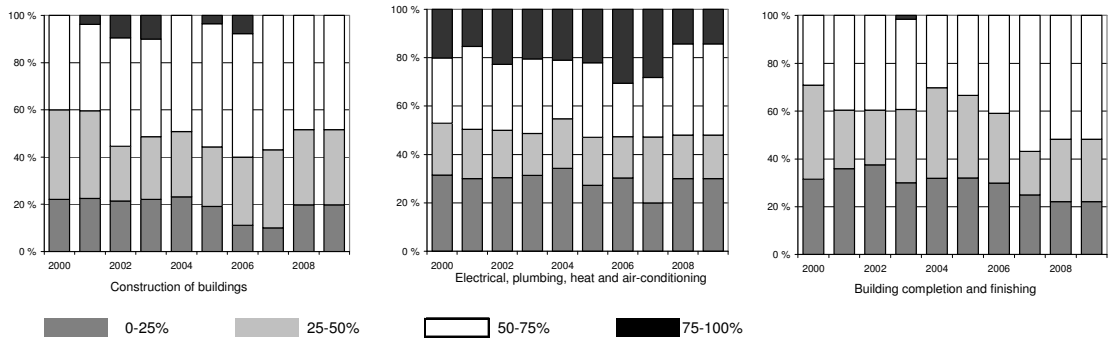

Figure 2. *The turnover from renovation building of building construction enterprises (Source: Statistics Finland).*

Generating customer value

As a result of the age structure of Finland's building stock, pipe repairs have become more common and created demand for special contractors in this field. Demand has created supply, and this is visible in the fact that for a large proportion of companies in this field, renovation is a more important business than new construction. For contracting companies, repair work is an almost identical technical procedure to installation of piping in new buildings. Of course, demolition of old structures and contracting are part of pipe repair work even in buildings that are in use.

Demand for pipe repair work has increased; demand has been met with products and services familiar from new technology. In 2008, both housing companies that had commissioned pipe repairs and the companies that had carried them out were surveyed on their experiences (Paiho et al. 2009). Both samplings were divided into projects that had gone well and gone badly. The customers were divided on the basis of their subjective answer to the question of whether they were satisfied with the purchased service. The businesses were divided according to their feeling as to how well the pipe repair work went.

The group of disappointed customers criticised the service ability of their chosen contractor. The criticism focused almost exclusively on the process. This is a feature that distinguishes renovation from new construction. New construction is an exclusively industrial activity in which, normally, customers only assess the final result. In renovation work, the object of assessment – more than the final result, even – is the process itself.

Satisfied customers valued the contractor's service ability as well as the workmanship and behaviour of the installers. They tolerated the disturbances and inconveniences caused by pipe repair work providing they were informed about them in advance. But if they came without warning, this prompted criticism. For this reason, renovation work is also seen as communications work. Companies also perceive communications to be a challenge. What makes it a challenge is that there is no need for it in the industrial process of new construction, and that non-professionals and professionals lack a common language. The recipients also vary in their ability to draw on and understand the information they are given.

DISCUSSION

Construction is a part of change

The Bon curve theory has been demonstrated by comparing economies at different stages of development. Examined this way, the development of construction has been made to look dramatic. The trend has been depicted in the form of a ∩-curve or even a Λ-curve. One gains the impression that construction is collapsing in developed countries, yet construction has not collapsed as expected, because quantitative demand has changed into qualitative demand and sustained new construction.

Theory that links the amount of construction to the structure of society has counted only new investment as construction. Including renovation does avoid the perception of collapse, but it does not constitute a major change in the theory's direction. Construction as a proportion of GDP in developed countries simply shrinks at a more gradual pace (Vainio 2010).

Disregard for maintenance and renovation has been and, unfortunately, remains the prevailing practice among decision-makers. In deciding on new investments, there is still a failure to simultaneously consider the degree to which future financial resources are committed to maintenance and renovation.

Renovate or replace?

In some cases, renovation work may be left entirely unaccounted for. Buildings may be used until technically or functionally exhausted, demolished, and then replaced with new buildings constructed in their place. This is financially justifiable if the price of the land is high in relation to the building's value, or if demolishing an old building allows a more profitable

business to be built in its place. New construction may be the more economical solution than renovation.

If the strategy is not to demolish and replace old buildings, the amount of renovation activity should grow linearly as a function of the amount of old buildings, and accelerate as a function of the buildings' age. The most surprising result of cross-sectional studies of renovation in Finland has been the high amount of renovation of buildings that are relatively new in relation to their technical operating life. Rather than being prompted on technical grounds, the renovations have been justified with reference to changes in premises requirements, among other factors.

Evolutionary economic theory about sector changes offers an explanation for this phenomenon. Changes and increasing complexity in the structure of the economy demand spaces that are different from those built for previous needs.

Renovation itself also embodies evolutionary growth theory, which says that growth requires both quantitative growth and diversification of content. The accelerating pace of change in economic sectors caused by exogenous variables requires renovation of the building stock. Endogenous growth factors are represented by a growing and ageing building stock. As each new generation of building stock comes up for renovation, the content of renovation activity becomes increasingly diverse.

Money flows matter

As is true of the construction market as a whole, the renovation market can be further divided into markets responding to demand from the private companies and housing companies owned by landlords, public sector and individuals. The two first ones have both revenues and expenses, the two last ones see only expenses.

Demanding clients, primarily construction professionals such as builders of commercial office space, are key drivers in the development and improvement of construction. New office buildings are also more technologically progressive than residential buildings. New construction technologies have first been adopted in construction of office buildings, whence they have gradually also spread to residential buildings.

There has also been a structural shift in commercial office space ownership. Companies no longer own their own premises, but instead operate out of rented premises and can easily move into new ones. Decisions to carry out renovation work on commercial premises are made on financial grounds. The buildings are renovated if it is financially sensible; otherwise they are demolished and replaced with new construction. International investment capital available in recent years has directed funds into new construction, with little effort made to renovate existing premises. Demolition will remain an attractive alternative in future, when implementation of new technologies in service production will see a reduced need for space. The virtual world is already becoming a noteworthy alternative to buildings and construction.

In public sector budgeting, too, decision-makers have been readier to approve new investments than direct funds towards maintenance of existing buildings. New construction has seen the accumulation of a large and, over time, aged building stock, as a result of which renovation needs now exceed the financial resources available to that end.

Housing companies are an interesting customer segment, because the prefabricated high-rise apartment buildings owned by them offer, in terms of their technology, a homogenous and moderately sized market even for companies operating in the local market only. As customers, housing companies are non-professional, decision-making is difficult and choices are made on the basis of price. Housing companies offer a large and interesting market, but they are of little or no help when it comes to product and production development.

Problems identified as far back as the 1980s continue to plague renovation. When problems have been identified, research programmes have been directed towards solving them. The most active actors in research programmes have been officials, property owners and representatives of the construction products industry.

The object of officials' concern has been the condition, housing health and occupational health of publicly funded buildings – especially rental properties. Officials have also been concerned about the condition of buildings in the education and health care sectors. Offices have received their own share of attention thanks to sick building syndrome (SBS). Tools have been developed to manage, assess and research the condition of buildings, to resolve air quality issues, and to plan renovations. What lacks is development of renovation site activities.

THEORY FOR RENOVATION AND FUTURE DEVELOPMENT

Evolutionary economic theory about the splitting of old sectors and the formation of entirely new ones offers an explanation for the growth in demand for both new construction and renovation. It also explains why so many space modifications are made to the building stock.

The development of the construction sector can also be understood in terms of evolutionary theory. Over time, different parts of construction have diverged into their own separate sectors. This trend will continue. New companies will eventually develop in response to emerging markets, while the most active companies will attempt to mould the sector's offering to suit themselves.

According evolutionary theory the development of a sector can push into fast motion internal changes, such as the innovation of a new technology or the discovery of a so-called "blue ocean" in an existing market. Evolutionary economic theory emphasises the impact of external disturbances. In construction, external disturbances have resulted in changes and irreversible effects throughout history. At the 2010 CIB conference, it was observed of the global financial crisis: "a good crisis should never be wasted."

For renovation, such a crisis might be the declared aim to improve the energy-efficiency of the building stock and cut greenhouse gas emissions. Something similar took place in the 1970s. At that time the effects of the energy crisis left their mark on new construction, but not on renovation. The energy-efficiency of buildings constructed in the wake of the crisis improved, and now standards have been set for renovation. Repairs alone no longer suffice; what are needed are much greater energy savings.

Sectors have been successfully renewed in a number of ways. Traditional sectors have been challenged by the emergence of new technologies that allow the same product or service to be produced more cheaply. Old sectors with a strong identity have also been able to reinvent themselves by questioning the status quo and changing their approach.

The construction sector, which has its own strong sector identity, has been able to renew itself. It has moved away from simply meeting demand for new construction to producing a range of services. Companies with an international presence have recently appeared on the market, learning from the global nature and information-intensive approach of the ICT industry. These companies have commodified their activities, concentrated on their product and invested in the expertise and technology it requires.

From the perspective of companies, renovation is divided into several markets. Renovation of commercially owned buildings largely corresponds to new construction of the same buildings. Property owners make professional decisions on renovations and associated purchases in accordance with their strategy. The strategy may emphasise economy or sustainable development. Companies can themselves decide on the conditions on which they bid for contracts.

The market for renovation of public buildings is contradictory but interesting from the perspective of companies. The projects are large but bidding is decided on price, because the renovation needs of public sector buildings outstrip available financial resources. The projects themselves can be completed under production conditions, because in the larger-scale renovations the buildings are evacuated for the duration of the work.

The renovation market in small, household-owned houses and housing companies is substantial but problematic. The project size is well suited to smaller companies, but, as has been seen, renovation completed according to this concept does not achieve great strides in development.

CONCLUSION

This study examined the period from the 1980s, when building construction was not recognised as part of the building industry in Finland. In the past 30 years, the building renovation industry has grown almost as large as the new construction industry. Initially, building renovation was expected to become a subsector for the building industry. It offered companies an alternative market that could be used to balance the effect of the economic cycles on the new construction market. Studies have shown that building renovation requires a different set of skills and technologies that new construction. Despite this, it has been considered possible for a company to alternate between renovation and new construction.

Renovation is only one means of improving the built environment. In future, it will face competition on this front from demolition. The requirements of sectors change, and existing buildings do not necessarily lend themselves to new needs. For example, activities may change in such a way that space is no longer needed for working humans, but for machines. An increasing number of existing buildings will be completely renovated for new purposes, treating the building as a raw material.

But there are still activities that cannot be replaced with virtual solutions. There are also property owners who are committed to their premises. For the owners, the systematic demolition of buildings and their replacement with new ones is a financial impossibility, an ecologically bad move, and would require more resources than are available.

The development of building renovation as part of the building industry follows the principles of evolutionary economic theory. According to evolutionary economic theory, economic growth requires the development of existing industries, rising profitability and the creation of new industries. Over time, the different branches of the industry then become specialised.

The objectives set for the energy efficiency of building stock and for reducing greenhouse gases will create both qualitative and quantitative challenges for building renovation. Small steps are not enough to overcome these challenges. Instead, a major developmental leap is needed, one that will only be possible with companies that specialise to building renovations.

Abstract
The opening and globalisation of the market presents additional information needs. In the closed market, planning information gave a clear enough picture of the civil engineering situation. The same source of information is still used when looking at the situation in the open market. Companies and central government have often viewed the economic cycle of civil engineering somewhat differently because there is different kind information available.

The goal of this research has been to distinguish from the information flood those pieces of information that best predict future development to help procurements and operative planning of companies. The market structure has become more complicated and more indicators are needed than before. The lack of quantitative data has to be compensated by expert opinions. The leading indicator candidates are the change of GDP, the outsize projects, the finance situation of clients and the expert opinion.

Keywords: leading indicators, civil engineering, market change

INTRODUCTION

Civil engineering has undergone a transition from a largely closed market to an open one resulted from EEA Agreement (1994). The migration of customer and production sectors to a market open both nationally and internationally has created discontinuities on many different levels. Customers do not need to content themselves with the local or national service providers. They have the chance to look for suppliers from an international market. Suppliers in turn can specialise in this regard and seek customers from a broader geographical area.

The rate of change in the open market is accelerating. The impact of changes in the international economy, international contracts, the marginal terms of the customer industry's economics, etc., on civil engineering are stronger and more direct (Nippala & Petäjä, 2004). It has been an objective of this project to find indicators that forecast future civil engineering market.

The remaining part of the paper is organised in the following way. Firstly, the research question is formulated. Secondly, the review of findings from European and Finnish civil engineering market are summarised. Finally, the results – leading indicators – are presented and for the last some conclusions.

RESEARCH QUESTION

In a closed market, activities are planned according to the available resources. In an open market, demand depends on the needs of customer industries and on financial considerations; as a result, the significance of reliable business information has increased. Information is needed both for short-term operational planning and for long-term strategic planning.

In the closed market, planning information gave a clear enough picture of the future. The same source of information is still used when looking at the situation in the open market. The economic cycle of civil engineering is typically said to be synonymous with the figure describing few large civil engineering investments in the government budget. If the paragraph outlines a major change due to an impending highway project, "civil engineering works are on the rise." The end of the highway project means that the "civil engineering works are in decline." This information is broadcast, being deemed reliable and easily accessible.

Companies and central government have often viewed the economic cycle of civil engineering somewhat differently. Central government sees the increase in its civil engineering funding, while companies see foundation and earth construction ending with the slump in residential construction. New indicators must now be found because the civil engineering market is more open and the old indicators fail to describe the future market. The business environment has become complicated and emphasises the meaning of reliable business information.

The research question is to identify limited amount but reliable and in common accepted leading indicators to describe civil engineering market development. The frame consist variables produced by the official statistic supplemented by tailored time series. The statistical information is historical and can be used only as starting point. The reliable foresee data is that companies and organisations need most.

In this paper the indicators are identified to describe the interaction between civil engineering construction and its operating environment. The interaction can be couched in specific terms, for example in the supply-demand situation and in the development of costs.

DEFINITIONS

Civil engineering business outruns statistical classification

The statistical classification of economic activities in the European Community, abbreviated as NACE, designates the nomenclature of economic activities in the European Union (Eurostat, 2008). It provides the definition of civil engineering. It includes general construction for civil engineering objects, including new work, repair, additions and alterations, the erection of pre-fabricated structures on the site and also construction of temporary nature.

Civil engineering consists of:

42120 Construction of railways and underground railways
42130 Construction of bridges and tunnels
42210 Construction of utility projects for fluids
42220 Construction of utility projects for electricity and telecommunications
42910 Construction of water projects
42991 Development and building of civil engineering projects
42999 Other civil engineering n.e.c.

The Statistical classification defines the industry according to its end product. Those works that are not end products are excluded. For example foundation engineering is not an end product. The definition of civil engineering does not cover the construction of underground spaces, earthwork connected with the commencement of mining activity, the foundation works of residential buildings, or the property maintenance of outdoor areas. All of these are market segments of interest to companies that operate in the civil engineering industry.

Business cycles and indicators
Fluctuation in the level of economic activity is quite common in developed countries. These movements are known as business cycles. A business cycle usually has four distinct phases: the upswing or recovery phase, the peak, the downswing phase and the trough. As most forecasters know, establishing one's current position in the business cycle is not that straightforward. Better results appear to be achieved, therefore, when combining quantitative and qualitative data in the economic forecasting models (Snyman, 2009).

Economic indicators can be classified into three categories according to their usual timing in relation to the business cycle: leading indicators, lagging indicators, and coincident indicators (Eurostat, 2010).

A leading indicator is an economic statistical indicator that changes before general economic conditions have started to change and therefore can be used to predict turning points in the business cycle. Typical examples of leading indicators are stock prices, business and consumer expectations. Within short-term statistics the number of building permits is a typical leading indicator.

A lagging indicator is an economic statistical indicator that changes after macroeconomic conditions have already changed. Typical examples of lagging indicators are unemployment figures, profits or interest rates. Within short-term statistics the number of persons employed is a typical lagging indicator.

A coincident indicator is an economic statistical indicator that changes (more or less) simultaneously with general economic conditions and therefore reflects the current status of the economy. Typical examples of coincident indicators are industrial production or turnover. A coincident index may be used to identify, after the fact, the dates of peaks and troughs in the business cycle.

REVIEW OF CIVIL ENGINEERING MARKET

European civil engineering 2000-2010

Depending on the country, civil engineering is mainly financed by local communities, other regional units or by the central government. The funding opportunities of the public sector affect the demand for civil engineering. A healthy economy increases tax revenues, which decrease when an economy is flailing. Civil engineering can be utilised as a tool to balance the national economy. Small new projects and renovations are often started when the economy is doing well (Graf, 2000).

The opposite also holds true: when the economic situation is bad, it can be a good time for civil engineers. In many countries, the effects of the international financial crisis were battled by starting or bringing forward civil engineering investments (Stemperini, 2009).

In particular, the imminence of local elections provokes acceleration in the civil engineering works carried out. After the elections, the preferences of the elected party become visible in the civil engineering projects. The Euroconstruct summary from year 2000 highlights the activity of private citizens or associations as a common reason for delays in the planned schedules of the works' completion.

It is also possible to order the commencement of civil engineering works by statute, as has been the case with clean water, waste water and air purification projects. The aim of Directive 2000/60/EC of the European Parliament and Council is to make the protection of waterways as effective as possible, to prevent the contamination of groundwater and to secure the supply of clean water (The European Parliament and The European Council, 2000). The implementation of the directive is clearly visible in the commencement of civil engineering projects. In turn, the aim of Directive 2001/81/EC is to create national emission limits for air pollutants (The European Parliament and The European Council, 2001). Meeting these requirements may necessitate the construction of new highway networks.

Investment in infrastructure is also related to the competitiveness of business and the functionality of society. The Trans-European Networks (transportation TEN T, energy TEN E and telecommunications networks eTEN) are going to link Europe by 2025. When compared to European-level networks, congested cities demand investment in mass transportation, such as underground rail network projects among others. The development of technology is closely connected to the construction of both TEN and other networks (European Commission, 2008).

The price of oil was emphasised as a factor affecting the civil engineering industry. The effects of the price of oil were two-fold: it increased investments in the energy industry, but it also increased the input costs of civil engineering. The discussion over the price of oil expanded to cover the entire energy industry. Since 2004 (Vries, 2004) the need to invest in renewable, emission-free or minimum emission energy has been mentioned energy directive (The European Parliament and The European Council, 2010).

Finnish civil engineering sector – structural change

The Finnish civil engineering market can be logically divides into three periods: time before 1990, 1991–2010 and after 2010. The first period consists of the time when state organisations and municipalities had their own planning and contracting units. Private industries, like the house building, were alone in contracting out to private contractors.

The middle period began 1991, when the first civil service department was incorporated. It was the Civil Aviation Administration, today Finavia Corporation. During the time period 1991–2010 also others changes occurred in civil engineering construction. Both the central and local government outsourced their contracting units. The last period begins 2011 when the last central civil service department - Navigation Administration - will be incorporated (VTT).

- time before 1991

Civil engineering has always been closely tied to the development of society and business life. Civil engineering is needed when suburban areas and communities are constructed. The needs of industries and societies affect the traffic, energy and communication networks. In addition to specific needs, the civil engineering industry was used as a tool in labour and regional politics up until the 1980s. The labour political dimension was discarded due to technological development and unemployment benefits, while the regional political dimension remained until the 1990s (Karjalainen & Pajakkala, 1985).

- time 1991–2010

Since the recession at the beginning of the 1990s civil engineering has also been guided by economic realities. Projects are given priority according to how they boost the economy. Part of the public infrastructure has become privately owned; in this respect, decisions are made on a purely economic basis.

In recent years, construction has been an outgrowth of the change in regional structures and by migration, which concentrates the population in attractive cities and their surrounding communities. The altered and increased traffic flows demand both mass transport solutions and highway investments. Construction in an existing urban area brings with it marginal terms: tampering with an existing built environment and taking part of the construction underground.

Since the mid 1990s many of the formerly closed markets of infra construction has been opened up for competition. This has brought an expansion in the selection of end products and increased significance for the private sector as constructor. However, the public sector still dominates, with 80 per cent of all infrastructures (Official Statistics of Finland A).

Investments in construction concentrate on the buildings, highways and networks of the existing built environment. While some investments are used for renovations, others are used to upgrade constructions to meet the requirements of society. The role of companies as implementers of investment work has grown to 70 percent and in infrastructure maintenance to 65 percent (VTT).

Currently, the end products of civil engineering can be either private or public. Often, they are classified according to their role as transfer or distribution networks, but most commonly, their classification is based on their functionality. As an example, a function can be the transfer and distribution of electricity.

The examination framework of the national economy divides the end products (use) between the public and the private sectors. This use can be either investment or consumption. Based on this division, construction can be divided into public sector construction investments and consumption, i.e. upkeep and maintenance, and to the corresponding construction investments and consumption of the private sector.

In addition to the work of their trademark industry, companies in the civil engineering industry also carry out foundation work for residential buildings and property maintenance of outdoor areas. By this definition, civil engineering work in Finland in 2009 totalled around EUR 6.1 billion. In recent years, the significant changes in the residential building industry have made a major impact on the civil engineering market (table 1).

***Table 1**. The % change of civil engineering production volume in Finland compared to previous years (VTT).*

	2009 EUR Billion	2007 %	2008 %	2009 %
Total	5,5	0	+2	-2.5
Investments	3,9	0	+3	-4
Maintenance	1,6	-1	-1	+1
Foundation work for buildings	0,6	+14	0	-27

- future

The period after 2010 starts with an insecure financial situation. The world monetary crisis in 2008 and the subsequent rapid recovery keep the oil price high and have influence on the Finnish civil engineering sector. The European economic situation is also insecure because of the Greek, Irish and Portugal economic difficulties.

The economic situation for the Finnish state is also worsening, with Finland having to pay back loans taken out for the 2008–2009 recession. For Finnish civil engineering this will mean a greater onus in future on the private sector.

The demand of metal minerals is growing because in developing countries. This has awoken mining companies' interest. In the Northern Finland there is dozens mining projects in their early stages. The mine investment itself and needed transport infrastructure demand civil engineering.

The energy efficiency targets set to building stock has already caused demolish projects. This is also business area for earth moving contractors.

POTENTIAL LEADING INDICATORS

Finland

Before 1990' the majority of civil engineering work was in the form of road building contracted by the state's own contracting unit. If extra money were available, more work (subcontracting) could be ordered during the year. Railway, street, water supply, sewerage and many other civil engineering sector constructions were also carried out by state or local municipal organisations, all with budgets and investment plans.

During 1991-2010 public sectors decreased ownership in contracting and also as infrastructure owner. Today investments in energy, district heating, water supply and airports are made by the private sector. These sectors, more or less dependent on the economic situation, decrease their investments very quickly if the economic situation gets worse. This makes GDP an important indicator (figure 1).

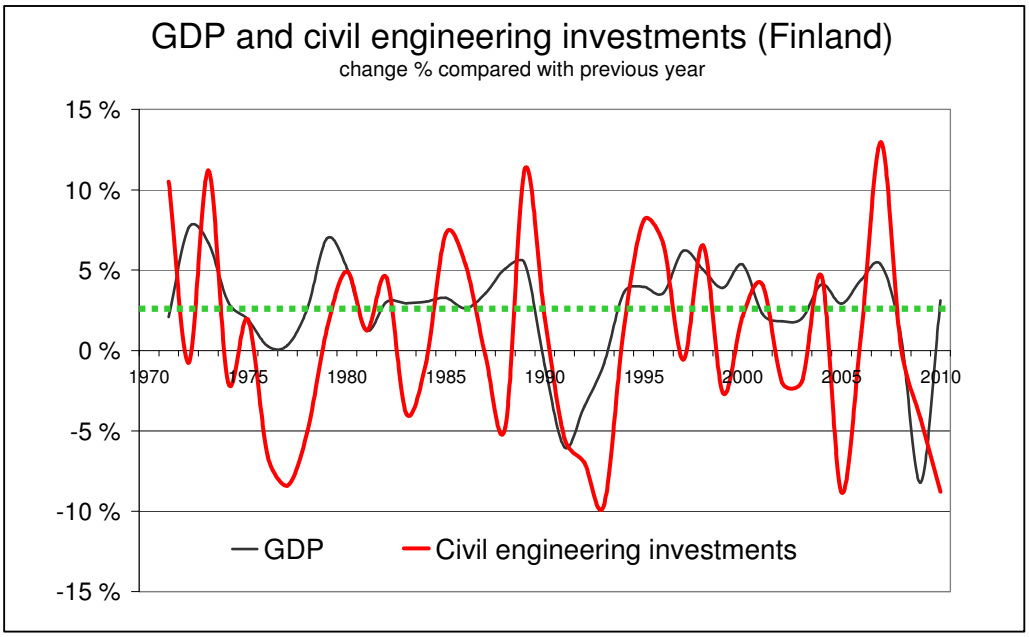

***Figure 1**. If GDP growth remains under +3 per cent, construction growth will be negative (Official Statistics of Finland B).*

The influence of outsize projects on the civil engineering market was realised as early as the 1980s. Outsize projects can have remarkable influence (figure 2). In the aviation sector, for example, one outsize project may double or triple the construction work for the whole year in that subsector (VTT). This information helps to forecast the construction volume for the following years. Even outsize projects have an important influence on the market they were properly followed up until after 2005.

Over recent years the survey of planning engineering offices has been reasonably successful in forecasting the changes in civil engineering (VTT). Contractors' surveys are another good indicator for future development, with knowledge months in advance of the forthcoming market situation based on the number of calls for bids. A further useful indicator is the number of contracts, although with forecasting only four months ahead there are some limitations to the use of this information.

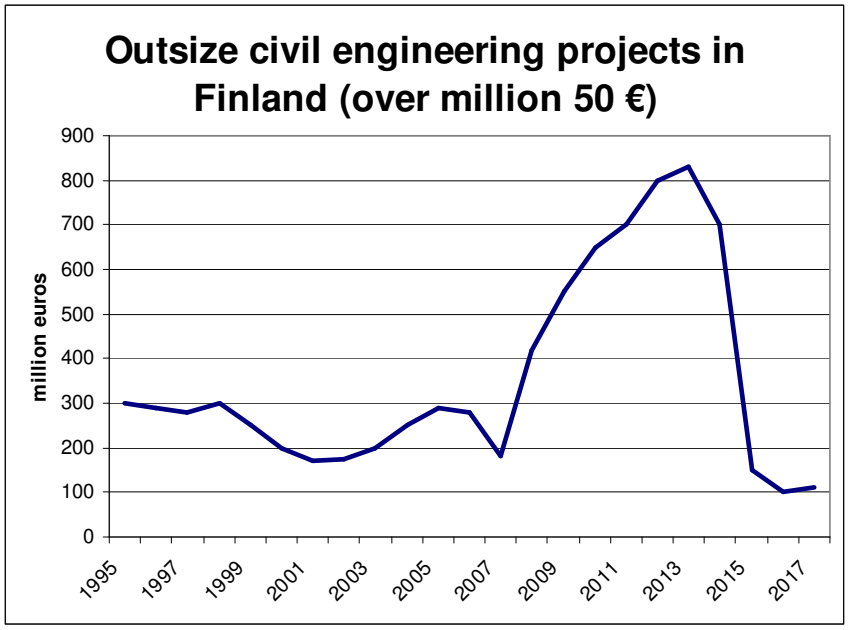

Figure 2. *Total for public and private projects (over EUR 50 million) in Finland, calculated at the end of 2009 (VTT).*

In Finland ministry of finance has established a group of experts to discuss civil engineering and the economic situation. The experts represent various sectors, such as contractors, scientists, ministries and associations. The group forecasts the civil engineering volume for the following year (Raksu, 2010).

The drivers and indicators from Finland and Europe are gathered to tables 2 and 3. In the table 2 are the drivers. At the general level nearly all European level drivers have some influence also over national level. But not vice versa, a small country doesn't have influence in the European level civil engineering markets. Short run indicators are presented in the table 3.

Table 2. *The identified European level and national level civil engineering investment drivers.*

Driver	***European level drivers***	***National level drivers, (case Finland)***

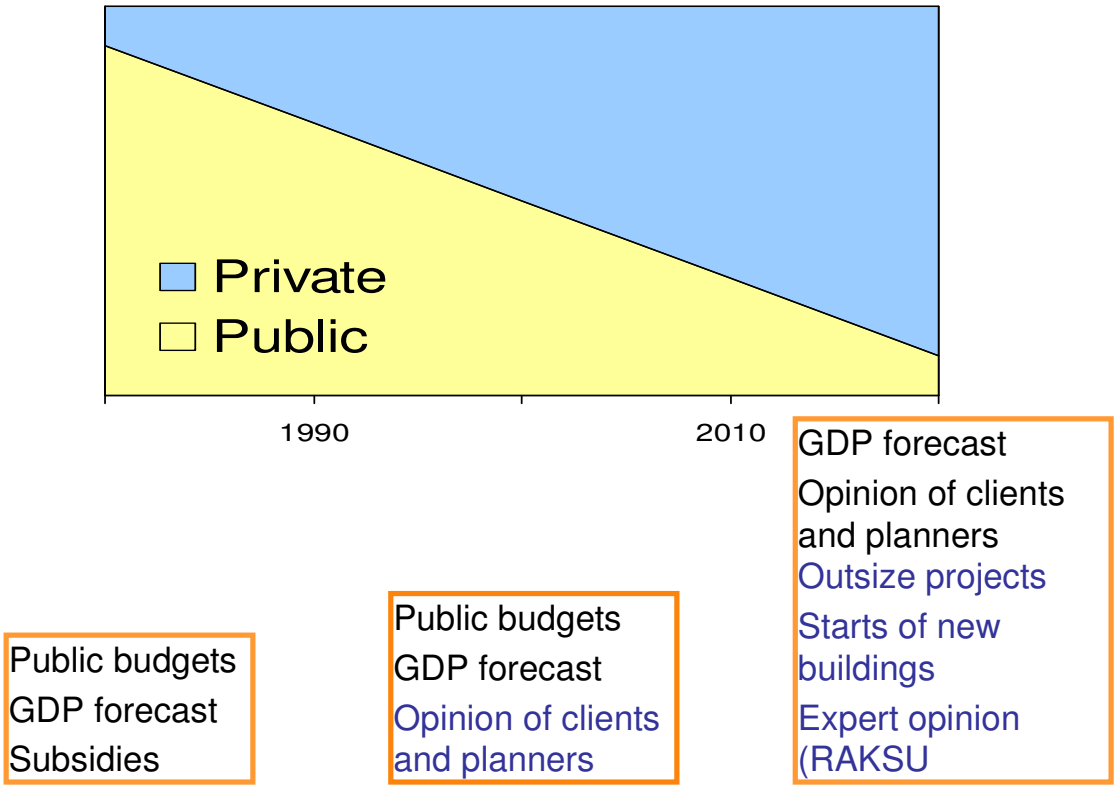

Figure 3. *The Finnish Civil Engineering can be divided to three periods: before 1990, 1990-2010 and after 2010 according to the private contractors' market share.*

DISCUSSION

When public sector contractor has significant share of market key indicators were public sector budget, state subsidies, region politics and GDP forecast. Despite the structural change the most important factor is the state main budget. The Finnish public sector has as client still approximately 55 per cent market share. The remaining 45 per cent share of other sectors is growing. That market development is followed up by opinion questionnaires of planners and infrastructure owners (clients).

In some certain part of markets outsize projects has big influence of market size. Public and private projects over EUR 50 million (outsize projects) make up about 5–10 per cent of the total construction volume in Finland. In some civil engineering sectors an outsize project may represent 50 per cent or even more of all investments. For example, the Vuosaari harbour project in the Helsinki Metropolitan Area constituted over 50 per cent of total waterway investment at that time.

The foundation of new houses forms about 15–20 per cent of the work carried out by civil engineering contractors. This is a key sector for companies operating outside growing city areas. The fluctuations in building construction have been remarkable. GDP is also a fairly accurate forecast of building construction. If we include building foundation work to civil engineering market the new building starts will be one leading indicator to civil engineering market.

All above mentioned are procyclic indicators and move in the same direction as the civil engineering market: they increase when the market is doing well; decrease when it is doing badly. In choosing the indicators also the importance and availability must be taken account.

Despites above mentioned indicators, there are many other. It is typical that indicators point the different development. This is one reason, why Ministry of Finance has called civil engineering sector professionals (“Raksu group”) to analyze markets and make together forecast. The opinion of Raksu group is also classified as a leading indicator.

CONCLUSION

The focus of this paper is on the key indicators for Finnish civil engineering construction. The only needed indicators before 1990 would have been the public sector’s investment plan (state) and regional investments (municipalities). The structural change 1991–2010 increased the private sector role as client.

From point of view anticipating the private sector as client is problematic because of the planning data is scattered. Some useful data is collected by industry organizations. The Ministry of Finance use the opinion of RAKSU expert group to describe this submarket.

The findings concerning Finnish and European civil engineering market are quite similar. The indicator system is suitable for analyzing international civil engineering construction. The most significant differences are the role of private sector and the time horizon. Even the Euroconstruct tries to foresee business cycles, the reports focus on long run drivers.

Development work on the key leading indicators continues in 2011-2012. A new research (Vainio & Nippala, 2010) will possess a more scientific touch, including testing of the theory described in this paper.

Abstract
After having researched a construction system based on CAD-CAM and CNC, we come to the conclusion that this system is appropriate for implementing it in refurbishment processes in old buildings. More precisely, refurbishment in buildings erected before industrialization with wooden structure and masonry facades in dense and historic city quarters. The main goals of the construction system are the recyclability of all elements, energy savings, bioclimatic performance, economy, accuracy and safety in the building site and simple procedures to write the project documentation.

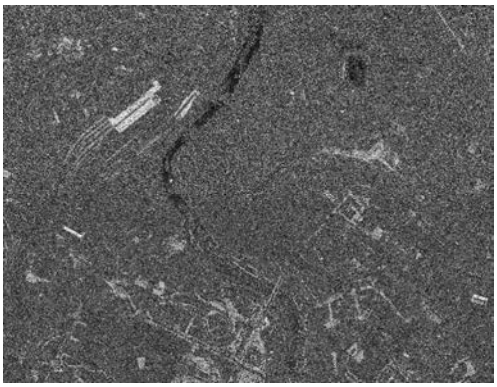
The old quarters accessibility is often a handicap for implementing standardized components. In this case, the structural panels can be elevated to the floors with a reasonable physical effort for the worker, using the staircase, instead of an electric elevator.

Moreover, the heterogeneous personal economical resources of the neighbours in the building, is often an added problem for executing overall refurbishment of buildings. This system allows to make partial refurbishments and can work in different phases.

The new program layout planned for the buildings or apartments solved with the common refurbishment technologies and systems, requires an added slab of 20 cm for the drainage piping system. The application of the system can avoid this.

The construction system is adaptable to any geometry. In this way, there is no problem to applying the system on non-orthogonal plots. Using a CAD-CAM coordinated system the structure is easily adaptable to irregular geometries and dimensions.

During the first industrial era, in the historic city centre buildings, the insertion of plumbing system in a wooden structure building was rarely successful. The wooden structure near these plumbing facilities, is almost always rotten or damaged. The proposed construction system offers a solution for this problematic.



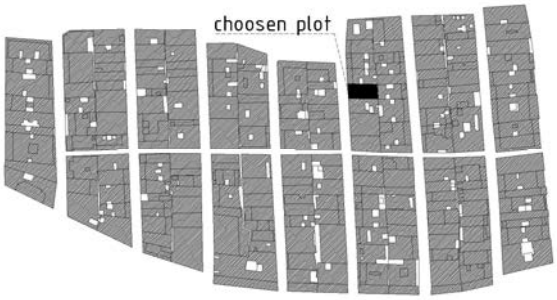
Normally such historic buildings don´t have a correct insulation. The system allows a bioclimatic performance of the whole building.

Keywords: CAD-CAM technology, historic district refurbishment

1.-INTRODUCTION: Research framework

1.1.-Urban context

This research is limited to the refurbishment of the Old Quarter of Bilbao. The urban shape of this part of the city was shaped between the 12th and 13th century. They used the so called ``Gothic Plot´´ to organize the structure of the city. Those plots are four meters wide and fifteen meters long. The front of the plot faces the street and the back of the plot to a "carcava" or gully (two meters wide medieval back street). In the beginning the buildings were two or three stories high, and they had a courtyard or a garden in the back side. But at the beginning of the 14th century, the whole plot became occupied by the building. Nowadays, the buildings have five floors, they form blocks and sometimes they share an inner courtyard. That means that the central area of each separate building has no sunlight. The current buildings were built around the year 1800, that is before the industrial era. Since then, they have been constantly modified. They are commonly divided in apartments in the first to the fifth floor and a commercial use space in the bottom floors.



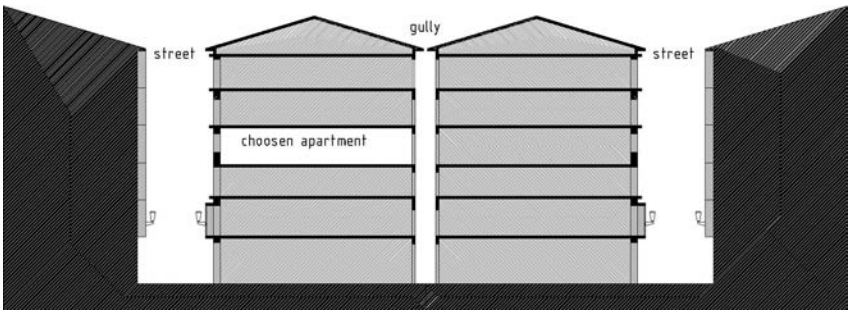


Figure 1and 2: *Orthophoto of the Old Quarter of Bilbao and location of the plot where the research has been made .*

1.2.-Built context

The buildings are built using a timber framework (beam and column structure). The floor structure is made up with rafters and boards. The last bay facing the street is filled with two feet brick masonry or stone wall. The bay facing the gully is closed with a one foot wide brick wall. The inner distribution was built with one quarter feet wide brick walls. Normally, the layout was the same in all floors. This distribution often ties the wooden framework and sometimes collaborates as a structural piece. The goals of this research are to create a tool for the refurbishment of those buildings and to repair the pathologies in the wooden structure.

1.3.-Property context

The property of those buildings is divided in two parts: The common use property and the private property. The common property is made up of the facades, roof, structure, common installation supplies and staircase (and the lift, in the few cases it exists). The private property concerns the inner area of each apartment and its installation system. The refurbishing works will be different if they are focused on the common part or the private property.

Figures 3 and 4: *Cross section and facade of the chosen building.*

1.4.-Technology

The tool created from this research, will be used in the following context:
-The architect or the designer uses three dimensional Computer Aided Drawing software.
-The fabrication or the different elements of the refurbished building is made using Computer Numerical Control machinery. This means, that the technology is available in the industrial companies nearby Bilbao.

1.5.-Materials

The Refurbishment System created from this research uses mostly plywood or laminated wood. Steel for reinforcement purposes will be used when necessary. Wood is available in the Basque Region and it covers the 30% of the territory land-surface. Timber industry is quite developed both for construction and for furniture. Steel working is also a developed industry.

2.-Why Refurbish the Bilbao's historic district.

2.1.-Environmental improvement

The buildings included in this research have needs to improve their thermal and acoustic insulation. Those building have five times less insulation than the required for new buildings by the Building Code (``Código Técnico de la Edificación´´).

Calculation of a Thermal insulation Resistance .

WALL

-Stone wall **60 cm wide.**

- Superficial Resistance of the enclosure in contact with interior and exterior air.

Rsi = 0,10 m2 K/W
Rse= 0,04 m2 K/W

Figure 5: *Calculation table: Thermal Insulation Resistance of a 60 cm stone wall .*

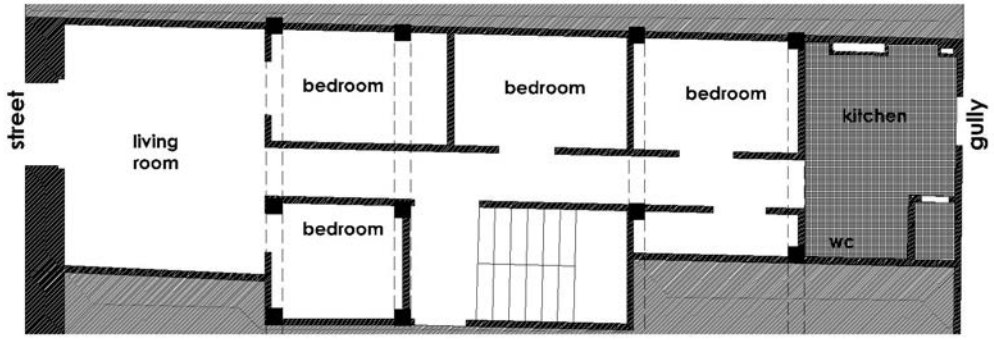
2.2.-Lack of land surface for building residential areas
In the last fifty years, the use of land for urban purposes has reached the 65 % of the total municipal area of the municipality of Bilbao. The Basque Region of Biscay (NUTS-3) is a Predominantly Urban Region. There is an evident lack of land.

2.3.-Empty dwellings or in disuse
The proportion of empty houses in the target neighbourhood doubles the one in the rest of the city. 616 apartments out of 3.206 are empty nowadays. That's near 20 %. Reasons are multiple but mostly, it's because these apartments don´t offer enough facilities. As it has been said before, these buildings are 200 years old. Within the empty houses, not all of them have sufficient comfort, such as heating, hot water or even a kitchen and shower. Another fact is that these buildings don´t have an elevator.

It is common for some apartments in the building to have been newly refurbished and others don't even have a shower. This is a consequence of the property system mentioned before. Refurbishment is necessary to turn all the empty space into proper and dignified dwellings. The local administration has made a subvention program for refurbishment, and it has been working with it during the last 25 years.

3.-Problems for Refurbishment in the Old Quarter of Bilbao

3.1.-Project
The council's office for Planning asks for a project whenever an apartment is going to be subject of new layout transformations. The ancient layout usually has up to four rooms, two of them usually lack windows. The kitchen and the bathroom usually are attached, both in the back side of the apartment.



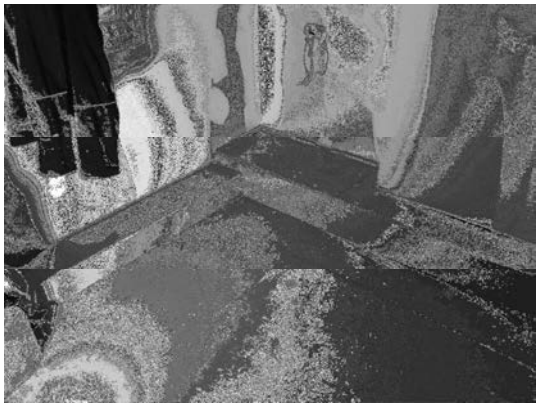


Figure 6: *Apartment´s floor-plan before refurbishment was made.*

The project must fulfil what the Local Plan -regarding technical and hygiene requirements- requires for a standard or basic home. Such apartment needs a space for living room and kitchen, a bedroom and a complete bathroom. The kitchen needs forced ventilation to the gully and not the main facade. All the spaces must have natural light and ventilation, except the bathroom, which can also work with mechanical air renewal. There are apartments within the Gothic plot which are four meters wide and fifteen meters long, with only two windows, one to the street one to the gully. The main drainage pipe of the building is usually in the back of the building.

During the industrial era, in the end of nineteenth century and in the beginning of the 20th, the plumbing system was inserted. The location of the system was always close to the gully. In order to keep the budget low, the kitchen and the bathroom were close to this plumbing system. During the project design process, in order to fulfill the local requirements for a basic home, the architect or designer ``needs´´ this area attached to the gully for placing the bedroom or living room. Otherwise, the bedroom will have no natural light or ventilation. Therefore, the bathroom is moved to the centre of the floor-plan. The displacement of the bathroom requires more room for the drainage pipe and also a longer one. The local building regulations oblige the placing of the private pipes and their connection to the main ducts within the apartment that they serve. In consequence, a step will have to be built in order to attain a correct evacuation of black waters. That is, the bathroom level is usually higher than the rest of the home. This is a common procedure to avoid installing mechanical pumps that often do not guarantee a continued use.

Figures 7 and 8: *Fecal pipe and its stair.*

3.2.-The rotten structure

As the demolishment is being carried out, the structure is unveiled. After 200 years, the wooden framework near humidity sources is usually rotten. The moisture sources are the plumbing system and the rain water in the back gully. This plumbing system, mostly built with steel pipes, has been worn out over the years. This system used to pierce or go through the flooring, so the wooden structure near the pipes is always rotten. During the refurbishment period the rotten framework must be reinforced.

Figures 9 and 10: *Rotten structure and typical steel reinforcement.*

3.3.-Neighbors
During the refurbishment process, it is almost inevitable to disturb neighbours. The property division between an apartment and the one below, is often a 2 centimetres wide wooden board and a 2 cm wide plaster board. Considering that near the gully the wooden board is almost always rotten, it's quite easy to make a hole -sometimes in consequence of rubble falling down-.

3.4.-Accessing the building site
Narrow staircases are an impediment for transporting material to the apartment. The proposed systems should deal with pieces in suitable dimensions for transportation purposes. A small scaffolding is commonly used but its has to be compulsory certified and signed by an architect -which will add on to budget-. Another limitation is that imposed by the pedestrian zone regulations. Cars are only allowed from 8.00 to 11.00 am.

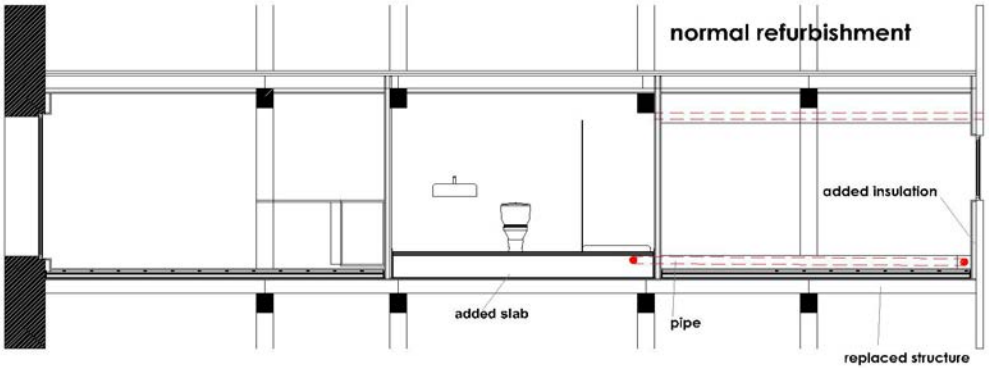

Figure 11: *Cross section of an apartment refurbished with common technology.*

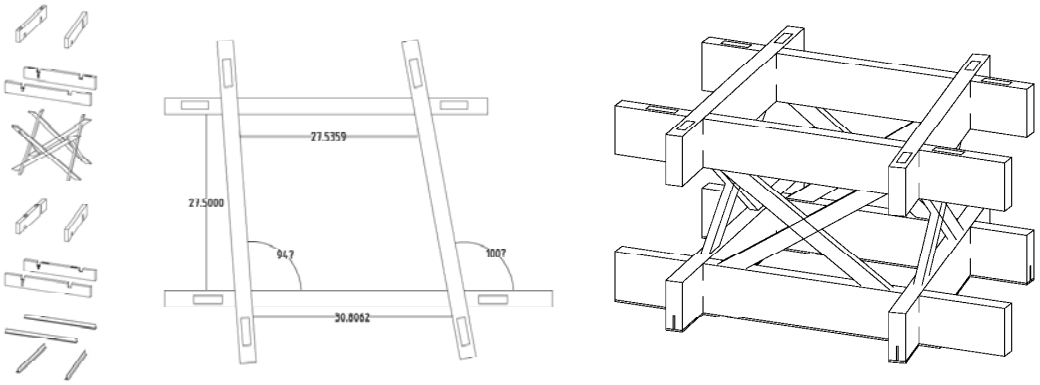
4.-Research methodology

The research is made with the aim to define and prove a Construction System for Refurbishment in Old City Quarters using CAD-CAM and CNC. Currently, the research is in the design and test of building elements phase. Both design and testing are made by computer. The next phase will be creating prototypes to test them in a real situation. Defining each part of this construction system is compromised by the research itself and by the outputs obtained with the prototypes.

4.1.-Approach to the construction system
The main goals of the construction system are the recyclability of all elements, energy saving, bioclimatic performance, economy, accuracy and safety in the building site and simple procedures to write the project documentation. Adaptability to geometries, and different building situations.

4.2.-Generic design, first approach
As it is has been said before, the system will be adapted to any building in the Bilbao Old Quarter. But first, a generic design has been developed. This generic design will be focused in:

Common layout level
-the structural reinforcement and the new structural framework
-the enclosure system, and specially the thermal and acoustic insulation



Private layout level
-the partition system, should be as adaptable as possible. The system is flexible in partition and in installations.
-providing space for the installation system

The Construction System will be modified and improved during the research process.

4.3.-Checking the generic design by computer simulation
A test with a three dimensional CAD model, will check some features of the system. The outputs of the simulation say that the structural behaviour of the system is correct.

With the 3D model, we can also check that the different pieces of the system can be produced in the CNC machine. This way, the cutting proposed for each element is based in state of the art technology, without wasting material.

4.4.-Conclusions and definition of the generic design
Once the results of the simulations are finished, the generic design can defined. The research is in this phase now

Figures 12, 13 and 14: *Pieces and Scheme of the structure made in CNC.*

4.5.-Projecting and building the prototype
Once the design is finished, the Construction System should be tested in real situation. For this purpose, a collaboration with local administration is needed. It seems quite difficult that a private owner of an apartment will expend money in a Construction System that it is not even proved. So, a public refurbishment work will be needed to apply the prototype in real case.

4.6.-Testing the prototype
The prototype will be tested structurally, thermally and acoustically. But the timing of the fabrication and building process as well as all the facts that could enlarge the budget will be also studied.

4.7.-Conclusions and final report for the application of the Construction System
After testing various prototypes, the System will be ready to apply in all the cases. A handbook or manual to use the Construction System as a designers tool can be designed. After the research, the system will be considered as a language or as a tool that both the designer and the builder will use. A computer plug-in could also be developed. This plug-in could be useful for the following:
-as data base offering frequent solutions.

-to adapt the construction solutions to the different geometry cases that will be refurbished.
-to calculate the needs of the structure and insulation.
-to generate documents for the project, such as budget report etc.
- to coordinate the designer and the manufacturer.

5.-REFURBISHING WITH CNC

5.1.-Building with CNC. The context nowadays.
CAD (Computer Aided Design), CAM (Computer Aided Manufacturing) and CNC (Computer Numerical Control) have been mostly used in industry more than in construction. Shipping industry, automotive industry are quite used to such tools. Within construction area, the furniture industry and the timber industry are the ones that have developed their own know-how.

There has been a more developed use of the CAD-CAM and CNC technology in new building constructions than in refurbishment processes. Particularly, when the designed form's complexity cannot be solved with traditional technology. It is also applicable when the budget is too high.

One of the earliest precedent in architecture for using CNC-CAM technology is professor Mark Burry's approach in 1.993 for the Sagrada Família church in Barcelona, which required a forehand research to reach Gaudi's original design. The next step was to make a 3D parametrical model using advanced CAD to define the future stereotomy. Then a polystyrene prototype was erected. And finally, the lateral and central naves, the 7 meter wide, 35 meter high Rose window screen wall for the West Transept were erected with just 10 mm tolerance.

Another examples are Frank O. Gehry's projects. The forms he designs, ``need´´ somehow to be built with CAD-CAM technology. The Guggenheim museum in Bilbao, finished in 1.997, is one example. Here, the main structure was made in steel, a material that is malleable and can be cut in CNC. The same architect, with the assistance of Thomas Bock used concrete pre-cast elements in the ``Neuer Zollhof ´´project, located in Düsseldorf (Germany). In this project, the polystyrene-formworks were produced by CNC-milling machines.

Recently, the CNC technology are being developed in timber structure buildings. These are a few of the recent and finished examples:

- Campus Restaurant with Auditorium for the Trumpf company in Ditzingen (Germany) by the Barkow Leibinger Architekten studio and finished in 2.008.

-Pompidou Media Centre in Metz (France) by the architect Shigeru Ban and finished in 2.010.

-Pavilion for the Federal Horticultural Show in Koblenz (Germany) by many authors and finished in 2.011

We can see that the technology for designing and building is already set. The mentioned examples show structures that mostly bear light weights, sush as roofs. Creating structures for bigger loads, such as floors, is the next challenge for this technology in timber structures.

5.2.-The generic design

The following paragraphs will explain the design process in a clear way. The starting point is the search for an optimal construction system.

A system which will allow for an up to date and manifold service in the same way newly built buildings do. A constructions system that can harbor a wide-range of uses during the life span of each space, from the ground floor all the way to the roof. An optimal system that can house all the needed facilities. A system that can guarantee a bioclimatic behaviour.

There is no intention in this first approach to come about new spatial solutions for architecture. It is rather a research for an constructive development. And so, the spatial solutions and partitions mentioned are of common and conventional character. Thus, we want to achieve a system that can serve a normal space.

Neither is the object of the present approach to design new facilities or service installations. On the contrary, we would like to house those systems in a proper way, in the correct place. We also intend for them to be totally accessible for repairing and follow ups.

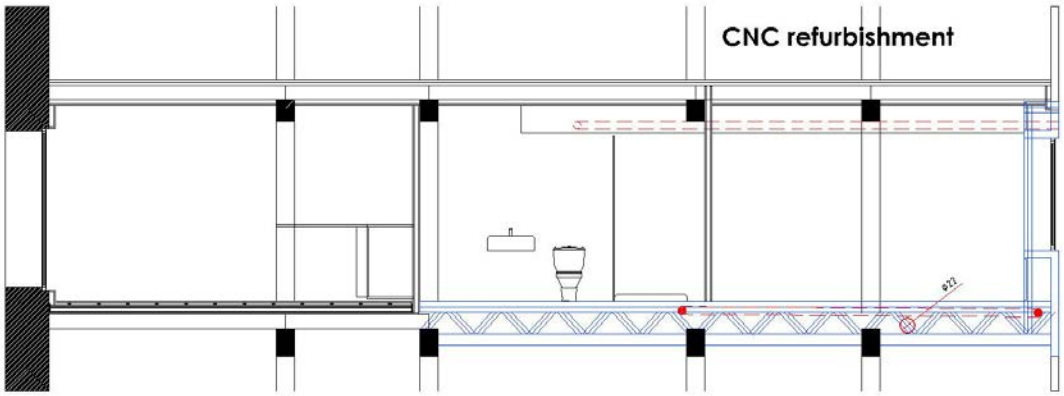


Figure 15: *Cross section of an apartment refurbished with CNC.*

Nowadays, the facilities take up more and more space and usually run along the ceiling. Air-conditioning and sanitation ducts are usually the ones with bigger dimensions. In consequence, they ask for a wide floor section. In many buildings the distance from the ceiling to the top of the finished floor can take over 60 cm. This is also observed in residential buildings. So, we will proceed to assume this distance (60 centimetres) for our building system. Moreover, the fact that the service ducts run independent of the structure or partition walls, allows for interior partitions to be flexible.

The construction system should be based in bioclimatic principles. It should keep energy in, lower the energy demand and profit from the solar energy in order to attain healthier interior environments. Therefore, and in order to achieve a higher heat isolation, a double skin facade is proposed. The two planes would be separated by 90 cm or more.

If we study the scheme, free of any structural support, we believe a double-support truss can be easily adapted by placing it in the interstitial space between the facade planes.

Ultimately, we will obtain 3 types of spaces. The primary one is the lived space and the secondary one “serves” the other one. This second level space can be optionally used for

storage and every day purposes. It will depend on the ruling use of the building, as well as on the width of the mentioned space. Finally, we must mention the third type of space which is located horizontally between two primary spaces. Its purpose is to exclusively house facilities and structure.

In order to develop this system, we should not despise the use of recyclable materials such as plywood, WPC, composite panels and the like. The choice will depend on how adequate it is for each project. At the same time, it is indispensable to create the building system using state of the art CNC cutting machinery. This allows:
- for adaptability in non –orthogonal plots; the machine is able to cut in a wide range of angles.
- we do not need to follow a certain module system; it is easy to coordinate with other dimensions. The cutting is realised with the needed accuracy depending on the context. It is a customised design.
- Project execution guarantee. What is projected, is drafted and built in site exactly.

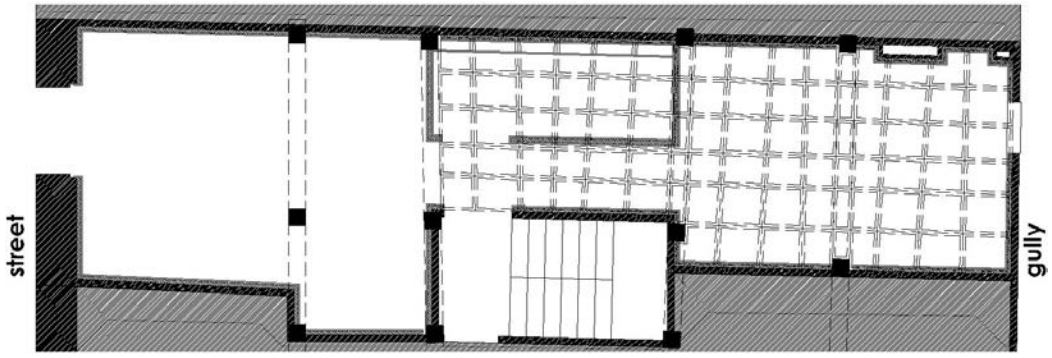

Figure 16: *Scheme of the reinforcement made by using CNC TECHNOLOGY. A none orthogonal grid is made.*

It appears that all buildings, just as other equipment, will be in the need of a continued maintenance and follow up by law. This also applies for the building services and facilities. The building, as it seems, will be required to guarantee the adequate service regarding the structure and the facilities. Our system should be adaptable to such a reality.

5.3.-Maintenance and flexibility
The system's structure, partitions and facilities are entirely flexible. The joints must be adjusted and released with a simple turn of a key. This would permit that the user, together with technical advice and the help of an architect, could move any element of the building. The facilities run through the horizontal structure. As an example, it is proved that in a 60 cm floor width, a drainage duct of 110mm diameter, can evacuate and reach the vertical duct with a 12% slope.

So, we can say that the only fixed element that should be reflected in each floor is a vertical thruway for facilities. The less 'elbows' a duct has, the larger efficiency of the service can be. This applies for most of the installations. The user in each floor is free to design an adapted layout, based on personal needs and taste. The same building can house different layouts without compromising the floors below or on top. In addition, they can also be changed through time.

5.4.-Project process and CAD-CAM coordination

The process starts with the project. Both project and building have to be coordinated. As mentioned before, a plug-in will be installed in the CAD program that the designer uses. So with this plug-in the designer can draw with accuracy the building. The designer starts the project using the data base solutions. One might think this way of working prevents the designers from being creative. Far from that, the system offers multiple choices to the designer. Making a parallelism, it can't be said that the laws and norms of concrete are a restriction for the designer, but instead offer multiple solutions.

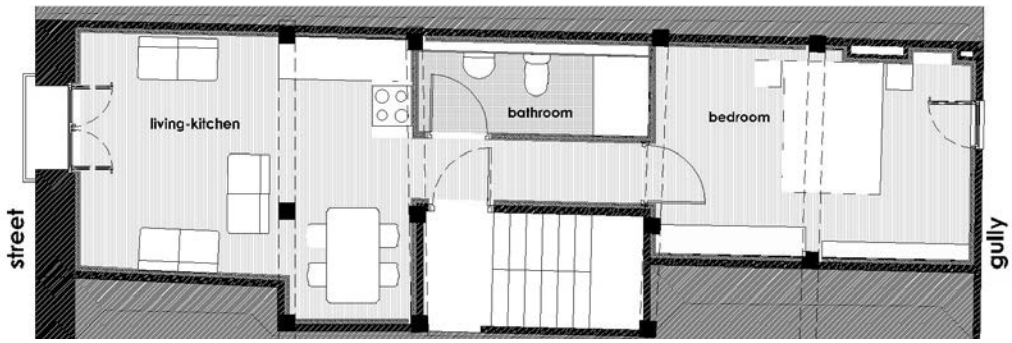

Figure 17: *Project for the apartment.*

With some general measurements as a starting point, preliminary and execution projects are developed. The project must seek the most precise dimensioning, but it is also convenient to take into account some tolerance variance. The designer has a complete control over what it is designed. Once the project is modelled in 3D, the designer could know if the solution proposed for each project fulfils the structural and insulation requirements and regulations.

5.5.-The process for building with CNC.

Once we receive the building permit, we will proceed to check the current state of the dwellings on top and below of ours. We will certify the state –existing cracks and other deficiencies- by writing a report. We should check if the partition walls on the top house and in ours concur. It is probable that they are in contact and so loads might be transmitted. In such case we will build discharge reinforcements to direct the loads towards the rafters. This must be done before starting to tear down the existing partitions walls. The reinforcement elements will be part of the new structure system. In order to install correctly these pieces, we will tear down the ceiling. By doing so, we will also manage to do a more concise diagnose of the state the top rafters and beams are in. A bigger quantity of reinforcement might be needed then.

Before starting to demolish the walls, we must locate a flexible element around the wall so it can cushion the strike of the toppling material. In this way we will prevent the floor from cracking and of rubbish falling down to the apartment below. It is recommended that a prop or post will be placed to avoid movements created by demolishment vibrations.

Once the partitions are put down, we can take apart the floor boards, and proceed to check on the rafters and beams below them. By experience, it is usually enough to do so in the floor of bathrooms and kitchen. In the rest of the bays, it is enough to look around the pillar bases. This process for demolishment can easily extend throughout two weeks. It is common to bring down the rubbish by hand through narrow stairways. This complicates and adds extra tiredness to the job.

At this stage of the process, the space is better read without the partition walls and with the structure unveiled. We can now take accurate measurements, either with measuring tape or digital tools. As for the next step, we must draft a proper and exact floor-plan, reflecting on it the possible collapses in the party walls and the planimetry of the floor as well as the ceiling.

Once we have produced the accurate 3D model, we shall redraw the project thinking on the manufacturing stage. The CNC machinery will produce accurate reproductions of the pieces on the 3D model.

A worthy advantage is obtained with this method, we can supply the building site with the needed pieces without having to store them in a warehouse. It is a direct and fast relationship between the workshop and the site.

5.6.-Maintennance of the building CNC.
All the project will be saved completely, element to element as it was built. Using the CNC technology permits that years later after the refurbishment was made, we can make the same piece as original. Even more, we can provide new pieces for new situations, and those new pieces could be attached or jointed perfectly.

The apartment that has been refurbished with this construction system will easily adapt to a new user. Apartments change from hand to hand. If we want to have this adaptability, there must be a maintenance, a parallel service has to be provided. This way, there will be a permanent link between the contractor and the user. This is not new, not even in construction world. The ideal situation would be that the building user could install or un-install the partition walls or structure elements wherever he or she is interested. The client or the space user could request this parallel service to provide change of structure from place to place. If he would need a piece, he could buy or rent from the maintenance service. Of course, a technician should allow all these changes.

The system is both flexible in structure, in partition and in installations. The joists of the structure and partition could be opened or closed with a simple wrench. So the user, with the help or guidance of a architect (or similar), could move the partition, the installation or even the structure. All this is supported by a flexible installation, partition and structure scheme. Almost everything is movable, the only element that should be kept in place or fixed on every floor, it´s an installation shunt (even this could me movable but not recommended).

Abstract
In 2004 the European Commission introduced the competitive dialogue as a procurement procedure to enable for an open public-private dialogue leading to more innovation, increased competition and more trust. Since 2004 this procedure has been increasingly applied in complex Dutch road infrastructure projects. In this paper experiences from practice are analysed to assess if the goals of the European Commission are met. Conclusions were drawn on the basis of interviews with experienced public and private actors and validated during expert meetings with contract managers.

Results indicate that the competitive dialogue can lead to more innovation when overcoming the reserved attitude and risk avoidance of public procuring authorities. Competition in Dutch procurement increased by use of the dialogue, and although the public-private contact in the procurement procedure leads to increased trust, it is hard to maintain this in an environment driven by competition. It is concluded that notwithstanding the use of de competitive dialogue, the ideal of an open public-private dialogue has not yet been realised. Recommendations are to stimulate innovation by not specifying the desired end-result in detail beforehand, reward openness and limit the dialogue to the complex issues.

Keywords: competitive dialogue, road infrastructure projects, innovation, competition, trust

INTRODUCTION

In 2004 the European Commission introduced the new procurement procedure competitive dialogue. The competitive dialogue can be applied in the case of particularly complex contracts, where contracting authorities consider that use of the open or restricted procedure will not allow the award of the contract. The new procurement procedure, an alternative to the negotiation procedure, is aimed to include a more open public-private dialogue, with more innovation and increased competition (European Commission, 2004).

Over the last years the competitive dialogue procedure has been increasingly applied in Dutch planning practice. Road infrastructure projects have become increasingly complex,

amongst others due to increased involvement of more outspoken stakeholders and scarcity of space. The competitive dialogue therefore has become a popular procurement procedure in road infrastructure projects at the national level. Illustrative for this is the fact that in 2007 16 construction projects (including road infrastructure as well as buildings) were procured by the CD procedure. In 2010 at least 15 infrastructure projects were procured by this procedure (Stichting CROW, 2011).

Although the procedure is becoming more commonly applied, it remains unknown whether the goals of the European Commission are met in Dutch practice. Evaluation of the instrument is often limited to its application in isolated cases; a thorough evaluation of the instrument relating to the goals of the European Commission is lacking. In this paper an analysis is described of experiences from the Dutch practice in order to assess whether the goals of the European Commission are met. Additionally, it aims to provide recommendations on how to improve public-private interaction in general and the competitive dialogue specifically.

EFFECTIVENESS ASSESSMENT

The question of how effective the CD procedure actually is, is an evaluative one. Without going into detail about all the methods used in policy evaluation studies, one can note some common typologies found in evaluation research. Next to plan evaluations, also process and product evaluations are defined (Swanborn, 2007). The evaluation of a policy instrument like the CD procedure is a product evaluation, also called end evaluation, effect evaluation, impact evaluation, outcome evaluation, summative evaluation or goal-fixed evaluation (Swanborn, 2007, p. 58). This type of evaluation study contains both impact and efficiency aspects, with the effectiveness assessment being one of three impact studies (see Figure 1).

Product evaluation
Impact study Sensu lato (Comparison between the objectives of the policy and its impact). o *Goal attainment assessment* (to what extent are the goals achieved?) o *Effectiveness assessment* (are the goals achieved and, if so, to what extent is this due to the policy?) Sensu stricto (Focus on the effects of the policy, without reference to the objectives) o *Impact assessment* (what are the effects of the policy (both aimed for effects and side effects, both direct and indirect)?) **Efficiency study** (The interrelatedness of the benefits/effects and the costs of the policy (cost-benefit analyses or cost-effectiveness studies))

Figure 1: *Types of product evaluation studies (Swanborn, 2007)*

Effectiveness is a criterion that reflects how the effects of a policy instrument relate to its objectives. Alongside the intended effects (the objectives) of the policy instruments, one also has to consider the unintended effects (side-effects), since these could make the policy less effective. This is why Vedung (2000, p.36) speaks of effectiveness evaluations as "side-effect evaluations". This is schematically illustrated in Figure 2 (Vedung, 2000, p. 50).

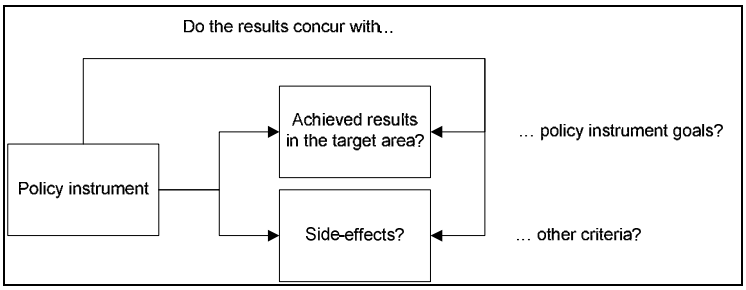

Figure 2: *Effectiveness assessment*

Thus, to assess the CD procedure's effectiveness, both its objectives and its effects need to be mapped. A description of the CD procedure its characteristics and the objectives of the European Commission (the policy rhetoric) is provided in the first part of this paper. The next part will describe both the effects and side-effects of the CD procedure, after which these are related to the initial objectives of the procedure and possible counter-effective effects, thus drawing conclusions about the overall effectiveness of the CD procedure. However, first the methodology and the validity of the research is discussed in the next paragraph.

RESEARCH DESIGN

As we have seen in the previous section, the assessment of policy instrument impact consists of overviews of both its effects and its side-effects. A description of the objectives of the European Commission with the CD procedure (the policy rhetoric) will be provided in the next Section. To compare these objectives with results in the target area and with possible side-effects, both effects and side-effects should be mapped. Interviews with several stakeholders in the process of procuring complex projects were conducted to come to this overview. On the basis of these interviews, conclusions were drawn about the experiences with the dialogue of involved public and private actors in several Dutch infrastructure projects. Subsequently, the results were validated during expert meetings with contract managers.

Interviews

The individually conducted interviews were of a semi-structured nature so that we would obtain general information concerning the EC's objectives with the CD procedure and to gain insight into these issues. The stakeholders interviewed at this stage of the study were experts from science, procuring agencies, contractors and advisors (See Figure 3). All of the 51 selected stakeholders were willing to participate in the interviews, which lasted 45 minutes and consisted of three main parts. Part A served to assess the general opinion of the experts about the CD procedure. Part B considered the positive and negative effects of the CD procedure, and Part C was included to determine chances and limitations of the CD procedure. This last part was added to the earlier parts about the direct (side)-effects to derive indirect (side)-effects of the CD procedure.

Main group		Function
A. Law / science	1	Professor in Dutch private law, contract law, construction and procurement law
	2	Professor in Construction law, Lawyer in construction and procurement law
	3	Lawyer in e.g. Construction, Development, International Arbitration, Joint Ventures, Projects, Public Procurement
	4	Attorney and lawyer in corporate law transactions, privatisations, large-scale contracting processes, PPP and project financing
	5	Lawyer in environment and planning practice, including PPP
	6	Chartered accountant and senior lecturer at the European Institute of Public Administration in PPP, public procurement and comparative public service delivery
B. Procuring agencies	1	Infrastructure project manager Dutch Department of Infrastructure and the Environment
	2	Contract manager Dutch Department of Infrastructure and the Environment
	3	Project manager Dutch Department of Infrastructure and the Environment
	4	Project director Dutch Department of Infrastructure and the Environment
	5	Advisor PPP Dutch Department of Infrastructure and the Environment
	6	Senior Financial Advisor Dutch Department of Infrastructure and the Environment
	7	Senior advisor Market relations and procurement Dutch Department of Infrastructure and the Environment
	8	Purchasing manager Dutch Department of Infrastructure and the Environment
	9	Advisor to the Infrastructure Board of the Dutch Department of Infrastructure and the Environment
	10	Contract manager Dutch Department of Infrastructure and the Environment
	11	Contract manager, Dutch Department of Infrastructure and the Environment
	12	Manager Back office, Dutch Department of Infrastructure and the Environment
	13	Purchasing manager, Dutch Department of Infrastructure and the Environment
	14	Contract manager, Dutch Department of Infrastructure and the Environment
	15	Judicial advisor, Dutch Department of Infrastructure and the Environment
	16	Planning manager, Dutch Department of Infrastructure and the Environment
	17	Judicial advisor, Dutch Department of Infrastructure and the Environment
	18	Environment manager, Dutch Department of Infrastructure and the Environment
	19	Judicial advisor, Dutch Department of Infrastructure and the Environment
	20	Contract manager, Dutch Department of Infrastructure and the Environment
	21	Project director, Dutch Department of Infrastructure and the Environment
C. Industry (contractors)	1	Project and contract manager, large construction firm
	2	Director Concessions, large construction firm
	3	Director PPP, large construction firm
	4	Project manager from a large infrastructure construction firm
	5	Project manager for discipline and work exceeding projects, large construction firm

Figure 3: *Stakeholder participants*

The qualitative data analysis software QSR Nvivo was used in the analysis of the transcribed interviews. After transcription, codes (called 'nodes' in NVivo) were assigned to text fragments using a bottom-up approach (starting without any strong prior assumptions about coding classifications). The purpose of bottom-up coding is to classify a large number of textual data units into a smaller number of homogeneous categories. The subsequent use of software in analysing the qualitative information allowed a more objective assessment and facilitated more complex examination of the data (Weitzman and Miles, 1995; Marshall, 2002), leading to conclusions about the effectiveness of the CD procedure on the procurement of complex construction projects.

Validation

Based on the results from the NVIVO database, we are able to tell what the majority of participants sees as most important effect of the CD procedure on the procurement of complex construction projects. Although the validity of these conclusions is strived after by several means of triangulation, we decided to validate the conclusions after all. This was done by discussing the conclusions in the form of statements with a group of 15 project managers from the Dutch Highways and Waterways Agency. The discussion did not fundamentally change the conclusions, but did lead to adjustments of the conclusions: the project managers nuanced some of the bold statements, making the conclusions doing more justice to reality.

COMPETITIVE DIALOGUE PROCEDURE

The European Commission provides several procedures for the procurement of public works: the open procedure, the restricted procedure, the negotiated procedure and the competitive dialogue. In the open and the restricted procedures contract negotiations are not allowed. In the negotiated procedure this is allowed, but there are no detailed rules as to how this should take place or when this should end before contract signature. This made the European Commission question the appropriateness of the negotiated procedure in complex projects as substantive negotiations with a preferred bidder could distort competition (OGC, 2008). Therefore, the competitive dialogue (CD) has been introduced in 2004. With the introduction the European commission aimed at achieving several goals: increased *competition*, increased

innovation, stimulated *trust*, and a more open and structured *dialogue* (see Hoezen and Doree (2008) for a reconstruction).

Competition is visible in the set-up of the procedure. The contracting authority has the possibility to select a preferred bidder over several rounds. In these confidential individual rounds , the contracting authority discusses the preliminary offer with the private competitors. The confidentiality and the staged selection ensure a competitive process.

Besides the competitive character, the CD is aimed to be a flexible procedure that could stimulate *innovative* solutions (Nagelkerke et al., 2008). Innovativeness is stimulated by applying MEAT-criteria (Most Economically Advantageous Tender). In these criteria more than just the price of construction work determines the outcome of the procurement. Quality criteria, which can contain all kind of factors, have to be used if the CD-procedure is applied.

In an advise of the Committee for Legal affairs and the Internal Market to the European Parliament it was suggested that "the content and limits of the negotiated procedure should be made transparent for both procuring authorities and contenders and, in the interests of both parties, should provide the basis for collaboration based on trust" (Committee on Legal Affairs and the Internal Market of the European Parliament, 2001, p.100). From then on, the objective of the CD procedure of *stimulating trust* was reflected in the design of the CD procedure.

Another aim of the CD-procedure is to stimulate an *open and structured dialogue*. In the procedure extensive negotiations after a preferred bidder is chosen is prohibited (OGC, 2008). The CD is restricted to particularly complex contracts, where contracting authorities consider that the use of the open or restricted procedure will not allow the award of the contract (article 1.11 of 2004/18/EC, European Commission 2004). Projects are complex if contract authorities are (1) not objectively able to define the technical means or capable of satisfying their needs or objectives, and/or are (2) not objectively able to specify the judicial and/or financial make-up of a project. When these conditions are met, negotiations in a dialogue are a crucial element to come to sound proposals and project delivery.

The CD-procedure consists of several stages (see Figure 4). Before the dialogue itself starts, the project has to be announced in an official notice in the journal of the European Union(1). Subsequently, bidders can be selected on the basis of pre-qualification criteria, after which the actual dialogue can start. The dialogue can consist of several rounds of negotiations between the procuring authority and individual bidders over (parts of) preliminary bids. After this phase of dialogues, the final tenders are submitted and the bids are evaluated on the basis of the predetermined award criteria. These need to be MEAT-criteria, that besides price also take quality aspects into account. Next, the preferred bid is chosen and the contract can be closed.

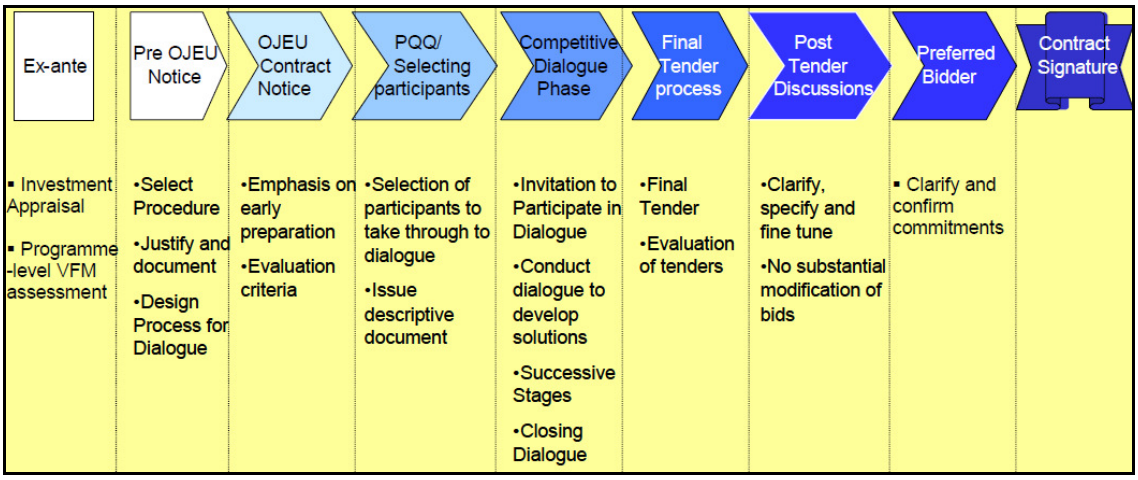

Figure 4: *Overview of CD-procedure* (Source: HM Treasury and OGC, 2008, p.11)

EFFECTS OF THE CD-PROCEDURE

This part will describe both the effects and side-effects of the CD procedure. But first an overview is given of some issues that play a role in the CD-procedure.

The CD procedure has been applied in several infrastructure projects since it was implemented into Dutch law in 2006. The size and order of the projects it concerns differ from small (about 25 million euro's) to large (about 3 billion euro's) and from constructing to reconstructing. The experts taking part in the interviews as well the contract managers involved in the validation were experienced in a wide range of projects with diverse characteristics.

General impressions

In general it can be stated that the set-up and the implementation of the procedure has improved looking back from the end of 2010 to the first experiences in 2006. To a certain extent, this can be attributed to the increased experience with applying the procedure at the side of the contracting authority. It is increasingly efficient in organising effective dialogue rounds, asking and answering questions, meanwhile keeping the level-playing field intact. Private competitors have also attributed to the improvement of the CD procedure. Designated tender organisations have been set in place in which experience with dialogues is shared and the gained experience with the 'open' initial rounds of the dialogue make the CD procedure run more smooth.

However, some operational problems still remain. It proves to be difficult to collect all relevant information for carrying out the dialogue and distribute information effectively from the contracting authority to the competitors. A reason are the different integrated contracts that are procured through the CD procedure. These contracts require that not only information concerning the construction, but also information on financing, maintenance and operation needs to be available up-front. If this information is available, the way in which it is distributed can also be improved. Currently, contracting authorities simply hand over all available information, which causes the competitors to be overloaded with information. They need to spend a considerable amount of time to assess the quality, relevance and usability of the distributed information.

Another issue that is discussed extensively is the compensation for participation in the CD procedure. In the Netherlands, it is common practice to compensate the private competitors for their efforts in the dialogue rounds. Time and money is spent to come to competitive bids that take into account the wishes of the contracting authority. However, according to the private competitors, the compensation often does not properly reflect the investments made to come to this bid. The transaction costs are higher than expected. Reasons can be found at both the public and the private side: The public authority often requests too much detail in the bids and the dialogue rounds and the private competitors work out their solutions too much to reduce uncertainties.

A last issue that deserves attention is the continuity in the personnel. The long span of infrastructure procurement processes makes that tender teams at both the public and the private side undergo changes during procurement. This causes a loss of valuable project-specific, tacit knowledge that is difficult to replace (see Lenferink et al. (2011) for an extensive discussion).

Now that the major issues in implementing the procedure have been described, the effects of the CD procedure will be discussed for the four main goals of the European Commission: innovation, competition, trust and dialogue.

Innovation

Results indicate that the competitive dialogue can lead to more innovation. However, this innovation mainly consists of *process innovation*. The private competitors prove to be more efficient in bridging the boundaries between different fields, and regarding projects in a more integral way. The project process innovation includes smart ways of combining procedures and methods to adjust activities in the several stages of a project to each other The project process innovations can positively influence the time planning a project takes and could amongst others, lead to less nuisance in construction due to smart phasing of activities.

Besides project process innovation, also the process of the CD-procedure has improved. The main driver behind this kind of process innovation is experience. The involved actors get more experienced with the procedure and with the processes involved. They have to spend less time fabricating requested products or discussing these products in dialogue rounds. For example, the functions and contents that should be in a “plan of action”, as often requested by the contracting authority in the initial stage of the CD-procedure, need not to be discussed anymore in a separate meeting. The competitors all have gained experience in writing such plans.

Product innovation on the other hand proves to be more difficult to achieve. A reason for this is the reserved attitude and related risk avoidance at the public contracting authority. Although it advocates open output specifications, on basis of which the private competitors can make their bid, the attitude in the dialogue is often reserved. It proves to be difficult for the public authority to distribute tasks and responsibilities fully to the private sector. This difficulty is reflected in strict planning and tender documents which limit the room for innovative solutions. The cautious attitude strengthens this effect; parties involved tend to prefer proven solutions to minimize risks.

Competition

The dialogue has proven to increase competition in Dutch procurement. In fact, the procedure is more dominated by competitive forces than expected beforehand by the European

Commission. Complex projects, in which the competitive dialogue is allowed, usually involve great sums of money. The involved competitors are therefore cautious to keep the perceived chances and opportunities to themselves. This is manifested in the character of the different dialogue rounds. Chances and opportunities which could be of added value to the project quality are only limitedly discussed and at a late stage in the dialogue. Because of the fear of cherry-picking, competitors keep the project-winning ideas as long as possible to themselves.

In contrast, the competitors are very open on perceived risks and threats. If they see problems, that affect their bidding price negatively, they want to make sure that the other competitors see it as well and take it into account in their offers. Together with the large sums of money involved, this makes the competition in CD-procedures fierce. Competitors are willing to spend some resources to come to a winning bid. It is therefore no surprise that the compensation offered by the contracting authority is perceived as insufficient.

Trust

The competitive dialogue procedure has led to increased trust between the public and private parties involved. The necessary exchange of information provides the parties with an understanding in each other's position and insight in the grounds for certain behaviour. Although the public-private contact in the procurement procedure leads to increased trust, it is hard to maintain this in an environment driven by competition. In this respect, also the strong focus on maintaining the level playing field plays a role.

Dialogue

The strong competitive forces that play a role in the CD-procedure make that the dialogue gets a judicial character. The contracting authorities are fuelled by fear of breaking the guidelines for applying the procedure. This puts a strong focus on maintaining the level-playing-field. The contracting authority is afraid of unconsciously giving a competitive advantage to one of the contenders. Therefore, interaction in the dialogue rounds is limited. At the contracting authority, there is a risk that a conservative attitude is stimulated that is reflected by the statement "just say nothing, so that there is no risk of saying something wrong".

CONCLUSIONS AND RECOMMENDATIONS

It can be concluded that although the competitive dialogue has proven to be a useful procedure to procure complex projects, the ideal situation of an open public-private dialogue has not yet been realised. Strong competitive forces and risk avoidance limit the openness of current dialogues, strengthening the judicial character with a focus on maintaining the level-playing field and limited innovation possibilities. Competition makes parties more reserved, it stimulates strategic behaviour and has a negative effect on trust-building. A successful CD-procedure is therefore dependant on an open attitude of the parties involved.

It is recommended for public authorities to provide more possibilities for innovation by not specifying the desired end-result in detail beforehand. This will stimulate real interaction on the basis of sincere questions, instead of the strategic masquerade that is sometimes currently taking place. Furthermore, openness of private competitors in the dialogue should be rewarded. This can be put into practice by partly selecting bidders on the basis of their cooperation. Also past performance could be taken into account. Another recommendation is

to limit the dialogue to the complex issues for which public-private interaction can lead to added value. Only the aspects that need discussing in the dialogue, because they are complex, should be discussed. This will prevent the CD-procedure from being penny-wise and pound-foolish.

Applying these recommendations could lead to less (unwanted) strategic behaviour, decreased transaction cost and an open dialogue with a focus on seizing chances and possibilities. This will also change the competition in the CD-procedure. Decreased transaction costs will allow smaller size competitors to join in the procurement. It will help the European Commission in reaching all the goals for innovation, trust, competition and dialogue.

SCHEDULING PROCESS: USING ONE-DAY SCHEDULING ON MULTI-FAMILY PROJECTS TO REDUCE DELIVERY TIME

BRUCE W. SMITH, MS CPC

USA
smithb2@auburn.edu

Abstract
The past fifty years has seen many changes in the construction process, but little has changed in the area of scheduling for most projects. There have been advances in the software used to manage schedules, but the same theories and practices have been used for decades. This process works well and will continue to be norm on most projects. Some home builders have incorporated a process "one-day scheduling." The process views the project as a linear sequence of days and identifies what activity is start and finish on that day. Several large home builders have found that the number of calendar days to construct an individual home as part of a large development has been reduced significantly, giving them a strategic advantage in the market. The following study looks at the implementation of a combination of traditional and "one-day scheduling" on multi-family residential projects as a method of schedule management, resource management, and cost control. The study reviews the management of the schedule during construction as well as the scheduling process. The end goal of any construction project is to deliver a project of the greatest value to the owner for the defined cost. The implementation of a method of scheduling which delivers a product more efficiently will conserve resources and enhance the goals of sustainable construction.

Keywords: Scheduling, Multi-family, Linear Scheduling

INTRODUCTION

Schedules and schedule management the core of the management process for construction projects. Activities are identified, defined, assigned durations, and linked by relationships to create a work flow and a critical path through the project that is effective and manageable. The Critical Path Method (CPM) works well on most projects and will continue to be norm.

Some residential contractors have changed their method of scheduling in an effort to be more competitive in the market. These contractors have adopted a scheduling method similar to production line scheduling, but instead of the product moving through as series of operations, the operations are moved through the product. The process is similar to the Linear Scheduling Method (LSM) and requires re-evaluating activities and the defining of activities and their durations (DiVosta Homes, 2002).

Proponents of LSM feel that the Critical Path Method (CPM) is not well suited to repetitive work, such as multiple housing units. The goal of LSM is to prevent interference between repetitive activities that progress linearly through the project. Interference is avoided by scheduling only one work process at a time in a defined area (Nunnally 2011).

One Day Scheduling (ODS) is derived from LSM. The following examines the development of ODS and its application in conjunction with CPM scheduling. Although residential construction is used as the context for the discussion, the principles can be applied to any repetitive process, whether there are several repetitive projects which stand on their own, or there is a group of similar and repetitive activities which are integral parts of larger projects.

BACKGROUND

LSM is based on the manufacturing process. In manufacturing, a product, such as a car or washing machine, would start out on the assembly line as one component, and move through the assembly line with additional components added until the final product is completed. The components are added during an operation (activity), and the operations (activities) are arranged in a sequence, with each operation completed before the next operations are started.

Although the current discussion is focused on residential construction, any repetitive function could benefit from LSM type scheduling. A recent hospital project in Florida had one hundred and seventy-eight patient rooms that were exactly the same. The contractor used prefabrication of components at an outside warehouse to facilitate the schedule. The assembly of the components used LSM type scheduling. The net result was valuable to the schedule and saw increased productivity of the workers. Part of the increase in productivity had to do with one trade not conflicting with another, as well as the repetitive nature of the work, and the ready access to all necessary materials and tools (Post 2010)

Since the manufacturing process is continuous, the movement of the line must be uniform. The uniform movement requires that each operation is performed in the same amount of time, referred to as standard time. Not every operation in the assembly process takes the same amount of time, so the activities need to "balanced" Balancing is the process of dividing up activities into multiple activities, all of which have the same duration as the standard time (Milas 1990). For example, if it takes two minutes for a worker to put on windshield wipers and eight minutes for one worker to put on the tires, the standard time could be placed at two minutes. The tire installation needs to be divided into four activities for the line to run smoothly. The four activities could occur sequentially or concurrently.

The speed is defined by the "standard time". The standard time is what is needed to complete each activity. The duration of the standard time is not the average time for an operation. Using the average time would result in about half of the operations failing to complete in the allotted time. The standard time is the duration required for the successful completing of each operation most of the time. As a result, the total time of production is longer than the minimum time that the product could be manufactured. The standard time is a balance between keeping the line moving all the time by have no time failures and line stoppage, and acknowledging and accepting some line stoppage to have a shorter standard time. The total duration of the assembly process is the total of moving and stationary time (Milas 1990).

There are three recognizable types of progressive assembly lines. The first is where the same product is produced. The second type is where two or more models an intermixed and run at the same time and use a predetermined and fixed sequence. The third type of progressive assembly line intermix two or more models, using varying sequences (Milas 1990). Construction of residential units would usually fall in the second category. Units may differ in many ways, but the sequencing would stay the same.

The LSM uses three steps in developing the schedule.

1. Determine the work activities
2. Estimate activity production rates, the same as in the CPM but the LSM uses the durations and the production rates to match the activity scope to the standard time.
3. Develop and activity sequence, similar to developing logical relationships. (Mubarak 2005)

The activities have a defined duration, and the activities are re-accruing. Over time, the productivity of crews may change, so adjustments are made to keep all the crews on schedule. Adjustments may involve extended hours, reduced hours, or adjusting the crew size (Mubarak 2005).

One-Day Scheduling (ODS) is an adaptation of LSM where the typical standard time is one work day, so activities have one day duration. Many construction operations take over one day to accomplish, so they must be broken down in separate activities, such as putting on the car's tires. Manufacturing refers to the process of breaking down activities as Dividing "Indivisible" Elements in order to create a standard time (Milas 1990). The defining of activities to be performed in a standard time of one day is accomplished through the collaboration between the general contractor and all the subcontractors.

A good example of how ODS works is shown by the experience of a construction company which has used the ODS since 2004. The example looks at how the company changed the way they schedule the gypsum installation and finishing in their homes.

Installing and finishing gypsum walls and ceilings have the following four elements:

- Hang
- Tape and bed
- Second coat of mud
- Finish coat
  (Gypsum 2007)

The company's previous scheduling method acknowledged that each element took about one day, and they allowed a fifth day to be sure that the gyp was completed before the next trade began their work. The gyp contractor agreed to provide more labor for larger homes to maintain the schedules. The gyp activity had a five-day duration on the schedule. Frequently, the gyp contractor failed to complete in five days and thus compromised the schedule.

Under ODS, Hunter Homes changed the schedule for gyp to:
Day 1 - Hang
Day 2 - Tape and bed
Day 3 - Second coat of mud
Day 4 - Finish coat
Day 5 - The trim carpenters begin

The subcontractor was required to be on schedule every day, and crews were adjusted by the subcontractor to make sure that the crews were successful every day. The change to ODS resulted in the gyp subcontractor completing their work in four days instead of five and being successful most of the time. Hunter Homes did not have statistics on the percent of successful completions for particular operations (Hunter Homes, 2006).

The previous example could have been accomplished by simply requiring the subcontractor to finish in four days, but the process was facilitated by the addition of more detailed control. Under the old system, the gyp contractor was not behind schedule until the end of the fifth day, which allowed little time for over-schedule work to be performed. Gyp work continuing into the sixth day would interfere with the trim carpenters. Under ODS, the contractor did not allow scheduled work to roll into the next workday. The process works for this contractor because of the commitment of the subcontractors and suppliers. The scheduling technique has resulted in advantages to the general contractor, the subcontractor, and the owners.

Advantages to General Contractors

There are several advantages that have been realized by companies who have adopted ODS. Traditional scheduling uses a heuristic approach to setting durations because of the number of variables that are present. The heuristic approach may actually be better that compiling large volumes of historic data and extrapolating durations, because the average duration will only be nearly correct, statistically, about 10% of the time. The heuristic approach lets the scheduler take into account some of the most important or predictable variables. ODS is used on repetitive projects, so historic data becomes more accurate.

Using shorter durations of one day, gives management a daily evaluation of the progress of each activity in the schedule, from first day until last. Inspections and jobsite monitoring are performed daily. Superintendents are able to look at a schedule and know what activity is being performed in each unit. The overhead is cut for the general contractor as managers and superintendents are able to manage more units in a year. The faster turn-around time improves the cash flow, which results in lower cost of internal financing. Finally, but most importantly, the subcontractors can charge less because the ODS increases the productivity of their crews and lowers their overhear cost.

Perhaps the greatest advantage to the process on One-Day Scheduling is the management process. The creation of detailed schedules which attempt to control the activities of all subcontractors on a daily basis would appear unmanageable. ODS allows this level of control only because of the repetitive nature of the subcontractors work and the involvement of the subcontractor in defining the activities to be performed in the standard time of one day.

Advantages to Subcontractors

The successful implementation of ODS requires coordination and cooperation from all subcontractors. As noted above, the subcontractors are a part of the decision process for setting the scope of the daily activities. This allows the subcontractors to allocate required resources. Subcontractors need to have sufficient resources to maintain the work flow as it is specified in the schedule. There are several benefits that the subcontractor receives for making the commitment to maintain the schedule.

First, the subcontractor builds a long term relationship with the contractor. Second, the repetition allows the subcontractor to identify costs and lower the risk due to unknown circumstances. Third, the subcontractor knows they will not have conflicts with other subcontractors trying to complete work on the same unit concurrently. Fourth, the subcontractor is able to level their resources and maximize the productivity of all the crews.

Leveling resources allows the subcontractor to have a defined number of workers for the general contractor. There is inefficiency in having to continually move workers from one

project to another. Having level resource requirements allows the subcontractors to keep workers productive and reduce turn-over due to changing labor needs.

Productivity of the workers can be increased. The elements that impact productivity are discussed in a following section, including the influence of ODS on some of the elements. The gyp subcontractor example shows the value of reduced duration on the calendar of five days to four days, allowing crews to complete five homes per month instead of four.

Advantages to Owners

There are two primary advantages that are received by the owners. First, and perhaps the most important, is that stringent schedule management promotes on-time delivery of the product. One of the accepted components of customer satisfaction is timely delivery. (Business Bear, 2011) The second advantage is the cost savings that can be passed down to the owner. The competitive nature of the construction industry requires successful companies to pass along savings realized through progressive management practices, while maintaining their profit margin which insures long term success.

Productivity

Since much of the strategic advantage of the ODS relies on the increased productivity of the workers, a discussion of productivity is in order. Since labor is about 33% of the construction cost, decreasing labor cost will benefit the project costs (Haskell 2004). The productivity of the workers has a direct impact on the cost and schedule, but the number of variables makes the measurement of productivity on construction projects is difficult.

"Send one boy to do a job and it will get done in one day. Send two boys and it will get done in a day. Send three boys and it will not get done at all." Lord Snowdon

Lord Snowdon points out that the allotment of additional resources may not increase productivity. The scope of work did not change, but the allocated resources changed with no increase in productivity. In fact, the productivity declined with the increase in resources.

Construction trades average about 32% productive time. The rest of the time is spent:

- Waiting 29%
- Traveling 13%
- Instructions 8%
- Tools and materials transportation 7%
- Late starts and early quits 6%
- Personal breaks 5%
    - (McCarthy 2008)

Productivity provides the greatest opportunity to reduce costs and reduce the schedule duration. A study in the United Kingdom was published through the Office of Government Commerce, showed that incorporating certain techniques resulted in efficiency gains of thirty percent in some public sector operations, while 30-50% improvements have been known in the private sector. (Clark 2010) Note that the gains were on specific projects not averages, but the study showed that significant gains are possible.

The methods used in the study are summarized by Sir Peter Greshom. "This is not rocket science - the basic principles are to: do the right things... (Eliminate unnecessary work), the

right way… (Use standard, streamlined processes), with the right people… (right skills, availability, location), using the right tools and equipment." (Clark 2010).

The *Mechanical Estimating Manual* lists sixteen factors that can impact labor productivity in construction (D'Amelio 2006). Examining several in relation to the four principles identified in Clark's study gives some reference in how some of the factors can be impacted by ODS.

- Stacking of trades – ODS is very specific about only having one trade in a unit on any day.
- Morale and attitude – There is difficulty in quantifying morale and attitude, but there could be qualitative assessment based on stacking of trades, crew size efficiency, concurrent operations, site access, fatigue, overtime, logistics, and supervision. Improvements in one or more of these areas could improve morale and attitude.
- Reassignment of manpower (change orders) – Change orders cause a disruption in any schedule. ODS is as susceptible to disruption as any other scheduling method.
- Crew size inefficiency (over manning) – The basis of ODS is the adjustment of crew size to maximize production during a defined duration.
- Concurrent operations – ODS is resource centered, so crews are assigned to a single operation at any time, avoiding division of resources and lowering productivity.
- Dilution of supervision – Supervision is critical in any scheduling method, but ODS sets daily goals for each crew which is well communicated to each crew.
- Learning curve and Errors – ODS incorporates crews moving from one location to another and repeating the same tasks. Keeping continuity in the people in the crew keeps the learning curve low and minimizes errors. Errors may appear as successor activities are accomplished, but the errors will be related and adjustments made quickly.
- Site access – Site access is the key element in ODS as each trade will enter an area that is prepared to receive their work with no encumbrance.
- Logistics – The Logistics become more important but should be easier, because the rate of production is defined and the dates of material delivery can be verified by the schedule.
- Fatigue and Overtime – Fatigue is always a consideration for workers because the work is all physical. Crew sizes may need to be adjusted based on the time of year because productivity will change on extremely hot or cold days. Without a change in the crew size, overtime may be necessary, which is not productive over long periods of time.

The gains in productivity realized by users of ODS were primarily from:

- Not stacking trades
- Using proper crew size
- Lowering the learning curve
- Ensuring site access
- Standardizing logistics.

CASE STUDIES

There are three case studies that follow. The first two are brief commentaries on two home building companies that currently employ one day scheduling. The third is a case study showing how ODS can be used in conjunction with CPM scheduling for a multistory residential condominium project.

Case Study: DiVosta Homes
DiVosta Homes uses One-Day Scheduling, and has found the construction time has decreased, quality control is up, and costs are under control. The company builds single family homes in their own developments in Florida. In 2003, one of their subdivisions was starting two homes per day using ODS. The homes were in the $400,000 to $450,000 range, with limited options on the overall design.

The company has identified 45 distinct work activities (operations) on homes, from beginning to end. Each operation has one day duration for a crew, except for some short duration activities. On certain short duration activities, the crew was given two houses per day, so only one crew was needed. Activities that normally take multiple days are divided into two or more operations, using multiple crews moving each day or rotating starts. The company incorporates pre-planning and extensive staging to facilitate the crews' success. DiVosta Homes uses a combination of in-house forces and subcontractors. Each are managed as separate entities', with the expectations for both to meet the schedules and provide profit for the general contractor.

DiVosta Homes has been able to consistently deliver homes in 45 working days from the start date. The shorter delivery time cuts the management time on each home so each superintendent and project manager can oversee more homes in a year, cutting overhead for management of the projects. Subcontractors are able to train crews and maintain consistent work forces on the project, without having significant overtime or battling the stacking of crews. The company is also to turn over the projects to customers faster and improving the cash flow. Cash flow is very significant when the company is finishing two $450,000 homes per day. (DiVosta Homes 2002).

Case Study: Hunter Homes
Hunter Homes is a medium sized homebuilder in Huntsville, Alabama. The company sells homes from $125,000 to $250,000 and starts two homes per day for all their subdivisions. All the subdivisions are within the same geographic area, so the same subcontractors are generally used throughout the company. All work is subcontracted, and the total duration of the projects is 48 working days. The activities are all one day long, although, like DiVosta Homes, one contractor may accomplish short duration activities is less than a day, such as attic insulation, which is not critical on the schedule for other operations.

The management of Hunter Homes feels strongly that the schedule is key to their competitive edge in their market. Before using ODS they were at the same price per square foot as other builders in the area, but now have a lower base cost due to several factors, most notably the schedule (Hunter Homes 2006).

Case Study: Eagles Nest
A schedule for the Eagles Nest project uses a combination of CPM and ODS. The Eagles Nest is a six-story, eighteen units, residential condominium building with mid-range finishes. The frame of the building is structural steel with precast hollow-core concrete elevated decks. The CPM scheduling technique is used for the foundation, frame, windows, exterior doors, skin, elevator, and mechanical, electrical, and plumbing services that serve the entire building.

The interior build-out and finish of the units is scheduled as eighteen activities, one for each unit, and each activity is twenty-one days in duration. The first activity, or unit one, begins

when the exterior is closed in from the weather. Unit 2 will start on the next working day, and the start dates for each subsequent unit will start on succeeding days.

Activities for each unit – each activity has a standard duration of one day.

1. Interior Partitions
2. Ductwork for HVAC Main Ducts (Two Days – two crews)
3. Ductwork for HVAC Branch and Return Ducts (Two Days – two crews)
4. Plumbing rough-in
5. Electrical RI- Place device boxes, Meter Base, Panel and feed Panel (Two Days – two crews)
6. Electrical RI- Pull wire to boxes and home runs (Two Days – two crews)
7. Insulation
8. Hang Gyp (Gyp Contractor has a crew for each of the four steps)
9. Tape and Bed Gyp
10. Second Coat Gyp
11. Finish Coat Gyp
12. Interior doors, base, and window trim
13. Prime walls and trim (Painting - Three Days – Three crews)
14. First Coat of paint on walls and trim
15. Bathroom and Kitchen Cabinets
16. HVAC finish
17. Electrical Finish
18. Plumbing Finish
19. Hard flooring in kitchen and Bath (One Crew – second day requires only one hour labor)
20. Grouting Flooring (one hour labor – 24 hour duration for setting)
21. Finish coat of paint on walls and trim

When two crews are specified, such as for the HVAC contractor, the activities can be handled in two ways. The first day's activities are completed by the first crew and the second day's activities completed by a second crew. Alternatively, crew one could work both days and complete the entire scope for the two days, while the second crew comes in the second day and completes all work in the second unit. The crews would leap-frog through the schedule completed every other unit.

The schedule for the interior of the building is a very simplistic schedule which shows the activity by number, which is being performed in each unit on each day. Table 1 shows part of the ODS for the eighteen units. The actual dates for the activities would be added from the master CPM schedule. The duration of the interior work would be eighteen consecutive work days, with the last unit starting on day eighteen and continuing for twenty-one days, for thirty-eight work days to completion.

The simplicity of the schedule creates the power as a management tool. One immediately notices that there is planned activity in each unit each day. Although this may be the goal of many builders, ODS provides a tool to manage the performance of the subcontractors. The methodology of creating the ODS from the manufacturing standpoint, where failure to meet the schedule and stop the assembly line is the unusual, not the norm, is based on the buy-in from all subcontractors, starting with the input on the activity creation and continuing to the commitment on the success.

Table 1
One-Day Schedule for the Build-Out and Finishes

Unit	Activity in Each Unit Each Day																					
1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	
2		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21
3			1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
4				1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19
5					1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18
6						1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
7							1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
8								1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
9									1	2	3	4	5	6	7	8	9	10	11	12	13	14
10										1	2	3	4	5	6	7	8	9	10	11	12	13
11											1	2	3	4	5	6	7	8	9	10	11	12
12												1	2	3	4	5	6	7	8	9	10	11
13													1	2	3	4	5	6	7	8	9	10
14														1	2	3	4	5	6	7	8	9
15															1	2	3	4	5	6	7	8
16																1	2	3	4	5	6	7
17																	1	2	3	4	5	6
18																		1	2	3	4	5

CONCLUSION

One-Day Scheduling is not revolutionary and it is not applicable for every type of project. ODS does work for large residential contractors and is applicable for other types of project that contain many highly repetitive sequences of activities. Traditional construction scheduling defines activities to be accomplished by in-house forces or subcontractors, without defining the resources required to accomplish the work in the time frame defined. ODS has an understanding of the crew sizes and equipment required and uses that information in setting the work required for the day in the schedule.

The work to be accomplished on any day in the schedule is agreed upon by the subcontractor and the general contractor to assure that the production required is achievable every day. It is possible to reduce the duration of the building process due partially because there is progress every day. Additionally, subcontractors are the sole trade in the unit during the activity, which, along with additional benefits, improves productivity. With increased productivity come lower costs and shorter schedules. There are benefits to the general contractor, the subcontractor, and the owner, which result from the schedule management and productivity.

The critical component to the success of ODS is the collaboration of subcontractors and subcontractors on the design of the schedule and creating the scope of work for each day. Upfront planning can be the key to success. Low bid contracting may not be a successful model. Negotiated bidding would provide a better contracting platform for success, as the schedule and activities are part of the contractual agreement.

DEFINING THE ECO-CITY: A DISCURSIVE APPROACH

ELIZABETH RAPOPORT

Abstract
This paper presents the results of a discourse analysis of documents describing six different eco-city projects: Dongtan Eco-City, Masdar City, Sonoma Mountain Village, Hammarby Sjöstad, Eco-village Ithaca, and Malmö bo01. The aim of the research was to uncover the diversity underneath the various uses of the term eco-city, and to determine the extent of convergence or divergence in the way projects conceive of what an eco-city should be. The research looked at five categories of urban sustainability discourse: the aspect of sustainability emphasised, whether eco-city projects saw themselves as a model for future urban development or as an educational tool, the way in which eco-cities proposed to make urban living more sustainable, the extent to which projects looked at achieving sustainability by design or through governance and management, and the type of actors that play a role in the eco-city. The results suggest that there is a great deal of diversity among projects considered to be eco-cities. In this sense, we argue, it is better to think of the eco-city as an ambition or objective which there will be multiple ways to achieve.

Keywords: Eco-city, discourse, sustainability, planning, environment

INTRODUCTION

With both the rapid growth of the world's urban population and increasing concern about the environment, the challenge of making urban living more sustainable is in the forefront of the minds of many designers, academics and government officials. In recent years, one response that has gained increasing prevalence is the idea of the 'eco-city.' Richard Register, a California based architect widely credited as the first to have coined the term defined an eco-city in 1987 as "an urban environmental system in which input (of resources) and output (of waste) are minimized" (Register 2002). As the term's usage has become more widespread, so too have the meanings associated with it and the diversity of projects adopting the label. Already in the late 1990s, Roseland argued that there was no single accepted definition of the eco-city. Rather, he proposed, it was more a collection of ideas about concepts such as urban planning, housing, transportation, and economic development (Roseland 1997).

Reading these early writers on eco-cities it is difficult to develop a clear, comprehensive vision of what an eco-city actually looks like. This began to change in the early 2000s when a number of ambitious plans began to emerge for brand new sustainable urban districts and cities. High-profile examples include Hammarby Sjöstad, in Stockholm, Sweden and Masdar City, in Abu Dhabi, United Arab Emirates (UAE). China in particular, through the State Environmental Protection Administration (SEPA), has supported the development of a number of eco-city projects around the country. Tianjin Eco-city, which is currently under construction, is due to be complete and home to 350,000 people by 2020.

Yet as the usage of the term spreads, what exactly constitutes an eco-city seems to be even more unclear. Today an ever-increasing range of existing cities and new urban projects, from minor retrofits to large-scale new-towns, call themselves, or are labelled, eco-cities. The most comprehensive survey of eco-cities to date was carried out in 2009-10 by Joss. Joss admits that the conceptual diversity and plurality of initiatives using the term makes it difficult to develop a meaningful definition. He ultimately questions the usefulness of attempting to define eco-city narrowly. Instead he elects to define the term using three analytical categories. Thus according to Joss an eco-city must be a development of substantial scale, occurring across multiple sectors, which is supported by policy processes (Joss 2011: 12).

This paper accepts Joss's definition as a starting point. However it will also question whether in the search for similarities among eco-cities, Joss glosses over substantial differences between these projects. The purpose of this paper is to use a discourse analysis to test the hypothesis was that there is a substantial diversity in the way eco-city projects promote themselves and are written about. The paper begins with a brief overview of the value of discourse analysis as an analytical tool in the social sciences. It then puts forward a set of categories of environmental discourses that are often used in discussions of urban development and sustainability. It then presents the methodological approach followed by a discussion of the results of the analysis. The findings are presented in tabular and descriptive format. This is followed by a discussion pulling out the points of convergence and divergence among the case studies, and a conclusion discussing the implications of the findings for future research on eco-cities.

ECO-CITIES AND ENVIRONMENTAL DISCOURSES

Much of the broader literature on sustainable cities is analytical, attempting to test various propositions about what makes a city sustainable. Work on eco-cities, however, tends to either attempt to describe the phenomenon (Roseland 1997; Joss 2010) or focuses on normative prescriptions for achieving eco-city status (Register 2002; Girardet 2008; Kenworthy 2006). From this prescriptive literature it appears that the eco-city could be understood as a way of practically applying existing knowledge about what makes a city sustainable to the planning and design of new and existing cities. However what is 'known' about the relationship between planning and urban design interventions and sustainability objectives is a subject of much debate (Bulkeley & Betsill 2005; Williams 2009). This means that realizing an eco-city requires making countless decisions about sustainable technologies, urban form, building design and governance.

How, though are these decisions made? Many contemporary scholars and theorists of urban and environmental planning processes argue that this occurs through a social process consisting of complex negotiations, and often disputes (Flyvbjerg 1998; Hajer 1995; Healey 2007). This paper adopts this perspective and hence views eco-city initiatives as socially constructed through design and policy-making processes. Thus the eco-city is not a model or a template, but the outcome of a social process involving numerous stakeholders. From this perspective it is easier to make sense of the diversity of different eco-city initiatives. The eco-city is the solution to a problem; perhaps the diversity of eco-city initiatives reflects different ideas of what exactly the problem is. Looking for the broader discourses behind the solutions proposed in different eco-city initiatives may reveal these different ideas.

The discourse of the eco-city

Hajer (1995) defines discourse as "a specific ensemble of ideas, concepts, and categorizations that are produced, reproduced, and transformed in a particular set of practices and through which meaning is giving to physical and social realities" (44).

In the social sciences, discourse analysis is used to study the way in which issues and understandings are socially constructed. It does so through the analysis of both statements, and the context in which those statements are made (Hajer 1995). A number of authors have demonstrated the value of discourse analysis to understanding how planning decisions are made (Kumar & Pallathucheril 2004; Portugali & Alfasi 2008). Similarly, in the field of environmental sociology, discourse analysis is used to explore the way that actors construct environmental issues (Dryzek 2005; Hajer 1995).

Discourse analysis can reveal the way in which problems are constructed. In the study of eco-cities then discourse analysis can reveal the basis of their claims that they can make cities more sustainable. Does the answer lie in particular aspects of their design? If so, which ones? Or does it lie in the way they are governed, or their citizens involved in decision making? All of these issues are subject to significant debate. How do the designers of eco-cities answer these questions? And, among eco-cities, is there any convergence around a particular set of answers? If there were, this would help identify what exactly it means to be an eco-city. These questions are pursued by looking at five categories of discourse about urban development and sustainability, each of which is explained below.

Category 1: Type of sustainability: economic, social or environmental?

Much of the discourse about sustainability talks about it as consisting of three dimensions: environmental, social, and economic. Ideally, for sustainability to be achieved, these dimensions need to be in balance. Is that actually the case in eco-city projects or does one dimension dominate?

Category 2: Which actors drive the eco-city?

The question of who should be involved in the development of an eco-city is also central to understanding its vision. Several categories of actors are frequently involved in large-scale planning projects. These are the private sector, individuals, civil society and community groups, government actors and expert advisors. What role do different types of actors play in shaping, developing and operating the project?

Category 3: Eco-city as a model or eco-city as an educational tool?

Given that the eco-city is a relatively new and ambitious model of urban development, one could anticipate that the actors involved would see it as more than just a place to live. On the one hand the eco-city could be about presenting a new model of sustainable urban living to the world, something to be replicated in other locations. On the other hand more emphasis could be put on using the eco-city as an educational tool. In this case the eco-city could, for instance, be used to increase the awareness of local residents and / or the public about sustainability.

Category 4: Behaviour change as solution or technology and design as solution?

How can an eco-city help achieve sustainability? In considering existing sustainable urban projects, there appear to be three ways for it to do this. First, inhabitants can be encouraged to change their behaviour in order to live more sustainably. The other possibilities are connected to technological solutions, which can be used in two different ways. Production focused solutions incorporate technologies to generate renewable energy into an eco-city.

Consumption focused solutions use technology and design to decrease the demand for resources, for instance through passive ventilation.

Category 5: Sustainability by design or management and governance?
Following from the above, the last category suggested relates to the role given to design versus governance in reaching sustainability in eco-cities. On the one hand, eco-cities may see sustainability as resulting from efforts made during the design phase: a city is an eco-city because it has been designed as such. On the other hand, being an eco-city may also depend on the way it will be managed and governed after project completion: a city is an eco-city because it is governed as such.

METHODOLOGY

The approach taken in this research was to analyse a set of documents for six different eco-cities in order to identify how and whether they talked about each of the issues identified above.

Selection of cases

In this paper eco-city is used as an umbrella term. As such, some projects labelled "eco-district" or "eco-village" are also considered here as eco-city projects. Joss's list of 79 was the starting point in selecting the cases for analysis. We then shortlisted projects on the basis of project type, size and ambition, and document availability. We eliminated eco-city initiatives in existing urban areas, focusing instead on urban projects that were developed from the beginning with strong eco or sustainability objectives. Projects also had to house at least 100 people and have a minimum of two land uses (i.e. residential and commercial). Having narrowed down the list, we then looked for a range of sizes and geographical locations. Through this process of elimination we were able to shortlist Joss's list to 22 projects. The next step was to identify the projects for which there was sufficient information available in the public realm and in English to do an analysis. This was to ensure that we had an adequate number of documents to analyse. Through this process we were also able to eliminate a number of projects that were clearly highly speculative. Ultimately, we settled for six eco-city projects. Table 1 lists each of the selected projects as well as some basic information about them.

Selection of documents for analysis

We selected three documents to analyse for each project. To ensure that the analysis would evaluate the projects on the basis of their basic characteristics and perceived virtues, we ruled out any documents that were critical, and used only documents that described the projects in neutral or positive terms. The documents range in length from 360 words to over 2000. The sources used also varied, and included professional magazines, online databases about sustainable planning, project websites, academic publications, and online magazines. A list of the documents used to analyse each project is presented in table 2.

Table 1: Summary of projects analysed

Project	Location	Description	Status
Dongtan Eco-City	Shanghai, China	Dongtan, promoted as the world's first eco-city, was planned for an 86 km^2 site near Shanghai. The British engineering firm Arup designed the city for the Shanghai Industrial Investment Corporation (SIIC), a public-private partnership and the commercial enterprise arm of the Shanghai municipal government.	Unbuilt
Masdar City	Abu Dhabi, United Arab Emirates	Masdar City, planned for a 1,483-acre site in Abu Dhabi, was designed by a consortium of British firms led by Foster and Partners Architects, for the Abu Dhabi Future Energy Company. The city, which originally aimed to be zero-carbon and zero-waste, will provide a home and testing ground for Abu Dhabi's Masdar Initiative, which aims to develop Abu Dhabi as a major energy research centre.	Under construction
Sonoma Mountain Village	Northern California, USA	Sonoma Mountain Village is a 200 acre mixed-use development on a former industrial site in California. It is initiated and financed by the investment holding company Coding. The project aims to integrate the principles of New Urbanism with the One Planet Living framework developed by the environmental charity BioRegional.	Under construction
Hammarby Sjöstad	Stockholm, Sweden	Hammarby Sjöstad is a 200 hectare development initiated and steered by the City of Stockholm. When complete the development will have about 10,000 residential units and 350,000 m^2 of commercial space, with about 35,000 people living and/or working in the area. In the district strong efforts have been made to close the material and energy cycle.	Mostly completed
Eco-Village at Ithaca	State of New York, USA	A small cohousing scheme of 96 homes in Ithaca, New York with shared facilities, collaborative decision making and energy efficient buildings.	Completed & being expanded
Western Harbour, Bo01	Malmö, Sweden	This district of 160 hectares is built on reclaimed industrial land and has room for 600 dwellings, offices and shops. It was developed in the context of the European Housing Expo that was held in Malmo in 2001.	Completed

Search terms

To help identify statements expressing each of the discourses developed above, we developed a list of words that, if used, were likely indicated the presence of that discourse. For example, for eco-city as an exemplar project, we searched the text for words such as model, exemplar, template, replicate, and first. Using a simple software tool, Textstat, freely available from the Freie Universität Berlin, we identified how many times each of these words was mentioned. This helped us identify each instance in which that particular discourse was mentioned. A full list of all search terms is included in table 3. Each time we saw a word mentioned, we then checked the context in which they were used to make sure that only those that had a connection with the discourse were counted. Moreover, we also made sure that words would not be counted twice (e.g. renewable technology). This enabled us to compile a database of all instances in which each project was discussed (for instance) as an exemplar. For the category "behaviour as change" however, a different methodology was followed. Identifying in the various discourses attempts at behavioural change would be too limited if the analysis was restricted to specific words such has behaviour or consume. Instead, we undertook a manual content analysis, carefully reading through the documents and looking for instances where behavioural change was suggested.

From this database we compiled a frequency table (see table 4). From the relative frequencies with which each discourse was mentioned, we then were able to make some initial conclusions about the ideologies of each of the eco-city projects analysed. It is important to note that these are general conclusions based on a qualitative approach and should not be interpreted as having undergone tests for statistical significance.

Table 3: Search terms used for the analysis of the eco-city projects

Category 1	Search terms
Environmental sustainability	Environment, nature, ecology, preservation, wildlife, biodiversity, green, renewable, efficient, reduce, passive
Social sustainability	Social, accessible, affordable, culture, diverse, attractive, equity, participate, health, spirituality
Economic sustainability	Economy, industry, commercial, employment, company, business, work, financial, job
Category 2	Search terms
Actors: private sector	Company, business, industry, developer, private, architect, contractor
Actors: individuals	People, residents, inhabitants, public, individual, society, everyone
Actors: community / civil society	Participation, resident, community, involvement
Actors: government	State, government, authorities, official, politicians
Actors: experts	Expert, consultant, university
Category 3	Search terms
Eco-city as exemplar	Model, exemplar, template, first, replicate, prototype, inspire, paradigm, experience, communicate, demonstrate
Eco-city as education	Educate, teach, workshop, training, student, campaign, information, tour, engage, visit, course, knowledge
Category 4	Search terms
Behaviour change as solution	Manual content analysis
Technology & design as solution: production-focused	Generation, renewable, technology, CHP, solar, wind, biomass, design infrastructure, photovoltaic, production
Technology & design as solution: consumption-focused	Efficient, reduce, design, needs, diminish, insulate, minimize, saving, passive
Category 5	Search terms
Achieving sustainability through design	Architect, engineer, design, plan, masterplan
Achieving sustainability through management and governance	Manage, operate

FINDINGS

Table 4 presents a summary of our analysis of the sets of documents for each of the six projects. For each project it lists how many statements we found that reflected each discourse. The type of statement that was dominant in each category is indicated by putting the relevant number in bold.

Table 5 summarises the results in each category for the six projects. We concluded that a particular discourse could be seen as dominant if that discourse was used at least twice as often as the others in that category. Dominant discourses are identified by the words in bold text. Table 6 presents the same results summary, however here the highlighted terms are those two categories that were mentioned most *overall* in the texts. The results are discussed in more detail below.

Economic, social or environmental sustainability?
In four out of six projects, discourses of environmental sustainability clearly dominated over economic and social. For three projects, Hammarby, Dongtan and Malmo, it was strongly dominant, and even for the two projects where it was not mentioned most, it was a close second. Its appears then that the environmental dimension of sustainability is important to the eco-city. Looking at the text, the importance of decreasing the environmental footprint of urban areas is a clear theme. For instance, for Hammarby Sjöstad, the goal for the district is to be "twice as good in relation to what goes for the best applied technology in today's new building design."

Masdar & Ithaca are interesting in their emphasis on different aspects of sustainability. Masdar's frequent mention of economic issues makes sense given that the city is presented as a vehicle for developing a renewable energy industry in Abu Dhabi. In this case, sustainability starts to be seen as a source of economic development. Ithaca's emphasis on social sustainability also seems to derive from the underlying aims of the project. The Ithaca website states that "as residents, [they] are engaged in a fascinating social experiment." This emphasis on social issues was unique among the cases studied.

Which actors drive the eco-city?
In the case of the actors that are playing a role in the eco-city, we found very few similarities among the projects. Each project seemed to focus on different actors. One interesting outcome was the impact that having a particular actor associated with the project had on the results. This can be seen in the case of Dongtan, where the designers Arup were mentioned many times and contributed to the dominance of the expert category. This was also the case for Sonoma Mountain Village, where the developer, Codding Enterprises, was also mentioned frequently and contributed to the dominance of the private sector as actor in the results for that project.

Mention of a category of actor did not necessarily seem to indicate it would be involved in shaping the project. In Hammarby the category the most frequently mentioned was individuals (37 times). For instance, one text stated that "all solutions have to be adapted to the needs of local residents." This seems to indicate that the future residents played a central role when designing the district and that it is built for them. However, the involvement of residents or inhabitants in the design of the district is only mentioned 4 times.

In this category Ithaca again stands apart from the other projects, with the community / civil society category coming up most frequently. Moreover, out of the 14 sub-categories of discourses examined in the analysis, it is the one most often used in the texts about Ithaca. From this it would appear that in projects where social sustainability is central, community groups might be more involved in the project.

Eco-city as a model or eco-city as an educational tool?
Each of the six projects is described multiple times as a model or example. A text written by the builders of Ithaca states "Our goal is to build a replicable model of a cooperative, environmentally sensitive village." In the case of Malmö, one text states that "the aim is to make Västra Hamnen an international leading example of a densely populated, environmentally sound neighbourhood." Masdar City is described as "a model for future development" and "the role model for the world," Dongtan as "a global template for sustainability in urban planning," and a "prototype for the future of all cities."

When talking about the eco-city, four cities see themselves mainly as an exemplars (Dongtan, Masdar, Sonoma and Malmo) while Hammarby Sjöstad and Ithaca are more focused on education. Somewhat surprising given that the Masdar Institute is heavily focused on research into renewable energy is that for this project the eco-city as an educational tool is not mentioned a single time. The project with the strongest emphasis on education is Ithaca, where this discourse was the second most mentioned of all the categories searched for. The eco-city as an educational tool appears as a crucial element of the discourse of the project. Actors involved in this project even talk about their "educational style."

Behaviour change as solution or technology and design as solution?
The use of technology and design are among the most frequently mentioned categories for all of the projects. In fact, every project studied mentions using technology and design as a way of achieving sustainability. However there was some variety in emphasis between projects when it came to whether this was for the production of renewable energy or the reduction of consumption. For four of the six projets, the use of technology and design was focused on developing more sustainable means of energy production. The two projects where environmental sustainability did not dominate over all the other dimensions, Ithaca and Masdar, were also the two most focused on using design and technology towards reducing consumption.

That said, Masdar and Ithaca have different ideas about how to reduce consumption. Intelligent design, the "latest high-tech monitoring systems" and "cutting edge technology" are described as helping to ensure that "Masdar City's use of resources will be far lower than that in conventionally designed communities." In Ithaca however, "passive solar design" or "south-facing arbours with deciduous vines minimiz[ing] overheating in warmer months" are mentioned as "strategies to achieve high energy efficiency." These extracts also highlight another point. When discussing reducing consumption, the texts focus on doing so through design. The need for residents to change their behaviour almost never came up in any of the texts. Instead, there is a recurring theme of making sustainable living effortless for residents. A text about Sonoma Mountain village for instance says that "the community is based on the premise that an ordinary resident will be able to live there sustainably with little extra effort."

Achieving sustainability through design; achieving sustainability through operation / governance
The one consistent result emerging out of the entire analysis is that in all of the cases, design is much more frequently mentioned than management as a driver of sustainability. Even in the case of Ithaca, while the texts suggested that governance is also important, it was not specifically mentioned.

DISCUSSION

The sheer diversity of approaches to creating an ecological or sustainable urban development found even in this small study would seem to indicate that, for the moment, there is no standard definition of what an eco-city is. Despite this diversity, it is still possible to draw out a few commonalities between all the projects. First, there was the overwhelming focus on

achieving sustainability through technology and design and the lack of attention paid to the ongoing government and management of these projects. That the notion of governance is not even mentioned in any of the cases studied is interesting when considering the increasing body of literature dealing with the notion of governance for sustainability. This may be related to the preference for a design-led approach to developing an eco-city. This leads to the question of whether the entire proposition of the eco-city is based on an excessively physically deterministic approach to planning.

Regarding strategies for achieving sustainability, again the projects' focus on design and technology dominated, this time over strategies to change the behaviour of inhabitants. Technology is in all cases used to deal both with consumption and production. However, no real patterns emerged about which of the two should be focused on. Finally, in most of the cases, one or both of these clearly appeared as one of the main discourses used to describe the project. This seems to indicate that technology is an inherent aspect of eco-city development and that it is seen as having a crucial role to play in achieving sustainability.

A third point of convergence among the projects studied was that they all aimed, in some way, to be seen as models or examples of urban sustainability. In some cases this ambition was more pronounced than in others but it was nonetheless always present. Additionally, the projects often discuss an ambition to be seen as models on a global, not just local scale. While most projects did not speak about education, in this sense they could all be seen as wishing to educate the world at large on what a new breed of ecological urban development looks like. This fits with a growing trend where places like Hammarby are becoming case studies of 'good practice' and field trip destinations for students of sustainable urbanism.

Finally there was the emphasis on environmental sustainability. Even for the two projects where other types of sustainability were more frequently mentioned, the environment was still a strong theme. This could reflect the challenge of incorporating economic and social issues into a design-led approach. Perhaps the designers of eco-cities are simply more experienced with and knowledgeable about how to address environmental issues. In the documents on Dongtan, which discuss environmental issues with great confidence, social and economic proposals are often couched in speculative language, e.g. the planners 'envisage' that local employment will be generated and 'feel that the Chinese should maintain local fishing and farming.'

The results presented in this paper are very preliminary and based on an analysis of only six eco-city projects, and there are some limitations to the methodology used. First, the requirement that documents be available in English limited the selection of cases. Second, the total amount of words analysed for each case differed quite significantly with the largest nearly 11,000 words and the smallest only 3,200. This was in part due to difficulties finding a balanced array of documents for each project. Despite these limitations, we believe the insights gained form this study can help progress an understanding of the ideologies behind of eco-city projects, and hope that the study has produced results which will be useful in directing further research.

CONCLUSION

The analysis in this paper demonstrated that there is a great deal of diversity among projects considered to be eco-cities. By looking for particular themes in the discourse about these

projects, we have demonstrated that this diversity goes beyond just their size, location and ambition. Indeed, it expands to their vision of what a sustainable urban future looks like, the techniques that planners and designers should use to achieve it, and the actors who should be involved.

We propose that this diversity may in fact be a good thing. As much as each of these projects wants to be seen as a model, perhaps it is better to accept that there is no single solution for making urban living more sustainable. In this sense, it is better to think of the eco-city as an ambition, an objective that there will be multiple ways to achieve. Many lessons can be learned from studying each project, both in isolation and in comparison with others. As time goes on and more eco-city projects are actually built, this diversity will allow for interesting and instructive comparisons.

The above may make it seem that we are remaining somewhat agnostic about the quality of these projects in relation to their sustainability goals. While our objective was to revel rather than judge, we can make what we hope will be some critically constructive comments about the projects studied. We are concerned about the lack of attention to ongoing governance and management of projects, and to the idea that people might need to change their behaviour. These characteristics could reflect a hesitance to engage with the more challenging and aspects of making urban living more sustainable. Perhaps the designers and developers behind these projects believe that these issues are beyond their remit, but we would counter that those interested in a comprehensive approach to sustainability must take them into account.

We hope that this paper will provide the grounding for further more in-depth research on eco-cities. We would particularly like to encourage qualitative analyses of the type that we have attempted, which try to uncover some of the underlying assumptions behind high profile projects. One reason for this is that as the demand for practical ideas about how to make urban living more sustainable increases, these projects are likely to get increasing attention from policy makers and practitioners around the world. Further research should focus on providing the information that these people will need to make informed decisions about how to achieve the eco-city objective in their own context.

Abstract:
Today, many new urban areas, such as cities, towns, villages, or districts, are being built worldwide and their completion requires the development of a number of infrastructures. Traditionally, these infrastructures are planned in parallel. However, increased environmental awareness is pushing cities to improve their environmental performance. One way to do so is by systems integration (e.g. connecting drinking water pumping with energy production).
The aim of this paper is to show how different actor networks lead to different process of integration. We especially focus on the influence of actor participation during the design phase. To do so, two case studies are presented: Hammarby Sjöstad in Sweden and EVA-Lanxmeer in the Netherlands.

Keywords: systems integration; sustainable urban development; techno-economic network

INTRODUCTION

When new urban areas are being built, their completion requires the development of infrastructures necessary to meet a number of societal functions. Among others there is a need for energy and drinking water provision, waste management and wastewater treatment, or transport facilities. Each of these functions can be conceptualized as being produced by separate socio-technical systems. Traditionally urban planners consider each of these socio-technical systems independently from each other. Infrastructure for wastewater treatment is developed separately from that for transport for instance.
In the last decades, increased environmental consciousness has been pushing cities and municipalities to minimize the environmental footprint of (re)developed urban areas. In

parallel to that, a number of academics have been advocating that in the quest for the sustainable city a transition should be made from linear to circular systems of production and consumption. This is expressed under concepts such as circular urban metabolism (Girardet 1996), cities as sustainable ecosystems (Bossel 1998; Newman and Jennings 2008), urban symbiosis (Van Berkel et al 1009) or symbiocité (Gontier 2005). Behind these concepts lies the idea that interconnections should be developed between different material and energy flows in order to improve efficiency and reduce waste. This kind of thinking is also promoted by scholars from the field of industrial ecology (McDonough and Braungart 2002; Graedel and Allenby 2003).

Therefore, the aforementioned socio-technical systems have to be locally integrated to each other. We will refer to this process as 'systems integration'. Systems integration happens when socio-technical systems initially operating as separate entities become connected. This connection results in new inter-linkages between both social and technical components of the two socio-technical systems. Among others, examples of systems integration are the use of domestic waste for energy provision or the use of the sludge remaining from the treatment of wastewater as source of energy for generating transport fuel. Systems integration is not limited to urban areas. Similar processes of integration can be observed in water management (integrating qualitative and quantitative management, navigation, tourism) industry (industrial symbiosis) or farming (industrial symbiosis in greenports).

Numerous cities and municipalities are making attempts at systems integration (see Joss 2010). However, a wide gap exists between what is theoretically possible and what occurs in practice. Outcomes highly depend on who takes responsibility for the realization of the system, which stakeholders are involved in the design process, to which degree and how. Outcome depends on the characteristics of the actor-network involved in the realization of systems integration. Moreover, the process of realizing systems integration when developing a new district goes through different phases. The system has to be designed, constructed and then operated. In this paper, the analysis will address the design phase only. In practice, it is this phase that determines whether systems integration gets implemented at all and how it will operate once it is there. Two components of the design phase will be addressed: vision building, including both developing a vision for the integrated system and gathering support for it, and the selection of technologies.

In this paper, we argue that the actor-network in the design phase shapes the integration process. This includes both the elements of integration and the extent of integration. The aim of this paper is to show how different actor networks led to different processes of integration.

In the remaining sections, the concept of techno-economic network (TEN) stemming from actor-network theory will be introduced, along with the four poles that compose it. Then, for each case, the analysis establishes which actors played a role during vision building and the selection of technological solutions. We identify whether each pole was filled and which influence this had on the realization of the integrated system. The paper ends with preliminary conclusions and suggestion for future research.

THEORETICAL BACKGROUND: ACTOR NETWORK THEORY

According to actor network theory, the existence of an innovation is bound up to the construction of an actor-world. Callon (1986) stated that "an actor world associates heterogeneous entities. It defines their identity, the roles they should play, the nature of the

bonds that unite them, their respective sizes and the history in which they participate" (Callon 1986).
Moreover, acknowledging that the process of innovation as well as its diffusion requires connection between the worlds of science and technology and the market, Callon introduced the concept of Techno-Economic Network (TEN) (Callon et al 1992). A techno-economic-network is defined as

'a collective set of actors which participate in the development and diffusion of innovation and which via numerous interactions organize the relationships between scientifico-technical research and the market place' (Callon et al 1992).
According to Callon (1992), TEN are organized around three poles:

- Technical pole: design of products and processes that have their own coherence.
- Science pole: the production of scientific knowledge. It includes institutions such as universities, or research institutes.
- Market pole: consumers, suppliers, practitioners, their needs and their preferences.

To the three poles model, de Laat (1996), later followed by Buchhorn (2007), introduced a fourth one around government agencies and public authorities. This is the political pole.

The concept of TEN has been developed in order to understand the processes through which innovation happens and diffuses. As such the scale at which TEN is applied is often rather broad, looking at processes within specific domains but in an entire country (Callon et al 1992; Buchhorn 2007). In this paper, the processes analyzed are, on the contrary, very local. However, there are some important similarities between the processes of systems integration studied in this paper and the concept of techno-economic network as defined above. Systems integration requires the development of technologies that go beyond the scale of individual buildings. A network of heterogeneous actors responsible for the introduction of systems integration will have to be formed. Its role will be about organizing, with a certain extend of political support, the relationship between science, technology and the market.
Nevertheless, we acknowledge that the characteristics of the poles playing a role in the TEN have to be adapted to that of the network studied here. For instance the role of science is fairly different as we are not dealing with science that takes place in laboratories but with the application of scientific knowledge into practice. The four poles are thus described as follows:

- Technical pole: the technologies as artifacts and the organization owning and operating them.
- Science pole: experts with access to scientific knowledge from both private and the public sector.
- Market pole: it remains essentially the same. The analysis will focus on the investors and the end-users. Depending on the size of the project investors could be private companies, and/or local authorities. However, inhabitants may also fulfill this role. The end-users would often be the inhabitants themselves but may also be private companies.
- Political pole: regional or national authorities also play a role by providing political support.

CASE STUDY ANALYSIS

The Hammarby Sjöstad case study builds upon previous research done by one of the authors (Pandis, upcoming) on the development of the Hammarby Sjöstad district. In addition, four semi-structured interviews with people personally involved in the formation of the Hammarby Model and a literature review were conducted. Regarding EVA-Lanxmeer, data presented here are the result of a literature review including a number of reports, brochures, business plan and communication documents written between 1993 and 2008, nine semi-structured interviews and two follow-up interviews.

Hammarby Sjöstad

Hammarby Sjöstad literally means the city around the Hammarby Lake. The district covers an area of 200 Ha. Its development should be finished by 2015. When completed, about 35,000 people would be living and/or working in the area (Fränne 2007).

In the 1990's a number of semi-legal or illegal small scale industries and storage facilities were present in the area which came to be known as the Shantytown (Bodén 2002). Over time the desire to redevelop this area grew stronger in the municipality. At the end of 1995 the city of Stockholm decided to make a bid for the Olympic games of 2004 and to propose Hammarby Sjöstad as Olympic Village (Stockholm Stad 1996). The high environmental performance of the district started to gain importance because the International Olympic Committee was calling for an environmental focus in the applications. This also increased the political interest in the district (Bodén 2002; Green 2006; Enberg and Svane 2007).

Vision building:

In 1996 the City of Stockholm developed an environmental program for Hammarby Sjöstad. In this plan an overarching vision for the district was specified. It stated that *"The environmental performance of the city district should be "twice as good" as the state of the art technology available in the present day construction field (Stockholm Stad 1996 p4)"*. Of more importance for this study is the vision concerning the use of energy and material in the district that was also specified. It stated that *"The city district is to be planned and built in accordance with the principles of the natural cycles, the kretslopp."(Stockholm Stad 1996 p4).* It is on this aspect of the vision that we will be focusing. From now on when referring to the vision, we will only be referring to the vision for the integrated technological system in development (the Hammarby Model) and not for the district as a whole (the Hammarby Sjöstad).

Vision building for the Hammarby Model was an interactive process between the City of Stockholm and the local infrastructure companies (referred to as the eco-cycle companies). In 1996, the City invited the eco-cycle companies to propose technological solutions that would materialize their vision. However, they contested this vision and showed little interest. The City and the eco-cycle companies both had different interpretations of the vision. On the one hand the City wanted the companies to develop solutions specifically for Hammarby. On the other hand for the eco-cycle companies closing the loop made sense only if their existing infrastructure could be used. During an interview, the head of the Chief Administration Office, stated that "*the [companies] thought the project was fuzzy and that there already existed a well-functioning infrastructure in Stockholm. Why mess with it?"*

The first proposition made by the eco-cycle companies turned out to be rather "business as usual" and for that very reason was rejected by the City (Pandis and Brandt 2009). In order to push the companies forward, the City made clear that the companies risked losing their share in the project. The eco-cycle companies started mobilizing new employees and made a more

innovative proposition. It was based on their existing infrastructure however, individual components would be further improved and new components added in order to better close the eco-cycle. The City embraced this new proposition and encouraged the eco-cycle companies to work further in that direction. A consensus was reached. This also marked the birth of what would later become the Hammarby Model.

Selection of technologies:
Once the vision is developed and has gained support, technological options have to be selected. In Hammarby Sjöstad, some options had already been mentioned during the vision building process. However, they still had to be developed further before they could actually be realized.

Biogas as transport fuel:
Biogas for transport, integrating the sewage system and the transport system is one of the most successful innovations implemented in Hammarby Sjöstad. Biogas is produced in Hendriksdal, the local wastewater treatment facility. Since 2003 the biogas is also upgraded to transport fuel quality in a nearby site.

Pole	Actor involved	Role	Position
Politics	The City of Stockholm	Provide political support	Collaborate
Market	Stockholm Water The City of Stockholm SL (Stockholm public transport company)	Invest Creates a local market, provide subsidies Buy the product	Lead Collaborate Collaborate
Science	Employees from Stockholm water	have knowledge from previous demonstration project	Collaborate
Technical	Stockholm Water	Owner of the wastewater treatment facilities; responsible for the previous pilot project	Collaborate

***Table 1**: biogas for transport: actors involved in each pole, their role and position.*

- Political pole: interest in clean vehicle dates back to 1994 when the City of Stockholm had taken the political decision to promote and invest in clean vehicles (Stockholm Stad 2004). In 1996, it also started supporting a pilot project in Bromma where biogas was upgraded to transport fuel.
- Technical pole: Stockholm Water is both owner of Hendriksdal, the plant where biogas is to be upgraded and of the plant where the aforementioned pilot project took place in 1996 (Energie-cites 1999; Held et al 2008).
- Market pole: first, the success of the pilot project encouraged Stockholm Water to invest further in that direction. Second, the City of Stockholm took the resolution to convert its own fleet into non-fossil, providing a market for biogas (Stockholm Stad

2004). Third, the City introduced programs to promote the use of biofuels in the city slowly creating local demand for biofuels (Stockholm Stad 2004). Fourth, SL, Stockholm's public transport company, started considering biogas as a potential fuel in 2002. The company had been previously focusing on ethanol but started having some difficulties with its supplier and decided to diversify its supply (Stockholms Lokaltrafik 2002). In 2003 an official contract was signed with Stockholm Water regarding the supply of biogas (Hallgreen undated).

- Science pole: Stockholm Water had knowledge about biogas upgrading.

PV:
PV integrating buildings and the electricity system were extensively discussed in the early plans about Hammarby Sjöstad. Their large scale introduction was even discussed. However, only very few have been installed and some of those installed are not performing as expected. Looking at the pole, we can see that some instead of working for the technology actually worked against it (see table 2).

Pole	Actor involved	Role	Position
Politics	The City of Stockholm	Provide political support	Support
Market	Fortum	Invest in the technology	Initially interested, then arguing against
	Constructors	Invest in the technology	Limited interest
Science	Fortum	knowledge of solar energy, its costs and efficiency	Contest
Technical	Fortum	Owner of the district heating company	Limited interest
	PV	The technology exists	Readily available

***Table 2**: PV: actors involved in each pole, their role and position*

- Political pole: the City of Stockholm wanted to introduce technologies that were new to Stockholm in Hammarby Sjöstad. PV fell into that category. However, as the project evolved, political support for alternative technologies that did not play a central role in the Hammarby Model diminished (Pandis upcoming). This is partly due to the City losing the bid for the Olympic Games.
- Technical pole: First PV are readily available in the market and show decent performances even in the Nordic Stockholm region (Brogren et al 2004). However, very few PV were present in Stockholm at the time. Another aspect worth mentioning is that most of Stockholm is connected to district heating network and so would the Hammarby Sjöstad. However, Fortum, the company owning the district heating which is mostly based on combined heat and power, saw PV as a competing technology. During an interview, the environmental manager in Stockholm Energi (that would later become Fortum) stated for instance that "*solar energy pushes away cogeneration or other useful techniques*".
- Market pole: Initially Stockholm Energi was interested in investing in PV on a large scale. However, the company later on changed its mind arguing that they were not

competitive. The privatization of Stockholm Energi in 1998 could partly explain this change of attitude. Moreover, the City of Stockholm provided only limited support for project developers to introduce PV who showed little interest. Moreover, when they did, PV were installed according to aesthetic criteria rather than optimal electricity production. The function of the building, in which aesthetics was a primary element, was not effectively reconciled with electricity production (Brogren and green 2003).

- Science pole: Fortum had access to knowledge about PV, their efficiency and their cost from existing project done by other companies but did not have in-house know how. Fortum actually contested that PV were an interesting alternative for Stockholm. During an interview, the environmental manager in Stockholm Energi said that *"during the formation of the Hammarby Model PVs and solar panels were discussed as an alternative, but we knew this was not economically realistic"*.

EVA Lanxmeer

EVA Lanxmeer is a sustainable urban district of 24 Ha developed in the municipality of Culemborg in the Netherlands in the mid 1990's. This municipality is part of the province of Gelderland. In total about 800 people live in the area. Moreover, a number of office buildings are also present on site combining living with working.

The district, which development was initiated in 1993, is the result of an initiative taken by Marleen Kaptein. She was triggered by the momentum developing around sustainability, the Bruntland report had just been published, and by the lack of success from the Dutch government to involve citizens in their environmental policy (Kaptein 2010). Initially, the idea for the district was not bound to any specific location. To be able to enter in negotiations with a municipality she created the EVA-foundation. Using her personal network she gathered renowned Dutch academics and political figures with direct connection to the ministry of Housing, Spatial Planning and the Environment around the project. To show their support they became members of the EVA-foundation.

<u>Vision building:</u>

The process of vision building and support in EVA-Lanxmeer happened very differently from that in Hammarby Sjöstad. The vision for the district to be was entirely developed by experts, including national and international academics and experts from the private sector, free from the influence of local policy makers. The vision included the following elements: an architecture in harmony with the existing landscape; integration of functions: living, working, recreation; reduced use of cars; use of ecological building materials; and most importantly for this paper sustainable water- and energy resource management and the involvement of future inhabitants; education & advice via the EVA-center (Stichting EVA 1995).

The next step was for the EVA-foundation to find a municipality that was willing to realize a district based on this vision. People interested in living in such a district were also looked for. The foundation found support from the Alderman responsible for spatial planning and the environment in Culemborg and from the head of the department of urban development. The municipality already had experience with sustainable building, citizen participation and management of green areas. They had the ambition to go further with urban sustainability and saw the EVA-foundation and its vision as an opportunity to reach that ambition (Stichting EVA; Goed 2010; Kaptein 2010).

Furthermore, Marleen Kaptein also found 80 families that signed a document stating that they would like to live in such a district wherever it would land (Stichting EVA; Goed 2010; Kaptein 2010).

Later on companies were also invited to join in the discussions concerning the specific solutions to be implemented in the district. However, to be able to actively participate in the process, they had to agree with the overarching vision. It was not going to be revised in the process. In fact the EVA-foundation was actually assigned the role of concept keeper by the city and would be guarding the concept or vision throughout the development (Stichting EVA).

Selection of technologies:
Before describing in detail the selection of specific technological solutions, we will first introduce the context in which these solutions were chosen. In 1997, non-professional workshops were organized where inhabitants could express how they wished their future district to look like. Later on, representatives of the inhabitants brought these ideas to professional workshops where they actually influenced the design of the urban plan (Stichting EVA). Even if this does not have a direct influence on the choice for specific technological solutions, this participation is still important to mention. Indeed, the inhabitants participated throughout the process in the design of their neighbourhood and were kept informed by the experts of the technological solutions that were being discussed.

Blackwater treatment and the production of biogas:
Early in the process came the idea to separate blackwater (toilet waste) from greywater (water coming from the kitchen and the shower), to treat it locally using biological processes and to use the remaining sludge to produce biogas integration of wastewater treatment and energy production (Stichting EVA; van Timmeren 2004; van Timmeren 2006). Organic waste produced in the district was also planned to be added to the sludge in order to increase biogas production. These two elements were both planned to be part of the EVA-Centre (see vision) (Kaptein 2010). However, the centre was never realized and with it these two technological solutions did not materialize. A summary of the results of the analysis can be found in the following table.

Pole	Actor involved	Role	Position
Politics	The municipality of Culemborg	Provide political support	Initially interested then released all responsibility
Market	GGR Gas Nuon	Invest in the technology Consume the biogas	Initially interested, then stopped supporting Reject
Science	Energy expert Architect	Knowledge of the treatment of blackwater, the production of biogas and its integration into a building	Provide information
Technical	GGR gas Blackwater treatment and biogas production	Operate the technology	Initially interested then released all responsibility Available

***Table 3**: blackwater treatment and biogas: actors involved in each pole, their role and position.*

- Political pole: the municipality of Culemborg initially supported the project. It was part of the vision for the district and the municipality had embraced this vision. However, over time interest diminished and in 2003 the municipality released all responsibility for the project (Kaptein 2010). This can partly be explained by the fact that the civil servant initially supporting the project left the municipality, and partly because during the time frame of the project, different municipal councils succeeded one another. New council members did not understand what was going on in EVA-Lanxmeer anymore (Kaptein 2010). The project leader for EVA-Lanxmeer employed in the spatial planning department also mentioned that "*the project was too ambitious for somewhere like Culemborg*".
- Technical pole: the company "GGR gas" was initially expected to operate the biogas installations. However, the company later on stopped its support (Bonouvrié 2010; Kaptein 2010). Moreover, for biogas to be produced blackwater treatment had to be done locally. The two technologies were intimately connected to each other. However both had already been introduced elsewhere in more or less large scale.
- Market: Large amount of biogas were expected to be produced and a market had to be found outside the district. One solution considered was to send (part of) it back into the gas network. However, Nuon, a Dutch energy company responsible for the gas grid in that area, rejected the idea (Bonouvrié 2010). There were thus many uncertainties regarding the availability of a market for biogas that was to be produced. This also partly explains why no large investors could be found for the project.
- Science: energy experts and architect worked on the EVA-concept. Scales models were made, together with a number of calculations and academic publications (van Timmeren 2004; van Timmeren 2006; van Timmeren 2007). Technical knowledge was thus available during the process.

Local treatment of greywater:
Part of the water concept was to locally treat the greywater produced in the district integration of wastewater treatment and aquatic ecosystem. This includes water coming from the kitchen and the bathroom. This was one of the solutions successfully implemented in the district (Stichting EVA).

Pole	Actor involved	Role	Position
Politics	The municipality of Culemborg Water board Rivierenland	Provide political support Provide support	Support Collaborate
Market	Future inhabitant Water board	Produce the greywater Financing and maintain the system	Participate Collaborate
Science	Academic and private experts Arcadis	Provide information Provide information	Inform Inform
Technical	Brinkvos water	owns the technology to build the system	Available

***Table 4**: local treatment of greywater: actors involved in each pole, their role and position.*

- Political pole: First the municipality of Culemborg supported the idea from the very beginning. Second the Water Board Rivierenland, a regional government body responsible for maintaining the level and the quality of the water in the area also supported the project (Bonouvrié 2010; Kaptein 2010)
- Technical pole: greywater treatment in Culemborg was new. However similar systems had already been built elsewhere. In EVA-Lanxmeer, technical calculations were done by Arcadis, a Dutch engineering firm.
- Market: First the Water Board Rivierenland played an important role here by allowing such an experiment to be realized (Verhaagen, 2011) and by financing it (Bonouvrié 2010; Kaptein 2010). Second the future inhabitants were kept informed of the technological solution chosen and their implications (Stichting EVA). This has been very important as for the biological treatment of greywater to function properly, chemical products such as bleach can't be thrown into the sink. Inhabitants thus have to adapt their behavior to the system in place.
- Science: academic and private experts, and Arcadis all provided information about the greywater system (Stichting EVA).

DISCUSSION AND CONCLUSION

The aim of this paper was to show how different actor networks led to different process of integration. The focus was on the influence of actor participation during the design phase, including vision building and selection of option. We used the concept of Techno-Economic Network developed in order to understand innovation processes to analyze attempts at systems integration in two case studies: Hammarby Sjöstad in Sweden and EVA-Lanxmeer in the Netherlands. It total four different attempts at systems integration were studied. A summary of the results can be found in table 5.

First, our results show two very different approaches to vision building. In Hammarby Sjöstad, as initiator, the City of Stockholm developed a vision and then tried to get support from local infrastructure companies. However to do so she had to both pressure the companies and agree to make some compromises. In fact, vision building was not a purely separated process but was also influenced by the initial selection of technological options. Moreover, we can see a dominance of two groups of actors: the City of Stockholm and the eco-cycle companies. We can also note that technology related actors have a prominent role while future inhabitants did not have a say in the process. We can observe that discussions focused on closing material and energy cycles through technological solutions.
In the case of EVA-Lanxmeer however, a number of experts developed a vision and looked for partners interested in working with that vision. The partners they sought were a municipality and future inhabitants. In this vision, the technological component only played a marginal role. No location was known when the vision was built so it had to be stated rather general to give space for local specificities to be expressed. Moreover, technical partners were later invited to join in the discussions but on the conditions that they agreed to work with the vision. It is the process through which these technological solutions were to be chosen, in interaction with the inhabitants that was given the most attention.

Regarding the specific technological solutions chosen, our analysis unsurprisingly shows that the two cases where implementation was successful had all the poles filled and often by more than one actor. Concerning biogas production in Hammarby Sjöstad, a variety of partners with different expertise gathered around the project. They all found interest in biogas either

as a way to expend their market, or to help meeting their corporate ambitions. The market and the science pole were filled by more than one actor ensuring the availability of knowledge and the presence of a future market for the product in development.
In EVA-Lanxmeer, generally speaking, the context in which the district developed was favourable for experimenting. Actors with political power were inclined to support, politically and financially, innovative solutions such as greywater treatment. The science pole was strongly represented giving credibility to the solution and its feasibility. The market pole, through the future inhabitants, was also well represented. This was especially important given the role that inhabitants have in ensuring the proper functioning of the system. However, this raises questions regarding the long term operation of such a system as new inhabitant have to be kept informed of the existing rules. This is especially challenging in situations where there is no formal institutional setting and where responsibilities are not clearly distributed. In EVA-Lanxmeer, it is the inhabitants themselves that, out of their own will, are organizing knowledge diffusion in the district.

Stage	**Pole**	**Hammarby Sjöstad**		**EVA-Lanxmeer**	
Vision building	Politics	Yes		No then yes	
	Market	No then Yes		No then some yes	
	Science	Yes		Yes	
	Technology	Yes		No	
Choosing specific technologies		Biogas	PV	Biogas	greywater treatment
	Politics	Yes	Yes	Yes then No	Yes
	Market	yes	No	No	Yes
	Science	Yes	No	Yes	Yes
	Technology	Yes	Yes	Yes and No	Yes
Final result		Introduction successful	Introduction very limited	No introduction	Introduction successful

***Table 5**: Summary of the findings. The words "yes" and "no" are used to express whether the pole is filled or not.*

Concerning solutions that were not realized, our data also tends to show that independently, political support (political pole), technological feasibility (technical pole) and knowledge availability (science pole) are not sufficient for systems integration to be realized. Moreover, in the two cases where implementation failed, the market pole was very weak. In the case of PV in Hammarby Sjöstad, the technology was readily available. However, it did not fit in the portfolio one of the key actor who even contested the usefulness of introduction. Moreover, shifting political support failed to create a real market for PV in the district.

Looking at backwater treatment and biogas production in EVA-Lanxmeer, out of the four poles, only the science one was actually fully represented and was actually driving the realization. The market was rather insecure and uncertainties remained around who would be building and operating the system. Political actors provided insufficient support, unconvinced of the economic feasibility of the project.

To conclude, results presented in this paper show that, as expected from the theory, all poles need to be filled for a successful implementation to happen. Results also show that partial implementation can be realized with only a few poles active. Moreover, the analysis suggests that the market pole is difficult to fill and that market actors are difficult to convince to join in systems integration practices.
These results also raise a number of questions. First, in this paper the analysis only shows the final results of various attempts at systems integration. A chronological analysis showing how the poles get filled from the moment when the idea was developed to its realization (or abandonment) would better reveal which pole drives the process and the dynamics behind systems integration. This may also reveal when and under which condition does the market pole start being filled. Moreover, the analysis done here shows what happens but does not explain why actors decide to join the process or not. Each actor, whether they are doing public transport, wastewater treatment, district heating, etc. is part of a socio-technical regime. This regime sets the norms and routine that drive actors and their activities. Including a more in-depth investigation of the actors and the regime to which they belong would give explanatory power to the analysis.

THE RISE OF THE ZZP'ER (SELF-EMPLOYED PROFESSIONAL) IN THE DUTCH CONSTRUCTION INDUSTRY

KARS VAN DER KAMP
University for Applied Sciences Utrecht
Nijenoord 1,
3552 AS Utrecht
Netherlands
Kars.vanderkamp@hu.nl

Abstract
55% of all carpenters are self-employed (zzp'er), 37% of plasterers and wall-/floor finishers is zzp'er, and 28% of the bricklayers and interpolators is zzp'er. Of all the work in the construction sector, zzp'ers now do 15%. Is there something special about these people or the construction industry and where do these characteristics originate in?
In this paper we will show a zzp'er is a hard working professional with a lower to secondary education, having an average age of 44: he is a former employee and has a desire to run his own small business. He wants to take his own decisions en he is proud of his craftsmanship. But, he lacks recognition of human needs in construction companies.
We will show you main differences in needs and thinking between zzp'ers and the construction companies. Zzp'ers look for freedom, autonomy, respect, and recognition. They are anti hierarchical, and prefer integration of thinking and doing, and collaboration based on friendship. Construction companies want to be in control, there structure is pyramidal, and the way they organize is based on a strict separation of thinking and doing; collaboration is forced. We think that (major) construction companies should ask themselves whether they want to continue their present policy with more all round professionals leaving or retain their people for which investments in a better place to work are required.

Keywords:
zzp'er=self-employed professional; labor relations; HRM policy

THE RISE OF THE ZZP'ER (SELF-EMPLOYED PROFESSIONAL) IN THE CONSTRUCTION INDUSTRY

Introduction

55% of all carpenters are self-employed (zzp'er), 37% of plasterers and wall-/floor finishers is zzp'er, and 28% of the bricklayers and interpolators is zzp'er. Of all the work in the construction sector, zzp'ers now do 15%. (Berkhout en Kok, 2010) These figures reveal a real innovation in Dutch labor relations, where people – to the 90s - were used to life time employment.
Zzp'ers value freedom at work more than the certainty of being a payroll employee. This raises questions. Is there something special about these people or the construction industry and where do these characteristics originate in?

Background

At the time we started the research on zzp'ers in construction in 2009, the number of zzp'ers was growing spectacular and the topic was frequently discussed at meetings and parties. Everyone noticed the increasing number of zzp'ers and everyone knew someone working as a zzp'er. People were speculating about the motives of becoming a zzp'er: was it trendy, did it earn more money, was it the status of independent worker, was it because people had lost their job and could not find a new regular position or was it a devious attempt by employers to reduce their risk by replacing full contracts by temporarily hiring zzp'ers? Or could it have been our society's individualistic culture? The absence of hard facts preserved a good discussion, but prevented an increase in knowledge.

Curiosity about the exact causes and the identity of the zzp'er lead to a first explorative study. This study quickly revealed that zzp'ers were not only largely represented in the construction industry, but also in other sectors, with as clear outlier the professional services sector. The CBS (Statistics Netherlands) presents the following data in 2009.

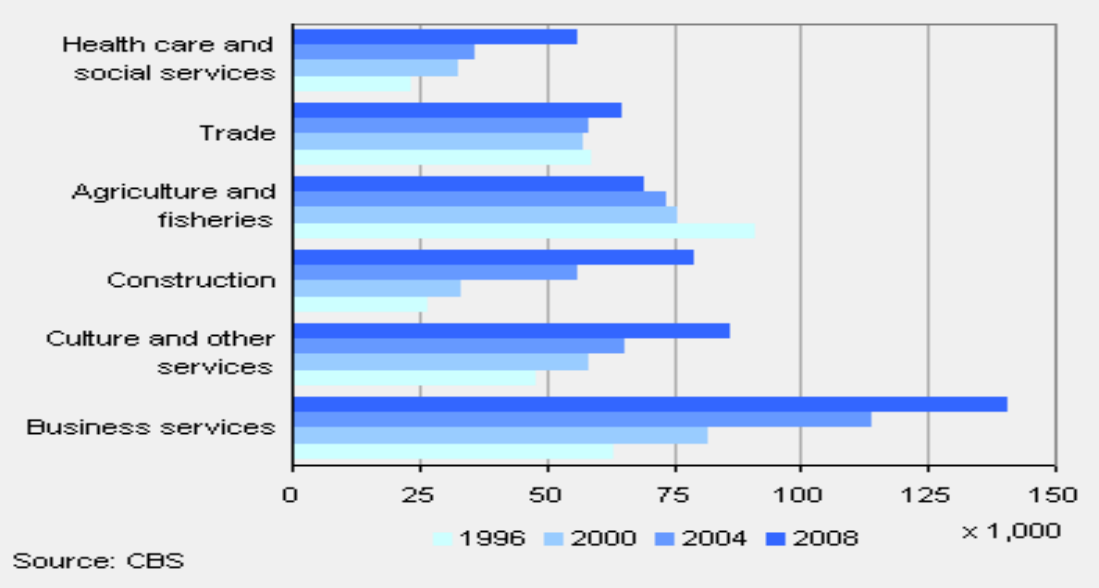

Figure 1: Self-employed without personnel in various sectors, CBS, sept. 2009

Remarkably the construction sector shows the highest growth rate in number of zzp'ers: a tripling since 1996. This growth rate is unknown to other branches and explains why the topic attracts this much attention in the construction industry.
Meanwhile a variety of studies on the zzp'er are published with telling titles such as *Van onbemind tot onmisbaar* (from unloved to indispensable) (EIM, 2007), and *De zzp'er lijkt ineens overal. Werken voor jezelf is ook een optie* (the zzp'er seems to be everywhere. Self-employment is an option, too) (CWI, 2008). In 2009, Arjan van den Born is the first in the Netherlands to get his PhD on the topic zzp: *the drivers of career success of the job hopping professional in the networked economy*.

At the end of December 2010 there are 704,000 zzp'ers in the Netherlands, an increase of 24,000 compared to the previous year (CBS, Dec. 2010). 704,000: that is around 10% of the labor force.
A certain aversion against working in large organizations, perceived as bureaucratic, seems to evolve (Van den Born, 2009). This is especially true for the younger generations, who think in terms of networks and cooperation without hierarchy (Boschma en Groen, 2007).

Everything points towards the zzp'er not as a passing phenomenon, but as the result of changing beliefs about organizing and labor relations.

Methodology
We decide upon a detailed exploration of the zzp'er and his working environment in general and the zzp'er at the construction site in particular (the construction-zzp'er) with at stake a qualitative exploration of the zzp'er and the context of his rise.

We perform the general exploration by means of a literature review. We choose a social-organizational perspective with the search terms: zzp'er, Human Resources Management and Labor relations and we use the expert network of the HU-professorship Cultural Change in the Construction Sector which encompasses among others Bouwend Nederland (Dutch Construction and Infrastructure Federation) and FNV/Zelfstandigenbond voor Bouw en Hout (labour union for zzp'ers in construction and carpentry) (around 12,000 construction-zzp members), and HRM-directors

In-depth interviews are conducted with 6 bouw-zzp'ers, 3 employers, 1 project leader, 1 team leader and 1 works preparation engineer. All interviewees are randomly selected out of the region Mid/West Netherlands.

We follow-up the interviews with a small survey among zzp'ers associated with the FNV/Zelfstandigenbond. Finally, we link our sample to an EIB research encompassing around 1800 respondents, which allows for generalization of certain parts of our research.

Literature research: Looking for the drivers behind the rise of the zzp'er
As to answer the questions who the construction zzp'ers are, what explains the increase of zzp'ers, and what in the construction industry makes that everybody seems to begin his own business, we start with looking of drivers on general societal level. Subsequently we focus on companies in the construction industry. As explained above we do will do this in a social organizational perspective.

The end of traditional labor relations?

When studying the literature on the rise of the zzp'er, we silently assume that work is being done in organizations and owner/manager and employee agree upon a labor relation. Legislation and branch specific regulations (collective agreement) apply, core to which are the employer offering labor and the employee offering his services; as well as the employer paying a wage for performed labor and the employee acknowledging the employer's authority.

Kluytmans (2010) points out that the employee does not have a free choice of co-workers. He has to align with the design and direction of the organization. Finally, an individual labor agreement determining working hours, free time, company car and other secondary or tertiary fringe benefits is drawn up at the company level. This is the traditional labor structure in the Netherlands.

The rise of the zzp'er appears to disrupt this pattern. Zzp'ers do not choose a labor contract, but a project-based contract. Conditions are fixed in a contract to accept labor or offer services; traditional labor legislation does not apply. From this perspective the zzp'er is an entrepreneur. The interpretation of the word zzp'er is diffuse, as it is not legally established, which induced different definitions and views on the zzp'er. We have chosen the definition provided by CBS Statistics Netherlands:

Self-employed without personnel (zzp'ers) are individuals who carry out work on their own account and at their own risk in their own business or practice or work in an independent professional setting without personnel.

There are more indications that the traditional labor relationships are on its way back. In the late 90s Hamaker, 1998) predicted the rise of the 'werkondernemer' (a contraction of employee and entrepreneur, roughly translated as working entrepreneur. In English I will use the word "Employneur"). In his book 'de kunst van zinvol werken' (the art of working meaningfully) he outlines a return to the pre-industrial era, when it was common to work at home as a self-employed professional. Hamaker introduces this new word "employneur" to stress that we can neither speak of an entrepreneur nor an employee, but something in between. This is exactly what we nowadays call a zzp'er.

His prediction has turned into reality. Increasingly more people market their competencies and (have to) use them as a starting-point to find new projects. The upcoming phenomenon of looking for work yourself is illustrated in newly published books such as 'het merk ik' (me – the brand) (Van Zwieten and Van de Grift, 2009),

The rise of ICT

Castells (2000, 2010) shows that the need for independency, and more broadly formulated the need for a new organization of labor and labor relationships, is strongly correlated with the rise of ICT. ICT allows labor to be time, place and distance independent. People can quickly exchange information online, worldwide and 24/7, which is why tasks can be performed at home, in train or car, in the office, anywhere abroad or wherever. There is no need for a place to go to every day on fixed times to perform your job.

In his PhD study Van den Born (2009) names ICT one of the structural drivers of the rise of the zzp'er. At first sight this development seems to be less relevant in the construction sector, but realizing how much administration and organization a zzp'er does with his mobile and

computer it is evident that even in industries largely relying on physical labor ICT influences its organization.

Cultural change: Individualization
Ever since the 60s of the 20th century Dutch people increasingly want to be seen and approached as an individual. The young baby-boomer growing up in the 60s wanted to realize himself, dismissing the background of the 'collective' 50s dominated by a 'rebuilding ideology'.
Development and self-realization, a humanistic psychology and new ideals such as equality, participation, having a say and democracy lay the foundations of an upcoming Ik-tijdperk (Me-era) (Van Galen, 1980). All supported by a strong economy and increasing welfare.

In the 80s a liberal range of thoughts replaced the dominant social thinking of the 60s/70s: the market as well as the free individual increasingly become the foundation of social and economic policy. The welfare state with its abundance of collective agreements is converted into a system of minimal facilities for the individual. Several studies by academic authors (Schnabel, 1999; Nagelkerke en De Nijs 2009, Mak, 2004, Felling, 2004) underline the big influence individualization has on many different aspects of life, such as ethics, religion, housing, working life, labour relations and trust.

Since the last decade we have been confronted with a new generation, grown up with the computer. They ask for new labor relations. Why go to the office, if you can do it at home? (Boschma en Groen, 2007)
The modern worker, employee or zzp'er, is critical. He uses social media for friendship and work, and organizes power on the internet. The network = power.
Today, managers in the office are confronted with many more workers, higher educated and they can rely less on authority as basis of power. They demand integrity, respect for their competence, co-creation, challenging tasks, and want to be part of a Hot Spot (Linda Gratton, 2010),
Meanwhile a variety of publications about 'new labor' and the 'new employee' appear.

Economical developments
For the last decennia Dutch economy, with exception of a few setbacks, has been flourishing and growing for almost every year. Good and well-organized relations between government, employers and employees certainly contributed to this consistent strong performance of Dutch economy. Good labor relations contribute to economical health.
The government played an active and stimulating role in the rise of the zzp'ers. These were psychological (growing the status of entrepreneurs) interventions, but also financial contributions and supporting tax regulations. ZZP'ers have been exempted from many of the normal employer's obligations.
Both the strong economy and the support by the government created a positive environment to start as a zzp'er

Why do organizations work with zzp'ers? Flexibilization and indivualization of labor relations on the organizational level
Anno 2010 a lot of labor organizations stopped functioning as some kind of 'plant' with standard hours, fixed work spots and collective agreements. Without much fuzz employees and other participants have adjusted collective agreements to individual wishes. In a study on collectivism versus individualism in labor relations, De Leede and Looise (2004) talk about a pragmatic method of designing decentralized and individualized labor relations. The use of a

wide range of different contracts and relationships became common practice. De Korte (2009) mentions fading organizational boundaries and the variety of individuals he interacts with.

Organizations have a stake in individualization. Their environment has become more dynamic, complex and competitive since the 80s and they need the individualization in order to successfully compete in this new context. Competition is not only located around the corner, the whole world is now their playing field.
To adjust to these development organizations had to thoroughly reorient. Core questions: what businesses do we do, does this fit our core competencies; what do we want to do ourselves and what do we want to outsource? The idea that an organization should conduct all activities itself was released and the new motto became: do what you do best.
Organizations started to reinvent themselves. Structures were flattened, processes more client-focused, departments and organizational levels dismantled and responsibilities decentralized.
Changes in the way of organizing had a large impact on staffing. Lifetime employment disappeared. Both the job and the employee could suddenly be sold off or contracted out, and internal job security was permanently at stake.
Human Resource Management (HRM) had to be reinvented as well. Inspiration was amongst others provided by Atkinson's (1984) model of the flexible firm. This model distinguishes employees according to their relative importance to the organization: in the center the core group, around that 2 layers of easily replaceable personnel. The outside layer contains groups with temporary contracts due to their specific expertise or flexibility. This approach provides the organization with the flexibility to adjust to economic cycles.
Flexibility became a key competitive advantage and Atkinson's model provided two different types: quantitative and qualitative flexibility. Quantitative flexibility means an in- or decreasing number of people, whilst qualitative flexibility stands for people able to perform more different tasks. An example would be the shelf-stacker who mans the counter during peak hours.

Atkinson's model implicitly breaks the equality principle that used to be at the foundation of HRM. This first shock in the system of labor relations opens the way to further differentiate personnel. Among others Schoemaker (1998) elaborates on this by identifying different types of labor in relation to management. Blue, silver, white and gold workers were born. Additionally, HRM instruments were reviewed or newly designed based on the idea of an employee's own responsibility for his career, facilitated by his employer. Investing in the employee made him more employable in the organization, increased organizational flexibility and strengthened the individual's position on the labor market .
In summary we argue that labor relations between employer and employee have become more flexible and individual. This has been caused by economic, technological and cultural developments. The philosophy of employees being all equal has been replaced by differentiation. Job security at one employer disappeared; at stake is job security through personal development. Life time employment has been replaced by life time employability.

Construction: a sector in change
The construction industry is changing significantly. This is not only caused by changes in society but also by the dynamics in the construction industry itself. In this context we can mention:

1) The need to conduct business in a transparent and integer way as a consequence of the findings of a Dutch Parliamentary Committee "Enquete commissie" especially installed to research fraud in the construction industry.
2) As criteria of sustainability have become more important in the Dutch society, also the construction industry will have to adjust into this direction.
3) Construction activities have more and more moved from the "meadows" to the inner cities. Where in the past 70% of construction work was taking place outside the cities nowadays 70% is being done in inner cities with significantly increasing complexity.
4) Renovation as percentage of all construction work is increasing and has already passed the 50% mark
5) Increasing and more complex legislation
6) The end user's demand to influence the product
7) On many construction sites productivity is below 50%
8) Cooperation both in the chain as well as on company level can improve significantly also by taking back fragmentation
9) Main construction companies are moving from "offering Capacity" to "offering products and concepts".

From this list possibly point number 8 is the most interesting for our research. Very significant division of labor anchored in a structure with contractors, sub-contractors and zzp'ers characterizes the construction industry. The leading business concept is that maximum division of labor is the most profitable.. Profitability is measured on the level of execution in numbers of meters… Taylor's Scientific Management is still well alive here.

This drastically division of labor has many negative consequences both on organizational as well as a human level although this seems not be known or to be dealt with in the industry. This is quite remarkable as a huge complain in the construction industry is that employees on the construction site are not involved. Also costs of failures are very high. There is not a common definition of cost of failure, but there is a general agreement that these costs include costs caused by failure in work coordination. It is also in the "genes" of the construction industry. Pries (2008) mentions the construction paradigm characterized by a typical engineer's philosophy; ration, analytical, control oriented, and 'what cannot be measured does not exist'.

In this culture people only exist as labor, which is a necessary means to deliver a product. In Taylor's thinking as well as in the construction paradigm mentioned above it is an advantage that people can be replaced easily. This decrease vulnerability in case of illness. However, this thinking also creates a self-fulfilling prophecy; As the human being is not important, he will not emotionally connect and because he does not do this, it is better not to count on him. The increased complexity and the very large fragmentation require the construction industry to renewal.. However, the construction industry's patterns and paradigms remain. They want change, but do not know how. (Pries, 2010)

It is in this context that the number of zzp'ers have been growing from 30'000 to 79'000 (2009) and a share in employment rate of 15%. The European Institute for the Construction Industry expects the speed of growth in number of zzp'ers to slow-down, but can continue to a level of 125'000 zzp'ers (Berkhout and Kok, 2010)

Research: What does the construction-zzp'er think himself?

Information out of the interviews

When we commenced our research in 2009 there was little hard data available on construction-zzp'ers. The goal of our interviews was gaining a clear picture of the zzp'er: core questions encompassed: what characterizes him as a person, including social context, what inspires him and how is it being a zzp'er?

The first step in our research was talking to the zzp'ers. Through a local soccer club we got in touch with six zzp'ers in the region mid-west Netherlands. Their occupations were painter, carpenter, tiler, handyman and bricklayer. We had a 2-hour conversation with each of them in their respective home situation. This lead, roughly categorized, to the following overview:

Name	**MvE**	**RvdrH**	**SdJ**	**PvM**	**MO**	**AR**
Age	36	42	37	38	47	31
Sex	M	M	M	M	M	M
Education	Mavo	LTS	LTS (geen dipl)	LTS	Mavo D	Mavo/MBO
Profession	Bricklayer	Painter	Tiler	Handyman	Painter	Carpenter
Zzp since	2006	2006	1996	2002	2002	2006
Marital stage	Married, child 9, 13	Married, child 12, 16	Married, child rond 7	Married,. 2 kids	Married, 2 kids	Married,. 5 kids

Figure 2: personal data interviewees

The overall picture is: the zzp'er is a married, male professional with a working wife and children attending school, aged about 40 with a low to average education. He started as zzp'er between the age of 30 and 40. Although no interviewee gets warm feelings for IT, they all make extensive use of their mobile/smart phone. Furthermore they are and have to be entrepreneurial, but do not want their own business. They deliberately have chosen to be a zzp'er.

Motives: why becoming a zzp'er?

MvE	*They said he had the competences for teamleader, but he didn't get the job. It's not because of you, they said. But still it is a disappointment..* *It characterizes M. he gave his career another direction. He decided – with full agreement of his wife – to start as a zzp'er*
RvdrH	*Together – R & wife - they made up their minds. My wife has a stable income, and I am able to run my own business. I start as zzp'er Just like his friends always advised him. Now I can combine work and private life better.*
SdJ	*My father died when I was 24. My mother, brother and I took over the business. We divided the tasks; working as a tiler was the best for me.*
PvM	*The work became boring monotonuous, and as a zzp'er there is more alignment between work and private life..*
MO	*The pressure to work faster grew and grew. And the qualitiy of work lowered and lowered .On top of that I hardly spoke my boss. For him I was a figure. He was always on the run, or just giving orders. I didn't want to work that way any longer. I wanted to give the customer a better quality, and to work in a more rewarding environment.*
AR	*It's a boys dream. I didn't want to speak it out loud, but there was always the hope to run my own business.*

Figure 3: motives

All interviewees started their career as an employee. They mastered their profession at one or more employers, but somewhere between the age of 30 and 40 they could not realize their full (growth) potential at their respective employers.
A second important motive seems to be the inability to combine a full-time contract with their family life, where wife and kids increasingly require more flexibility.

What inspires the zzp'er, gives him satisfaction?

MvE	*The most important is the project; getting things done. Maybe that's the main difference with an employee. An employee stops when the clocks strikes four.* *M. is ambitious in a positive way. He wants to be more than just an employee, working for a boss, waiting for another day with the same job*
RvdrH	*The freedom. To manage your own life; to decide yourself when private or work things come first. That;s the best of being a zzp'er.* *The acquiring of work is fun. (….) and it gives me a good feeling when I am asked to give an advice*
SdJ	*My satisfaction in being a zzp;'er is most of all being my own boss, and being able to decide when and how I am doing my project.*
PvM	*He loved to work hard, and to learn on the job. So he had different professions and different employers in different branches. He learned by doing, he was a real self made*
MO	*To work in line with your needs, and to get recognition form your customers. That's most emportant..*
AR	*(…) the variety in work(...)t the responisbilty. .It is my job, and if I do well, than it is by me. If it's wrong, it is because of me Freedom is important, although freedom is relative. You have to work, but as a zzp'er you can manage it yourself.*

Figure 4: inspiration and satisfaction

The key answer to what inspires the interviewees circles around aspects such as attention, appreciation, recognition and development/growth. Zzp'ers get it from the private persons, Large construction projects lack these aspects and turn employees into numbers.
Money does not seem to be a driving factor and is only mentioned when asked.. It is appreciated to earn a nice salary, but the work is hard. Zzp'ers work 24/7, also on Saturdays; life has not become easier. However, being able to choose what projects to accept, and how and when to do them makes up for all of the disadvantages.

How does the zzp'er acquire jobs?
There is unanimity among zzp'ers on how to get work: quality sells itself. It might take several additional hours of work, but it is still cheaper than advertising. Your name will be mentioned at birthday parties; mouth-to-mouth will do the work. Additionally zzp'ers work with flyers, which offer their services: one of the painters used this to gain publicity whenever he started working in a new neighborhood.
However, the general line of thought is that acquisition is not needed. Mouth-of-mouth advertisement will gain us new clients.
A few of the interviewees indicated they operate in a network of zzp'ers, passing work on. These networks consist of friends who exactly know each other's strengths and weaknesses and trust each other. Together a network can do larger projects, such as the renovation of an old farm. The competitive force of such a network is large and can be a threat to small construction firms due to their lack of overhead costs.

Overall picture
The interviewed zzp'ers became all frustrated in their jobs and companies around the age of 30. A start as zzp'er offers a great solution because of the possibility (and necessity) to be entrepreneurial. On top of that, they get appreciation and recognition for their professional skills from private persons, who act as their new principals; and there is room for a personal opinion and creativity.

Information out of the FNV/Zelfstandigenbond survey
The survey contained questions similar to the interviews conducted by ourselves. We used a large sample to generalize findings to construction and carpentry. As the overall response rate was too low, we also used EIB data (Berkhout and Kok, 2010) on zzp'ers in construction to ensure the representativeness of our data.
We first discuss the FNV/ZBO survey data to sharpen our picture of the zzp'er and will get back to the EIB research later.

Personal characteristics
Again we see the zzp'er is a man; his average age is 43, he has primary to secondary (professional) education, and his average tenure as a zzp'er is 5.5 year.

But what characterizes him further? Along the career anchors by Schein (1977) the respondents indicated to what extent the aspects entrepreneurship, security, craftsmanship, independence and leadership marks their personality.
Their answers show that security least represents their personality. Entrepreneurship, craftsmanship and independence characterize the true zzp'er.

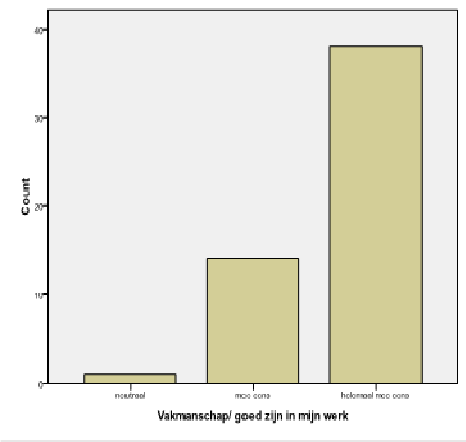

Figure 5: Craftsmanship

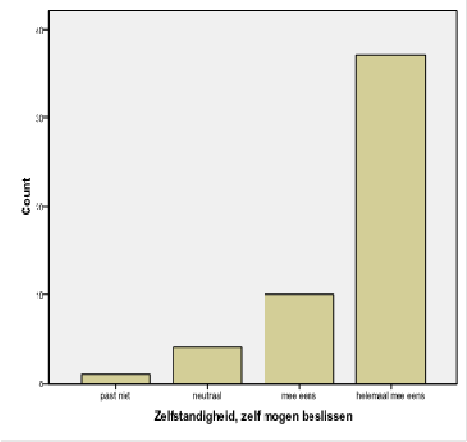

Figure 6: independence

A large majority answers they agree or fully agree to the proposition: I prefer to work alone. This does not allow us to conclude that zzp'ers are soloists, but does allow to conclude that there is a large chance on solo behavior in their work. When asked who they prefer to cooperate with, over 80% indicates to prefer to work with other zzp'ers.

Motives to become a zzp'er

The interview round taught us that money is only mentioned when asked for and is of secondary importance. Money is no decisive criterion, but who does not want to be better off? One does not become zzp'er to be worse off.

The survey indicates that more than half of the respondents mark the opportunity to earn more as a motive. Is this in line with the interview results? We do not see a fundamental difference. We do think we can add to our analysis that money is an important motive for zzp'ers in the age of 20-30.

	Responses		
Motives to become a zzp'er	N	Percent	Percent of cases
I can earn more money	28	18.8%	52.8%
I can align work and private life better	22	14.8%	41.5%
I became unemployed	10	6.7%	18.9%
I prefer to be my own boss	22	14.8%	41.5%
I had not enough freedom in the organization	7	4.7%	13.2%
I get more appraisal and recognition	27	18.1%	50.9%
I needed the adventure	26	17.4%	49.1%
Miscellaneous	7	4.7%	13.2%
Total	149	100%	281.1%

Figure 7: motives

Of all respondents, 50.9% mentions appreciation and recognition as zzp'er as a motive. This is in line with our interview round. Especially in large construction companies employees feel treated as a number in the organization. Contact is impersonal and whether A or B does the task is indifferent to the organization, as long as it is performed. Personal appreciation and recognition for the delivered achievement is missing.

Here, the interviews indicate that the customers of zzp'ers (private persons) score well. They show appreciation and recognition.

Finally, 49.1% says to seek adventure. An answer that suits entrepreneurship and independence and is confirmed by the fact that over 40% prefers not to serve under a boss.

Main concern

The last question in the survey considered the zzp'ers main concerns. The high response on maintaining sufficient work reflects the economic downturn, which greatly reduced employment in the construction sector.

Remarkable is also the high score on the ability to '*maintain physical health.*

	Responses		
My main concern is	N	Percent	Percent of cases
Will there be work enough in future?	30	35.7%	65.2%
How do I realise time for myself?	15	17.9%	32.6%
Will my craftmanship meet future requirements?	5	6.0%	10.9%
Will my physical condition stay steady in future?	25	29.8%	54.3%
Does being a zzp'er fit with my personality?	1	1.2%	2.2%

My administration	8	9.5%	17.4%
Total	84	100%	182.6%

Figure 8: Main concern

Additional data
Over 70% of the respondents work for private persons most of the time. Acquiring jobs: 65% is asked, nearly 30% actively searches and only 6% offers his services through mediating organizations.

Information out of EIB research
The focus of our own research was largely on the identity of the zzp'er, his inspiration and realization of his goals, which is more specific than the EIB research. However, the similarity in the survey sample on hard aspects such as age and education allows us to exchange data between the two studies.
From the EIB/Kok and Berkhout research we take the information that the average bouw-zzp'er is a 44 year old male with an average gross annual income of €42,000 (2007). He works a lot more (2175 hours per year) than his colleagues employed at a construction company. Over 80% of the zzp'ers followed primary to secondary (professional) education.
Zzp'ers are professional; at the average age of 35 they (83%) ended their payroll agreement and started as zzp'er. 80% works for private persons and for over 50% private persons are the most important principals. There they earn 1 euro per hour extra (compared to earnings at construction companies)

Kok en Berkhout indicate that experts in the construction industry cannot unanimously explain what caused the sudden growth in the number of zzp'ers. The main motive for the main contractors seems to be the increased flexibility. This limits the financial risks.
Summarized they conclude: the abolition of the 'Vestigingswet' combined with economic prosperity and greater flexibility at employers as the most important drivers of the rise of the bouw-zzp'er.
Derived from the EIB-study, we would like to mention a number of other drivers that are important in the context of this paper:

- Advancing IT offers opportunities for small sized companies.
- Not all employees value collective agreements and perceive these as obligations they do not have as zzp'ers.
- There is a need for modern labor relations with flexible working hours and part time jobs. Fixed hours are an obstruction and independence is a solution.
- People long for freedom: organizations with increasing bureaucracy and management layers create feelings of restriction.
- More skilled craftsmen can earn more as zzp'er than on payroll.

The employer and the rise of the zzp'er
Bouwend Nederland, the employer's association in the construction sector, acknowledges the rise of the zzp'er and the need to create a vision on this phenomenon. The zzp'er is irreplaceable in the flexible layer organizations required for continuity of their business (Bouwend Nederland, framework 2011-2013).
A vision on how to deal with this phenomenon has not yet been developed.
To the contrary, one of the largest construction companies in the Netherlands does have a clear vision, represented in a recent interview: *the zzp'er allows a company to align with the*

state of the economy. There is no fear of problems in times of tight labor market. *Technology can assist us and we can always make use of foreign employees. However, there is a discrepancy between Lean working, which largely requires commitment and brains and the use of zzp'ers who are more difficult to influence by the organization.*

Conclusions and discussion

Starting point of this paper was the rise of the construction zzp'er. Leading questions were: who is the construction zzp'er, what are his motives and how does he realize these? We were also interested in finding out the motives of construction companies to work with zzp'ers. Finally we put the question why so many people in the construction industry choose to be a professional zzp'er.

In general

The literature study shows that the rise of the zzp'er fits into the pattern of increasing individualization of Dutch society. Autonomy and freedom become more important
Entrepreneurship is stimulated and ICT developments technically facilitate this process.
From an organizational point of view zzp'ers limit financial risks caused by a decrease in demand. It also meets the desire for customization in labor relations.

.

Zzp'er profile

A zzp'er is a hard working professional with a lower to secondary education, having an average age of 44, is a former employee and has a desire to run his own small business. It is important to him to be able to ake his own decisions en he is proud of his craftsmanship. He slightly prefers individual jobs and if necessary he prefers to collaborate with other zzp'ers. From the interviews we learn that his partner has an own income, which makes it easier to decide to change to zzp'er.

Motives and satisfaction

People move to become a zzp'er on average at age 35. By that time he has developed himself, in the construction industry, as an all round professional. He has no opportunities to further develop professionally unless moving to leadership positions. As a zzp'er he creates significant personal growth opportunities.
The zzp'ers motives tell us a lot, directly and indirectly, about working at a construction company:
He lacks attention and recognitions as well as growth opportunities in construction companies
He lacks independency
He lacks room for creativity and influence

From his choice to work for private persons it becomes clear that he believes that this is a better place to work, despite they make only 1 Euro more per hour.

The construction company and zzp'ers

Construction companies basically work with zzp'ers to limit their financial risks. From literature and interviews with employers we learn that the human being is seen as cost, afterthought in the entire design process, labor.
The social psychological nature of human mankind is disregarded by the construction industry. This is characterized by the keywords: world of engineers, rational, analytical, hierarchical and control.

From the zzp'ers and literature studies we learn that construction business has far too little attention for the needs of human beings. The building business and zzp'ers think differently.

ZZP'ers	Construction company
Freedom and autonomy	control
Anti hierarchy/networking	pyramidal organization
Thinking and doing together	strict separation of thinking and doing
Collaboration based on friendship	forced collaboration

(Major) construction companies should ask themselves whether they want present developments to continue with more all round professionals leaving or retain their people for which investments in a better place to work are required.

Discussion:
It seems that companies break into networks, the zzp'er being the smallest element of the network. Working in projects is the favorite working method. But, is that a sustainable way of organizing? What are the drivers for collaboration, for friendship and teamwork?

THE INEVITABLE AND CONTINUING GROWTH OF REGULATIONS FOR PLANNING AND BUILDING

Abstract
This paper aims at answering the question: How can we explain the evidently unstoppable growth of regulations for planning and building? The answer to this question is of relevance, since we have been (and still are) confronted with the negative consequences of an overly complex and comprehensive legal framework for planning and building. This does not only apply to the Netherlands but to many (if not all) other countries as well.
This paper shows that a variety of factors is responsible for the ever growing complex of rules for planning and building. Important reasons for growth of regulations are: (1) the liberal interpretation of the principle of legality, (2) the rise of the welfare state, (3) the failure to deregulate and (4) the law of increasing complexity.
The prospects of limiting or reversing the growth of regulations are bad. According complexity theory any addition to the system will make it more complex and instable. This will eventually lead to a collapse of the system. Only once that has happened, a new and less complex system may be established.

Keywords: regulations, legislation, deregulation, complexity theory, legality principle.

INTRODUCTION

Traditionally, governments have felt the need to regulate *land-use*. The (local) government wants to determine the purpose for which a certain piece of land can be used, with examples including agriculture, housing, streets, public green spaces, industry or flood defence. Likewise, the government also wants to exercise its influence on *building plans*, which apply to, for example, permitted building height, structural safety and fire safety of buildings, aesthetic appearance and building physics features (daylight access, ventilation, heat regulation, and moisture and noise reduction). The motivation for regulations surrounding land use and building plans were, and still remain, grounded in the public interest.

In the course of the decades, this regulatory framework started to grow and continued to grow. In recent years, the growth of the regulations more and more is seen as a problem. The problems typically relates to matters such as:

- regulations contradict each other;
- regulations are too complex for private building initiators;

- regulations are too complex for governmental bodies as well;
- the abundance of regulations causes unnecessary bureaucratic delays;
- regulations require overly detailed and costly research reports (regarding for instance archaeology, energy performances, nature compensation) from building initiators.

At the same time, initiatives to cut regulations (deregulation) seem to be of limited success. In that context, the research question of this paper is: *How can we explain the evidently unstoppable growth of regulations for planning and building?* Even if we know that the size and complexity of the regulatory framework for planning and building has negative consequences, its growth seems unstoppable. Which forces are at work here? The method of literature review will be used to answer these questions.

HISTORIC GROWTH OF REGULATIONS: EXAMPLE OF THE NETHERLANDS

Historically, building regulations in the sense of legal instructions have existed in the Netherlands for a long time. In fact, they have been around since the first cities were established in the Low Countries around the year 1200. Kocken recently wrote an interesting monograph about the first period of Town Planning Law (Kocken, 2004). It is amazing how wide-ranging the motivation was for the regulation of the city, even in the Middle Ages. Kocken (2004: 69) lists such motives as:

- the defence of the local community;
- the fire safety of the buildings;
- the structural reliability of the buildings;
- the concern for the appearance of city and land (building aesthetics);
- the provision of necessary living space (making land available for building);
- residential protection (i.e. protection against trouble resulting from the building activities of neighbours);
- traffic safety considerations.

Many of these regulations are staggeringly topical; they are just as relevant today as they were then. To give a concrete example in relation to the *public thoroughfare*: in 1413, awnings in Amsterdam could be no more than 7/4 ell wide and had to be at least 8 feet above the ground (Kocken, 2004: 172).

In modern times, the *1901 Housing Act* (Dutch: Woningwet) provided the impetus for the preparation of urban development plans that had legal significance. This Act contained a regulation relating to the 'expansion of built-up areas'. The Municipal Council was given the authority to prohibit the construction of buildings on land that was intended for a street, canal or square. The plans to set aside public spaces sought to prevent poor living conditions. For councils with more than 10,000 inhabitants or a strong growth it was compulsory to adopt an *expansion plan*, in which land was designated that would be used for streets, canals and squares in the near future. Expansion plans could be combined with a building ban. Bregman labels this a case of a legally binding regulation for particular types of (infrastructural) works (Bregman, 2001: 34).

An important amendment to the Housing Act came in 1921, when the expansion plan was no longer limited to streets, canals and squares. The scope of action expanded into a plan

'whereby the use in the near future of land included in the plan is allocated.' From that moment, the expansion plan could regulate the nature and location of permitted structures (Van Buuren et al., 2006:14). This expansion plan was, in fact, the predecessor of the current land-use plan.

Another important aspect of the 1921 amendment concerned the building permit. Conflict with the expansion plan became compulsory grounds for the rejection of a building permit application (Bregman, 2001: 35). The connection between the building permit and the statutory urban development plan that was established then still exists today. (The 'statutory urban development plan' refers to the urban design in its statutory form. Based on the 1901 Housing Act, this is an expansion plan; based on the Spatial Planning Act, this includes the land-use plan.)

Since the 1901 Housing Act took effect, the expansion plans had been regulated in a paragraph concerning urban planning. In 1962, an Act was drawn up exclusively for statutory development plans: the *Spatial Planning Act* (Dutch: Wet op de Ruimtelijke Ordening). This act introduced the local *land-use plan* as the successor of the expansion plan. Since then, the Spatial Planning Act has been changed on several occasions, but the core has always been the power of the Municipal Council to adopt a land-use plan.

Nowadays the Constitution (article 21 of the Constitution of the Kingdom of the Netherlands 2002) refers to planning tasks of government:

> *It shall be the concern of the authorities to keep the country habitable and to protect and improve the environment.*

The *conclusion* of this very brief historical exploration is that (spatial) planning has always gone hand in hand with rules and regulations. Furthermore, since the first cities were established, regulations regarding planning and building started growing. I used the example of the Netherlands, but other countries have gone trough a similar process of growth of regulations.

Planning & building on the one side and law on the other side turn out to be inseparable phenomena. In the next chapters of this paper their relationship will be further explored.

THE ORIGINS OF REGULATORY POWERS: THE PRINCIPLE OF LEGALITY

With regard to existing land-use, landowners as a rule already concur with the public interest, as specified (in a plan) by the (local) government. Should existing land-use not be in accordance with such a plan, many landowners are prepared to adapt the land-use voluntarily, with or without financial help from the government. The same applies to building plans. Initiators are usually willing to comply with the building regulations proposed by the government of their own accord.

However, it is also possible that the current use of land is not in agreement with what the government considers to be in the public interest, and landowners may have no intention of changing their plans. Furthermore, it is also possible that the initiators of building plans (building planners) do not intend to comply of their own accord with building regulations concerning, for example, the aesthetic appearance of a building.

The government would be fairly powerless to implement its plans and regulations if they were solely dependant on the voluntary compliance of citizens and companies. Public interest, which after all constitutes the foundation of regulation, would be poorly served as a consequence. Private interests, in the case of landowners and initiators of building plans, could then thwart the public interest. To prevent this, the government must be able to require compliance from citizens and companies, which it cannot do without good cause. Landowners and initiators of building plans cannot be forced to comply with governmental plans and building regulations just like that. This is interrelated with the operation of a crucial cornerstone within a constitutional state: the *principle of legality.* The principle of legality is also known as 'the rule of law'.

This principle holds that the government is only authorised to intervene in and determine limitations on the freedom and property of its citizens on the basis of statutory power (P. de Haan et al., 2001:21). Without such a statutory basis it is not allowed for government to determine limitations on freedom and property. When applied to land use and building plans, this principle signifies the following: we cannot prohibit an individual or organisation from building on or using their land as they see fit, unless a democratically ratified act is in place that regulates the issue. The principle of legality, therefore, relates to the *powers* of public bodies (Michiels, 2006: 10).

The principle of legality expresses two core values: (1) universal equality before the law, which means that the law applies equally to everyone, and (2) legal certainty, which means that the powers of public bodies are predetermined (Boon et al., 2005:4).

Currently, the principle of legality is interpreted liberally in the Netherlands. The belief is that government action *in general* must be founded on statutory power. This, therefore, includes not only actions of a restrictive, authoritative or prohibitive nature, but also actions of a favourable nature, such as the granting of benefits or subsidies. This results in a growing number of laws and other regulations (Herweijer et al., 2005:12). This also applies to the realm of spatial planning.

Following on from the principle of legality, there are acts in a constitutional state that regulate 'land-use' and 'building regulations.' In this case, there are acts that give the government the authority to terminate land use that is in conflict with the governmental plan. Likewise, acts are in place that authorise the government to require initiators of building plans to obtain a permit before commencing with construction. Should the building plan fail to satisfy the building regulations, the permit will be denied. In point of fact, the principle of legality contains the rationale behind the many laws concerning planning and construction. Without such statutory foundations, the government is not authorised to require compliance from its citizens, organisations and companies.

We can draw as a *conclusion* that the use of the principle of legality and especially the liberal interpretation of the principle of legality is one of the factors responsible for the enormous growth of regulations.

THE RISE OF THE WELFARE STATE: PROACTIVE LEGISLATION

Powers in the field of spatial planning and building, which are attributed to the government by law, fall into two categories: reactive powers and proactive powers. The difference made here between reactive and proactive powers is inspired by the distinction Buijs made between two basic functions of spatial planning: the regulatory function of planning (reactive) and the development function of planning (proactive) (Buijs, 2000).

Reactive powers

Reactive powers are powers with which the government reacts to private sector development initiatives, which generally mean building activities. The government reacts to development initiatives from individual citizens, companies or organisations. The key reactive governmental power is based on the Environmental Licensing (General Provisions) Act (Dutch: Wet algemene bepalingen omgevingsrecht) and requires initiators of building plans to be in possession of an environmental permit. The government makes a preventive assessment of private sector development initiatives. Private parties require governmental *permission* before the initiative can be carried out. Permission is only granted after certain predetermined criteria have been satisfied. These criteria make up the assessment framework.

Proactive powers

Proactive powers are powers that enable the government to take development initiatives, which may concern urban expansion, infrastructure construction, land development and hydraulic engineering works, for example, but also the development of a buffer zone. This type of development always requires a certain form of control over the use of land. Sometimes the government already owns the land, which negates the need to arrange for control.

However, the land is often owned by someone other than the government, necessitating that it gains some form of control. Sometimes 'absolute' governmental control of land is necessary in connection with intended developments, such as the construction of new roads. In this case, the government can *purchase* the land under private law. Land can also be acquired by exercising what are known as *pre-emption rights* (Dutch: voorkeursrecht), which are based on the Municipal Pre-Emption Rights Act (Dutch: Wet voorkeursrecht gemeenten). This gives the municipality the right to be the first to enter into negotiations with a seller who intends to sell land and buildings. A forced means of acquiring land is via *expropriation* on the basis of the Expropriation Act (Dutch: Onteigeningswet).

In most cases, absolute governmental control of land (ownership) is not necessary to achieve planning objectives. The government can limit itself to stipulating to the landowner what the land can be used for, in combination with issuing building regulations applicable to that land (such as maximum building heights). This is done in a *land-use plan*. The municipality's power to determine land-use plans in their territory is laid down in article 3.1 of the 2006 Spatial Planning Act. More accurately, the municipality not only has the power, but is obligated to do so. It is easy to see that land-use plans can significantly influence the financial and economic value of property by allowing or denying development possibilities. The municipality's authority to determine land use by means of a land-use plan therefore comes with the duty of the Municipal Executive to award (on request) damages to parties that have suffered financial losses in specific cases. This falls under *the right to compensation* (Dutch: tegemoetkoming in schade).

After the Second World War the *welfare state* came to a rise. In the welfare state, the state plays the primary role in the protection and promotion of the economic and social well-being of its citizens. In the welfare state, the state actively seeks to promote public goals. Thereby, the welfare state has led to a strong growth in the field of 'proactive' legislation.

PUBLIC LAW AND PRIVATE LAW PLANNING INSTRUMENTS

The discussion of the growth of regulations for planning and building cannot be limited to *public law* regulation. To get a full grip on government's steering of planning and building, we should include government's use of *private law* instruments.

The law that is mostly relevant to planning and development can roughly be divided into two parts: public law and private law. Public law and private law differ from each other regarding the topics that are regulated, the way of enforcement and the interests that are served and protected.

Public law is that part of the legal system that regulates the structure of the state and the relationship between the state and individuals (citizens, companies). This includes constitutional law and administrative law. Examples of public law acts in the field of urban planning and development are: the Spatial Planning Act (Dutch: Wet ruimtelijke ordening), the Environmental Licensing [General Provisions] Act (Dutch: Wet algemene bepalingen omgevingsrecht) and the Expropriation Act (Dutch: Onteigeningswet). Many of the public law acts relate to the powers of government towards citizens.

Private law is that part of the legal system that involves relationships between individuals, without direct involvement of the state. This includes the law of contracts, property law and family law. Examples of private law in the field of planning and development are: the Civil Code (Dutch: Burgerlijk Wetboek) and public-private partnership agreements.

We can simplify the differences between public law and private law as follows: public law focuses on the state itself and of issues that affect the general public. Private law focuses on issues affecting private individuals and corporations, without direct involvement of the state.

Governmental bodies, for instance municipalities, can make use of private law. For example: a municipality commissions a contractor to build a new city hall. In this example the municipality concludes a contract. In this case the municipality acts just like a private person would: concluding a contract with a contractor. The contract between municipality and contractor therefore falls under private law.

The description of public law and private law shows the differences in the topics that are regulated and differences in the interests that are served and protected. Further, both parts of law differ in the way of enforcement. In private law, enforcement is in the hands of the interested parties themselves. If necessary for enforcement, or if the law says so, the help of certain bodies – for instance the judge – can or must be called in. If, for instance, a contract is not properly executed, the injured party may call in the judge to force correct implementation of the contract.

In public law, however, government lays down a set of (general or specific) standards. Government then is the only party that has the power to change the standards and – if the

standards are not observed – the power to enforce them. The justification of laying down standards by government and enforcement of standards usually lies in the fact that government must look after the public interest. By example, suppose a permit is granted by the municipal executive to a company in order to build a new office. If the conditions to the permit are not observed, only the municipal executive has the power to withdraw the permit.

Public law planning instruments

Dutch municipalities, as said, have the most important powers in Dutch spatial planning. Seen from the viewpoint of statutory law (and in practice) national and provincial governments have less power than municipalities. Municipalities have control of many *public law* instruments for spatial planning and development. The powers relate to both development *projects* and spatial *plans*.

Private law planning instruments

Apart from public law instruments, government – particularly municipalities – may also use *private law* planning instruments. For example, municipalities have the power to purchase land, on which 'private objectives' are planned, such as residential areas or office areas. Municipalities can buy undeveloped land, prepare it for construction and then sell it to developers. The developers, subsequently, realise the houses and offices. In this way, municipalities can make substantial profits. Furthermore, Dutch municipalities are allowed to participate in public-private partnerships by which market risks are carried by government. In the Netherlands, public-private partnerships in the form of a legal entity in which (financial) risks are shared between the public and the private parties, are legally allowed and commonly used. This demonstrates that the Netherlands, unlike Anglo-Saxon countries, does not follow the principle of a strict division between the public and private domains. With that is meant here that in the Netherlands local government in principle can act as a market party. Municipalities can, as it were, act outside the public domain and inside the private domain.

COMPLAINTS OF OVER-REGULATION AND ATTEMPTS TO DEREGULATE

For many years, different parties in planning and construction in the Netherlands (particularly developers, designers and contractors) have expressed their discontent about the number of permits required to build and the complexity of the permit assessment framework. To draw attention to their problem, regular actions are held: hand trucks filled with building regulations are literally put on stage in the presence of an outraged public. The complainants do have a point – building regulations are extensive and quite complex. Various governments have made deregulation of the planning and building regulations into policy objective, which has been successful in several areas. The introduction of the environmental permit in 2010 has – in any case for developers/applicants – brought a major simplification.

The new environmental permit replaces around 25 previously existing permits. This one permit holds permission for demolition, as well as building, renovation, causing environmental nuisance (for instance noise, bad smell, air pollution) and other activities. The former situation, in which an applicant needed to collect all kinds of different permits, has come to an end. The former permits that have been replaced by the environmental permit include, amongst others, the building permit (Dutch: bouwvergunning), the environmental permit of the Environmental Management Act, the demolition permit, the construction permit

(Dutch: aanlegvergunning), the felling license (Dutch: kapvergunning) and the monuments permit. All these permits do not exist anymore. They are replaced by the single environmental permit as regulated in the Environmental Licensing (General Provisions) Act. However, not all previously existing permits have been replaced by the environmental permit. Some separate permits still exist, for instance for projects in nature conservation areas.

The single environmental permit can be seen as a successful example of deregulation. However, given the enormous amount of regulations in the field of planning and building, it can merely be considered to be a relatively small success. At the same time it appears that our highly developed, complex and demanding society continually sets new and even stricter requirements. These are then laid down in regulations. Deregulation is difficult, because 'behind' every rule there is an interest and, most likely, a special interest group to 'protect' this interest. Complaints from an overly regulated planning and construction will, therefore, continue to exist.

GROWTH OF THE REGULATORY SYSTEM AS A RESULT OF THE LAW OF INCREASING COMPLEXITY

Another explanation for the growth of regulations can be found in 'complexity theory'. My summary of this theory is based on the discussion of complexity by Janssen (2010). Janssen refers to W. Brian Arthur. Arthur explained (Arthur, 1993) that every system is subject to 'the law of increasing complexity'. This also goes for legal systems. Every system has the inclination to connect to its surroundings. New functions are added to the system and adjustments are made to the system, in order to push out frontiers or to cope with changing conditions. Thus, new elements are added to the system, in order to improve it. This results in extension of the legal system and further refinement (Demeersseman, 2011).

At a certain point in time, new additions only complicate the system and do not have any more added value. Under those circumstances, usually radical attempts are made to 'save' the system. However, chances are that this will not succeed and people lose their trust in the system. This may eventually lead to a collapse of the system (Arthur, 1993). In that case the legal system would become unmanageable. A legal problem than has more and more aspects, solutions will require more and more intermediate steps (Demeersseman, 2011). The legal system would be trapped in its own size and complexity. This would severely affect the implementation of planning policies and building projects.

My assessment is that - in the Netherlands - we have not (yet) reached the point of collapse of the legal system for planning and building. Indeed, radical attempts are made to save the system. An example can be found in the Dutch Crisis and Recovery Act (Dutch: Crisis- en herstelwet). This act aims at reducing complexity and shortening of procedures for new large infrastructure and major urban developments. However, by adding new instruments, it further complicates the system.

CONCLUSION

This paper aims at answering the question: *How can we explain the evidently unstoppable growth of regulations for planning and building?* The answer to this question is of relevance, since we have been (and still are) confronted with the negative consequences of an overly

complex and comprehensive legal framework for planning and building. This does not only apply to the Netherlands but to many (if not all) other countries as well.

The analysis in this paper shows there a multiple explanations:

- The use of the principle of legality and especially the liberal interpretation of the principle of legality is one of the factors responsible for the enormous growth of regulations.
- The rise of the welfare state has led to a strong growth in the field of 'proactive' legislation. In the welfare state, the state actively pursues goals in the public interest. The legitimisation of the powers to do so, requires legislation.
- Deregulation is proven to be difficult, because 'behind' every rule there is an interest and, most likely, a special interest group to 'protect' this interest. Deregulation requires that legislators in parliament will have to 'hurt' these special interests. Doing so is, in essence, opposite to nature of politicians since it may cause the loss of voters.
- The legal system is, just like every system, subject to 'the law of increasing complexity'. There is no escape from this law. Only after the collapse of a system, a new and less complex system may be established.

It may be argued that at this moment in the Netherlands radical attempts are made 'to save the system'. However, according complexity theory this type of attempts eventually will not solve the problems, since every new attempt further complicates and thereby destabilised the system. If that is true, we are close to the collapse of the legal system for planning and development and a new and less complex system can be established.

Abstract
The Malaysian Construction Industry Master Plan (CIMP 2006-2015) identified the innovative approaches of Industrialised Building Systems (IBS) and its supply chains as having important roles in improving the productivity and quality of construction processes. However, the fragmented scenario in the construction industry leaves the IBS supply chain players with noticeable difficulties in terms of competitiveness and efficiency. Supply chains in IBS involve relationships between many organisations and processes, with the evolution of many specialised roles and embedded relationships. The procurement method is utilised as a mediator tool and as the means of controlling integration between players. Although efforts have been undertaken to enhance the IBS practice in Malaysia, various integration challenges have risen from amongst the IBS players. The purpose of the research is to identify the challenges of IBS supply chain integration with regard to existing project procurements. The methodologies involved a thorough review of literature and the qualitative method of using semi-structured interviews which were conducted amongst IBS contractors in Malaysia. The findings reveal role and responsibility, understanding the knowledge, risk liability, financial and contract matters and attitude and relationship are the challenge factors that hinder the successful integration between the contractor and other related parties. Such issues require much attention in pursuance of greater integration within the supply chains in the Malaysian construction project.

Keywords: Industrialised Building System, Integration, Malaysia, Procurement, Supply Chain

INTRODUCTION

The construction industry has commonly been plagued by fragmentation issues. These issues are attributed to the fact that the industry is made up of separate parties from diverse

professions that operate by their own rules. An analysis of the key characteristics of the construction industry indicates that the problems facing construction can be categorised into five broad areas (Morledge et al. 2009) which are: fragmentation, adversarial relationships, project uniqueness, separation of design and production and competitive tendering. In addition, weaknesses are caused by the increase in organisational complexity and contractual adversity which influence the efficiency and effectiveness of construction project teams (Dulaimi et al. 2001). Its complexity has been deemed to be very disintegrated and a more integrated approach to supply chain has been identified as a solution to various problems (Vrijhoef and Ridder, 2007).

Thus, in today's increasingly globalised economy, managing the entire supply chain has become vital to the successful completion of a construction project. Competitive global markets which result in increasing supply chain integration make it imperative for the construction industry to change, so that improvements are made to the relatively disconnected and fragmented construction supply chain. The strategy to manage economic demand through construction will be more effective when projects are implemented innovatively and speedily. Furthermore, for Malaysia to be a productive and high-income nation, Malaysians must be globally competent and competitive. This necessitates the Malaysian government to embark on rigorous initiatives and adopt the Industrialised Building System (IBS) as an innovative approach.

As a consequence, the IBS Roadmap (2003-2010) has been taken as an initiative to move forward. IBS provides speedier work completion due to the introduction of components replacing on-site construction. The use of IBS assures valuable advantages in context of the local construction scenario but new innovative management and procurement in IBS have still not been fully realised by the industry players. This is especially so in terms of good Supply Chain Management (SCM), the basic principle of which is rarely based on 'integration' approach. Thus, such initiatives may be hindered by the non-integration and adversarial relationship modes currently practiced in construction.

A number of case studies have shown that managing the entire supply chain has become a major factor in delivering a successful IBS approach (Blismas and Wakefield, 2009; Faizul, 2006), with the procurement method arrangement being utilised as a mediator tool and as the means of controlling integration between players (Pan et al. 2008; Gibb and Isack, 2001). A good supply chain integration practice will lead to good integration amongst players. This new way of working has to be related to the current trend in the Malaysian construction to move towards a more innovative and competitive scene. While much effort has been taken to enhance the IBS practice in Malaysia; establishing integration between IBS players is still a major hindrance, due to the lack of supply chain procurement practices (Faizul, 2006; Kamar et al. 2009). Therefore, the challenges in achieving successful delivery of IBS projects would be looking at encouraging integration through supply chain integration, which may have a value-added impact on the success of IBS project implementation and delivery.

This paper is structured into three parts. Firstly, the review covers a broad range of literature, providing a concise overview on the general approach of IBS in the Malaysian construction industry, challenges in supply chain integration and reviews on the supply chain, SCM, integration and procurement. The second part discusses the methodology adopted to collect data, including the choice and size of the samples. The final section includes a discussion and conclusions derived from evidence from the literature review and the qualitative semi-structured interviews.

IBS AND THE SUPPLY CHAIN INTEGRATION CHALLENGES: AN OVERVIEW

In today's global business, with regard to the development of technology and characterised by its great degree of repetitiveness and mass production, off-site manufacturing or IBS has been widely adopted across the globe. IBS is deemed to offer many advantages in overcoming problems such as influx of foreign labour and in enhancing the productivity and the quality of the construction industry. While IBS is being acknowledged generally as the term representing the prefabrication concept in Malaysia, various definitions have been offered to IBS over the past years. Warszawski (1999), defined IBS as a set of interrelated elements that act together to enable the designated performance of the building. In addition, Leesing et al. (2005) asserted IBS as an integrated manufacturing and construction process with well-planned organization for efficient management, preparation and control over resources used, activities and results supported by the use of highly developed components. While CIDB (2003), defined IBS as a construction system where components are manufactured in a factory, either on or off site, positioned, or assembled into place with minimal additional site work.

In this research the present authors emphasis IBS largely as construction process and an approach on manufactured components off or on site. Therefore, the understanding and interpretation of IBS is very important before its implementation. Following new emerging technology, the components of IBS in Malaysia can be categorised into five major types (CIDB, 2003): Precast Concrete Framing, Panel, and Box Systems, Steel Formwork Systems, Steel Frame Systems, Pre-fabricated Timber Frame Systems and Block work Systems.

Even after IBS had long been introduced in the Malaysian construction industry, it appears that the implementation of IBS is still low compared when compared to other developed countries. To cope with these challenges, the IBS Roadmap (2003-2010) was designed to assist Malaysia to move forward and capitalise on new technologies for the construction sector. One of the approaches taken by the Malaysian government to increase the level of IBS usage is by demanding more IBS approaches to be used in the construction industry. These initiatives can be seen through a series of developments starting from the provision of IBS in annual National budgets. In the 2005 budget, policies were outlined to give full exemption of levy imposed by CIDB for housing projects with IBS content of more than 50 percent. In the 2006 budget, IBS manufacturers were given Accelerated Capital Expenditure with a maturity period of three years on moulds. Then, in the Ninth Malaysian Plan Report and Treasury Circular, public projects were made to adopt or contain up to 70% of IBS construction approaches. This is further enhanced by the establishment of the National IBS Secretariat as the Coordinator through the Ministry of Works and an IBS Centre as the One Stop Centre.

Even with much support, encouragement and directions in Malaysia, the usage of IBS is currently much lower than it could be. These problems demonstrate that although the long introduced IBS has promised to solve and improve the current construction process, these practices have characteristically been facing a difficult task to establish integration and cooperation between parties involved (CIMP, 2007; Faizul 2006). Abd Shukor et al. (2009) conducted research to identify the key problems in the construction industry in general and IBS in particular. They classified possible problems into 16 significant themes and revealed that both the industry and the IBS players had not been very successful in their attempts to find the right solutions to the challenges encountered whilst indicating that the supply chain and procurement to be the root of most problems.

Among the challenges encountered were communication in terms of flow of information, conventional mindsets, problems in terms of coordination between various works and funding factors where the process of payments were not in order (Abd. Shukor et al. 2010) and through their research, they also revealed that there are a range of procurement stages that have prominent problems which make it difficult to integrate people. The same problems apply to the 'Design' stage and among the prominent problems encountered were the lack of coordination in design management among architects and engineers (discrepancy in design), lack of resources and budget limitations**.**

CIMP (2007) highlighted poor knowledge and unfamiliarity with IBS concepts and its benefits as one of the factors hindering integration among IBS players. In order for IBS to succeed, construction professionals should support and understand the construction and product delivery of IBS. Lack of integration among relevant players in the design stage has resulted in the need for plan redesigning and additional costs incurred if IBS is adopted. The disintegration happens because IBS manufacturers are involved only after the design stage (CIMP, 2007). Rashid (2009) in his statement argued that the possible mis-match between the design capabilities of the local engineering consultants and the manufacturing capabilities of the local building product manufacturers will disrupt or create upheavals to the IBS project delivery.

Therefore, the establishment of the IBS provision in the integration of the construction supply chains must take place. The challenges of integration amongst the IBS chain players need to be assessed in relation to the working practices in the current project procurement delivery arrangements approach in order to ensure cooperative working relationships that will lead to supply chain excellence.

SUPPLY CHAIN INTEGRATION THROUGH PROJECT PROCUREMENT

A review of literature indicates that the productivity and performance of the construction project is achieved by positive integration of supply chains involved. Thus, at the global level, managing and integrating supply chains has become a major factor in delivering successful construction projects. The term Supply Chain (SC) is usually informed by a wide range of definitions. Various definitions of SC exist in literature and have risen to prominence over the past several years. A review and analysis of the generic SC definitions from the early 1990s uncovered the definition of SC as interdependence of activities or process (Simchi-Levi et al. 2007; Lin and Shaw, 1998) as the linkages of companies (Samaranayake, 2005; Trent, 2004) and as a network of facilities or organizations (Mabert and Venkataramananrt, 1998; Christopher, 1992). It was agreed that all these definitions are relatively similar, with an emphasis on the linkages or networking of organizations or activities connected by demand and supply flows that are supported and accomplished by people.

The complexity of SC may vary greatly from organization to organization and activity to activity. It exists in both service and manufacturing organizations. Typically on larger construction projects, SC consists of a large number of players and involves a number of activities within each tier of players (Dianty et al. 2001). However, SC can be scoped in terms of the number of firms, activities and functions involved (Cooper et al. 1997). But, the integration and management of those supply chains in any situation is very important (Mentzer et al. 2001) and is promoted as a way to achieve supply chain success and

consequently, the success of the project delivery. SC and its management are vital for gaining competitive advantage in the globalized economy. Supply Chain Management (SCM) represents a new way of managing the business and relationships with other members of the supply chain. The concept offered by SCM has been recognized over the past several years as a tool, which will lead to a better integration amongst the construction industry players. A key word and basic principle of SCM is 'integration'. The focus of SCM in this research is on supply chain integration, a word that is rarely associated with the construction process as it is characterised by fragmentation.

Difficulty to integrate is attributed to the variety of professions and skills involved in the project delivery. The present authors also reviewed and analysed generic integration definitions in the literatures from 1973 – 2006. Definitions of integration were used to describe a sharing of knowledge, data and information (Vincent and Kirkpatrick, 1995; Funk and Wagnalls, 1973) a flow coordination (Fergusson, 1993) a merging of different disciplines and organizations (Jaafari and Manivong, 1999) a cooperation and working together (Barkley, 2006; Baiden et al. 2003; Strategic Forum for Construction, 2003; Austin et al. 2002; Moore and Dianty, 1999).

In today's scenario, competition in the construction industry is no longer between one-on-one organization but rather by their supply chains (Tommelein et al. 2009). In order to enhance the competition, the organization should work on integrating supply chains rather than executing tasks single-handedly. Furthermore, they must work in a cooperative manner (Zhendong and Zhenmin, 2010). This will enable the supply chains to focus on shared goals and objectives, leading to mutual benefit for individuals, organisations and society, but without undermining the ability to advance and compete by differentiation of skills, products and services (The Strategic Forum for Construction, 2003). Therefore, Vrijhoef and Ridder (2005) agreed that supply chain integration should be more successful in delivering construction projects and in granting more value and profitability. Clearly, there is a need for a mechanism through which these supply chain can be integrated.

The introduction of varied project procurement systems was brought on by the transformation of technology and the industrialisation scene. This was to ensure efficient and innovative project delivery systems and better performance aimed at meeting the changing demand of clients or customers. Saad et al. (2002) noted, alternative procurement routes, which include (Two-stage Competitive Tendering, Design & Build, Management Contracting and Construction Management) represent some differences in relationships, roles and power between design and cost consultants and the main contractor, and between the main or managing contractor and the specialist and trade contractor. These new approaches to procurement have resulted in some potential for greater collaboration and integration. Baiden et al. (2006) conducted research on the integration of project delivery teams by looking at the practices that took place within the context of procurement approaches because the current practice and arrangement of the players within the construction project supply chains helped to integrate the activities of the various players. Thus, procurement routes appeared as one of the enablers of supply chain integration because they provide the formal links within which supply chain integration is accomplished and prolonged (Hall et al. 2000).

Poor performance has been attributed to the continued use of procurement practices that do not encourage integration of the parties involved (Love and Gunasekaran, 1998). Traditional procurement method is usually competitively tendered to a contractor before work starts. The design must be completed before the commencement of construction. Each construction

process is undertaken by different parties, where individual parties are mainly concerned with their own interests. The Design and Build procurement method provides a single point of responsibility by the contractor and the client has only to deal with one person if faced with any problems. In Malaysia, the arrangements of IBS supply chains in Design and Build involve either in-house manufacturers who employ external designers and quantity surveyors or outsourcing to IBS manufacturers to precast and install and employing of external consultants to carry out design (Abd Shukor et al. 2011). Khalfan et al.(2005) described both procurement approaches varied in their roles and responsibilities but one of the key elements in all procurement methods is the management of the supply chain.

In the context of this research, integration of supply chian could be summed up and viewed as "bringing together a series of different organizations consisting of IBS key players (client, designer, contractor and specialist/manufacturer) which are linked by a flow of practices, information, financial and contractual relationships. This is to allow them to work together towards design and construction practices within the context of the project procurement delivery arrangement approach with the same common goals and objectives". In order to achieve effective integration, an assessment of the challenges faced by contractors in supply chain integration has to be conducted, in context of the Malaysian IBS construction project.

RESEARCH METHODOLOGY

Literature review and qualitative semi-structured interviews with consenting respondents were used in data collection. By interviewing a variety of IBS key players (clients, contractors and manufacturers), challenges of supply chain integration were identified. However, only the perspectives of IBS contractors are presented in this paper since all interviews were still ongoing as this paper was being written. Therefore, the data presented in this paper is only a portion of that which was collected and the conclusions presented here are based on interim findings to date.

Literature review was the first phase of the research with the secondary data derived from relevant books, journals articles, thesis and dissertations, conference proceedings and reports. The second phase involved the collection of primary data, wherein the information was collected through semi-structured interviews. A semi-structured interview approach was employed to achieve the aims of the study. All interviews were recorded and transcribed verbatim, each interview lasting approximately ninety minutes.

The respondents of these qualitative semi-structured interviews were selected from the IBS public projects provided by the Public Works Department. The respondents were selected on the basis of their experience on IBS and their interactions with other IBS players in the project. Letters were posted and e-mailed to the IBS contractors. Then, follow-up telephone calls were made for the interview arrangements. Accordingly, there are nine (9) contractors "Class A" under the Contractor Centre (PKK) and "Grade 7" under Construction Industry Development Board (CIDB) who were involved in IBS public project and have agreed to be interviewed.

FINDINGS AND DISCUSSION

To begin with, the interviewees were asked about their basic background, brief description of their position in the company's organisation and basic characteristics of their projects. Table

1 exhibits the respondents' current positions, experiences, types of IBS components and procurement adopted and project categories. The majority of the interviewees were in the top and senior management level and were very experienced. Their designations and experiences portray their high level of authority in strategy and decision-making processes. This indicates that the data obtained are quite reliable and accurate. The various projects that have been undertaken in Malaysia using IBS can be arranged according to the categories of buildings constructed. The results revealed that the majority of the interviewees undertake precast panel as the most familiar type of IBS involvement and that the Traditional procurement and Design and Build procurement were the common types of procurement used in IBS in the Malaysian construction industry.

Company	Current Post	Experience (years)	Type of IBS components	Types of procurement	Project Categories
A	Manager Design Management	15	Precast Concrete Panel	Design & Build	Schools
B	Senior Manager Business Development & Contract	11	Precast Concrete Panel	Design & Build	Residential Buildings
C	Senior Manager Procurement	9	Precast Panel	Traditional	Commercial Buildings
D	General Manager Contract	12	Precast Panel/Shear Wall	Traditional	Commercial Buildings
E	Project Manager	19	Precast Panel	Design & Build	Residential Buildings
F	Contract Manager	18	Precast Panel	Design & Build	Schools
G	Senior Project Manager	15	Precast hollow system	Design & Build	Hospital
H	Senior General Manger	13	Precast Concrete Panel	Design & Build	Schools
I	Project Manager	10	Precast Concrete Panel	Design & Build	Schools

Table 1: *Current Post, Experience and Project Characteristics.*

In order to identify the challenges that prevent integration amongst contractors, the interviewees answered questions on how they interacted with other IBS members in the supply chain of a particular project within the procurement arrangement they adopted. Based on the results of the interviews the perceived challenges to their integration were presented as follows:

Roles and Responsibilities

More than half of the interviewees claimed that everyone especially the designer should be aware of the responsibilities of the project and fully understand the way of work. Seven out of nine interviewees mentioned that the designers are not fully aware and fail to understand

the implications of their design choices. This results in the contractors themselves having to do extra work to solve the conflict and to find solutions to their construction methods and choices of IBS components. Furthermore, Interviewees B and C raised the problems of interdependencies in traditional delivery entrenched the problems of integration between IBS players. The problem occurs as everyone does not work on the basis of what is actually needed by the person who is going to use their works (Nicolini et al., 2001). Moreover, Nicolini et al., (2001), highlighted that the interdependence issues are aggravated by traditional rigid demarcations between designers and builders. Simarly, the other five interviewees who adopted Design and Build procurement with design and construction under one responsibility, declared the same challenges.

Knowledge and Understanding

More than half of the interviewees claimed neither the architect, mechanical, structural engineer nor the client themselves understood or were familiar with the process and components of IBS. Four out of seven interviewees claimed that the architects' drawings did not match with the structural engineers' drawings, and this was made worse when the mechanical engineer came over to match their services. Besides, interviewee H stated that they are limited specialists/manufacturers in the market and even though they are experts, they do not have any experience in handling school jobs or the big volume. Thus, they fail to advise suitable solutions for the right type of design component. Furthermore, interviewees B and H, also highlighted in Design and Build procurement detail client requirements should be considered at the early stage before construction starts, because the IBS approach will incur more cost if there is failure in design which will create more problems during installation. Out of seven, the other two interviewees stated they do not have any problems with regards to knowledge or interdependencies, because they have their own group of consultants who understand each other's capabilities. Furthermore they claimed they have knowledge and experienced in IBS. Lack of knowledge or understanding of IBS by other players will hinder interaction between the main contractors with their supply chain, whether in traditional procurement methods or design and build project delivery. This is supported by the research done by (Blismas et al. 2009; Blismas and Wakefield, 2008) who assert that the strong theme for the drivers and constraints in offsite manufacturing both concern skills and knowledge.

Risk Liability

Risk liability between structural designers and specialists/manufacturers is very important in manufactured components. Hallowell and Toole (2009) pointed out that the manufactured component must have a proper engineering design because each of these components has a direct impact on the performance of the final structure. Interviewee H claims that they have problems on design and supervision issues between their structural engineer and specialists/manufacturers since most of the structural elements are designed by IBS specialists/manufacturers. He further explained that even though under Design and Build procurement, the contractor is the leader, they have difficulties to work together and coordinate with their team. This is because the structural engineer declined to verify and be responsible for the drawing that has been designed and produced by the manufacturer although it has proper engineering design. The engineer even refused to supervise the work although this has been accounted for in their professional fees. Meanwhile, the specialists/manufacturers also refuse to supervise the work on site because they are not paid for that supervision. This has been supported by (Thanoon et al. 2003) who found that IBS implementation has been heavily criticised by lack of coordination among parties involved.

Financial and contractual matters

Financial and contractual issues appeared to be important matters for the main contractors. Interviewees B, C and D claimed that under client related causes, the traditional method of payment seemed to present challenges. A major reason posited among the contractors to adopt IBS is that IBS construction project delivery is seen to be more expensive than the conventional method. IBS is seen as incurring high initial and set-up costs (Blismas and Wakefeld, 2008; Badir et al. 2002). The procurement of construction material is the responsibility of the contractor. Once the materials are already on site, the contractor is paid 75% for materials on site in their progress payment, which are not incorporated in the permanent works, to ease their financing costs or cash flow. However, the IBS set-up is different; the contractors have to pay the specialists/manufacturers huge amounts of payment at the initial stage in order for the manufacturer to proceed with their precast component order. Thus, this shows that IBS involves factory-produced building components where their material on site (precast component) is ready at the manufacturing site. This scenario is identified as one of the hurdles of IBS adoption for the contractor whether in Traditional method or Design and Build delivery, because they need efficient management and planning of their finances. This is more so as delays occur under certain circumstances.

As highlighted by one of the interviewee: "*….the client should be aware our problems, especially on precast product, the client should consider our material (precast product) at the manufacturing factory as material on site."*

It was thought that, in order to improve IBS project delivery and enhance their working relationship the client should trust the contractor to undertake the task and responsibilities or any win-win situation between them through improvement of their method of payment. This is also supported by Bilsmas and Wakefield, (2009) and Kamar et al. (2009) who revealed that IBS players need more reliable payment mechanisms and contracts. They added if they change conventional methods to IBS; the payment mechanism for IBS should be duly reviewed.

A second financial and contractual challenge is due by client and consultant factors. According to interviewees F and H, the problems arise when the client amended their original concept of design and build where client pay direct fees to the consultants (direct payment concept). This will discourage cooperation and disable response and the consultants will not readily adapt according to the main contractor's needs. Design and build entails the sole responsibility of the contractor to carry out and be responsible for not only the construction but also the design of the works including engagement of the design team who are, therefore contractually linked with the contractor and not the client (Molenaar and Gransberg, 2001; Ndekugri and Turner, 1994). The challenges of misunderstanding and conflicts that occur during the design and construction stage hinder integration amongst them.

Communication and Information

As the integrator of numerous supply chains, problem related to communication and information flow is identified as crucial to the main contractor. Most of the interviewees claimed that communication problems form an important part of the challenges they face in IBS construction supply chain. Some of the contractors complained about enforcement of "Forced Marriage" between consultants and contractors by the client under design and build as this impacted on the quality of communication and information of their integration. Unfamiliarity with each other causes problems arising from the lack of cooperation between the contractor and consultant. Problems include inaccurate design information, reluctance to

accept other members' opinion, inaccurate data, late updating of the required information and late submission to the local authority. This indirectly influences the quality of their IBS project delivery.

Interviewee C who procured through Traditional procurement highlighted that: *"they can communicate well, very good communication but everybody think about dollar and cent, limited transparent of information….there is hidden cost from the manufacturer/precaster…"* In design and build procurement, Interviewee F highlighted that, *"…even though the manufacturer have done business relationship with them but there seem no trust element between them…for example…photo cannot be taken while visiting their factory*" . He claimed that there is no sharing of information and the manufacturer is not ready to share their technology. He further explained that unfamiliarity hindered their shared interest to complete a project as one integrated supply chain. Developing efficient communication throughout the tiers of the supply chain will ensure superior and reliable flows of information (Briscoe and Dianty, 2005).

Attitude and Relationship matters

Generally, attitude of the designers were criticized by the main contractor as one of the factors that challenge the integration between IBS supply chain. For example, the architects pride and arrogance about their design concept to protect their professionalism. They were reluctant to change their designs even though the designs will cause difficulties in the mould system of IBS components. Moreover, the main contractors who procured under design and build complained that the architect acted as the leader and held no respect for them, as the main contractor. There is no respect, understanding and commitment amongst IBS players. Furthermore, the majority of the main contractors interviewed felt that the designer was reluctant to change and stuck with their old mindsets as with the conventional process. This is supported by Kamar et al. (2010) who revealed that there is critical need to manage the design and manufacturing differently from the traditional way as IBS is different and needs a different mindset along with the right environment. This attitude impacted the time in designing and delivering the IBS project. Rethinking the old processes is now critical if the industry is to move forward (Kamar et al. 2010)

INTERIM CONCLUSIONS AND FURTHER RESEARCH

The research reports the data based on findings to date through literature review and semi-structured interviews on the challenges faced by IBS contractors on the integration of the IBS supply chain with regards to the existing procurement methods that they undertake. Role and responsibility, understanding of knowledge, risk liability, financial and contract matters and attitude and relationship are established as the challenges that hinder the successful integration of the contractor with the parties involved. The same problems are also experienced in UK, Dianty et al. (2001) and Millett et al. (2000) addressed the significant barriers exist to main contractor and supplier integration within the UK construction industry are the lack of knowledge and information, lack of trust and negative attitudes. These findings are in tandem with the thorough literature reviews conducted. The research findings also confirm that the IBS contractors whether procured through Design and Build procurement or Traditional procurement face similar challenges. This is justified because there are various supply chain arrangements in Design and Build procurements that might influence integration and the performance of the IBS project delivery. Thus, the issue of better integration is important to be addressed within the IBS construction. More extensive empirical research work on these areas is needed, especially on the appropriate practices and

the success and barriers factors of integrating the supply chain players with the arrangements of project procurement delivery. Finally, the study presented in this paper is part of an ongoing research, which will eventually attempt to further enhance the practices and implementation of Supply Chain Integration in relation to procurement systems, particularly in the IBS project delivery in Malaysia. Such developments augur well in support of the government's aspiration in moving towards a more efficient IBS construction approach.

Abstract
In The Netherlands, public works are contracted more and more in integrated ways. In recent literature, it is argued that procurement procedures will influence project performance. Even more, the procurement climate itself is found to influence the project performance by strengthening or altering the relationship between procurement procedure and project performance. In this paper, the relationship between procurement procedures and –climate and project cooperation is defined, project cooperation being an important indicator for project performance. The results of the literature study and the qualitative survey show a clear need for a procurement procedure not merely based on the project itself, but also on collaboration and soft parameters. In-depth case studies are used to analyze abovementioned relationships and find more detailed descriptions. The procurement procedure, procurement climate and project cooperation of three projects were assessed: KOSMOS STAKAN, 2nd Coen Tunnel, Houten-Castellum alliance. The added value of a collaborative procurement climate is emphasized by the in-depth case study results. Based on those results, suggestions for further research are given.

Keywords: project cooperation, procurement procedures, procurement climate, project performance, coopetition.

INTRODUCTION

Since the eighties of last century, three main developments have propelled changes in Dutch construction industry. The combination of increased project complexity (Baccarini, 1996; Laufer et al., 1996; Alderman et al., 2005; Walker, 2007), a changed role of the government (Blanken, 2008) and the sector's poor professional functioning (Egan, 1998; National Audit Office, 2001) form the context in which several changes in the construction industry are embedded. These changes are twofold: on the one hand they are aimed at new structures (formal processes and contracts) and on the other at new working relationships (informal processes and understandings).

Due to the mentioned developments the tasks and roles of market and government have become different. Public clients have less influence on the contents of works, yet are striving after 'professional commissioning', leading to more and more outsourcing to market organizations (Huque, 2005). The public client confines itself to monitoring and checking from the public matter (Blanken, 2006, p. 181). Market organizations at the other hand get next to the executive- also more substantive tasks. Stemming from these changing tasks and roles, structures have been amended and are continuously developing. Integrated contract forms, PPP constructions, and active discussions about aspects like price, risks and contractual terms are more and more common during the procurement of construction projects (Bult-Spiering and Dewulf, 2006). Yet, there is also growing attention paid to the 'soft' aspects of construction. The call for new cooperation forms, increased mutual trust, improved communication and mutual understanding becomes stronger (Dorée, 2001; PEC, 2002; PSIBouw & RegieraadBouw, 2007). One is, for example, experimenting with procurement based on the orientation of candidates towards cooperation with the public authority.

The increased attention for soft aspects matches with the notion that project cooperation enhances project performance. Project performance is here defined in terms of cost, time, quality, environmental impact, work environment and innovation (Eriksson and Westerberg, 2010). Several academics have shown how cooperative behavior in projects is of positive influence to project performance. Collaboration may be regarded as "the instrument" that allows the parties to realize the project goals (Kamminga, 2008, pp. 53).

Project partnering, an elaborate way of project cooperation, is said to have several expected benefits: lower bidding prices and project costs; increased efficiency; increased opportunity for innovation; better quality products and services; improved design; better identification and clarification of project risks; better utilization of labor; better communication leading to higher levels of team member collaboration; fewer conflict, claims or disputes; improved supply-chain collaboration and, finally, more informed decision making for project participants (Crespin-Mazet and Portier, 2010).

Research has indicated as well, that project performance is influenced by choices in the procurement of projects. The use of collaborative tools during procurement, for example, is positively correlated with project performance in terms of costs, time, quality, environmental impact, work environment and innovation (Eriksson and Westerberg, 2010; Alderman and Ivory, 2007). This might have to do with the influence of usage of this kind of tools on project

cooperation. However, proper research upon the influence of procurement procedures and climates on project cooperation is lacking. Therefore, our research is guided by the central question which procurement procedures and climate are, and in what manner stimulations to project cooperation.

RESEARCH DESIGN

Answer to the central research question is sought in a two-staged research. The first stage of the research was formed by a series of interviews to provide an overview of procurement procedures and aspects of procurement climate which might be of influence to project cooperation. The interviews were conducted with procurement experts from the Dutch construction industry, whose expertise differed from scientific expertise to legal expertise. The individually conducted interviews were semi-structured: containing a number of pre-determined open-ended questions in the form of an interview schedule, which guided the researcher whilst providing the flexibility to ask additional questions. The semi-structured approach was used to obtain a general list of procurement procedures and –climate, in combination with insights into the manner in which these might influence project cooperation. Interview reflections were coded by the qualitative data analysis tool QSR Nvivo, using a bottom-up approach to classify the large number of textual data units into a smaller number of homogeneous categories. The use of software in analyzing the qualitative data allowed for a more objective assessment, and facilitated a more complex examination of the data (Weitzman and Miles, 1995; Marshall, 2002). Thus, an overview was provided of the procurement procedures and – climate aspects which might stimulate project cooperation.

The by interviews created idea of the procurement procedures and –climate which might stimulate project cooperation, were then further studied in a series of in-depth case studies. This is the most suitable research approach, given the explanatory character of the question how procurement procedures and –climate stimulate project cooperation, and the limited extent of control over procurement situations (Yin, 2009). Case study protocols were created using literature on the, by the experts identified procurement procedures and – climate, combined with specific literature on project cooperation. This grounded approach led to protocols which were combining practical with theoretical insights (Eisenhardt, 1994).

PROCUREMENT PROCEDURES AND CLIMATE ASPECTS WHICH INFLUENCE PROJECT COOPERATION

Semi-structured interviews

A series of 20 interviews with procurement experts provided us useful background information on procurement procedures and –climate aspects which might be of influence to project cooperation. Practitioners and consultants as well as researchers supported the importance of procurement procedures and climate, and their assumed effects on project cooperation and performance. 90 Percent of the experts argued that new ways of contracting (i.e. D&C, DBFM, PPP, et cetera) ask for project members with different competences than needed for traditional

contracting, and a different attitude as well. This underlines the need for well-suited procurement procedures to find exactly those people.

Two factors were found to be of importance for well-suited procurement procedures and -climate. First, they might benefit greatly from effective and open communication, resulting in an understanding of each other's risk attitudes. Second, client and contractor will have to change their attitudes to be able to act according to the new roles integrated contracts impose. Two issues though were regarded to be main impediments for a more cooperative procurement climate. First, tender teams hardly ever continue to be the final project team during realization. Contractors as well as clients assign their best suited people for each phase and tendering is something quite different from project management during realization. Second, contractors are faced with contradictory interests of competition and relationship-building. The willingness to come to a trustful relationship with the client is hampered by the competitive tender climate. Being totally transparent to a client is desirable, but often not feasible.

Practical solutions to make cooperative procurement possible without the drawbacks were found in the field of alliance contracts and Best Value Procurement procedures, to find an "expert" contractor with less transaction costs. Also, the effect of the drawbacks could be minimized by starting the team-building process only after the contract has been awarded.

Procurement procedure

Procurement by competitive bidding has lately received criticism for leading to disputes and adversarial relationships that consequently will lead to time and cost overruns, diminished quality and, eventually, poor customer satisfaction. A competitive bidding procedure, on the other hand, may significantly increase resource consumption and generate waste in the delivery process. Transaction costs that seem to be low at the start of the project, will rise due to tedious and complex change order processes stemming from too early detailed plans and specifications (Elfving, Tommelein and Ballard, 2005).

A more cooperative procurement procedure will consist of limited numbers of trustworthy and competent bidders, incentive-based compensation and careful partner selection (Pesämaa, Eriksson and Hair, 2009). Spending time on a good start-up phase (including aspects such as communication, supplier selection and relationship management) and less time on formal specifications, facilitates necessary contractor involvement and some level of co-creation for complex performance (Caldwell, Roehrich and Davies, 2009). A paradigm shift from competitive tendering to co-operative and caring environments might overhaul current public sector procedures that often work against open relationships (Ng, Rose, Mak and Chen, 2002).

Another distinction that is found in literature is between transactional and relational approaches of procurement. The transactional paradigm is focused on competition, whereas the relational paradigm stresses the importance of ongoing interaction and less formal communications (Lian and Laing, 2004). Relational contracting is also used to describe the effects of a more fluid boundary between public and private organizations when working together. It is said to reduce costs, speed up time to market and promote innovation (Parker and Hartley, 2003). The growing success of relational contracting implies the more often us of selection of team players based on their relational capabilities (Kumaraswamy and Anvuur, 2008).

Eriksson and Westerberg (2010) identify three types of procurement procedure, being competition, coopetition and cooperation. With them, we label a procurement procedure more or less competitive, coopetitive or cooperative according to the following criteria:

- The level of integration between client and contractors in the design stage;
    - Specification by supplier or client (competitive) to Joint specification with one party responsible (coopetitive) to Joint specification with shared responsibilities (cooperative).
- The number of contractors that are invited in the selected tendering process;
    - Multiple (competitive) to Selected tendering (coopetitive) to One (cooperative).
- The focus on soft parameters in the bid evaluation;
    - Low (competitive) to Medium extent (coopetitive) to High (cooperative).
- The extent to which both client and contractors are jointly involved in subcontractor selection and integration;
    - One party fully responsible (competitive) to Joint selection with one party responsible (coopetitive) to Joint responsibility (cooperative).
- The usage of collaborative tools;
    - Low extent (competitive) to Medium extent (coopetitive) to High extent (cooperative).

Opposing to Eriksson and Westerberg (2010), we argue that two criteria belong to the project cooperation phase as they do not really influence behavior during initial procurement but only when the contract is closed. Therefore, their sixth and seventh criteria, method of payment (more or less incentive-based) and method of performance evaluation (more or less by the supplier), are labeled by us as criteria of project cooperation.

Procurement climate

Eriksson and Westerberg (2010) argue that besides the procurement procedure, a more cooperative climate will also have a positive effect on project performance, whether by moderating the effects of the procurement procedure on the project performance or by mediating the effects of the procurement procedure on the project performance. The level of trust and commitment between parties are measures of the procurement climate, according to their research.

Kadefors (2004) cites three types of trust. First type is Calculus-based trust: trust, primarily based on economic incentives for co-operation or contractual penalties for breach of trust. Second type of trust is Relational-based trust: trust developing when parties obtain personal information and experience, forming the basis of trust through emotions and personal attachment. The third type of trust is Institution-based trust: trust which is created by necessary pre-conditions like legal systems and societal norms regarding (among others) conflict management and co-operation.

Real co-operation, however, will only arise if relational trust develops between people interacting directly and over a longer period of time in procurement procedures. Key personal characteristics for this to happen are individual competence, benevolence and integrity. Competence being the skills and competencies for a particular situation, and benevolence being

the attachment of the parties to each other besides economic profit motives. Finally, integrity is defined as including principles such as consistency, fairness, reliability and openness. Partnering methods can influence the development of trust, but the effects can be ambiguous as overly reliance on team building processes and monitor systems might indicate and thus initiate distrust (ibid).

Commitment in our view is a combination of intent and behavior. Often, commitment to project success is expressed by project officials at the beginning of the project. The extent to which all management levels express their commitment to the success of this particular project, is one aspect. The other aspect is the actual behavior, and the readiness to overcome problems. In other words, the flexibility with which problems are solved that are in the way of project success. Too little commitment on the side of clients and, due to commercial pressures, of contractors are found to be reasons for lacking continuous open and honest communication (Ng *et al.*, 2002).

From the above, we derive the following elements to describe the procurement climate in our case studies:

- Mutual trust during procurement; higher trust indicates a more collaborative climate:
    - Competence, benevolence and integrity of individual project officers.
    - The level to which partnering methods created trust or distrust.
- Mutual commitment during procurement; higher commitment indicates a more collaborative climate;
    - Expressed intent at all (management) levels of the project.
    - Flexible problem solving behavior.

Project cooperation

In construction projects, cooperation can differ from forms of co-creation in a design & construct project to shared service exploitation in DBFMO contracts. Project cooperation can in any case be seen as a social setting, in which client and contractor work in a multi-organizational project setting in more or less integrated ways (Cicmil and Marshall, 2005). Construction teams are often cross-functional, with members of organizations with different interests. High levels of coordination and cooperation are thus needed (Pesämaa *et al.*, 2009). Project performance is threatened if client and contractor do not cooperate adequately to meet the various challenges in a construction project. After Kamminga (2008), we consider the cooperation successful when the interaction process between client and contractor leads to achieving the project goals.

From research on alliance contracts, success factors for effective cooperation can be identified: trust, clear goal alignment, commitment, partnering tools and procedures, constant joint evaluation of team synergy and open and continuous communication at all levels in a timely manner (Rowlinson and Cheung, 2005; Black, Akintoye and Fitzgerald, 2000; Ng *et al.,* 2002). But, project partnering in a project alliance is only one of a number of ways of organizing them. Both contractor and client will borrow from this concept what they think will help them most in a particular setting (Alderman and Ivory, 2007).

Thus, we will use the following indicators to describe project cooperation in our case studies:

- The level of trust after contract close;
    - Competence, benevolence and integrity of individual project officers.

    - The level to which partnering methods created trust or distrust.
- The extent to which goals of client and contractor are aligned;
- The level of commitment after contract close;
    - Expressed intent at all (management) levels of the project.
    - Flexible problem solving behavior.
- The extent to which partnering tools and procedures are used after contract close;
- The extent to which team synergy is jointly evaluated;
- The level of open and continuous communication at all levels and in a timely manner.
- The extent to which payment is based on incentives related to project performance criteria;
    - Fixed price (competitive) to Fixed price and shared profits (coopetitive) to Shared profits (cooperative).
- The extent to which performance evaluation is based on contractors' self-control;
    - Fully by the client (competitive) to Both by client and by supplier (coopetitive) to Fully by the supplier (cooperative).

CASE STUDIES

To find an answer to the central research question which procurement procedures and climate are, and in what manner stimulations to project cooperation, we started with interviews and a literature study. As a result, we came to clear indications by which the concepts of procurement procedures, procurement climate and project cooperation can be described. Based on recent work of ours (Hoezen et al., 2010; Hoezen, 2011; Laan et al., 2011) these indicators are put in line for three case studies which were all procured by different procurement procedures by different project climates. From this, the effect of these indicators of procurement procedure and project climate on project cooperation will be derived in order to come to an indication of how procurement procedure and project climate are stimulations to project cooperation. After a short description of each case study, in Table 1 a summary is given of the project characteristics as identified from the cases.

Case study 1: KOSMOS STAKAN

The KOSMOS STAKAN project (see Hoezen, 2011 for an in-depth analysis) consisted of renovations to a large number of infrastructure objects. Construction works which needed major maintenance were bundled and contracted to the market in an Engineering and Construct (EC) contract. KOSMOS STAKAN was procured with the restricted procedure.

Procurement procedure

The level of integration between client and contractors in the design stage could be described as coopetitive. Although some of the tasks to the project were shared (problem definition, for example), the main load of work was simply divided between either the client or the contractor. With 5 selected contractors to the tendering process, the number of invited contractors is coopetitive as well. In the bid evaluation, the focus was on price, time and risk. Soft parameters were not included at all. This focus is therefore qualified as low (competitive). Subcontractor selection and integration was not influenced by the client, yet remained to the full responsibility of the contractor. Payment was mainly based on a fixed price, and collaborative tools were not

used at all. Concluding, the procurement procedure for KOSMOS STAKAN can be described as being competitive - coopetitive.

Procurement climate
In terms of mutual trust, KOSMOS STAKAN, the competence, benevolence and integrity of individual project officers was average. Partnering methods, which were practically not used, did not create extra trust nor distrust. When the construction of the project started, project officers stood neutrally towards each other. The expressed intent was neutrally as well, at all levels of the project. The roles during procurement were clear, and both client and contractors acted upon it. The problems arising were treated in line with this: the responsible party was looked at to come to solutions. Concluding, the procurement climate could be called coopetitive: project participants were not cooperating nor competing.

Project cooperation
The project cooperation within the KOSMOS STAKAN project could be characterized by medium levels of trust. Although project officers praise each other's competence, benevolence and integrity and show how they empathize with each other's situation, the created levels of trust fluctuate during construction. This mainly has to do with problems, faced in this stage of the project. Given the medium intent at all levels of the project, and the fact that problem-solving behavior was as traditional as had shown during the procurement stage of the project, problems got resolved, however not in a cooperative manner. The level of commitment was neutral, and the extent to which goals of client and contractor were aligned low. This had to do with the fact that the levels of communication were not always as open and continuous as one desired. Within KOSMOS STAKAN an attempt was made to have the contractor evaluate its own performance. Due to difficulties in achieving this, the client closely monitored as well. When the parties identified this, they started conversations to come closer to each other, however other partnering tools and procedures were not used. The team synergy is evaluated as average (not good, not bad) by all project officers.

Case study 2: 2nd Coen Tunnel
The second Coen Tunnel project (see Hoezen et al, 2010 and Hoezen, 2011 for in-depth analyses) consisted of the renovation of an existing tunnel and the construction of a new tunnel next to the existing one. Construction, reconstruction and maintenance were contracted within a Design Build Finance and Maintain contract. The second Coen Tunnel project was procured with the competitive dialogue procedure.

Procurement procedure
In the design stage of the Coen Tunnel project the level of integration between client and contractors could be described as coopetitive. The contractors were puzzling with the documents they got from the client, and although there were many detailed conversations about the project, the design task was for the contractors alone. The number of contractors was five, a coopetitive number. All parameters in the bid evaluation were hard. Although the client asked for a list of subcontractors, the subcontractor selection was the contractor's responsibility. The intensive conversations which were part of the competitive dialogue were the only collaborative tools used. Concluding, the procurement procedure for the second Coen Tunnel project could be described as coopetitive.

Procurement climate

At the start of the procurement, parties were positive about each other's competences. Benevolence was average, and integrity was not a point of discussion. However, during the procurement several issues arose. The client started to doubt the contractor's integrity, whilst the client's competence was discussed by the contractor. The partnering method used (competitive dialogue procedure) did enhance opportunistic behavior of the candidate contractors, leading to mutal distrust at the end of the procurement stage. Commitment to the project, however, was average. The parties expressed intent at most levels of the project, however their problem solving behavior was not too cooperative. Both parties were digging in and awaiting the other party to make a move. Concluding, the procurement climate in the Coen Tunnel project was competitive.

Project cooperation

During the construction stage of the project, the level of trust improved only slowly. This was not due to partnering methods, but to a change of persons involved in the project. Given that these people did not have a mutual history in the project, there was more benevolence between them than between the persons involved earlier. However, doubts about the competence of the client at the contractor's side and about the integrity of the contract from the side of the client, remained. The overall level of trust during the construction stage was therefore somewhat medium. Project performance was part of the incentive structure, although extra performance was not rewarded. Performance evaluation for the second Coen Tunnel project was on the basis of contractor's self-control. The goals of client and contractor differed and could not be brought in line. This had to do with unsolved problems from the procurement stage. The level of commitment was therefore low: there was only little intent at management level, and the problem solving behavior was stiff. This situation did cause however the use of partnering tools like meetings and the help of reflectors, to bring around more open and continuous communications. The team synergy was therefore evaluated becoming more positive as the project developed. Concluding, the project cooperation in the Coen Tunnel project was assessed as competitive.

Case study 3: The Houten-Castellum alliance

In the Houten-Castellum project (See Laan et al, 2011 and Laan, 2008 for in-depth analyses), an existing rail track in the domain of a medium-sized city is doubled over a length of about 5 km. Besides the doubling, the existing station will be rebuilt and a new one will be added, and a rail crossing auto tunnel, a bus tunnel, a pedestrian underpass, a large cycle shed and an underpass for cyclists will be realized. The client at first decided to procure the Houten-Castellum project with a design and construct contract. However, after bid evaluations it became clear that the project risks were high and hardly controllable by one of the project partners. Therefore it was decided to convert the initial design and construct contract into a project alliance contract and a construction contract.

Procurement procedure

In the design stage, initially the level of integration between client and contractor was average. However, during the contract negotiations, the integration level increased. When converting the design and construct contract into the project alliance, the client organization became more involved in the design process and the contractor organization actively thought along about how to govern the project. In the selected tendering process, three contractors were invited. In the bid evaluation, the attention to soft parameters was medium to high, since the client organization

recognized the importance of soft aspects for jointly being able to tackle possible risks. However, subcontractor selection remained for the responsibility of the contractor organization. The project alliance had strong incentives for the maximization of project performance, since financing of the alliance came from all client's and contractor's design, management and risk budgets. Of this fund, design and management costs were paid, as well as emerging risks. Savings resulting from optimizing the project design would boost the fund. Use of collaborative tools was a bit more than average during the construction stage. Besides the regular project-startups, the process of discussing the project alliance conditions helped creating collaboration. Concluding, the procurement procedure could be qualified as being coopetitive - cooperative.

Procurement climate

The procurement climate in the Houten-Castellum alliance was cooperative. Started from average perceived levels of competence, benevolence and integrity, during procurement these perceptions increased. The conversations about the project alliance brought people from the contractor and the client organizations closer together and created trust amongst them. Commitment was high, and the intent was expressed at all levels of the project. Problems were solved in a very flexible manner: one did not ask whose task it was to solve a problem. Instead, all parties involved tried their best to prevent problems to occur. The mutual commitment therefore was strong. Concluding, the procurement climate in the Houten-Castellum project can be characterized as cooperative.

Project cooperation

The level of trust, high in the procurement stage of the Houten-Castellum project, was even growing in the construction stage of the project. Under influence of joint goals and open, continuous communication, the trust level developed along virtuous cycles. When considering the project alliance as a partnering method, this method created trust to a large extent. At the end of the project, any positive or negative outcome of the alliance fund was 50/50 shared between the client and the contractor. The project performance ultimately was monitored by a team of client and contractor organization members. Goals of client and contractor were optimally aligned, and the level of commitment was high. This all resulted in a very positive jointly evaluation of the team synergy. Concluding, the level of project cooperation was assessed as cooperative.

	KOSMOS STAKAN	2ND COEN TUNNEL	HOUTEN-CASTELLUM ALLIANCE

CONCLUSION AND DISCUSSION

In this paper we have made a start with researching the relationship between procurement procedure and procurement climate at the one hand, and project cooperation at the other. From the notion that cooperative project cooperation influences project performance in a positive manner, we are looking for aspects by which project cooperation could be stimulated. Literature study provided us with a range of indicators by which we have characterized three construction projects: KOSMOS STAKAN, the Second Coen Tunnel project and the Houten-Castellum project. The case study results show how project cooperation seems to be mainly influenced by procurement climate, with procurement procedure showing to be of minor influence. In all of the three cases we studied, the project cooperation which resulted from the procurement developed in line with the procurement climate rather than with the procurement procedure (see Table 2).

	Procurement procedure	**Procurement climate**	**Project cooperation**
KOSMOS STAKAN	Competitive - Coopetitive	Coopetitive	Coopetitive
2ND COEN TUNNEL	Coopetitive	Competitive	Competitive
HOUTEN CASTELLUM ALLIANCE	Coopetitive - Cooperative	Cooperative	Cooperative

***Table 2**: Indicators per case*

From the notion of Laan et al (2011) that vicious and virtuous cycles of trust development exist, we assume that these cycles are the main forces in this relationship: a trusty climate in the procurement stage of a project is likely to result in cooperative project cooperation in the construction stage of the project. Whether or not procurement procedures are of influence, remains unclear. The procurement procedure might influence the development of a procurement climate to a certain extent, yet might as well be of less influence.

Based on the study, described in this paper, we recommend further research into the relationship between the three concepts of procurement procedure, procurement climate and project cooperation. With robust operationalization of the concepts and a wide range of well-documented and accessible projects we suggest a quantitative approach to make strong conclusions. Aside from the outcome of such a research it should be said that creating a cooperative procurement procedure and –climate takes investment, both at personal level and in terms of finances. Furthermore, not all projects will need project cooperation to come to improved project performance. Implementing cooperation strategies should therefore be well-thought before.

Abstract
This study proposes a method and presents a proposal to re-qualify social housing complexes, with diversification and expansion of units. The construction of large social housing condominiums can be criticized from several points of view. These projects has limited financial resources and there is a gap among the project and user' requirements, generating a low quality product, which have an accelerated degradation and generate more maintenance' waste in life cycle. Building renewal is a form of recycling and has influence in social, economic, and environmental issues. The aim of this paper is to propose a design methodology for the renovation, which is sustainable and oriented to value creation. It consider environmental and economic feasibility based on embodied energy in materials and hedonic price models, respectively. We conducted design simulation, focusing on a typical housing complex, located in the Rubem Berta settlement, in Porto Alegre, Brazil, and verify a potential for value adding. This work contributes to the discussion of alternatives to social housing deficit in Brazil.

Keywords: Social housing; Design; Building renewal; Sustainable construction; Waste reduction.

INTRODUCTION

There are several benefits on rehabilitate existing buildings, such as maintaining structures of social or historic value and already adapted to urban and architectural reality; take advantage of the energy involved in the existing physical structure, with less need for new resources;

maintaining social relationships, community and neighbourhood; and provide value adding in the region and the building itself (Gorse and Highfield, 2009). A part of existing social housing estates in Brazil has problems of conservation and rehabilitation is an important measure to restore the quality of life of their users. Improving the use of existing buildings reduces the need for new buildings and then decreases the need for new urban land, contributing to sustainability.

There are examples of mass housing rehabilitation on developed countries. In North America the main focus is on reducing energy consumption (retrofit). In Europe the problem is also linked to the renewal of a large number of buildings built after the II World War. The standards adopted at the time of construction are considered not suitable for the present moment, and people look for new solutions to expand the built environment and reduce energy consumption for heating in addition to value adding of the region. The low population growth in developed countries and the search for sustainability does not recommend demolition (Bragança et al., 2007; Cukovic-Ignjatovic and Ignjatovic, 2006; Giussani, 2007; Ham and Schamhart, 2006).

Developing countries have different needs, such as production to cover housing deficit, as well as economic viability. Still, part of the housing issue is linked to poor care of the demands of users, caused by deficiencies in the original design or aging buildings, in addition to the problems based on the low quality of social housing (Bonduki, 1999; Boselli, 2007).

Housing deficit in Brazil is about 10%, regarding to existing stock. A part of this deficit is inadequate housing. As well as, a family have a housing, but with lower quality or size that your needs (FJP, 2004). Rehabilitation is a way to fix this part of deficit. In Brazil, an opportunity to study is in the vertical housing complexes built in the period of the National Housing Bank (BNH), from 1964 to 1986. In quantitative terms, that production is significant in several Brazilian cities. In general, these housing complexes were originally designed to low-class or low-mid class people. Most complexes are composed of hundreds of apartments with 2 or 3 bedrooms. They have social areas and parking areas, and had at building time reasonable architectural and building standards. Projects built around the country have large similarities (Azevedo, 2007; BNH, 1979; Bonduki, 1999, Sampaio, 2002).

However, too many properties currently present a bad conservation state and lower market values. It has impact on property tax, generating in some cases a lack of interest of the public administration to invest on improvements in the region. It is also common to occur the stigmatization of the residents. There are lost in relation to the quality of life for families and beyond, in the neighbourhoods. This situation occurs in Brazil and in other countries, such as Argentina and Chile (Dunowicz and Hasse, 2005; Krasuk and Gerscovich, 2005), with some known proposals for renewal (Ganem and Esteves, 2003; Ganem et al., 2005, Rodriguez and Sugranyes, 2004).

This phenomenon occurs in Latin America and several developed countries (Brattbakk and Hansen, 2004, Hastings, 2004; Verhage, 2005). To Brattbakk and Hansen (2004), there is evidence that some of the social and economic problems are linked to the repetition of the projects. To these authors, seems to be a relationship between long sets of buildings for social housing and the existence of social problems such as segregation and prejudice. The generation of stigma is most common in large housing complexes. The media identify or amplify the problems occurred in a given set, but the population can be generalized to other sets of similar project (Brattbakk and Hansen, 2004). In addition to overcrowding and poor

quality of design and construction, many residential complexes are built on the fringes between urban and rural areas with poor infrastructure, exacerbating the problem.

Chanagnon et al. (2003) state that one of the objectives of the rehabilitation of social housing in Europe is value increasing. Another objective is to reduce energy consumption. Ham and Schamhart (2006) argue that the renewal allows the utilization of existing infrastructure and structure, with less waste generation and lower energy consumption. Camarero Martínez et al. (2008) argue that rehabilitation should include sustainable design features.

Hastings (2004) argues that urban regeneration must consider the public image of the housing complexes along with the physical renewal. There are cases of urban renewal projects developed in Britain in which the poor image remained after the completion of the works. Esteban Galarza (1989) discusses some social consequences of regeneration projects in urban areas, such as increased levels of property prices and attracting groups with higher income levels, but at the risk of displacement of the original people. One of the known consequences is the gentrification. Gentrification is the conversion of marginal properties for working class areas located in central city areas in new residential uses for middle or upper class, by reflecting a movement of private capital investment. Was related to the recovery of damaged buildings architecture as well as supply of new services and usually occurs in the CBD (the city "core"). With this conversion, lower classes are displaced. In some cases, improvement it do not appropriate, on the contrary, it creates peculiar types of spatial segregation, often with increased income concentration (Smith, Williams, 1986; Zukin 1987).

Meanwhile, as well as the degradation of the built environment causes economic and social waste, building renewal has the potential to improve the quality of life of families affected and of the cities as a whole. It is possible to reduce poverty and crime improving built environment. Of course, projects requirements includes sustainability, looking at environmental (preference for low-impact materials), economic (economic viability) and social aspects (low impact on users).

This paper presents some results of research on sustainable solutions for building renovation. The work begins listing some elements to build a methodology and exposes a simulation study in a social housing complex in Porto Alegre, a Southern Brazilian city. Results indicate a good potential to consider rehabilitation as an alternative to contribute to the social housing issue.

SOME ELEMENTS TO BUILD A METHODOLOGY

The basic premise adopted is that to expand, improve and prolong the useful life of buildings is a form of recycling, avoiding new constructions, and then reducing the generation of waste, saving natural and financial resources, energy and urban land. It is assumed that there are economic benefits and better resource use with the renovation of buildings.

The rehabilitation project must be based on certain assumptions, including: (i) technical and economic feasibility, with proposing solutions to renew the appearance of buildings, promoting economic increasing, (ii) use of materials available in the region, low cost, that generate less waste and are recyclable, (iii) propose solutions that allow flexibility of use. These three points establish economic, environmental, and social sustainability. These premises are detailed to follow.

Viable and valued projects

Construction costs are a very important element in the social housing sector. In general there are too few resources and projects should attempt too many needs. So it is important to examine carefully the costs of rehabilitation projects to be economically viable. And further on, solutions must be technically feasible.

The costs were calculated by conventional budgets, measuring materials, labour, additional works, and administrative and legal costs. This part follows the traditional methods of budgeting. The feasibility analysis also requires estimates of increase on property values. We propose a basic way to measure the value using hedonic pricing models (Appraisal Journal, 2001; Rosen, 1974; Pagourtzi et al., 2003).

The models relating the price of a property with their characteristics are known as hedonic pricing models, which are econometric models, with a long application in economic studies and research (Rosen, 1974; Sheppard, 1999). Thus, value increasing may be measurable by comparing the current situation with the potential situation, which is based on the proposed rehabilitation.

For this, it was developed a pricing model for the correspondent property sector, according to traditional procedures for hedonic pricing models. This procedure is not detailed here for space limitations of this work. The information about sales data of the units was obtained from Sales Tax files in the Porto Alegre Tax Department, and statistical analysis was developed with 41,975 condo sales data in the period from 1998 to 2010. The resultant equation is as follows (Equation 1):

$$\begin{aligned}\text{Price} = (&73.59658 + 0.98101*\text{Building_Area} + 0.01836*\text{Land_Area}^{0.5} - 0.83540*\text{Building_Age} \\ &+ 1.02090*\text{Sale_Month} - 4.21273*\text{Sale_Month}^{0.5} + 6.22984*\text{Building_Standard} + 0.48867* \\ &\text{Settlement_Quality} - 3.75147*\text{Distance_to_Parks} - 1.23628*\text{Distance_to_Shoppings})^2 \end{aligned} \quad (1)$$

Where: Price is the selling price in US dollars; Building_Area is the total surface of the property (in m^2); Land_Area is the ground surface (m^2); Building_Age is the age of the building (years); Sale_Month is the time of sale (Month = 1 is October'98); Building_Standard is the quality of construction; Settlement_Quality is the quality of neighborhood; Distance_to_Parks and Distance_to_Shopping are distances to these points (kilometers). The model in Equation 1 was adopted before proven by the conventional tests, such as ANOVA, significance of the variables, and behavior of the errors; and it has a R^2 of 0.906.

Data sample is large in size and time period, allowing a reasonable confidence about market behaviour covering. In future applications, one may add new market data and to recalculate the model. Market do not change a lot in small time periods (e.g. some months), then it can expected small changes in the coefficients (the "shadow prices" of each building characteristic present on the Equation 1).

Sustainable projects

It's very clear the influence of buildings on the environment. The buildings require significant resources for its construction, as well as for operation and maintenance. The built

environment accounts for almost 50% of emissions of greenhouse gases, and a similar fraction of energy consumption and water (Gauzin-Müller, 2002; Yeang, 2001).

The issue of sustainability in construction have a link to sustainability in general, including problems of degradation of the natural environment, climate change and greenhouse effect, for example, and has three basic aspects: economic, environmental and social. These aspects should be pursued consistently (Gauzin-Müller, 2002).

There are several available criteria and principles for sustainability in construction, based on life cycle analysis, recycling of materials, components or construction and calculation of the energy involved (Kibert, 2005). Rehabilitation is a form of recycling the building, which attempts to use the existing structure of the building and infrastructure in the region, with less waste generation and lower energy consumption in the life cycle of the building. For the specification of new materials are adopted the choice based on the energy involved in each option, considering also the costs and the need for resources in the life cycle (Boussabaine and Kirkham, 2004).

Flexible projects

The repetition of the project can be considered as a cause of devaluation of social housing. In general, the mass housing market is seen as low quality housing, monotonous and intended for low-income population (Brattbakk and Hansen, 2004, Hastings, 2004; Verhage, 2005).

Kleinhans (2004) recommended the diversification of housing types and encouraging various economic activities (shops, offices, services), in order to attract a population with different socio-economic conditions. These are important actions to reduce crime and pollution, to expand and qualify the transport and urban infrastructure. Verhage (2005) also maintains that the building and urban renewal should encourage diversity of typologies, to attract different people and thus reduce the possibility of segregation.
Another premise is that the building should accommodate users along its life cycle and not vice-versa. For this, the design must incorporate some degree of flexibility. The research line "Open Buildings" continues studies of Habraken (1972, 1998) and represents a strategy of design, construction and operation of the built environment looking for flexibility (increasing the ability to adapt to the changes that occur throughout the life cycle of a building).

From this point of view, the building has basically two parts: shell (constructive form with durable characteristics) and infill (internal parts that can be performed with lightweight materials and should provide flexibility to adapt). This concept applies to new projects, where one can specify the structures, fences and building systems in a simple, yet also adaptation or renovation projects of buildings can (or must) take into account the flexibility (Habraken, 1998 , Kendall, 2005). There are some rehabilitation studies in Brazil for the social housing sector, such as (Folz, 2008; Marroquim and Barbirato, 2007; Szücs, 1998).

SIMULATION STUDY IN PORTO ALEGRE

This part of the work presents a study about on the possibility of renewal of an housing complex in Porto Alegre, Brazil. The investigation was conducted following the principles presented through simulation of alternative projects with actual costs and market values.

These projects usually have a repeating pattern and follow a common pattern (BNH, 1979). There is hundreds of this kind in Brazil, and in many cases they are in not too good conditions, or they have no requirements that families need today. It is still important to think about collective solutions to the joint through a strategy that will allow differentiation of the properties without losing the characteristic of the housing estate.

For build the proposals, were also considered good examples of social housing built in Brazil and other countries (French, 2008). It is important to note that we do not discuss the architectural quality of the project alternatives itself, which were generated to allow analysis and discussion of some issues. In addition, a more precise analysis of a building renovation project must involve the users (Giussani, 2007; Suschek-Berger and Ornetzeder, 2005).

Description of condominium blocks

The case study is about Rubem Berta settlement, considered the largest housing settlement of the state of Rio Grande do Sul and one of the largest districts in the country. It is an 8.7 km² built area and about 80 thousand inhabitants. The occupation in this region began in the 50's, to be formally established by a municipal law of Porto Alegre in 1968. It is a neighborhood occupied almost entirely by vertical buildings (Rigatti, 1999, Severo, 2006). Figure 1 show an aerial image, where one can see the density of occupation in the neighborhood, and a set of blocks in detail, with some façades. This set is located on the 22' Street (Rua Vinte e Dois). It was completed in March 1980 with the financing of BNH, consists of four blocks, with 4 levels and 8 apartments per floor, with a total of 5,872 m^2 and 128 units. The region has dozens of blocks of similar size and standard.

Figure 1 *– Aerial image and façade – 22' Street - Rubem Berta settlement*

Figure 2 shows the original floor design. It has three types of apartments, with one (R1=35m^2), two (R2=46m^2) and three bedrooms (R3=56m^2). Each level has 367m^2, with 5 double bedroom units, 2 units of 3 bedrooms and a single bedroom unit. Construction is on conventional reinforced concrete structure and masonry bricks walls covered with mortar joint; the windows are built on steel tubes, the roof has asbestos-cement shingles, and the rooms have parquet on the social areas, and ceramics at the service fields. There is no lift on the building.

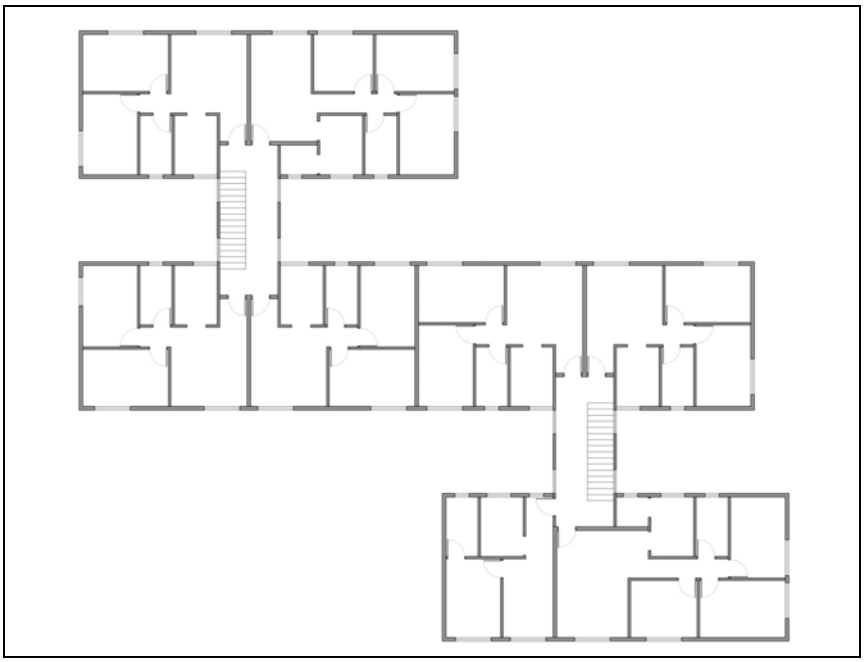

Figure 2 *– Original floor design – with 1, 2 and 3 rooms*

Internal rehabilitation design

This proposal seeks to use the existing structure, still generating internal differentiation in the building. They were proposed alterations from the original floor plant. The internal diversification of the apartments was explored, recombining existing units to form lofts, horizontal and vertical duplexes; with a greater variety of floor plans in the building (Figure 3). The project includes the expansion of the blocks including a new level. The flexible plan allows residents of the building to change property type without change your address along time. Thus, neighbourly ties are not lost and the community remains united.

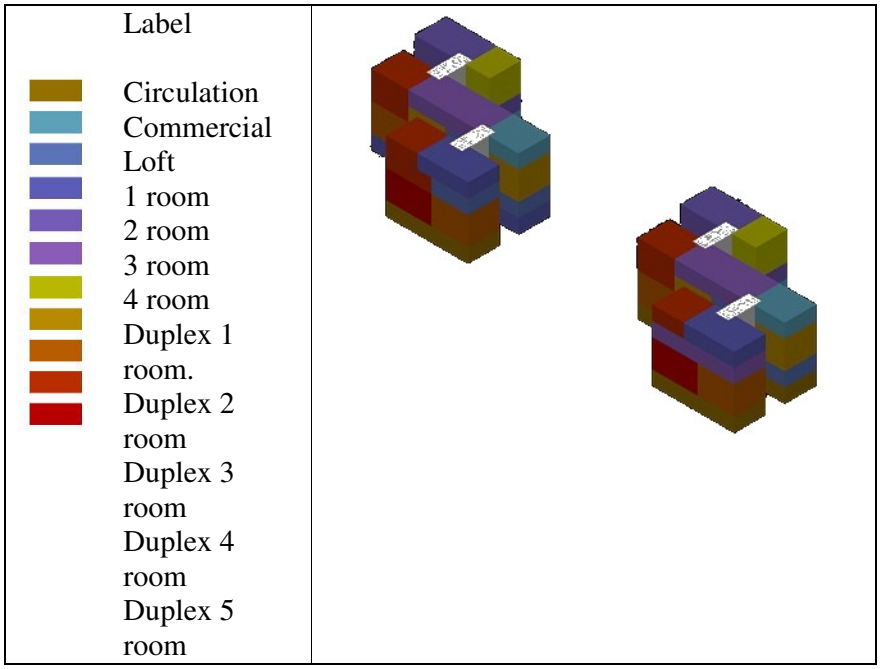

***Figure 3** – Different building types – Two block examples*

The project includes the expansion of the blocks including a new level in some blocks. The reinforced concrete structure is conventional. It has 30 years old and was calculated according to odd customs and rules, perhaps more demanding than today. We checked the quality and status of this structure through detailed field inspections. Can be seen that the structure is to extra-dimensioned in relation to existing concrete structures. Under these considerations, we can add a further layer in the block without loss of structural performance. The income from the sale of new units may finance the work. One can make the differentiation of units without undoing the basic features of the condominium, which maintains a regular appearance (Figure 4).

***Figure 4** – Buildings with different levels – 4 and 5 stories*

Façade rehabilitation design

The proposal adopts metal structural elements connected to the building's facade, including open or closed balconies. All the balconies incorporate barbecue equipment (grill), which is a very important element on local culture. The part of balcony positioned side by side on living room is open while the part at side of bedroom it's closed by a mobile brise (Figure 5). It was designed to obtain major environmental comfort on bedroom, which reduce sunlight and at the same time, allow free air circulation. The location of the wind may vary according to the needs of residents, keeping the same building pattern (Figures 5 and 6).

Figure 5 *– Façade options – building with and without balconies; open and closed balconies*

Roof housing rehabilitation

The structure is relatively old and we can say it's extra-sized in relation to existing concrete structures. In addiction, the new plant allows the use of a green roof. This green roof collects rainwater for reuse (Figure 5). The roof also contributes to the upgrade of the facade. We propose two different roof styles. In the first, the cover remained as originally, and on another was covered with a green protection, with thermal effect about the last level apartments (Figure 6). They have similar costs.

Figure 6 *– Roofs – Option A (conventional) and B (green roof)*

Economic viability of the rehabilitation project

The costs were calculated per apartment (average per unit). After that, we did the calculation of value adding using Equation 1. There are many different configurations of building renewal, but we presented one option, to examine the feasibility and to demonstrate the methodology of analysis. It is the simplest (assumed to be the most likely option in a real case): the inclusion of balconies with barbecue equipment, a very important element in local culture. Budget was considered for the buildings with one, two, or three bedrooms. Costs are different by building type (Table 1).

Table 1 – Budgeting details of façade renovation – average by unit – on USD

Rooms	Simple (R1)		Double (R2) or Triple (R3)	
Element	Dimension	Cost	Dimension	Cost
Foundation – radier on concrete	3.5 m^3	900.00	4.0 m^3	1,000.00
Steel balconies: 5.6m^2 – structure, floors and laterals	490 kg	3,950.00	650 kg	5,250.00
Aluminum brises	6.0m^2	1,350.00	8.0m^2	1,800.00
Inner changes (masonry, carpentry) – changes on windows, changes on the external walls		810.00		820.00
General painting	47.0m^2	910.00	49.0m^2	970.00

Project, tax, management	12.5%	880.00	12.5%	1,120.00
Unit costs		8,800.00		10,945.00

The market values for each apartment were calculated using the actual data of each type of building, for the month of December 2010. These values were obtained for the current state of the building. In a second stage it was proposed lowering the age for 15 years and increases the standard of level 2 for 3, for the purpose of updating and renovation of the façade (compare Figures 1 and 5, 6). It is a use of the concept of "apparent age" as used in commercial appraisals (Appraisal Journal, 2001; Pagourtzi et al., 2003). The change of standard is justified by the addition of the balcony with a barbecue equipment. In addition, we calculated the effect of increasing the area by the addition of the balcony. The calculated values for each unit are shown in Table 2. As the valuing is greater than the costs, we demonstrated economic viability. There is an advantage of about $ 300 to $ 1,100 per unit with the renovation. This small difference may decrease the risk of gentrification, why not bring a significant enhancement to the property. Properties maintain affordability, as well as, target group is not removed of your dwellings after refurbishment project.

Table 2 –Economic analysis of façade renovation

Apartment	Area (m^2)	Original value – USD	Area (m^2)	Value with renovation – USD	Valorization – USD	Profit – USD
Simple room – R1	35.00	36,800	40.6	46,700	9,900	1,100
Double room– R2	46.00	41,060	53.5	52,330	11,270	325
Triple room – R3	56.00	45,133	63.5	56,910	11,777	832

Economic viability has been demonstrated. Design strategy allows the differentiation of the blocks without mischaracterize the condominium. The quality of life for residents is extended with the addition of balconies and brises, and improving thermal comfort of the units. Sustainability is achieved through the use of steel, which is cheaper and has less energy incorporated than reinforced concrete.

FINAL CONSIDERATIONS

The Brazilian condominiums developed under BNH' period were built since the late 60's to the beginning of the 80's, with thousands of similar estates. Actually there are opportunities for renewal. This study used simulation proposing building renovation with maximum use of existing infrastructure. We develop design alternatives with budgets based on real costs. Final cost of refurbishment was compared with predicted value calculated by hedonic price models. HPM was based on a large data sample (in terms of size and time period), allowing confidence about market behaviour covering.

The renewal proposal adds differences in the condominium. The overall appearance of a monotonous, repetitive complex, with all the equal blocks, shown in Figure 1, is changed to a set that has common design features, but it has different characters in each block, with different heights (Figure 4), with balconies (Figure 5), conventional or green roof (Figure 6), and so on. In addition, there are buildings with different number of rooms, allowing that families with different configurations can share the same urban space (Figure 3).

The design process incorporated sustainability features, with the analysis of energy involved - preference for materials of lower total energy and greater potential of recycling - and economic viability analysis, which confronted the costs of implementing the building renewal. To partially fund the renovation of the building by selling units, or replacement of the residents of each block was designed adding a new level. This research has already shown it is possible to rehabilitate old buildings and blocks design with flexible design units, with this flexibility vertical or horizontal.

The small differences verified on property prices reduce the risk of gentrification. Properties maintain affordability and people are not removed of your dwellings after refurbishment project. To refinement of this method, we recommend to test different design options, to verify the best one, in economic and environmental terms.

ACKNOWLEDGEMENTS

This study was partially founded by Brazilian Research Councils CAPES, CNPq and FAPERGS.

Abstract
By adopting a theoretical framework from strategic niche management research (SNM) this paper presents an analysis of the innovation system of the Danish Construction industry. Theories within SNM look upon innovation in a sector as a socio-technical phenomenon and identify three levels of socio-technical interaction within which sectorial innovation can be explained. The analysis shows a multifaceted landscape of innovation around an existing regime, built in the existing ways of working and developed over generations. The regime is challenged from various niches and the socio-technical landscape through trends as globalization. Three niches (Lean Construction, BIM and System Deliveries) are subject to a detailed analysis showing partly incompatible rationales and various degrees of innovation potential. Based on the analysis, the paper further explores how companies can be introduced as drivers for innovation in the construction industry. By bridging SNM with business development activities through an adapted version of Ansoffs growth matrix, companies continuously and consciously can develop a competitive advantage by targeting new and existing markets with new or existing competencies/niches. The paper concludes with a discussion of how this approach can help to solve the challenge of retrofitting the existing building stock and thereby enabling the development a low energy consuming society.

Keywords: Innovation, Niche, SNM, Companies, Business development.

INTRODUCTION

The construction industry is often characterised as a tradition bound low innovation sector which struggles with low productivity. The constant comparison of the construction industry with other industries e.g. in relation to innovation is however problematic. The construction industry could be viewed as fundamentally different from many other industries by being project-oriented with a significant proportion of unique production. Construction is linked to a specific location and the design and production team is organized uniquely for each project. This dynamic frames the innovation process in contexts where continuous development is more or less impossible. Consequently many of the innovations are confined within the single project (Thuesen 2006).

The consequence is that numerous companies fail to evolve independently, but are subject to an industry development and regulation that fixates businesses in their existing working practices and institutional role.

Nevertheless, innovation processes *are* going on at all levels of the construction industry - from the builders at the construction site to the major development programs. Consequently a small but significant strand of Danish research has been conducted around innovation e.g. Clausen (2002), Simonsen (2007) and Vind and Thomassen (2009).

Despite the strong interest in stimulating innovation in Danish industry, the innovation programs are facing striking difficulties. Clausen (2002) concludes in his analysis of sectorial development programs that a mapping of innovation activity in construction industry is needed, focusing the interplay between strategically oriented and formalized activities and informal innovation processes on construction projects. (ibid: p. 13)

In this way it relevant to investigate how the construction industry capacity for innovation can be accelerated so that and how the industry can respond to new societal challenges such as the move towards CO2-neutral societies.

AMBITION

The ambition of the paper is to analyse the innovation system in the Danish construction industry (Thuesen et al 2011), and discuss by the use of innovation maps how companies can be introduced as vehicle for innovation driving towards a low energy consuming society.

THEORETICAL FRAMEWORK

The research of the innovation system of the Danish Construction industry draws upon a theoretical framework from strategic niche management research (SNM) (Schot and Geels 2008).

Theories within SNM look upon innovation in a sector as a socio-technical phenomenon and identify three levels of socio-technical interaction within which sectorial innovation can be explained (Schot and Geels 2008, p. 545). Illustrated in the following figure.

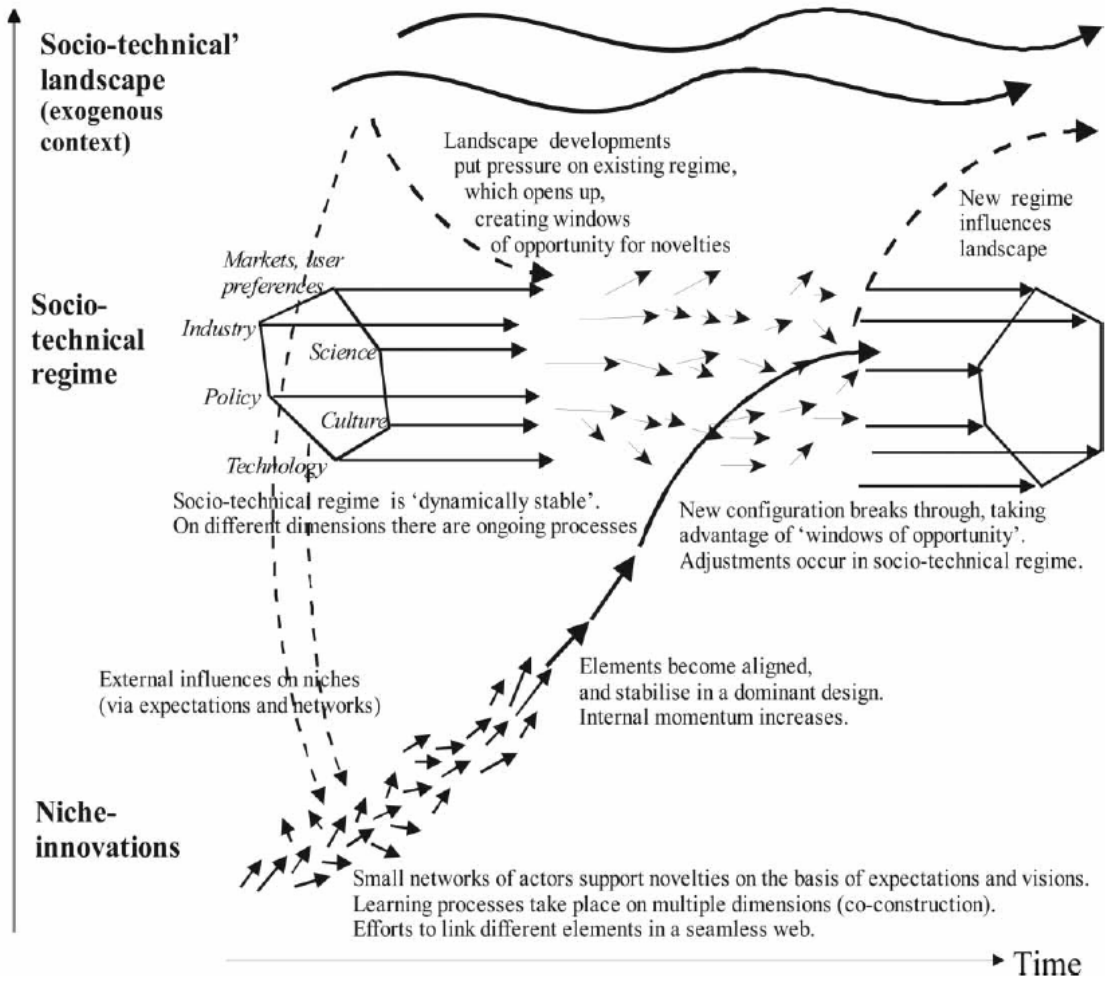

Figure 1: *Innovation in a sector explained in three levels (e.g. Schot & Geels 2008, s. 546)*

Niches form the micro-level where radical novelties emerge. The socio-technical regime forms the meso-level, which accounts for the dominating stabilized socio-technical pattern of interaction which is reproduced by institutionalised learning processes. The macro-level is formed by the socio-technical landscape, an exogenous environment beyond the direct influence of niche and regime actors (e.g. macro-economics, deep cultural patterns, macro-political developments).

According to Geels and Kemp (2007) researchers within sociology of technology and evolutionary economics have stressed the importance of niches as driver of innovations, from where new socio-technical regimes can be developed (Schot 1998, Levinthal 1998). Niches work as incubations environments for new ideas by being protected from the traditional selection mechanisms of the marketplace.

By distinguishing between market and technological niches Schot & Geels (2008) explains how innovation can be achieved through institutional learning processes linking technological niches to niche markets. These changes could potentially lead to regime shift as outlined in the following figure.

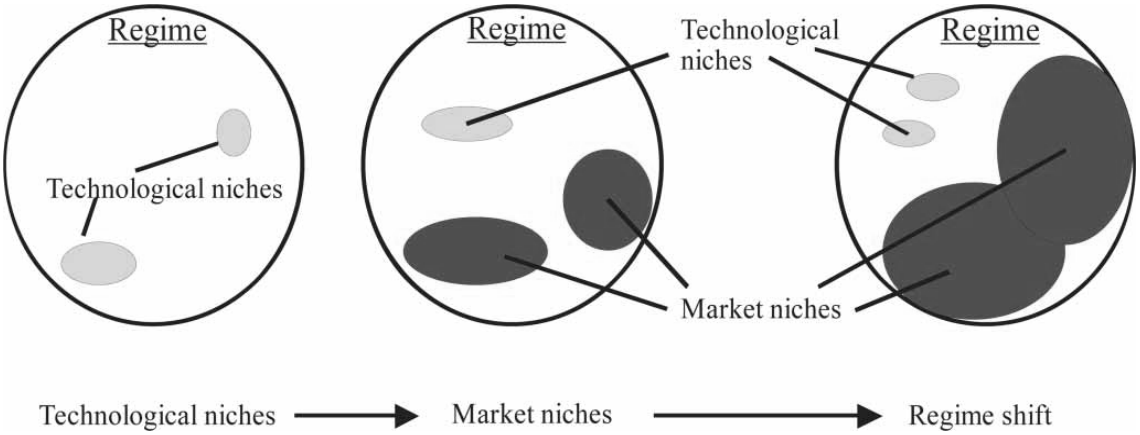

Figure 2: *Regime shifts from niche development (Schot & Geels 2008, 540)*

The regime is challenged as (1) technology matures in some closed technological niches (2) these technical solutions addresses a limited market need (3) and through the growth of the markets the technologies further matures and win wider acceptance in the entire regime.
An important premise for the development and maturation of ideas in the form of niches are learning processes and the building of social networks that support new innovations and investments (Schot et al 1994, Kemp et al 1998 & 2001 and Hoogma et al 2002). The development of niches through these activities is achieved through ongoing project-based learning processes which over time provides a certain direction / rationality as outlined in the following figure.

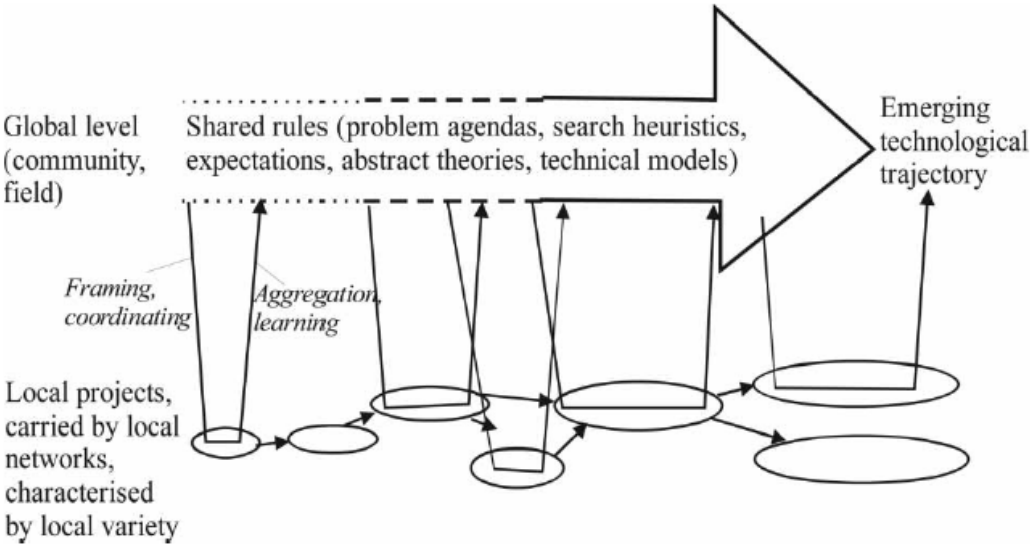

Figure 1: *Niche learning processes (Schot & Geels 2008, p. 544)*

It is precisely this common sense making which integrates the niches and develop its own sense of identity - a rationality that legitimizes the stakeholders' actions even though they may be in opposition to the dominant regime. Jensen et al (forthcoming) explain the rationality based on three mutually constitutive concepts an interpretive resource, a sector representation and a strategic orientation. Thus, they want to explain how a "tool" (the interpretive resource), forms a certain image of the existing regime (sector representation) and develops corresponding practices (strategic orientation). Rationality in the niche can thus

be explained by using a key metaphor in which a set of problems (the sectorial representation) can be unlocked with a corresponding solution (strategic orientation) by the key (the interpretive resource).

METHOD

Based on the theoretical concept, the collection of empirical material for analysing the innovation system draws on multiple sources like qualitative workshops, semistructured interviews, existing analysis and analysis of central texts.

The analysis of the existing regime draws upon a Foucauldian analysis of the development of the Danish construction industry (Gottlieb 2010) combined with an analysis of the past 25 years of development of construction based on the driving myths of construction (Thuesen et al 2009). This is supplemented by the IT element, based on Berard (2006) and Jensen (2011).

The three analysed niches in Thuesen et al (2011) have been selected from an initial larger sample of 'candidates' according to their innovation potential and the main drivers of the development being either the governmental or sectorial driven. The niches are the concepts around Lean Construction (Last Planner System LPS), BIM (Building Information Modelling) as a part of a general digitalization of the Danish construction industry and an emerging niche around new industrialization termed "system deliverances". The empirical material for analysing the niches consists of two qualitative workshops, eight qualitative interviews combined the central texts and theories of the niches. The material was collected in the period from the autumn of 2009 to the spring of 2010 starting with execution of the two workshops in communities around the niches followed by semi-structured interviews (Kvale, 1996) of persons in playing different roles the niche development. By asking the persons similar and different question based on their role it was subsequently possible to identify coherency and differences in their understanding of the niche and its relation to other niches and the existing regime. The material from Thuesen et al (2011) is supplemented by material on BIM from Berard (2006) and Jensen (2011).

ANALYSIS

The analysis of the innovation system is structured in three sections, firstly focusing on establishing an understanding of the predominant regime, secondly juxtaposes the three niches and finally analyzing the niches up against the existing regime.

The construction regime - developed through generations

The existing regime is developed through generations in a process characterised by periods of more and less stability and moments of radical changes in the construction practices. Although the moments of change encapsulates periods of fundamental different construction practices as between the premodern (-1945), modern (1960-70) and postmodern (1980-) construction the historical practices are to some extent sedimented in the present postmodern construction practices. Based on a historical analysis (Gottlieb 2010) the postmodern construction regime is identified as having the following characteristics according to the theoretical dimensions Technology, Industry, Market /customers, Policy, Culture, Education and research.

Dimension	Characteristics
Technology	Building materials: many different materials are in play all though there has been a preference around concrete elements since the introduction in the 60'ties. Processes: Phase models, in-situ production, planning tools based on Critical Path Method (CPM) wide spread, but "islanded" use of information technology, project management as the predominant management philosophy.
Industry	The organization of the industry is characterized by strong interest organizations representing many different professions like crafts, engineers, architects, contractors, and material producers. The value-chain is fragmented with a strong separation of design and production.
Market and customers	The market is heterogeneous and characterized by fluctuation. The customers are addressed by the architects, who tailor unique projects specifically to the customers' individual needs.
Policy	The sector is regulated around competitive bidding, tendering systems, shared standards and general conditions for work and supply. The development of the regulation happens in close collaboration between the interests organizations and the governmental anchoring (Danish Enterprise and Construction Authority, EBST), but also increasing EU.
Culture	The cultural organization of the industry is based on professions which are sustaining craft differentiated education institutions with a strong element of apprenticeship learning processes. The building organization has over time developed a strong separation between design and production favouring the development of cultures around problem solving. The institutional learning processes have the past 30 years, been centred on the myth about the unique building, make the actors perceive the nature of the build process as complex or even chaotic. Final there is a strong focus on collaboration rethorics among actors in the future development of the industry.
R&D	The organization and division of labour is mirrored and reproduced by the educational system. This system spans a wide way of cultural knowledge's from tacit and embodied situated in crafts to explicit and scientific in the academic professions. The central management practice is Project management, which is inscribed in the educational system and is influencing the research agendas.

Table 1: *overview of the building regime*

The regime is situated within a broader societal context which challenges it and creates new possibilities of innovation. Trends like globalization, climate change, an aging population, new technological breakthroughs partly destabilize the regime making it vulnerable to niche innovations and other dynamics. When this happens it can be understood as windows of opportunities for change of the existing regime.

Niches represent different sources of innovation

This window of opportunity might be addressed by different niches. We will here look closer to the niches around the Lean Construction, BIM and System deliveries illustrated in the following figures.

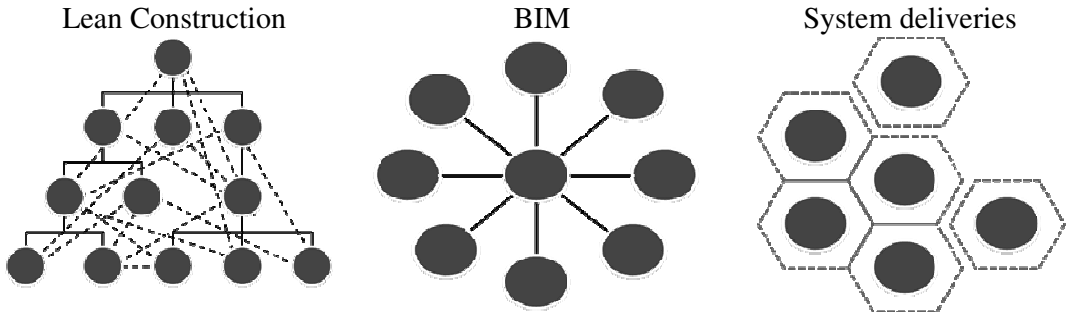

Figure 4: *Illustration of niches*

While the niches all try to address the regime, they represent different logics for building developments that are more or less compatible. The table below summarizes some of the key differences in rationality between the three niches.

	Lean Construction	**BIM**	**System deliveries**
Key (Logic)	Process planning tools around LPS	The object oriented 3D model / BIM	Mass-customization
Understanding of the existing regime (Sectorial representation)	The complex and chaotic building process makes long-term planning impossible.	The construction industry as a series of inconsistent and uncoordinated information flows	The construction industry as an under-modularized mode of production characterized by project-specific problem solving and short term collaboration, which hinders innovation and specialization
Solution (Strategic orientation)	Development of tools and processes for optimizing value and flow based on short term planning and involvement of crafts	The development of a shared object-oriented classification and information infrastructure able to ensure unequivocal information capable to coordinate the complexity of the construction process	Project independent design and production of modular and customizable products and services through product platforms, strategy partnerships and value-chain integration

Table 2: *Different rationalities of the niches*

The three niches perceive the existing regime from various perspectives and are consequently formulating different problems and solutions. In LC is the building process considered as complex and even chaotic, which prevents long-term planning. As a result is LC developing tools and processes for optimizing value and flow based on short term planning and involvement of crafts symbolised in the Last Planner ´System LPS. The perspectives offered by the BIM and System deliveries niche is different as they claim that the building process can be tamed and standardized so that information flows and processes can be coordinated. System deliveries also notes that the short-term collaborative constellations often prevents the development of the industry, and thus seeks to create a better process understanding across the actors enabling value-chain integration. As the different niches don't have identical

understandings of the regime their diagnosis of the regimes problems are different. Their different diagnoses and keys (logics) also allow different strategic development directions. While LC is trying to handle the complexity of the building process through short-term planning, the BIM concept is trying to manage complexity through common systems and standards for information exchange (interoperability) and final are System Deliveries strategy to reduce complexity through modularization.

While the niches have different rationalities, they are also major differences in terms of radicalism. While Lean Construction tries to change the regime from within reproducing the existing building practices (*reproduction*) system deliverances fundamentally tries to reorganize the regime from outside (*transition*). In between these BIM is trying to digitalize the existing regime while not fundamentally changing the organisation of the industry (*transformation*). The niches are thus having different innovation potential as summarized in the following table

	Lean Construction	**BIM**	**System deliveries**
Potential	Can strengthen the effectiveness and value-creation within the existing regime Short ROI – can be implemented at project level	Enables a more efficient exchange of information between building partners. Enables a greater complexity in construction	Addresses productivity challenge Delivers product of high quality, faster and cheaper
Barriers	Can't facilitate cross-project optimization – pursuing economy of scale. Requires change a in cultures	Hard to get all parties to agree => implementation is difficult. Can't optimize across the value chain – pursuing economy of scale. Long ROI	Long ROI Can't be realized at the project level, but requires a market of a certain size and extensive knowledge of customer needs Requires reorganization of the division of labour in regime.

Table 3: *Barriers and potentials of the niches*

The conflicting rationalities among the niches internally and towards the regime put emphasis on strategy development in the companies. Thus is it important to develop strategies which will be able to handle these differences and navigating in the innovation system.

DISCUSSION: COMPANIES A INNOVATION DRIVERS

Companies present innovation practices

Thuesen, Koch and Nielsen (2010) show how SME's is navigating in the innovation system today. They identify that companies have a reactive practice towards development, where companies try to follow the development in the market rather than shaping their own market in strategy processes which are characterized by being unstructured, undocumented and non-reflexive.

The table below compares the results from Thuesen, Koch and Nielsen (2010) with a similar study of SME in the general industry (DI 2011), showing that strategy processes among construction firms are not nearly as formalized and deliberate as in the industry.

Companies with …	Industry companies	Construction companies
no strategy	19%	39%
a strategy	81%	61%
a strategy which is implemented	27%	17%

Table 4: *Differences between industrial and construction companies' business development processes*

The non-reflexive strategy combined with the fact that the input to the strategy direction does not differ significantly from competitors' input makes the companies move in the same direction as the competitors. Consequently will they reproduce the existing division of labour in the industry.

This development has resulted in that most businesses operate from a Cost+ model, making the companies compete on their overhead rather than their core processes (Nicolini et al 2001). In this sense the market place is characterised as a typical red ocean environment, where the companies in the absence of core competencies compete on their overhead rather than their ability to reduce production cost and create value – as described by Kim and Mauborgne (2004, 81):

Red ocean strategy	Blue ocean strategy
Compete in existing market space	Create uncontested market space
Beat the competition	Make the competition irrelevant
Exploit existing demand	Create and capture new demand
Make the value/cost trade-off	Break the value/cost trade-off
Align the whole system of a company's activities with its strategic choice of differentiation or low cost	Align the whole system of a company's activities in pursuit of differentiation and low cost

Table 5: *Characteristic of red and blue oceans*

Companies as innovation drivers – combining markets and competences

Thuesen, Koch and Nielsen (2010) stress that although the red ocean market puts pressure on margins in each company making them struggle for survival it also represents an opportunity for creating an uncontested market space pursuing a blue ocean strategy.

A premise for the development of a blue sea strategy, however, requires a conscious approach for business development. This is supported by the DI study which identifies that 48% of companies that have a formulated strategy expect growth in the coming years, while only 12% of those who do not have a strategy expect growth (DI 2011, p 3). So there is a connection between conscious business development and growth.

By upgrading business development skills of managers of construction companies, while at the same time providing them with an overview of the socitial challenges which should be addressed and what potential tools and competences they can apply, we could potential realize an untapped potential for innovation in the industry's.

One of the classical approaches to strategy development is how company can combine competences and markets. The following figure, which is inspired by Ansoff growth matrix (Ansoff 1957), formulate strategy choices as a matter of combining new and existing competences and new / existing markets. In this way it can help to translate the concepts around niches and markets to the classic strategic tools.

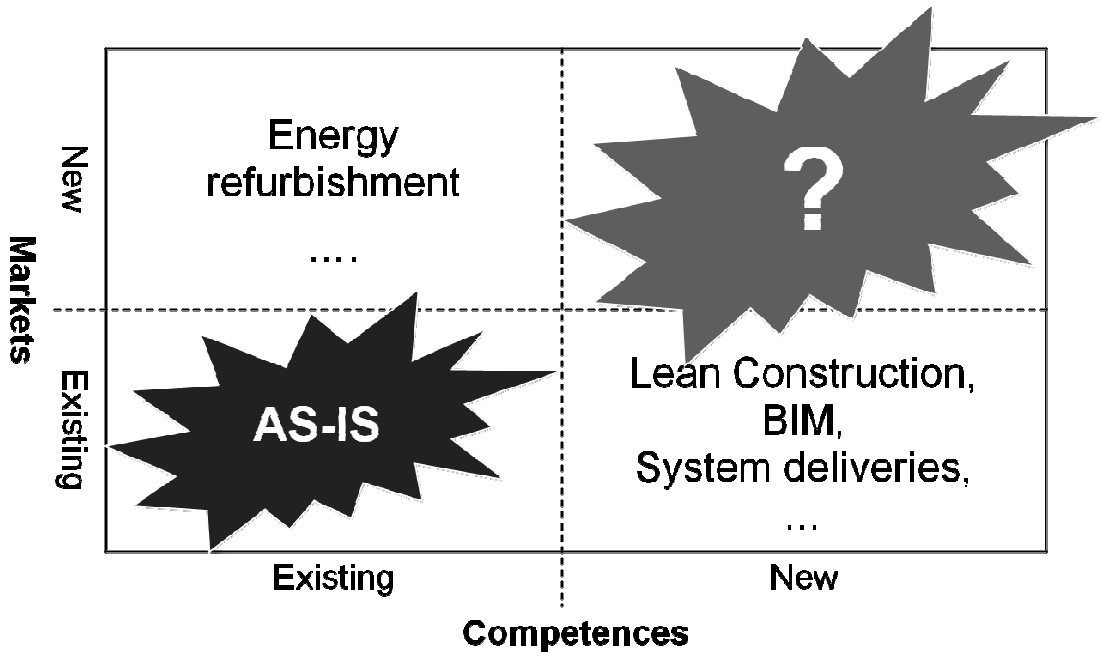

Figure 5: *Strategy as a combination of market and competences*

The companies which have to drive the innovation forward is neither large nor small, but a combination of different types and sizes, across sectors and roles. This means that companies do not have the same setup and hence not be able to make the same strategic choices. As an example it will be difficult for a small company to implement System deliveries because of the requirement to invested capital.

While the local strategic position of the company influences the possible strategic choices so do the internal compatibility of niches and markets. Not all the technologies/competences and markets that are well-matched. E.g. can the general market for energy renovations be addressed by System deliveries, LC and BIM, but if one have to build a one-of-a-.kind opera houses, system deliveries would not be as relevant as LC and BIM. Conversely, will a project of energy refurbishment of an opera house not be suitable for system deliveries. It may therefore be beneficial to help businesses to assess which technologies can be applied to which markets as outlined in the following table.

Market	**Energy refurbishment**								
Submarket/-complexity	**Dwellings**		**Apartment blocks**		**Offices**	**Simple**		**Complex**	
Size	Small	Large	Small	Large		Small	Large	Small	Large
Niches / competence									
Lean Construction	-	-	+	+	+	-	-	+	+
System deliveries (component)	-	+	-	+	+	-	+	-	+
System deliveries (concept)	+	+	+	+	-	+	+	-	-
BIM	-	+	+	+	+	-	+	+	+

Table 6: *Possible combinations of markets and competences*

The table shows the possible good and bad matches between technological niches and market niches exemplified by markets around the energy refurbishment. As an example will it not be very wise to renovate single-family homes based on LC, as these type of projects typically are small are therefore not sufficient large to bear the costs of implementing the LC on each project. Conversely, will it be obvious to address a big market around the renovation of single family houses with System deliveries (e.g. the ones build in the 60-70'ies) since the size of the market easily could cover the development costs across projects.

This analysis is of course a gross simplification, but is nevertheless trying to describe what constitutes good combinations. Therefore it may be appropriate to subdivide "niches" like it have been done around System deliveries since the applicability of these is very different if they focus on building components or concepts for entire buildings.

The flexibility in which companies can experiment with linking various technical competences with potential markets will ensure the testing of various combinations of markets and competencies. By the different strategic choices the companies will drive the innovation and since some combinations will be more successful than others the level of innovation in the industry can be strengthened.

Innovation map

In order to make the companies capable of navigating in the innovation system – their strategic direction can be supported by a map.

A central premise for the facilitation of innovation through in this perspective is the development of a "language" through which the industry can understand and articulate innovation and strategies. Here it is appropriate to draw on the theories presented in this paper. Through concepts as niches, regimes, etc. these theories offers a typology which can be ordered in a map. Such a map could provide an overview and orientation points for navigating in the innovation system. Moreover, the map could clarify the interfaces of key players such as the different interest organizations and governmental institutions. Consistency and transparency in the innovation activities can be developed internally among government agencies and between public and private players including construction companies.

By combining the past, present and possible futures in an innovation map, companies can orient and position themselves strategically and thus be the basis for the launching development initiatives in the individual company. By creating an overview of innovation in

the industry, companies can reflect on where they want to go. Will/can we focus on the short or long term? Will we take the risks needed to invest in System Deliveries or should we just choose to deploy LC ... or should not do anything. In this way, the map will be a tool for a more focused and deliberate business development where leaders do not just subscribe to every existing development agenda, but work with a limited, compatible and consistent number of elements ... in relation to the company's existing competencies, the industry's current regimen, technological niches and potential markets.

From a company perspective two elements are necessary in such a map – information about niches and markets.

The analysis of the niches can be inspired by the methodology one presented in this paper focusing on rationality and the potential and barriers with the niche. Furthermore can information about the niche relation to the existing regime, involved actors, possible networks and funding possibilities.
The analysis of the market can build on existing market analysis. These analyses which traditionally include quantification of existing markets could be expanded to include future niche markets. Furthermore could the analysis be added extra dimensions such as; sustainability impact, addressability, return on investment, market homogeneity. The figure below illustrates such a market analysis of the market for energy refurbishment of the existing building stock in Denmark (Thuesen 2011).

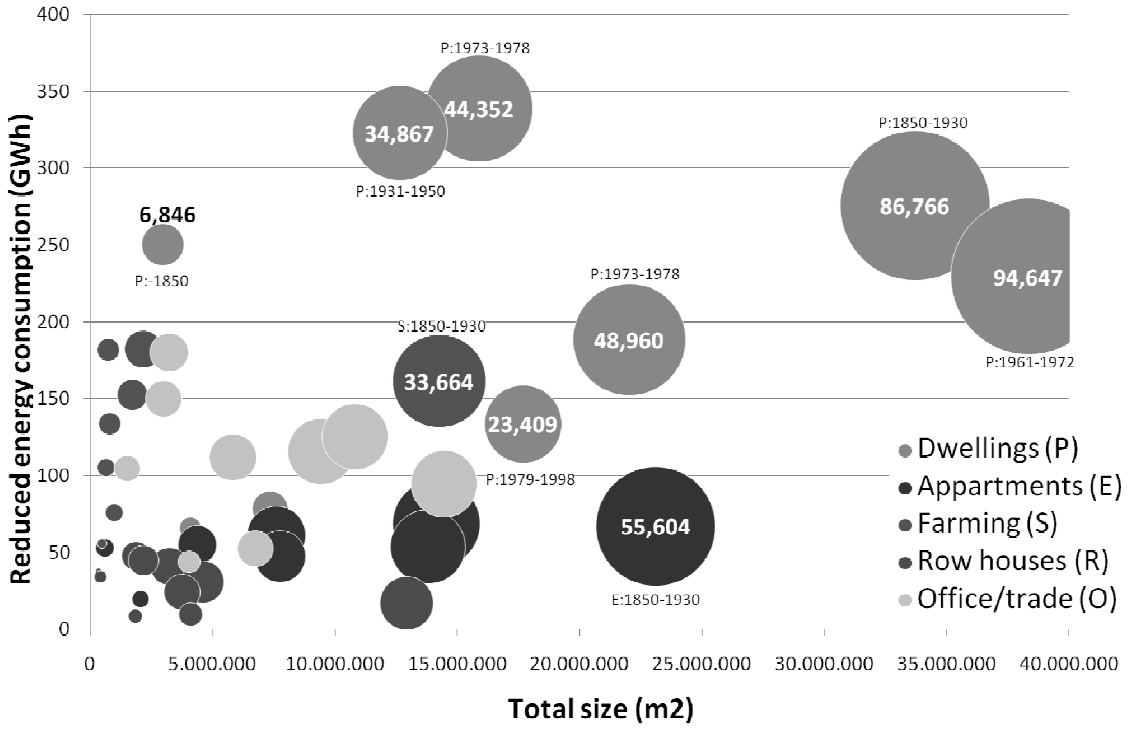

Figure 6: *Quantification of market for energy refurbishment of the existing building stock (the size of the circles represents the market size in Billion DKK)*

By adding different dimensions to the market analysis certain innovation agendas such as sustainability can be facilitated as it informs the company's strategic choices. In this way can the innovation map combined with aligned policy initiatives help to solve the challenge of

retrofitting the existing building stock and thereby enabling the development a low energy consuming society.

CONCLUSION

Based on the theoretical framework from strategic niche management research (SNM) the paper presents an analysis of three niches and a strategy for understanding and facilitating innovation activities in the sector by mapping the predominant regime, overall societal trends and different niches.

The analysis shows a multifaceted landscape of innovations around an existing regime, built in the existing ways of working and developed through generations. This regime is challenged from various niches and the socio-technical landscape through micro and macro trends. The detailed analysis of the three niches Lean Construction/Last Planner System, BIM, and System Deliveries, and their compatibility with the existing regime, show how they represent partly incompatible rationales and various degrees of innovation potential.

The conflicting rationalities among the niches internally and towards the regime put emphasis on reflexive strategy development in the companies. Thus is it important to develop strategies which will enable handling these differences in order to navigate in the innovation system.

By mapping some of the most influential trends and promising niche innovations and relate these to the existing paradigm, an innovation map can act as a medium in which policymakers, interest organization and companies can develop and coordinate future innovation activities.

INNOVATION IN THE CONTEXT OF A DEVELOPING COUNTRY: A CASE OF GROUP HOUSING PROJECT

ARUN BAJRACHARYA
The British University in Dubai
Dubai, UAE.
arun.bajracharya@buid.ac.ae

Abstract

This paper presents a case of group housing project that was new of its kind implemented in the underdeveloped economy of Nepal. The concept of the project as a whole has been taken as a contextual innovation because of its newness and uniqueness in the context of the country at the time of implementation. This study presents a detail account of the project implementation emphasizing the challenges faced by the involved key parties. It provides important insight into the project which eventually proved to be a significant and successful initiating push in triggering a promising new real estate sector in the national economy. Qualitative approach was used for the research in which the main instrument for collecting primary data was face-to-face semi-structured interviews with the key people involved in the project. The findings have been presented in terms of the categories of challenges as the initial perceived constraints, management level challenges, and project level challenges.

Keywords: Innovation, group housing project, project implementation challenges, underdeveloped economy, Nepal.

BACKGROUND OF THE NEPALESE HOUSING SECTOR

General features of Nepalese housing sector in urban area can be explained on the basis of its specific socio-cultural, economic, regulatory and physical aspects. Nepalese society is a multi-racial, multi-lingual and class-wise stratified society (Nepal, 2006). It is traditionalistic and relatively collectivistic, tilted towards high masculinity, high power distance and short-term orientation, and it prefers uncertainty avoidance (Agrawal, 2001; Gautam et al., 2005). Descended from the traditional feudal or semi-feudal values, the land and housing is taken as a major asset and as the symbol of economic well-being, prestige and the power of a family (Mathema, 1999). Almost all of the Nepalese families are paternalistic joint families characterized by the eldest male member as the head of a family (Pant, 2004).

Besides direct purchasing, the ownership of the land and housing in Nepal is inherited from generation to generation in a family. In the Nepalese tradition of family succession, all the male offspring are entitled to the parental property including land and housing (Chapagain, 2001). As the family tree expands and as the joint family gets divided into several other related joint families, the family owned land and housing also gets divided and distributed as per the number of male members in the family.

Probably because of the traditional value system, Nepalese people have a deep rooted preference on building their own independent house in their own land with their own resources (Bhattarai, 2002; SAMN, 2005; Sherchan and Lamsal, 2005). Procuring a house is therefore a long process with the owner's self involvement in purchasing land, building house by own resources in various phases and then in providing infrastructure and utilities services later. Such housing system is termed as the Owner Builder System (NSP, 1996), in which self-financing mechanism is the predominant form of housing finance (Hada, 2001). As such, about 92% of Nepalese households own their housing units, 5% are renters (pay rent) and 2% live on rent-free housing units (CBS, 2004, Vol. 1, pp. 27).

As in other developing countries, there is high attraction differential – in terms of infrastructure facilities, job opportunities and securities – between the urban areas, especially the Nepalese capital Kathmandu, and the other parts of the country. Such differentials have created high immigrant pressure in the capital. About 40% of the population in Kathmandu is migrants from outside (Shrestha, 2004), and it has highly increased the demand and value of land and housing in Kathmandu. As such there is a high deficit in the supply of housing in the capital – for instance there was shortage of about 300,000 units of houses in 2000, and it was increasing at the rate of about 7% per year (Hada, 2001; Bhattarai, 2002).

On the regulatory front, there are separate Nepalese land and property laws that guide the regulatory policies pertaining to the land and housing. However, the government policy in the zoning and distribution of land is not strong and clear. Furthermore, the state administration of land and housing standards are relatively relaxed, and till now there is no public sector housing programs or comprehensive/consolidated land development schemes – except some recent and limited land pooling and development attempts in Kathmandu (Oli, 2003; Spotlight, 2003) – that have facilitated access to housing or land to any class of people, rich or poor (Mathema, 1999).

The socio-cultural, economic and regulatory aspects have significantly influenced the physical development pattern of land and housing in Kathmandu. The "sub-divide and inherit" practice in Nepalese family, the preference of own separate housing, the owner builder system, the high demand, value and consequent shortage of land and housing, and the weak regulatory system are some of the main reasons behind the typical fragmented land distribution and haphazard housing development pattern in Kathmandu. The tendency of haphazard housing pattern is remarkably severe in the high value urban center such as Kathmandu (Spotlight, 2003). Consequently the government has been unable to provide adequate infrastructural facilities to the haphazardly developed housings. Infrastructural facilities such as access roads, drinking water, electricity, sewerage and waste water drainage, arrangement for solid waste disposal, and open spaces have been increasingly becoming deficient for dwelling units (NSP, 1996; Spotlight, 2003). At the same time the quality of housing itself is also not satisfactory – only about 41% of housing in urban area are of permanent type, whereas the remaining housings are semi-permanent, temporary, traditional, and squatter types (NSP, 1996).

THE INNOVATION

The fragmented, haphazard, and low quality land and housing development pattern ingrained in the socio-cultural, economic and regulatory fabrics of Nepalese urban area has been a glaring example of the tragedy of the commons. There was an urgent need to reform the basic

concept of housing. However, changing the age old housing concept in the complex setting of urban area is a highly challenging task. In 1999, a Nepalese private business house came forward with a new idea of an organized group housing project in Kathmandu. The group housing project was a very important innovation in the whole concept of housing in Kathmandu (Humagain, 2001; SD, 2000). This significant housing concept innovation has been chosen for a detail case study in this research.

THE GROUP HOUSING PROJECT

The organized group housing project which is the first of its kind in Nepal was named as "Kathmandu Residency". It is basically an apartment-based housing project which is located at a suburb of Lalitpur District in Kathmandu valley. The project occupies about 1.76 acres (7125 square meters) of land in which a total of 145 apartment units were built. It is an integrated and self-contained residential complex which consists of a range of apartment types from studio apartment to one-bedroom, two-bedroom, and three-bedroom apartments with all the required amenities such as abundant water supply, sufficient electricity and power back-up, an efficient drainage system, private parking, 24-hour security, in-house club, crèche, convenient shopping and enough open spaces and greeneries. The total cost of the project was NRs. 300 million.

The Kathmandu Residency project was initiated by Chaudhary Group of Nepal in joint venture (JV) with Ansal Group Ltd. of India. Chaudhary Group is one of the big business houses of Nepal. The group is a conglomerate organization that accommodates more than 40 companies under its umbrella. Ansal Group Ltd. is one of the major Indian real estate and construction companies. The established JV Company was registered as Ansal Chaudhary Developers Pvt. Ltd. (ACDPL) in Nepal.

The ACDPL appointed a Nepalese local contractor company as the main contractor of the project. The local contractor company was a joint venture of three local contractors – M. B. Construction (an A-class contractor), Safal Builders (a B-class contractor), and R. M. Builders (a C-class contractor) – led by a Director of Safal Builders. The JV main contractor was selected by local tendering process and appointed on the basis of the cost plus fee contract. The ACDPL sought the function of construction from the market and appointed the main contractor. Another important function of architectural and engineering consultant was however internally arranged within the Ansal Group. The architectural and engineering consulting tasks of planning, designing, detailing and quantity survey of all the buildings and ancillaries of the apartment system were undertaken by the Ansal Group itself. All the designs, drawings and bill of quantities were supplied from the Ansal's office in New Delhi. Supervision of the construction works were jointly done by ACDPL.

The client JV together with a set of terms and conditions of the alliance. The Ansal Group and Chaudhary Group had 51% and 49% of shares in the JV respectively. On the other hand the main contractor JV was formed with the alliance of Safal Builders, M. B. Construction and R. M. Builders. These three local contractors formed their JV with a formal set of terms and conditions, and agreed to work together with their informal agreement.

The Chaudhary Group which initiated the project was the Origin Organization (OO) (Dulaimi et al., 2003) of the innovation. The other parties – the Ansal Group, M. B. Construction, Safal Builders, and R. M. Builders – were the main Supporting Organizations (SOs) (Figure 1).

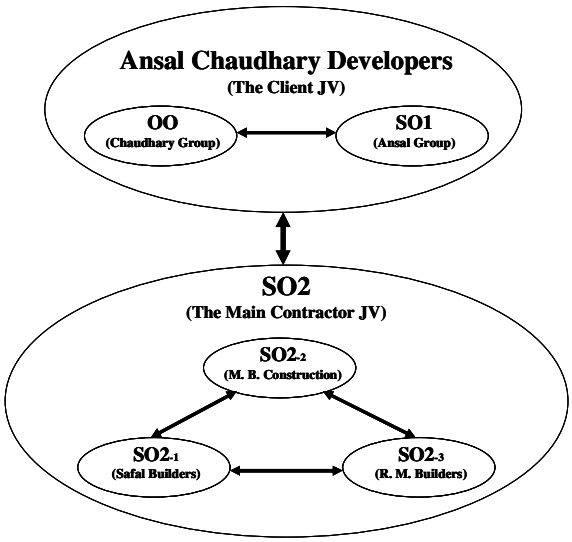

Figure 1. *The Key Parties in the Project*

IMPLEMENTATION OF THE PROJECT

Regulatory Backdrop

Before 1998 the Nepalese land and housing act was traditional one and it was primarily based on the individual or family ownership system. There was no national act that accommodates the concept of group housing. There was the law in vertical division system of land and houses, but there was no law that describes the horizontal division of land and houses. In 1994 a group of three local business houses came up with the idea of group housing in Kathmandu. The group was influential in the national politics and they were successful in raising the issue of group housing act in the parliament. However the process of formulating and enacting the new housing law took a long time, and it receded in the political turmoil of the country. Therefore the group had to abandon the group housing project they had conceptualized. They had even procured the land for the project, but they had to sell-off the land instead. The absence of the law and regulatory mechanisms led their innovative move into a failure.

Even though the first attempt was failed, it contributed in pushing and eventually producing the first laws and by-laws pertaining to group housing in Nepal. In 1997, Nepal Building By-Laws and Apartment Act were promulgated (NBBLAA, 1998).

Formation of the ACDPL

After the law was enacted, the Chaudhary Group moved its step towards the concept of group housing project in Nepal. The President of the Group set up a separate task group under him including the experts in group housing from India. The task group started its work with the feasibility study of the project. The local market study and economic analysis of the project was conducted. The group housing practices in other countries were also observed by visiting

some of the successful projects in India, Thailand, Malaysia and Singapore. At the same time the task group sought an experienced business partner to undertake the project. It contacted several Indian real estate companies, and eventually it was successful to form a partnership with the Ansal Group. The partnership was formed on both the financial and technical parts of the project, and it launched the ACDPL JV.

Initial Marketing

The initial concept and building designs were prepared at the design cell of the Ansal Group's Delhi office. Then the project was formally launched and publicized in the local media in 1998 as a new kind of housing system named Kathmandu Residency. As a part of the publicity, wooden show-piece mock-up apartment blocks were displayed for the marketing purpose. The initial marketing effort was successful in attracting the customers and they were willing to pay the booking advance which was 30% of the total cost of the proposed apartment unit. The ACDPL was successful in tapping a substantial amount of cash inflow from the booking advance.

Searching and Appointing a Main Contractor for Construction

After formally launching and publicizing the project, detail designs, drawings and bill of quantities (BOQ) were prepared in Delhi. As per the design and BOQ, a tender was called in Kathmandu to select a main contractor who would undertake the whole project package. The tender form was distributed only to selected 11 local contractors including a Chinese one. The tender amount was about NRs. 90.8 million. The tender was eventually awarded to a Nepalese local contractor joint venture team on the basis of negotiated lowest bid. It took about six month, since the first lot of customers made advance booking, to appoint the Nepalese local contractor joint venture team as the main contractor of the project.

Receiving the Construction Permit from the Lalitpur Municipality

After appointing the main contractor, the process of receiving the construction permit from the local Laltipur Municipality was initiated. The ACDPL involved the main contractor with its project personnel in dealing with the Municipality. As it was a new kind of project for the Municipality, it took about a year to study and grant the construction permission.

Construction and Handover of the Project

The construction of the project was started after the main contractor was assigned the job. As the Municipality took a long time to grant the construction permission, the construction was actually started before the permission was granted. The main contractor completed Block 1 to 8 within 18 months, Block 9 to 24 within 26 months, and the Block 29 to 32 within 29 months. The original schedule of the construction of the project was 24 month; however it was delayed for about 20 months. The remaining Blocks 25 to 28 and 33 to 36 were departmentally constructed by ACDPL specifically for the Chaudhary Group employees.

As the apartment units were completed with finishing, they were handed over to the customers who booked them. The occupying process of the booked and completed apartment units, and the construction of the remaining blocks went side by side. All the apartment units were fully occupied after six month of completion of the whole apartment system.

CHALLENGES FACED BY THE KEY PARTIES IN THE PROJECT

Initial Perceived Constraints

Chaudhary Group: As the OO of the innovation, the Group had to face several constraints before initiating the group housing concept. The constraints can broadly be explained in terms of the socio-cultural, economic, regulatory and physical aspects of urban housing in the Nepalese context.

The deep rooted preference of Nepalese people in building their own independent house in their own land with their own resources was a major perceived socio-cultural constraint in initiating the group housing concept in which people had to appreciate a different type of housing ownership system. The ownership of a space rather than a distinct piece of land and house, overlap in the private and common property, and the occupants' mandatory responsibilities on the common facilities management in the apartment system were some of the challenging aspects to be introduced in the traditional Nepalese society. Moreover, the psychological preference on the "self-built quality" may not readily appreciate the "quality built by others". Therefore the lack of trust of general Nepalese on the quality and reliability of a ready-made house was a potential constraint.

One of the underlying reasons of the preference on the Owner Builder System is the economic constraints in affording the cost of the whole house within one stretch of construction time. Building a house phase by phase as per the availability of money is a very common practice among general Nepalese. Because of such practice, owner has to directly get involved in building a house. In such economic setting, the low affordability of the Nepalese family was also an important perceived constraint in selling the ready-made apartment units at a full cost.

On the regulatory front, although the government had enacted the new housing act, it might not be complete and reliable as it was the first such act in the country. The government has a poor track record of drafting and implementing laws to cover new and potentially growing industries. Therefore the reliability and completeness of the government regulatory mechanism was also a potential constraint.

Physical infrastructure facilities – particularly water supply, sewerage and waste water drainage, and solid waste disposal – to be provided by the government might not be sufficient and reliable for the mass housing system. Moreover the narrow access road and the surroundings of haphazardly developed lands and housings around the project land might undermine the very concept of organized settings of the project.

Besides the above constraints, the unstable national political situation was a concern for all including the Chaudhary Group. The fluid political situation could disturb the project execution process and the confidence in the private sector investment.

Despite the constraints, there were some opportunities for the group housing project particularly in Kathmandu. At the socio-cultural front, there were certain segments of the society which prefer living in organized houses rather than the unplanned settlement in the city. Especially the modern and working families who do not have time to get involved in

building their own houses would prefer the ready-made ones instead. Economically such families can afford the apartment housing, or otherwise there was a high possibility that the local banks would come up with the provision of housing loans. As there was a high deficit in the supply of housing in Kathmandu valley, the housing and real estate market and thus its financing arrangement would shoot up once the organized development is triggered.

For the Chaudhary Group the prospect of housing market in Kathmandu was attractive amidst the inherent risks in the constraints. As the Group has a very strong corporate set-up in the country, it could manage the regulatory and physical constraints for the project.

Besides the above external constraints, the Chaudhary Group also had an internal constraint in the lack of core competency in the new business area of housing and real estate. In order to overcome this internal constraint, there was a way for the Group in seeking a partnership with a foreign JV partner who would be competent in the housing and real estate business.

Therefore with the market prospect and the possibility in acquiring the core business competency from a foreign JV partner, the Chaudhary Group considered that a medium size hosing project would help fulfill their expected goals amidst the inherent risks in the constraints.

Ansal Group: In the proposed housing project, the Ansal Group had to share the same socio-cultural, economic, regulatory and physical constraints as the Chaudhary Group. Moreover the Ansal Group also needed to bear the risks in a foreign country such as local political, regulatory and social risks. However, the Ansal Group trusted the Chaudhary Group as a "reliable and resourceful" partner to share the risks in a foreign country's new market. Therefore, with the perception of manageable constraints, the Ansal Group expected that its goal/s would be fulfilled with the project.

M. B. Construction, Safal Builders, and R. M. Builders: These three local contractors had the constraints of lack of technical and managerial capabilities in carrying out the relatively large size local project individually. Even though it was an A-class contractor, M. B. Construction could not bid for the project individually because during the tendering time its resources were diverted in one of its other projects for a long time. The contractor could not manage necessary resources to participate in the project individually. Safal Builders and R. M. Builders as B and C class contractors could not participate in the project individually. It is because according to the Nepalese Construction Enterprises Act 1998, the permissible range of bidding amount for class D construction firms was up to NRs. 3 million, for class C from NRs. 2 to 10 million, for class B from 6 to 30 million, and for class A any amount exceeding NRs. 20 million (CEA, 1998). However, when they together formed a JV company, they could bid for the project and eventually they were successful in winning the tender of the project.

Management Level Challenges

Receiving the Construction Permission from the Lalitpur Municipality : The management of the ACDPL had to deal with the hurdles in receiving the construction permit from the Lalitpur Municipality, and it was a significant management level challenge for both the Ansal and Chaudhary Groups as well as for the main contractor JV.

As the project was the first of its kind for the Municipality, it had to study and work in detail on the project before granting the permit. The Municipality officials were adept in dealing with small scale individual houses, whereas it was a considerable task for them to scrutinize the larger project. The project had the built-up area of about 17,150 square meters with a larger requirement of infrastructure facilities. The project land was surrounded by about 285 numbers of neighbors. The Municipality had to inform and receive the "no objection" papers from all the surrounding neighbors. The public around the project site generally become sensitive when there is news of a large project at their place. It took time to convince the general public and it was quite a clumsy task to do so in the local context in Kathmandu.

Another site specific issue in the project was the high tension 64KVA electrical transmission line across the project land. The apartment blocks were designed with 6 feet clearance from the transmission line whereas it should be at least 27 feet by rule. This critical issue also delayed the Municipality process.

In order to avoid the delay in the project due to the Municipality hurdles, the ACDPL along with the leader of the JV main contractor lobbied directly to the Mayor. After much deliberation they were successful in creating a special understanding with the Mayor, with which the project team started the construction work before receiving the formal permission. The Mayor had to put a special effort in convincing its Municipality staff, Local Town Development office, and the surrounding neighbours for starting the construction at the project site. After a year of starting the construction, the ACDPL was eventually successful in receiving the permission from the Municipality.

Project Level Challenges

After the construction was started, a series of challenges cropped-up in the project. All the parties in the ACDPL JV and in the main contractor JV had to face the project level challenges, some of which were critical for them.

The Main Contractor's Cash-Flow Crunch: One of the critical challenges for the main contractor was the management of cash flow for the project. The local Nepalese contractors have very limited financial capability to participate in a large project. A reason behind the formation of the JV between the three contractors was to formally show that they were financially, technically, and experientially capable to undertake the project. However, among the three parties, there was an informal understanding that the Safal Builders would bear the major financial obligations for the project and the remaining two would provide other necessary input when-and-where they could. The team leader of the JV from the Safal Builders provided the 3% (NRs. 2.7 million) of the total contract amount (NRs. 90.8 million) performance bond bank guarantee from his side.

The construction was started with NRs. 2 million mobilization advance from the ACDPL. However, the main contractor team leader claimed that because of the ACDPL's process of running bills payment, it was very difficult to manage the cash flow in the project. The total payment in each monthly running bill would be divided into two parts in the proportion of 75% and 25%. The Kathmandu ACDPL office would release the payment that amount to 75% of the running bill within 21 days of submission. For the remaining 25%, approval had to be granted by the Ansal Group's Delhi office and it would again be cleared only after 21 days of submission. The main contractor team leader claimed that according to the agreement, the 75% amount should have been released within 7 days – but it was never done

so. The remaining 25% was also delayed for 3 to 4 months. Each running bill would amount to NRs. 2.5 to 4.0 million, and because of the payment delays, it was extremely difficult to manage the cash flow.

The main contractor's shortage of the cash flow created ripples effects in terms of the delay in payments for the labor gangs and the material suppliers. It also dissatisfied the M. B. Construction and the R. M. Builders as they could not get timely return on their resources and efforts in the project.

Exacerbating Political Turmoil in the Country : The cash flow delay with the main contractor was further exacerbated by the political unrest in the country. The infamous Royal Palace massacre took place within the first fourteen months of the construction period. The transportation of materials and labor from one part of the country to the other part used to remain frequently blocked for days because of the political turmoil during the construction period of the project. The shortage of labor and materials delayed the work of the main contractor. It generated stress in the project schedule and lessened the amount of the running bill. It also generated confusion and disappointment at the ACDPL side, and subsequently it further delayed the main contractor's payments.

Error in Quantity Estimate: While the infighting for the cash flow started between the main contractor and the ACDPL, the former party found a serious error in the quantity estimate of the Rebar (Reinforcement Steel Bar). The error was made by the quantity surveyors (QS) at the Ansal Group's consulting cell in Delhi office. The total quantity of Rebar in the contract package was 327 MT (Metric Tonne) whereas the actual requirement was 612 MT. The error in the BOQ (bill of quantity) of Rebar was suspected at the eighth month of construction time because the consumption at that time was 150 MT, much more than expected. The main contractor raised this issue to the ACDPL, and it conveyed the information to Delhi office. It took time to convince the Kathmandu ACDPL team, to convey the information to Delhi, to be checked and confirmed the error in the BOQ by the QS in Delhi, and to get approval in the revised BOQ. The Ansal Group's QS approved for 572 MT whereas the main contractor calculated 612 MT. The deficit of 40 MT was later compensated by the ACDPL. The error and delay in the amendment of the significant Rebar quantity estimate generated confusion and dispute between the ACDPL and the main contractor.

Price Escalation and Adjustment in the Contract Amount: The uneasy situation created by the major amendment in the Rebar quantity was worsened by the price escalation in Rebar itself. During the verification and approval process on the Rebar quantity in the Delhi office, the price of the Rebar increased from NRs. 21 to NRs. 27 per Kg. The price escalation in Rebar and other materials along with some variations in the building designs were expected to increase NRs. 20 million (nearly 22%) in the cost of the project. Due to the probable project cost increment, the ACDPL wanted to save money in terms of the contract tax and the VAT (value-added tax) by curtailing the total contract amount up to NRs. 60 million. The ongoing disputes with the main contractor also supported the case for the curtailment in the contract amount. Therefore the ACDPL decided to limit the taxable formal contract amount up to NRs. 60 million and for the remaining works it decided to execute them under departmental works which was not taxable. With this arrangement the ACDPL could save 1.5% of contract tax and 10% of VAT for any works beyond the formal NRs. 60 million works.

The Main Contractor's Grievances: Under the curtailed contractual arrangement, the main contractor could only complete up to the structural works of the Blocks 1 to 8, 9 to 24 and 29

to 32. All the other Blocks and the finishing works were undertaken departmentally by ACDPL. The curtailed contractual arrangement was not only a major set back for the main contractor in getting expected return out of the project, it was also a basis for the ACDPL to hold the performance bond along with the latest running bill payments. Because of the adverse situation, the JV team of the main contractor got separated well before the new contractual arrangement was enforced. The ACDPL however retained the team leader from Safal Builders to manage the labor and material supply as an internal employee for the work beyond NRs. 60 million. The team leader agreed to work because he had to recover his investment on the project.

Turmoil in the ACDPL's Project Team: The ACDPL's project implementation team was assigned the task of coordinating and monitoring all the activities of the project so that they could be executed within the stipulated time and cost with the specified quality level. It was quite challenging for the project team to coordinate and monitor the activities amidst the main contractor's cash flow problem, the political disturbances, the error in quantity estimate and the material price escalation. There were frequent schedule slippages and the project team could not directly blame the main contractor and impose penalty to keep him in track. There were factors that were beyond the control of the main contractor, and he would direct his frustration towards the ACDPL management. On the other hand the ACDPL management team would pressurize the project team to keep the work in order. The management team would want to control the main contractor blaming on its ineffectiveness. In such situation, the project team was sandwiched between the main contractor and the ACDPL management. Because of the intense pressure, the key project leaders had to quit the project – they could not be committed with the unfavorable results. There were changes of at least three technical vice-presidents (project team leaders) and three senior managers in the project team. The main contractor therefore had to deal with the new and learning project leaders, and it created considerable impact in the schedule of the project. Moreover, at the end of the project, there was no project team leader to settle the final bill of the contractor. It was settled only after one and half years of completion of the project.

SUCCESS OR FAILURE OF THE INNOVATIVE PROJECT?

The first group housing project in Nepal was in general completed successfully and eventually satisfactorily handed over to the customers. The construction period, however was highly turbulent with about 85% time delay and some cost overruns. Despite the delay, as the finishing works of the completed apartment structure was carried out in parallel with the construction of remaining blocks, ACDPL could hand over the successively finished apartment units to the customers. The whole apartment system was fully occupied within the six month of completion of all the works. The success, however, has to be interpreted from the view points of the involved parties.

M. B. Construction, Safal Builders, and R. M. Builders: For the three local contractors, the project was not a successful undertaking as they could not satisfactorily achieve their expected goals out of the project. They could not complete the project as they were assigned in the initial contract. Even on the part of their work, that is under the "with material" contract sub-package, there was about five month delay. Moreover because of their interaction, especially at the implementation stage, they were not successful in establishing a good business relationship with the client. Financially they were unsuccessful in making profit out of the project. All of the three contractors had to bear a considerable financial loss

in the project. After the project experience, all the three parties were not willing to work together again in the future. However, in terms of track record, all the three parties were successful in adding the project in their respective company profiles. Because of their experience in the first group housing project, they were able to secure jobs in other housing projects which were launched by other parties after the success of the Kathmandu Residency project.

Chaudhary Group and Ansal Group: With the completion of the project, the Chaudhary and Ansal Groups were successful in establishing the ACDPL as their pioneering housing and real estate company in the country. Although the client JV had to bear a total of two year delay in the project and consequently they had to face some unsatisfied customers, the eventual success was well publicized in the media. The client JV was successful in imparting the impression on the general public that the project was a breakthrough in the Nepalese housing sector. The project was actually successful in crossing all the perceived socio-cultural, economic, regulatory and physical constraints in the housing sector of the country. After the completion of the project there was a phenomenal growth in the private sector housing in Kathmandu and beyond. There were about twenty major registered private housing companies as of June 2005 that were supported by about 14 banks and financial institutions in Kathmandu (SAMN, 2005). It was estimated that there were about 1820 housing units completed or under construction by June 2005 (Sherchan and Lamsal, 2005). It was further developed and got established as a well organised and growing real estate sector contributing significantly to the national economy (Rajbhandary, 2011).

The Chaudhary Group was therefore highly successful in establishing a promising new housing and real estate portfolio in its corporate house. At the social front the Group showed that the organized group housing concept is possible to be implemented in the traditional Nepalese society, which could be taken as a starting point to show that the haphazard urbanization process in Kathmandu can be controlled to some extent with such housing concept.

The Ansal Group was also successful in starting its business expansion in Nepal. Both the Chaudhary and Ansal Groups were successful in making good profit out of the project. They were successful in harnessing good cash flow from the booking advance. After a couple of month of launching the Kathmandu Residency project, the ACDPL procured another plot of land for their second housing project using the cash collected from their former project. They were again successful in collecting booking advance from the proposed second phase project. Virtually they did not need to make any substantial separate financial investment from their sides. As soon as the construction of Kathmandu Residency project was completed, construction of the second phase was started on the basis of labor contract. ACDPL did not hire any external contractor but undertook the second phase under their own management. At that stage the Ansal Group wanted to further move with a third phase immediately. However, the Chaudhary Group opted not to move so aggressively. As there were risks such as the construction delay that was experienced in the first project, accumulation of new projects would add on more risks. If ACDPL could not manage the risks it would directly impart negative impression in the market. As the Chaudhary Group had to operate in Nepal with its other businesses, it was sensitive in its reputation in the country. Therefore the Chaudhary Group wanted to move bit slowly. The Ansal Group on the other hand was working in the huge Indian real estate market and it wanted to increase its scale of operation in Nepal also. Probably the company wanted to get benefit of the economies of scale with the rapid expansion of the business. The two groups however could not agree with each other in this

issue of slow or rapid business move. The common expected goal of both the parties was to expand their real estate business. However, they could not agree on the way to achieve the goal. With this basic difference in the respective expected goals, the two parties went through a conflictive situation. As no significant concession was offered from both the sides, the result of the dealing was finally perceived unfavorable. Therefore they decided to terminate the JV and the Ansal Group left the on-going second phase project. Then the on-going project was fully undertaken by the Chaudhary Group under its company's name. As per its policy, it started the third phase only after completing the second phase.

Abstract

Many authorities have supported the concept of integrated working or partnering. They claim a number of advantages of partnering such as greater co-operation, cost savings, timely completion of projects and improved quality but there remain a number of difficulties both at a theoretical and practical level. These difficulties manifest themselves in the views expressed by some specialist contractors, whose voice is all too often overlooked.

A number of issues can be seen in the responses of specialist contractors to questions put to them in the quarterly survey of the National Specialist Contractors Council. These include measures of interim payment periods, tender prices, suppliers' prices, profit margins, contractual behaviour, methods of appointing specialist contractors and the time allowed to price a proposal. These measures can be compared to the state of specialist contractors' markets to reveal the underlying causes of main contractor behaviour and treatment of their subcontractors. For example, market constraints in times of economic difficulties may indeed directly affect such behaviour. If the gains and benefits of partnering were truly shared between all parties, then it is significant to note the views of specialist contractors and the fact that the difficulties they face in dealing with main contractors have not diminished over time.

Key words: Specialist contractors, supply chain management, integrated project teams and partnering

INTRODUCTION

Following the serious construction recession of the early nineties and before the subsequent period of sustained growth until 2008 a period of introspection within the industry brought about many changes to practice in both procurement and delivery of construction projects. Many construction partners and indeed the associated education and training sector largely embraced the concept of integrated working and project partnering as one technique with the potential to improve the behaviour and hence the performance of an industry hitherto subject to accusations of an adversarial culture and under performance.

However, rather than a deliberate attempt by firms in the construction industry to improve their behaviour, Smyth (2002) posited that the adoption of partnering was essentially a

procurement issue driven by client demand in an attempt to avoid what in relationship marketing is called switching costs – that is, the costs involved in replacing one supplier with another.

Switching costs and client loyalty levels are discussed by Smyth, who nonetheless identifies the advantage of partnering as providing market stability. Even where switching costs are low advantages are identified for partnering. For example, partnering is seen as meeting client needs more directly, helping to build up construction business and continuous client relationships. However, low switching costs may also encourage clients to take advantage of the lowest cost bid and limit the adoption of partnering.

SUPPLY CHAIN MANAGEMENT AND INTEGRATED PROJECT TEAMS

A number of papers have looked at the relationship between main contractors and specialist contractors, including, for example, Winter and Preece (2002) and Van der Vaart and Van Donk (2004). While Van der Vaart and Van Donk looked at the main factors that shaped the level of integration of different supply chains or networks, Winter and Preece examined, main and specialist firms in both Germany and the UK, in an attempt to determine the nature of their relationship and the extent to which relationship marketing had extended down through the supply chain. They found that where main contractors considered that a partnering approach directly with clients was seen as improving overall business, it was never seen from the point of view of the supply chain. This relationship with suppliers was characterised by a traditional approach without any reference to the potential benefits of partnering.

Winter and Preece identified pressure on prices, lack of trust, poor communications, inadequate information and perceived poor service as impacting on the relationship between main contractors and their suppliers. Nevertheless, some main contractors had identified the advantages of dealing with the issue of main and sub contractor relations in order to improve the 'internal market' within the construction process.

Van der Vaart and Van Donk (2004) also considered supply chains, where cost was the main order-winner and make-to-stock production, where shared resources might be necessary to achieve a high utilization of the processes involved. They concluded that in construction a high level of integration is difficult to achieve and is not always necessary given the fact that cost is important and setting up a genuinely integrated process can be a costly exercise. In any case sufficient time may not always be available to achieve the desired ends.

Vrijhoef and Koskela (2000) also point to the shortcomings of the construction supply chain. They examined the management of the construction supply chain. Reviewing modes of project integration, they cited studies showing partial and superficial integration, (e.g. Bennett et al., 1996; Konchar and Sanvido, 1998), concluding that the benefits of design-build, for example, are minor. They found the presumption to have been that improvement of the organisational structure alone would suffice.

Instead they found the construction supply chain consisted of the following elements: a temporary, converging supply chain, producing one-off construction projects through repeated reconfiguration of project organisations. They defined the construction supply chain as one typified by instability, fragmentation, and especially by the separation between the design and construction, a typical make-to-order supply chain. However, for projects of a

particular kind, the process can be similar. The majority of the causes of waste and problems, according to Vrijhoef and Koskela, can be attributed to traditional management of the supply chain. They go on to propose a number of their own principles and methods in order to provide a solution.

A VIEW FROM THE SPECIALIST SECTOR

Setting aside the findings discussed above, the National Specialist Contractors Council (NSCC), being a federation of trade associations, publishes guidelines for its members, extolling the benefits of integrated working, a form of partnering, which is claimed to include better financial performance, a specialist input to design and planning, better problem solving, a fairer share of risk, the opportunity for repeat business and better payment terms. Further, the NSCC recommends the setting up of integrated project teams (IPT) as an organisation or a single team with common goals.

In turn, the NSCC is a member of the Strategic Forum for Construction, which also publishes its own toolkit guide (see Strategic Forum for Construction, 2011) to both integrated supply chains and IPTs with the aim of improving project delivery, profitability, reduced operating costs, more sustainable outcomes, predictability of programme, price and quality.

The Strategic Forum also offers guidance on IPTs with the aim of streamlining transactions and in particular developing closer relationships with subcontractors. The case is made for an holistic approach to projects and thereby establishing the organisational desirability of collaborative working from identifying the need for the project to ensuring all the value criteria are met with due acknowledgement of the process, culture, methods and tools required.

This supply side engagement with the concepts of integration has been matched by the demand side principally through the involvement of government, which is still the largest sponsor of construction activity. Thus, the Office of Government Commerce (2007), now part of the Efficiency and Reform Group, set out a suite of procurement guides reflecting developments in construction procurement over recent years, not least building on government clients' experience of implementing the Achieving Excellence in Construction initiative.

The 2012 Construction Commitments, (Strategic Forum, 2012) recommend procurement to require ethical sourcing, best value and the early involvement of the supply chain. It also recommends an integrated project team to work together in terms of design, buildability, environmental performance and sustainable development.

Specifically, it recommends all members of the construction team should be identified and involved at an early stage, particularly during the design process, and encouraged to work collaboratively. Supply chain partners are required to demonstrate their competency, commitment to integrated working, innovation, sustainability and to a culture of trust and transparency. To ensure effective and equitable cash flow for all those involved, all contracts should also incorporate fair payment practices, such as payment periods of 30 days, no unfair withholding of retentions, project bank accounts and mechanisms to encourage defects free construction.

In the private sector changes in practice have taken place more rapidly. For example, the adoption of integrated projects was most notably addressed by the British Airports Authority (BAA), who were reported in an article in Building (2006) to be launching a procurement strategy for the following 10 years, a policy however quickly reversed in 2008. According to Building (2008), by 2008 the approach had changed to one of finding deficiencies in the supply chain and cutting them out. A reference to the successful completion of Terminal 5 Heathrow was tempered by the view that it was one of the most expensive terminals ever built, delivered on budget, but the key point to note was how high that budget was.

Major influences on the further development of integration must include the impact of debt, both public and private, downward pressure on pricing, client behaviour and of course politics. Clearly, the practice of integrated working and partnering has some way to go to match the rhetoric of its proponents.

Evidence for the implementation of supply chain management and integrated project teams can be seen in the responses of the survey of specialist contractors over time. This survey is taken from the point of view of specialist contractors. If the culture of the construction industry had been changed by the introduction of the concepts of supply chain management and integrated project teams, then it could be expected to be reflected in changes in the NSCC survey.

METHOD

An important player during this period of industry review was the National Specialist Contractors Council (NSCC), which established a quarterly survey of its member firms in order to provide evidence for the Latham Report (Latham 1994) on the state of the industry. Conducted and written by an academic, the NSCC State of Trade Report has developed along with the shifting interests of member firms through the changes in the construction industry and the economic climate.

The NSCC mission is to represent the interests of trade organisations within the specialist and trade sector of the construction industry and it currently brings together the common aims of 32 specialist trade organisations, amounting to some 7,000 firms, within the construction industry. NSCC member organisations cover a wide spectrum of the sector and include for example:

- Association of Interior Specialists (AIS)
- Contract Flooring Association (CFA)
- Council for Aluminium in Building (CAB)
- Federation of Piling Specialists (FPS)
- Glass & Glazing Federation (GGF)
- Mastic Asphalt Council (MAC)
- National Access and Scaffolding Confederation (NASC)
- National Federation of Roofing Contractors (NFRC)
- Painting and Decorating Association (PDA)
- The Tile Association (TTA)

The NSCC is an authoritative voice of specialist contractors in the UK and is therefore used by a number of leading organisations including:

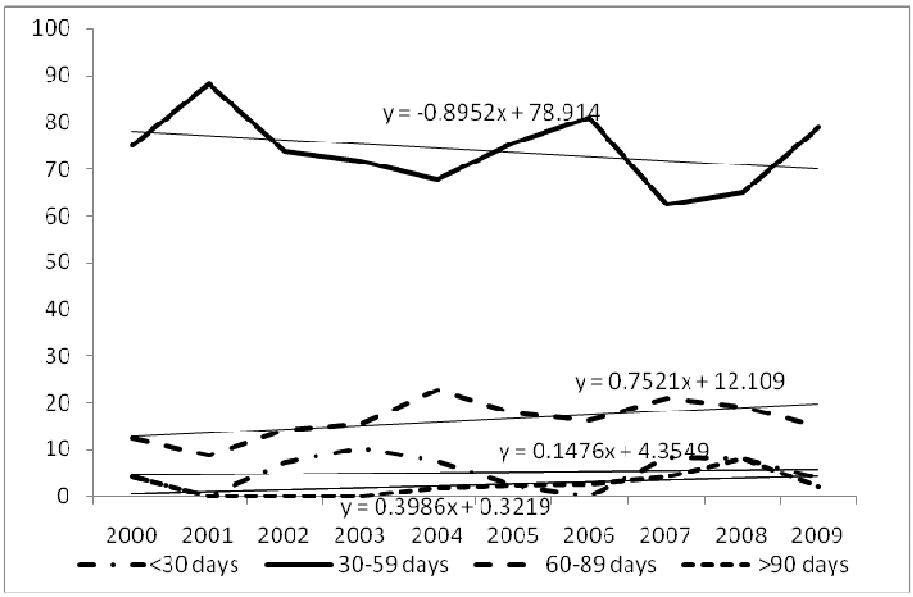
- Construction Skills Certification Scheme (CSCS)
- ConstructionSkills
- Cross-Industry Construction Apprenticeship Task Force (CCATF)
- Health and Safety Executive (HSE)
- The Joint Contracts Tribunal (JCT)
- Safety Schemes in Procurement (SSIP) Forum
- Strategic Forum for Construction.

Since the first quarter of 2010, NSCC has contributed its survey findings to the industry wide quarterly State of Trade report compiled by the Construction Products Association (CPA) thus ensuring that the specialist sector viewpoint is represented, not least at the government hosted Consultative Committee of Construction Industry Statistics (CCCIS).
The information gathered by the survey has been used extensively, for Ministerial briefings and to assist in campaigns to promote the interests of members. The most recent campaigns have involved briefings to government on retentions, the Better Payments Campaign and Supply Chain Integration for Specialists. Supply Chain Integration is the subject of this paper.

The survey is conducted on-line and respondents are invited to complete a questionnaire covering the following main areas of activity: enquiries, orders, labour availability and change, labour, capacity and workload, planning, price and margin analysis, procurement, payment periods, retentions, contract abuse, and adjudication. Members are also invited to comment freely on the issues most affecting their businesses.

The questionnaires are sent to approximately 700 firms, all member firms of NSCC affiliated trade associations, covering the whole range of specialist activities. The average response rate is approximately15%. This is a higher response rate than was achieved using the original postal survey, which had been conducted quarterly until 2007.

In line with similar surveys the responses indicate, where appropriate, the actual percentage of respondents reporting increases or decreases in particular variables. A 'balance' indicator gives the best single measure of trend. The balance is the difference between the percentage of respondents answering 'more' or 'increase' of a variable less the percentage answering 'less' or 'decrease'. For example, if 30% of respondents report 'increased orders', 20% 'no change' and 50% 'reduced orders', the balance is –20%. Generally, a positive balance implies that a variable has increased and a negative balance implies a decrease. Balances close to zero imply no significant change has occurred.



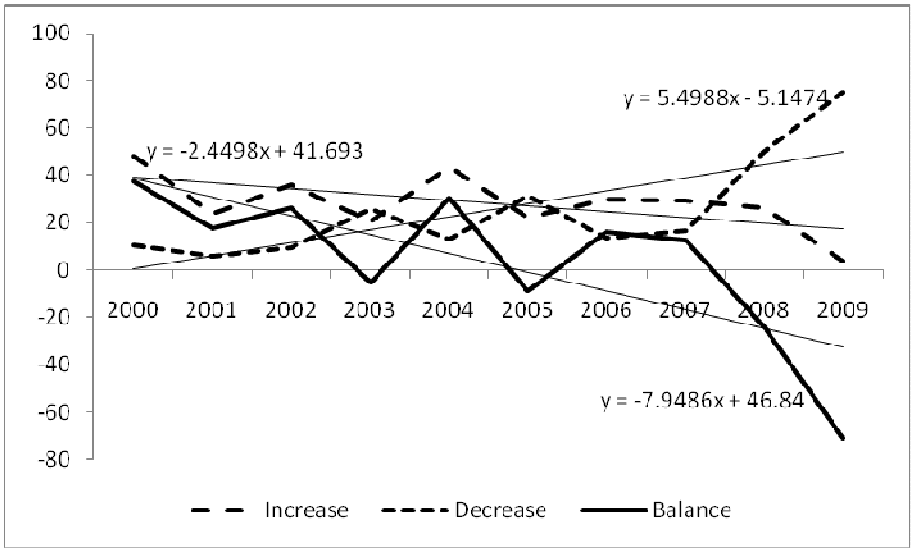
The findings below are largely taken from the quarterly survey of the NSCC State of Trade Report 2009 Quarter 4, but they are also derived from all the surveys conducted over the previous 10 complete years from the first quarter of 2000. Using the third quarter data of the NSCC survey, a trend analysis based on a linear regression was applied to the data.

FINDINGS

Firstly, one of the key drivers in establishing the NSCC trade survey concerned payment regimes between main contractors and specialists. This refers to excessive delays in paying specialist suppliers by main contractors, even when there are no reasonable causes for the delay. It continues to remain a major issue and has been responsible for the Fair Payments Campaign run by NSCC, which resulted in fair payments being adopted government

procurement policy. As recently as 2009Q4 fewer than 5% of specialists reported being paid within 30 days. Little noticeable change has taken place since 2000, with the rate of increase in the percentage of firms reporting prompt payment between 2000 and 2009 at 0.148 per cent per annum, according to the trend analysis shown in Figure 1, which shows the period of time specialist contractors reported they waited for interim payments. In contrast the percentage of firms reporting payments of between 30 and 59 days declined at approximately 0.895 per cent per annum. Although the percentage of specialist firms reporting payments from main contractors were taking longer than 90 days to pay appears to have declined in 2008 and 2009, if anything the time taken by main contractors to pay invoices increased in 2007 and 2008 during the worst of the financial crisis.

Both those firms waiting 60 to 89 days and those waiting more than 90 days to be paid grew at 0.752 and 0.399 per cent per annum respectively, although their actual numbers were small. These figures do not indicate the size of the outstanding payments but they do show that for the bulk of payments, firms were waiting longer than 30 days for payment, a period in breach of most specialist firms' terms and agreements. It is possible that the decline in the number of specialist contractors waiting 30 to 60 days in the decade was due to the need to re-engage with supplier firms during a period of steady employment. The reduction in the interest rates also reduced the incentive to delay payments.



Source: NSCC State of Trade Survey: Q3 2001 – 2009
Note: Figures do not round to 100 as some respondents did not complete this question

Figure 1 *Interim Payments Period: average time for payment in 3rd Qtr 2000 - 2009*

The commercial pressures prevailing on this sector are emphasised by the percentage of specialist contractors reporting tender price increases. This data is given in Figure 2, which gives the percentage of firms reporting rising and falling tender prices. The balance shows the difference in the percentage reporting increases and decreases. By the 4th quarter of 2009, there was a large negative balance of 69%, signifying far more firms reporting downward pressure on tender prices, a characteristic of a buyers' market. As the buyers in this particular market are main contractors, this reveals their relatively strong bargaining position vis-à-vis their suppliers. The weak increases in tender prices had been offset in the deepest part of the

recession by reduced suppliers' prices, but there has now been a return to some supply side inflation. Increases in suppliers' prices placed pressure on margins, which continued to fall but respondents anticipated that the sharpest falls had passed.

Source: NSCC State of Trade Survey: Q3 2001 – 2009
Data is taken from the 3rd Qtr survey each year.
Note: Figures do not round to 100 as some respondents did not complete this question

Figure 2 *Specialist contractors' tender prices, 2000 - 2009*

Those reporting a decrease in tender prices grew by 5.5 per cent per annum between 2000 and 2009 but this downward pressure on specialist contractors was mainly due to the impact of the financial crisis of 2007. From 2000 to 2007 the number of firms reporting declining tender prices only grew by 1.6 per cent per annum. This implies that the pressure on specialist contractors to reduce their tender prices existed even before the financial downturn. The converse of this is given by the decline in the percentage of firms reporting increasing tender prices. The annual rate of decline of firms, given by the trend line in Figure 2 was 2.45 per cent per annum. By 2009 only 4 per cent of firms reported that they were still submitting higher tender prices than in the previous year. These figures are reflected in the balance, which shows the summary of the relationship between those firms reporting higher and lower tender prices. The balance shows a decline of almost 8 per cent per annum, leading to a prevailing pessimism in construction markets.

This pessimism is further shown by specialist contractors, who cite late payment, weak cash flows, valuation disputes and a strong disregard for retention. Late payment, bid peddling and Dutch auctions have the most significant effects on specialist contractors' businesses. Further evidence from the 2009Q4 survey indicated that 84% of respondents still had monies withheld against them in retentions with an average of £125,082 per respondent and of that amount an average of £38,522 per respondent (27% of retention monies withheld) was overdue for release.

Although the UK Government's announcement that it had made fair payment a contractual requirement on public sector works from 1 April 2010, this measure has yet to be seen as having an effect on contract behaviour.

A significant challenge to the notion of integrated working within the sector is evidenced by only 6% of specialists reporting that they were chosen by nomination. When selected to make a proposal 50% of specialists are given less than 10 days to submit a bid and 18% of specialists did not even receive their contract documentation until after they have started the work. Generally it would appear that most specialists have less than 10 days to prepare and price a proposal.

Finally, when asked to identify the major issues affecting their business, specialist contractors' comments included the following:-

- Start dates being moved (by months in some cases)
- Main contractors were taking longer to pay than agreed. As a consequence a cash flow problem emerged.
- Obtaining credit cover on main contractors through credit insurance.
- Poor credit rating of main contractors and onerous and complicated payment terms.
- Extended payment terms imposed even when the contract is government funded.
- Difficulty in getting retentions paid.

DISCUSSION

One would have expected clear changes to have emerged in the attitude of specialist contractors if changes in supply chain management and IPT's had been successfully adopted. Improvements in the attitudes and behaviour of main contractors towards specialist contractors would have been reflected in the quarterly survey. However, none of these are yet apparent by the time of the fourth quarterly survey.

This is therefore indicative of a failure to introduce supply chain management by gaining the collaborative working environment that might have been hoped for. As far as the NSCC survey is concerned there is little or no evidence to support the claim that supply chain management has improved the degree of collaborative working.

The difficulties facing specialist firms is caused by the fact that according to the terms of their contracts, much of their work is carried out prior to payment. It therefore follows that their bargaining power, vis-à-vis main contractors, is severely weakened as they are then not in a position to impose costs on the project or the main contractor. If they cannot delay completion of a project, there are few other practical sanctions that can be used by subcontractors other than seeking adjudication, arbitration or litigation.

A large question remains. To what extent does the data reported here reflect basic economic realities and conflicts embodied in the relationships between main contractors and their suppliers, the specialist subcontractors? If the data given here reflects basic conflicts found in markets, then they represent universal conditions and similar surveys in other countries would produce largely similar results. We hold that the findings here are probably generalisable and that they therefore have relevance and implications universally.

As long as construction relies on markets to provide specialist skills and services, there will be conflicts between main and subcontractors. Only when firms themselves become fully integrated would common corporate identity begin to provide opportunities for truly collaborative working practices. Even then interdepartmental conflicts and rivalries arise within the same organisation and there can never be a guarantee that construction projects or any kind of production process is necessarily carried out on a co-operative basis.

CONCLUDING REMARKS

At a project level it would appear from the findings that there is still a need to train managers on the implications of supply chain management to alter the culture of confrontation and mistrust that arises on construction sites. The message needs to be communicated down to those, who actually manage the interface between main contractors and specialist contractors. The evidence from the NSCC survey does not provide support for the argument that this is happening effectively. Only once the behaviour of main contractors begins to show understanding of the difficulties faced by their specialist suppliers will the promises of management theories designed to improve the work attitudes, productivity and outcomes on construction sites be achieved.

The findings of the NSCC survey begin to show the divergence of opinions about the performance of contractors as far as specialist contractors are concerned. This calls into question the gains to the supply chain in the construction sector claimed by some of the proponents of integrated working. Further, the practice of partnering has not extended its reach throughout the sector as much as might have been expected.

One conclusion that may be drawn is that the drive to partnering has been mainly marketing exercise by contractors, not matched by practice. Instead it has allowed the strongest players in the building team to continue to take advantage of the weakest members and that the time has come to call the concept of partnering as practiced in the UK a failure.

COLLABORATIVE DESIGN OF PARAMETRIC SUSTAINABLE ARCHITECTURE

HANS HUBERS
Technical University Delft
j.c.hubers@tudelft.nl

Abstract
Sustainable architecture is complex. Many aspects, differently important to many stakeholders, are to be optimized. BIM should be used for this. Building Information Modelling is a collaborative process where all stakeholders integrate and optimize their information in a digital 3D model. Sometimes it is called Green BIM. But what exactly is that? Is the International Standard Organization IFC standard useful for this? And is it compatible with new developments in parametric design? Advantages and disadvantages of BIM are listed. Full parametric design is needed because it keeps the design flexible and open for changes until the end of the design process. However it is not compatible with IFC; only object parametric design is. A possible way out of this paradox could be the use of scripts that only create objects if they are not already in the BIM database and otherwise only adapt their properties. An example of parametric sustainable architectural design explains the mentioned issues.

Keywords: Sustainable architecture, BIM, collaborative design, parametric design, IFC

INTRODUCTION

Sustainable architecture is architecture that meets the needs of the present without compromising the ability of future generations to meet their own needs (adapted from WCED 1987). One of those needs is energy for heating, cooling, lighting and equipment of buildings. Estimations show that buildings use 20 - 40% of the energy in Europe (IEA 2008).

During the energy crises in the seventies of last century people became aware of the necessity to protect the environment and to find alternatives for fossil fuel. The book “Small is beautiful” had a big influence (Schumacher 1973). Function integration is still an important issue. Passive solar energy became popular, insulation of outer walls in buildings was improved and double glazed windows became the standard. There were small scale experiments to use rainwater and reuse grey water in households and compost toilets. Green roofs were re-introduced (they existed already in the stone age of course). PV panels appeared on buildings, high efficiency boilers were installed, heat pumps and heat exchange equipment were introduced and recently rest heat from industrial plants is used in buildings nearby.

The built environment is our habitat. This word is used in Ecology to address the circumstances that make species flourish or not. Our habitat should be built with all stakeholders in mind. Municipalities could play an active role in this. They should not only approve or ask for changes in the plans, but actively interfere from the start with the design of the habitat of its citizens. Municipalities could demand for design teams with delegates representing all stake holders (including the building professionals). Such multi-disciplinary design teams can develop designs that optimally fulfil the needs and demands of all concerned.

In 1984 the author designed a sustainable office building (Figure 1). It had a floating foundation, because of the risk of flooding and also to take profit both in summer and winter of the constant ground temperature of 10 ^{o}C. The roof construction would be made of round wood with Ethylene TetraFluoroEthylene (ETFE) cushions, and has been realized several times since then. It had collection and treatment of rainwater, heat storage in salt, fish culture and a vegetable garden. The feasibility study for this innovative office for the multidisciplinary centres of Delft University of Technology took 2 years. And finally it turned out that there was a negative return of investment, mainly caused by the expensive foundation. In order to speed up and to improve this kind of evaluations, multidisciplinary ICT projects were initiated.

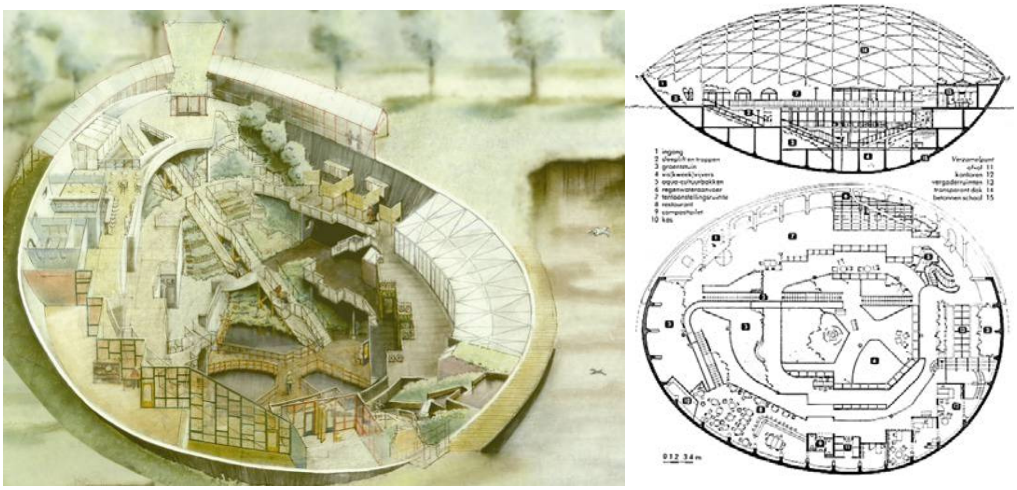

Figure 1. *Ecological office building "The Egg" (Hubers 1986).*

Also around 1985 the Biosphere 2 was realised in the U.S. as a closed ecological system. Fifteen years later the Eden project was realised in England. Governments started to fund research into sustainable architecture end of the last century. Demonstration projects were funded and alternatives were stimulated with grants. The report of MIT to the Club of Rome in 1972 about the limits to growth had a big impact. People became aware of the endlessness of fossil fuel and other resources (Meadows et al. 1972). The Brundtland report in 1987 introduced the concept of sustainability. Later the triple P was added: People, Planet and Profit. Prof. Duijvestein, one of the founding fathers of sustainability at Delft University of Technology listed in detail the criteria for buildings under every P (SenterNovem 2009).

Feminias (2004) gives a nice overview and analysis of demonstration projects in Sweden and The Netherlands. She concludes that though important real-world data as reference are very important, there is a lack of incentives and interest for learning; deficiencies in the production of reliable and useful information; and a lack of institutions for information dissemination.

Reuse of existing resources with as less degradation as possible (cradle to cradle) is important (McDonough and Braungart 2002).

But it was not until vice-president Al Gore went over the world in 2006 showing the spectacular movie: "An Inconvenient Truth", that people became aware of global warming, the ozone hole, widespread land degradation and declining biodiversity. Standards were developed to express how well buildings perform energetically. The United States Green Building Council (USGBC) was founded in 1993. The LEED standards begin in 2000. There

are many other standards like BREEAM (NL, UK), Itaca (IT) etc. Every country has its own regulations and standards. The work of Jón Kristinsson should be mentioned, especially his design for the Floriade 2012 (Kristinsson 2010). Of course the IPCC reports are important references.

SUSTAINABLE BUILDING DESIGN

The biggest challenge stays with existing buildings, because it represents 20-40% of the energy use and CO2 emission and because it is more difficult to reduce this in existing buildings than to avoid it in new ones. Special attention should be paid to lighting and air-conditioning. When buildings get insulated lighting becomes relatively more important. And because of airtightness the indoor air quality becomes an issue and buildings don't lose heat during nights that easily.

Recently the author developed together with greenhouse, sustainability and other specialists a proposal for synergetic greenhouses on existing flat roofs in the cities. It is called SynSerre.

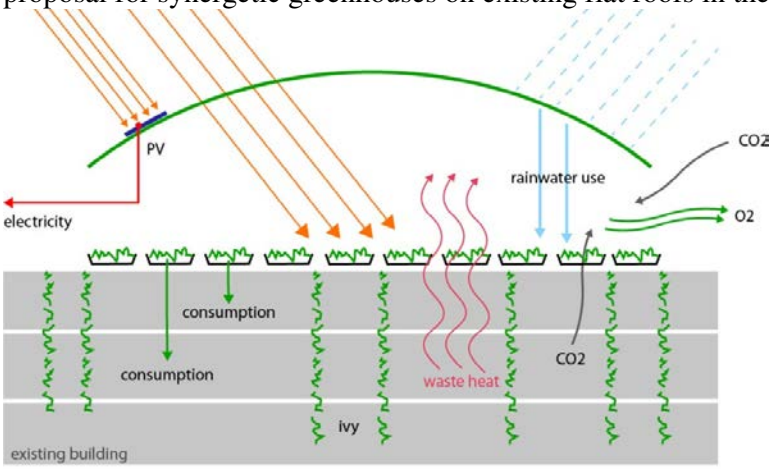

***Figure 2**. Schematic representation of the SynSerre project.*

One of the proposed eco-innovations in this project is the combination of multilayered ETFE cushions with reflecting patterns on the film that concentrate the spectrum of sun light which is not useful for plants (~50%) to PV disks mounted on space frames of round wood. Through in- and deflating the right chambers in the cushions the system becomes interactive.

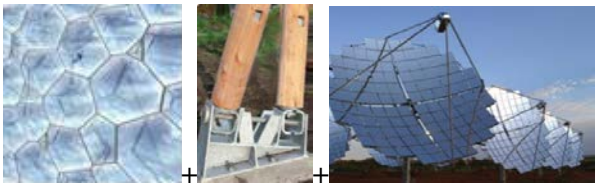

***Figure 3**. ETFE cushions + Tentech round wood connection + PV concentration*

But it could well turn out that SynSerres in Northern countries need a different solution than in Southern. Up to 77% of direct sunlight for PV reduces the cooling capacity by 4.

A SynSerre is not just a traditional greenhouse superposed on the roof of an existing building. That wouldn't be competitive with normal greenhouses. The innovation is the combination of all the points listed below. This project proposes solutions for the following problems.

1. Depletion of fossil fuel. SynSerres supply energy and insulate existing buildings.
2. Flooding in the world's delta areas due to climate change endanger the food supply of the growing cities. SynSerres bring food production into the cities on high and dry places.
3. Many existing buildings in European cities with flat roofs from the sixties and seventies need renovation. Well designed and styled SynSerres are beautiful and synergetic alternatives for traditional renovation.
4. Many of those buildings are in problematic neighbourhoods. SynSerres create jobs and offer social activities.
5. There is a lack of space for extending greenhouses in the green areas around cities (VROM 2010). The roofs and facades of existing buildings offer considerable space for SynSerres.
6. Cities run out of space and the value of buildings in the target areas is decreasing. There is added value through double land use.
7. Low quality of food in supermarkets. Neighbours profit from fresh herbs, vegetables, flowers, plants and control the quality.
8. Global warming due to CO2 and particulates. Plants convert CO2 in O2 and plant material. Particulates stick to ivy on the facades which are linked to the SynSerre.
9. High cost for maintenance of green areas in the cities and e.g. ivy on the facades. The greenhouse farmer maintains the green on and around the building.
10. Overflow of sewage system during rain fall. Rainwater is collected, stored and used to grow plants.
11. Little awareness of sustainability. SynSerre attracts attention and has an educational function.
12. Transport causes much pollution and accidents. Less transport because of local production and trade.

Because existing buildings vary enormously, the SynSerre concept is adaptable. Parametric design software will be used and dimensions expressed in variables. The number of modules and their dimensions are matched with the existing buildings. The SynSerre will be offered as a parametric product through websites as www.conceptueelbouwen.nl. as part of an innovative turn towards an offer based building market. Clients (i.e. greenhouse farmers) buy the product in about the same way as a customisable car. The local team receives the command, adapts the design in some days and prepares the building permit request. The consortium offers SynSerre in principle as a Design & Build contract and shares the profit.
The idea of SynSerre is obviously inspired by the design of Figure 1, but combined with other ideas. In 1992 ONL, one of the partners in the project, participated in a study where greenhouses were planned on top of housing (Bahlotra 1992).

Figure 4 *Elkas (WUR 2010)*

However not on existing buildings and more as an urban design. Grau (2009) proposed to integrate greenhouses on the roofs of Barcelona, however also not on existing buildings and not developed as a realistic product. SynSerre partners from the leading greenhouse research centre in Europe, the Wageningen University and Research centre in the Netherlands, showed the advances of energy producing greenhouses like the Elkas and the Fresnel greenhouse (WUR 2010). This together with the ideas of Urgenda (2010) and the initiative of Rotterdam (2010) to turn existing flat roofs into green roofs led to the idea of this project. The Elkas produces 18-15 KWh/m2 year at the curved side of the roof by reflecting and concentrating the Near Infrared Radiation of the sun to an adaptable line of PV cells.

The SynSerre project will develop innovative business models where energy production, plant production and sales, environmental maintenance, educational and social activities are integrated with innovative synergetic solutions like new photovoltaic technologies. Small scale SynSerres could be exploited by restaurants or shops, while larger ones by professional greenhouse farmers. The focus will be on the latter. Two greenhouse farmers are participant in the project.

Another eco-innovation will be the integration with climate control of the existing building; e.g. convert CO2 rich exhaust air into O2 and plant growth. The examples mentioned in 1.2. will be used as starting point. There is an urgent need for feasibility studies of this concept. Two real scale test models of 100 m2 will be built and monitored; one in Delft and one in Rome. For monitoring we will use wireless Arduino based systems as can be found at http://sense.almende.com.

Now is the time to develop synergetic greenhouses on existing buildings, because the above mentioned problems are getting quickly more important and most of the suitable buildings from the sixties and seventies in the European cities need refurbishing and renovation.

Besides fossil energy use, CO2 emission and the problems mentioned before, there are other criteria that a sustainable building should answer. The author made the list in Table 1and used it during a test case of collaborative design (Hubers 2008). The list was meant to be completed by the design team. It turned out that the multidisciplinary design team only focused on a few criteria and didn't take the time to add other criteria or to evaluate all of them. Also other research shows that weighted criteria evaluation is not reliable (Lawson 2006). But maybe it is better to have a badly used list of criteria, than no list at all. It at least helps efficiently focussing the discussion on the main subjects. Subjects team members don't agree about (standard deviation in Table 1).

A multidisciplinary design team needs more than a list of criteria. It needs to have good ideas! Developing ideas and evaluating them with criteria are the two main sub processes of design (Lawson 2006, Hubers 2008). Knowledge sharing and management is important. We plan to use Wikis for this. Wikis are websites that everybody that is authorized can easily edit. Well known is Wikipedia. Creativity is needed to turn experience and knowledge into ideas. Different techniques can be used. The use of different representations and different media is one of them (Stellingwerff 2005, Schön 1983). The work of Edward de Bono shows several methods like Random Word Stimulation, Analogy thinking, Brain storming etc. (Bono 1980). The Environmental Maximisation Method of Duijvestein is interesting though a bit laborious (Duijvestein 2002). It consists of drawing the design only from the point of view

of one function, e.g. water, green, sun or wind power, traffic, housing, parking etc. and later integrating the plans. Recent developments in ICT make it possible to share all this information in 3D digital models. We call this Green BIM.

Table 1. *Criteria for sustainable buildings*

BIM

BIM is mainly used in the meaning of Building Information Modelling, the process of making a Building Information Model. Collaborative design is one of the main aspects of BIM (Eastman et al. 2008, Hardin 2009, Hubers 2008). We define it as follows. Collaborative architectural design is multidisciplinary simultaneous design from the very start of a project. It is also called co-design or concurrent engineering.

The pressure to use IFC based BIM is growing. IFC is an ISO standard. A good introduction to IFC-based BIM is to be found in Khemlani (2010). Autodesk adopted it a.o. in Autodesk Revit. Other major CAD developers in the AEC industry support it too. The Dutch part of the

buildingSMART association, which develops IFC, states in her newsletter that the directions of Governmental Services of U.S., Denmark, Finland, Norway and the Netherlands signed an agreement for adopting IFC based BIM for all major government projects (BS 2010). Contractors for a long time are working on this and recently the Dutch Conceptual Building network starts working in this direction too (CB 2010). The conceptual building approach converts the demand market into an offer market. Providers of concepts no longer wait for a client to define a demand, but develop complete adaptable solutions that clients can order. It is more or less like in the car business: lean production and mass customization.

The simulation of buildings is a vital benefit. VR systems like CAVEs and Head Mounted Displays are used for that. Delft University of Technology developed a lab called protoSPACE which uses these techniques (Hubers 2009). Eastman et al. report 10 case studies of realized buildings.

Feasibility study	
1	Support for project scoping and cost estimation (2)
Concept design	
2	Scenario planning (2)
3	Early and accurate visualizations (3)
4	Optimize energy efficiency and sustainability (1)
Integrated design/construction	
5	Automatic maintenance of consistency in design (8)
6	Enhanced building performance and quality (5)
7	Checks against design intent (3)
8	Accurate and consistent drawing sets (8)
Construction execution/coordination	
9	Earlier collaboration of multiple design disciplines (6)
10	Synchronize design and construction planning (5)
11	Discover errors before construction (clash detection) (5)
12	Drive fabrication and greater use of prefabricated components (5)
13	Support lean construction techniques (2)
14	Coordinate/synchronize procurement (4)
Facility operation	
15	Lifecycle benefits regarding operation costs (1)
16	Lifecycle benefits regarding maintenance (1).

Table 2. *Advantages of BIM (Adapted from Eastman et al. 2008, p. 321)*

The 16 reported benefits are summarised in Table 2 with the number of projects that had these benefits. Benefit 9 'Earlier collaboration of multiple design disciplines' is in the Construction execution/coordination phase and thus not collaborative design as we define it. Not one project had all those benefits. Besides benefits of BIM there are also drawbacks of course. It is obvious that BIM asks for much knowledge about 3D, 4D, 5D, nD CAD knowledge (4D is planning, 5D is cost, nD is management etc.). Then there are the difficulties of author/ownership and liability of the BIM. Contracts like Design Build and Guaranteed Maximum Price have enormous impact on the concerned professional practices (Hardin 2009).

Recently parametric design software is used. Two main groups of parametric design software can be distinguished: object parametric or process parametric. The problem is that only object parametric design software is compatible with IFC (Hubers 2010).

CONCLUSION

Sustainable architecture has many criteria to fulfil of many stakeholders. A promising idea is to develop synergetic greenhouses on flat roofs of existing buildings. Research is needed to find ways to use both IFC based BIM and full parametric design software. Only then multidisciplinary teams can work efficiently together on sustainable architectural designs. A solution might be the use of scripts that only create objects if they are not already in the BIM database and otherwise only adapt their properties.

ABSTRACT

To gain a competitive advantage, project organizations are interested in sharing knowledge gained through their experiences across the organization. Despite the advantages, this can be particularly challenging for multi-national engineering organizations. These organizations not only encounter typical knowledge sharing constraints due to lack of resources, individual motivations, and a project-based focus; but also the additional challenges of geographical, cultural and disciplinary boundaries. However, gaining knowledge from the diverse environments in which multinational engineering organizations work is a large advantage for working globally. To better understand the networks that exist for sharing knowledge within these organizations, this research employed a case study of a sustainability network within a large multinational engineering organization. The organization selected individuals from offices that were dispersed across nineteen countries. These individuals responded to ego-centric social network surveys that contained questions about their background and the people with whom they share knowledge. The results found that geographic distance created large barriers in the knowledge-sharing network. There was a high prevalence for regional knowledge sharing, which resulted in regional and country level silos with weak ties to offices in other geographies, particularly for knowledge sharing that occurred on a more frequent basis. The research also found a significant focus on knowledge centered from and with the home region for the organization. The results also found that a person's disciplinary background influences the frequency of knowledge sharing within the network. Intra-disciplinary knowledge sharing connections increase with knowledge exchange that occurs on a more frequent basis. The results highlight the need for focused strategic efforts by the firm to encourage knowledge sharing ties between offices and countries separated by geography. In addition, to reap the advantages of working globally, firms must focus on creating low levels of centrality to encourage knowledge flow from offices in emerging countries.

Keywords: Knowledge Management, Organizations, Networks, Global

INTRODUCTION

To meet the trillions of dollars of needed infrastructure (Launch 2003) for a growing global population, multinational engineering and construction companies are expanding their operations to a diverse array of markets and regions (ENR 2010). A common goal of multinational organizations is to learn from each market that they enter to gain collective organizational knowledge across geographical regions (Miller and Chen 1996). In fact, this attribute is one of the key advantages of the multinational organization because the ability to

use the organization's collective knowledge acquired throughout the world is expected to achieve higher performance (Ghoshal 1987; Zahra 2000).

However, in order for an organization's collective knowledge to add value, the knowledge needs to be accessible when and where it is needed. Creating global knowledge sharing networks is fundamentally important for communities of practice (CoP) within multinational organizations because connections between people that span physical barriers can increase opportunities to access information and improve performance (DeSanctis & Monge 1999). Specifically, recent research has demonstrated that task-relevant knowledge sharing between people in different geographic regions can boost performance at the project level (Cummings 2004) and at an individual level (Cross and Cummings 2004).

Organizations that are successful at fostering inclusive knowledge sharing relationships have the potential to reap rewards of not only improved project and individual performance, but also innovative changes in the way they conduct business. Much of today's environment has diverged from the past. Rather than a traditional exploitative, cost-based relationship, a growing number of multinational organizations want to include employees within emerging markets within their knowledge networks to gain benefits. Specifically, emerging markets are believed to help an organization create disruptive innovations that can help the company adapt to operate in emerging markets, and they also have the potential to alter the way business is done throughout the world (Economist, 2010). However, this potential can only be realized if organizations can engage knowledge flows across the organization regardless of location.

Connecting people across geographical and cultural boundaries, in addition to the project and disciplinary boundaries inherent in construction and engineering, has its challenges; however, there is a clear need to integrate knowledge by fostering these connections and creating an inclusive global knowledge-sharing network. This paper seeks to increase our understanding of knowledge sharing connections in multinational organizations by analyzing individual attributes of employees engaged in knowledge sharing connections. Specifically, we analyze the influence of geographical location and discipline practice on the creation of knowledge sharing network connections.

ORGANIZATIONAL KNOWLEDGE

Many organizations are learning disabled: they "don't know what they know" they "know more than they can tell" (Polanyi, 1967). As a result, in recent decades, organizations have aimed to improve their knowledge sharing abilities, as this can help to encourage new collaborations, foster new ideas and share best practices while avoiding repeated mistakes and the "reinvention of the wheel". In fact, under the knowledge-based theory of the firm, organizational knowledge is a resource with at least the same level of importance as capital (Grant 1996, Spender 1996). If, however, knowledge is the most important resource of the firm and knowledge resides within individuals, then the most important organizational capability is the *integration of* individuals' knowledge (Grant 1996). Therefore, an organization must concentrate on connecting employees to encourage knowledge sharing within communities of practice (CoPs) to build competencies and achieve high performance.

Connecting people to enhance knowledge sharing across an organization is particularly difficult in the project-based engineering and construction industry. The autonomy of projects can cause the project team to become siloed, making knowledge sharing challenging across projects and regions (Sydow, Lindkvist and DeFillippi 2004). In addition, the incomplete transfer of knowledge can cause unnecessary rework and delay for projects and the engineering or construction organization (Paulson, 1976; Jin and Levitt, 1996). However,

due to the fragmented nature of tasks in the engineering and construction industry, coordination and sharing of knowledge is fundamental for projects (Jin and Levitt, 1996), innovations (Taylor and Levitt 2007), and organizational success. Therefore, the engineering and construction industry in particular must focus on breaking barriers inherent in the industry to share their knowledge across the organization.

GLOBAL KNOWLEDGE NETWORKS

Today's global environment creates additional hurdles due to distance and dispersion. Organizations no longer have the luxury of discussing projects and strategy in the corridor or around the water cooler in the same office. Instead, they must coordinate and share knowledge globally through virtual platforms. But these challenges do not end with physical distance. Organizations are no longer homogenous; they are now comprised of employees from multiple cultures and countries, creating an office with diverse socio-cultural backgrounds. These backgrounds condition how individuals perceive information and interact in various countries and locations (Hofstede 1991, House 2004) and can increase costs and schedule delays on projects due to misinterpretation and miscommunication (Orr and Scott 2008). In addition, engineering and construction organizations employ specialized actors with diverse disciplinary backgrounds to meet project requirements. The geographic distance, socio-cultural differences and interdisciplinary CoPs all increase the complexity and uncertainty of networks within the global organization and thus increase the challenges of coordination and knowledge sharing.

Despite these challenges, the global environment in which we operate can offer significant benefits. The long-known concept of "boundary spanning" influences how information enters organizations (Tushman, 1977). More recently, research has found that relationships that cross department or functional boundaries are important for effective knowledge transfer within organizations (Tsai, 2001) and that relationships spanning geographic locations can boost performance at the project level (Cummings, 2004) and at the individual level (Cross and Cummings, 2004). Thus, a key competitive advantage for global organizations and teams is the ability to foster the exchange of diverse ideas from people of various backgrounds, helping to facilitate learning and innovations (Barkema and Vermeulen, 1998; Ghosal 1987). However, this only becomes an advantage if knowledge and ideas can be shared across members.

Recognizing the need for inclusive global knowledge sharing networks and addressing prior calls to explain network emergence (Monge & Contractor 2001, 2003), this research will fill an important gap, focusing on the unit of analysis of network connections to understand how and why these connections are formed and maintained.

To answer these questions, we will utilize and expand upon social network analysis applied to construction. Social network analysis is a tool that provides researchers an understanding of a group's social structure and relationships visually and mathematically. Therefore, the analysis is ideal for understanding how knowledge-sharing connections exist within an interdisciplinary community of practice. Chinowsky and colleagues developed the Social Network Model for Construction to expand the traditional focus on efficiency within the engineering and construction industry to focus on performance (Chinowsky, Diekmann and Gallotti 2008). The model incorporates a social network perspective to recognize the importance of collaboration and knowledge exchange to achieve this higher performance without abandoning the required dynamics of information exchange for task completion. This model has been applied to both construction project teams (Chinowsky, Taylor and DiMarco 2009) and management teams (Chinowsky, Diekman and O'Brien 2010) within construction and engineering organizations.

RESEARCH METHOD

To determine knowledge sharing connections and patterns, we employed social network surveys and analysis within a community of practice (CoP) in a multinational engineering organization. We worked with the organization to identify a CoP that was interdisciplinary and globally distributed across all operating locations and selected the sustainability CoP. The sustainability CoP is comprised of people from the majority of disciplines within the organization, including mechanical engineering, civil engineering, environmental engineering, environmental consulting, structural engineering, etc. The goal of the CoP is to develop and share sustainability knowledge, primarily environmental, but also social, and sustainability tools across the global organization. Selecting this global, interdisciplinary CoP was important to encourage boundary-spanning ties across disciplines and geographic distance. Because the sustainability CoP included 1,333 employees, the organization selected employees that represented the major regions and countries in which the organization has a permanent office to participate in the research. This allowed us to examine regional and disciplinary representation in the knowledge-sharing network.

Ultimately, thirty-seven of the CoP employees responded to the questionnaire. These employees represented thirty-two different offices within nineteen different countries. These individuals answered the questionnaire, which was developed from the Social Network Model for Construction (Chinowsky, Diekmann, and Galotti 2008). The questionnaire asked three categories of questions, including mechanics, dynamics and attributes. On the mechanics side, the survey included questions on information and knowledge exchange. For example, on the mechanics side, respondents were asked: "What individuals have you exchange job related sustainability issues with?" and included various questions regarding frequency of communication from annual up to daily communications. On the dynamics side, the questionnaire elicited responses to questions that asked respondents to rate the amount of dependence, reliance and trust they have that the other individual will complete their job related sustainability tasks. In addition to the prior questions developed from the Social Network Model for Construction, we asked additional questions related to individual attributes that may influence the mechanics and dynamics of the network. These questions included the respondent's professional discipline, location of birth, business practice, generation, level within the organization, number of years employed by the organization and prior physical locations worked. We used Network Genie, an on-line survey system designed specifically for managing social network analysis surveys (Hansen et al 2008), to deliver the survey.

"Egos", or the respondents to the survey, reported 407 knowledge sharing connections across a network of 320 individuals, which included both the "egos" and "alters", or people that did not respond directly to the questionnaire but whom "egos" reported knowledge sharing connections with. Attribute data on the alters was obtained through the organization. Data collected from the survey was used to identify and analyze the global knowledge-sharing network and connections within each organization using the UCINET Social Network Analysis software (Borgatti, Everett, and Freeman 2002). The UCINET software provides the mathematical measurements (Wausermann and Faust 1994) as well as the graphical representations required to conduct a Social Network Analysis. Additionally, we analyzed survey responses using traditional spreadsheet analysis to report connections and test the influence of attributes.

RESULTS

For the purpose of this paper, we analyzed the global sustainability network for frequency of job-related knowledge sharing based upon geographical location and discipline.

Influence of geographical location on knowledge sharing

To understand the global distribution of knowledge sharing, we first analyzed the existence and frequency of communications according to geographical location. When respondents were asked who they exchanged job-related sustainability knowledge within in the last 12 months, 407 knowledge sharing connections were reported. The graphical representation of these annual knowledge-sharing connections is shown in Figure 1. Within the network figures depicted, a shape or node represents each individual, while the knowledge sharing connections are displayed as lines between the nodes. We attempted to display these graphically according to region (Asia, Australia, Africa, Middle East, UK, Eastern Europe, Europe–Other and North America). The black nodes represent individuals whose information is not known, either because they left the company or could not be identified from the survey.

Within the annual communications, we witness a propensity towards regional knowledge sharing. Specifically, 62% of the knowledge-sharing connections are between individuals from the same office (e.g. an employee from the San Francisco office sharing knowledge with another employee from the San Francisco office), same region (e.g. an employee from the Cape Town office sharing sustainability related knowledge with a person from the Johannesburg office) or similar region (e.g. a person from the Milan office sharing knowledge with a person from the London office). 29% of the knowledge-sharing connections occur between employees located in different regions (e.g. a person from the San Francisco office sharing knowledge with a person from the Bangkok office) and 9% of the connections are tied to individuals with whom no geographical information is known.

The analysis of these knowledge sharing connections reveals that knowledge sharing patterns based upon geographical location (either the same office, same region, or similar region) or sharing knowledge with the "home office region", in this case, the UK. Table 1 lists the percentage of knowledge sharing connections originating from a region (e.g. Australia has 27 knowledge sharing connections reported from the region) along with the percentage of ties to other regions (e.g. 89% of Australian employee's sustainability knowledge sharing connections are with other employees located in Australia). All regions exhibit the same knowledge sharing patterns, with the majority of knowledge sharing connections existing amongst employees within the same region and the second highest percentage of knowledge sharing connections with employees from the home office region of the UK.

From these results, we build the following propositions:

Proposition 1: Of the knowledge sharing connections that exist between employees in a globally distributed community of practice, the majority of connections will exist between employees located in the same geographical region.

Proposition 2: Of the knowledge sharing connections that exist between employees in a globally distributed community of practice, the majority of connections external to a region will exist with employees from the home office region.

We analyzed these connections further to determine if geographical location impacted the frequency of knowledge exchange. Figure 2 depicts the knowledge sharing ties within the CoP based upon quarterly knowledge exchange. Analyzing the quantity of connections by region for quarterly communication, we discover that 80% of the knowledge sharing connections occur within a region, 14% occur between a region, and 6% of the connections

are with an alter whose location is unidentified. Table 2 lists the percentage of knowledge sharing ties according to region for quarterly communications.

When we analyzed the knowledge sharing connections at increasingly higher frequencies of exchange, we witness increased regional knowledge sharing with decreased global knowledge exchange. For example, 88% of the 139 connections that exchange knowledge at least monthly (depicted in Figure 3) are located within the same region. For the sixty-nine connections that exchange knowledge at least weekly (depicted in Figure 4), 93% of the exchanges occur within the same region. Table 3 lists the knowledge sharing connections according to frequency of knowledge exchange for intra-region, inter-region and unknown connections.

From these results, we build proposition 3:

Proposition 3: Geographical location impacts the frequency of knowledge exchange. Knowledge exchange that occurs on a more frequent basis will occur between employees located in the same region.

Influence of Discipline on Knowledge Sharing

Within the sustainability network, interesting results also emerged regarding the influence of discipline on knowledge sharing connections. Whereas we expected to see a bias of knowledge sharing within the same discipline, 58% of the connections were classified as interdisciplinary, 15% were unknown, and only 27% of the knowledge sharing connections occurred between individuals with the same disciplinary background.

Similar to the geographical location, we analyzed these knowledge sharing connections further to determine if the frequency of communication was impacted by disciplinary background. Table 4 displays the inter-disciplinary, intra-disciplinary and unknown knowledge sharing connections based upon frequency of knowledge exchange. As the frequency of communication increases from annual communications to weekly communications, we witness an increase in intra-disciplinary knowledge sharing connections and a decrease in inter-disciplinary knowledge sharing connections. Specifically, interdisciplinary knowledge sharing connections make up 58% of knowledge sharing connections on an annual basis, but gradually decrease to 38% of connections on a weekly basis. Conversely, intra-disciplinary knowledge sharing connections make up only 27% of the annual connections, but increase to 41% of the connections that share knowledge on a weekly basis.

From these results, we build proposition 4:

Proposition 4: Background discipline impacts the frequency of knowledge exchange in interdisciplinary communities of practice. Intra-disciplinary knowledge sharing connections increase with knowledge exchange that occurs on a more frequent basis, whereas inter-disciplinary knowledge sharing connections increase with knowledge exchange that occurs on a less frequent basis.

CONCLUSION

Prior findings have highlighted a need to share knowledge across departmental boundaries to increase knowledge flow (Tsai 2001) and across geographic locations to increase performance (Cummings 2004, Cross and Cummings 2004). However, little is known about how geographic locations and disciplinary backgrounds of participants in an interdisciplinary engineering CoP influences frequency of knowledge sharing.

This research found that the majority of knowledge sharing connections occurred within a region. When we analyzed knowledge exchange according to frequency, we found that knowledge exchange that occurs on a more frequent basis will occur between employees located in the same region. This becomes a large concern based on research in small group communication that emphasizes the need for frequent exchange to ensure the transfer of ideas between participants (Fisher 1974).

When knowledge-sharing connections were analyzed inter-regionally within the network, we found that the majority of knowledge sharing connections was with the home region, in this case the UK, for all regions in which the company operates. This may be indicative of a transfer bias towards centralized knowledge exchange patterns which limits the amount of flexibility firms have to create "boundary spanning" ties to increase innovations.

In addition to geographic location, we wanted to study the influence of disciplines on the creation of knowledge sharing connections within interdisciplinary CoPs in an engineering organization. In addition to the knowledge sharing barriers created in a project-based industry, the industry is also comprised of individuals with diverse disciplinary backgrounds. When we analyzed the knowledge sharing connections for the attribute of disciplinary background, a surprising result was that a majority of ties were interdisciplinary. However, when we analyzed the network for more frequent connections, we discovered that inter-disciplinary knowledge sharing connections decreased and intra-disciplinary knowledge sharing connections increased for more frequent knowledge sharing connections. If, in fact, knowledge sharing that occurs more frequently adds increasing value, this again highlights an area of concern for the organization. Because today's large challenges require an increasingly diverse combination of disciplines to solve, organizations will want to focus on creating connections that span traditional disciplinary and functional backgrounds.

Our future work plans include analyzing the additional attributes collected to determine their influence on both the dynamics and mechanics of the knowledge sharing network. In addition, we plan to expand the study to include additional CoPs from other multinational engineering organizations that include both interdisciplinary and discipline- specific CoPs.

Abstract

The City of Amsterdam has ambitious goals as to become climate neutral. This will only be possible through a structured approach to both new and existing neighbourhoods.

Following steps from the New Stepped Strategy - as used in the Rotterdam Energy Approach and Planning (REAP) - and using the methodology of Energy Potential Mapping (EPM), the Amsterdam Guide to Energetic Urban Planning (in Dutch: Leidraad Energetische Stedenbouw, LES) must become the manual that will support urban area (re)development towards energy neutrality.

The Guide clarifies local Amsterdam energy potentials, both natural and anthropogenic, and gives an extensive overview of measures and data to be used for the sustainable provision of electricity, heat and cold. This is presented in a very tangible manner, practical to urban planners, architects, housing corporations, developers, public institutions and politician.

The Amsterdam Guide has been tested on two sites, one to be newly constructed and another to be redeveloped, and the incremental approach proved worthwhile, enabling energy neutrality in both cases. The Guide has incited discussions on both short-term actions and long-term visions needed to facilitate real climate neutrality in the city of Amsterdam.

INTRODUCTION

Urgency

In spite of some discussion caused by inaccuracies in their 2007 reports, the general conclusions by the IPCC [2007] still stand and are widely supported. The climate is changing at an unprecedented rate and mankind is one of the major causes as acknowledged.

Although the earth receives almost 9000 times more energy from the sun than that mankind needs, energy is becoming a huge problem. Western societies heavily rely on energy, fossil fuels in particular. The Netherlands for instance produces less than 4% of its energy by means of sustainable sources [CBS, 2008]. The rest is fossils and a bit of imported nuclear energy. As Mackay [2009] demonstrated, it is very difficult to establish a society fully run on renewables. However, Cullen & Alwood [2010] showed that most of the energy we use is lost as non-functional waste energy. So the initial demand can be reduced by more effective usage, such as by low-exergy means [Stremke et al., 2011].

Although estimates of resources fluctuate, it is apparent to both energy experts and oil companies that the end is coming near. We have passed peak oil [ITPOES, 2010]: these days we consume more oil than can be produced. That this is a literally dangerous situation was demonstrated by the two gulf wars and recent turmoil around gas from Russia (first: Ukraine disconnected, second: Belarus threatening to halt the throughput of Russian gas). Apart from this international perspective and its influence on the price of energy, few people from the West understand how dependent they have become on energy, and that a collapse in the provision would have devastating effects to everyday life.

Last but certainly not least, the western appetite for energy is severely limiting the opportunities of developing and emerging regions to catch up in prosperity. As figure 01 indicates, western countries owe their prosperity to limited use of energy in other parts of the world. Needless to say this situation deviates strongly from the equity goals posed by the Brundtland Committee in 1987.

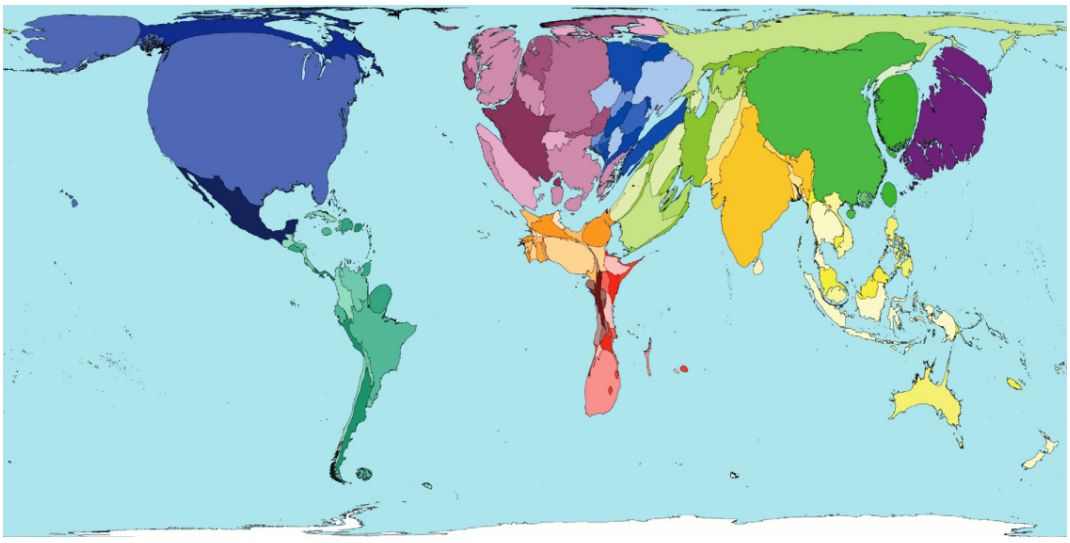

Figure 1: *Developed countries above the equator infest on other regions for energy… Countries and the area of land respective to the amount of fuel they consume [Dorling et al., 2009, downloadable from www.worldmapper.org]*

The abundance – until now – and relatively cheap and easy access to fossil energy has made the world lazy and inactive to search for local possibilities that would avoid demand from alien energy in the first place. We need to learn this again: planning and designing in such a way that local resources are optimally seized before any demand is posed upon other areas.

How can an urban area become energy neutral ? To accelerate this transition planning and design are crucial aspects to consider. Urban planners are in need of planning tools that bridge the gap between mapping, planning, zoning and designing on one hand and understanding of spatial implications of energy, technical energy data, energy solutions and energy scenarios on the other hand.

Climate-neutral ambitions

10 September 2008 the Amsterdam municipal council decided that as of 2015 new construction projects need to be climate-neutral. This means that projects need to comply with the definition of climate-neutral building (see section 1.3), with a 9.0 - 9.5 score of the Dutch EPL (energy performance on location. This council decision implies that energy will become an integral part of area development, a challenge and opportunity as cooperation between projects and connection with the surroundings offers added value at various scale levels.

The Amsterdam approach to climate-neutral building aims at project development and the contribution authorities can make therein. Agreements can be made, for instance, on the thermal insulation rate as well as energy consumption and generation. The ambitions can only be realised through a structured approach to both new and existing neighbourhoods.

Definitions

In Amsterdam, 'climate neutral' is defined as "building without use of fossil resources for the building-related energy demand" [Ontwikkelingsbedrijf Amsterdam, 2009]. This encompasses heating and cooling, hot tap water, ventilation and lighting, all ingredients of the energy performance of a building, however approximately half of all energy used in buildings. The other half is user-related (predominantly from user appliances).

In terms of the Amsterdam definition of climate neutral, critical connotations can be made, as the term actually implies a net zero effect on the climate, including all emissions with an influence on the climate, not just carbon dioxide (CO_2), yet also nitrous oxide (NO_x), water vapour, chlorine-fluorine-carbons (CFCs), methane (CH_4), ozone (O_3) etc. Through the avoidance of fossil fuels for building-related energy demands, emission of carbon dioxide, and a great deal of methane, nitrous oxide and water vapour is avoided, but not everything. Usage of biomass – provided it is replanted – may be considered as climate- or carbon-neutral, but the technical means to enable this may not be as such. The story is slightly different when using solar energy, wind and geothermal heat. These sources produce no CO_2 and their equipment for energy conversion will be energetically earned back within a certain time-frame, leaving no climate marks on the planet.

In this sense the Amsterdam definition rather equals energy neutral than climate neutral. Also carbon-neutral would describe the aim better than climate-neutral. Perhaps even better would be 'fossil energy free': avoiding any use of fossil fuels in building-related energy consumption.

This said, the official objective of the city is clear through its own definition of climate neutral, and we can proceed how to achieve it.

METHODOLOGICAL BASIS

The Amsterdam Guide to Energetic Urban planning is founded on methods previously developed: Energy Potential Mapping (EPM) and the Rotterdam Energy Approach & Planning (REAP), which in its turn is based on the New Stepped Strategy. All of them will be discussed in this chapter.

Energy Potential Mapping

The foundations for the method of Energy Potential Mapping (EPM) were laid during the Grounds for Change project [Noorman et al., 2006], where new perspectives were sought for a sustainable energy system in the Northern Netherlands (provinces of Frisia, Groningen and Drenthe). This region traditionally had provided the country with energy – peat in the 19th and early 20th century, mineral oil since the 1950s and natural gas since 1960. and is de methodiek van energiepotentiekaarten ontstaan. The design team of Grounds for Change [Roggema et al., 2006] introduced a cartoonesk way of charting potentials in the region for energy harvest.

The method of EPM was significantly improved and provided with a scientific approach through a study for the new environmental plan (POP) of the province of Groningen [Dobbelsteen et al., 2007]. Based on rudimentary information from topographic, climatic, geophysical and infrastructural maps, various new GIS-based maps were produced for potential production of renewable fuels, power generation, heat and cold potentials and even possibilities for carbon sequestration. Figure 2 clarifies the method developed.

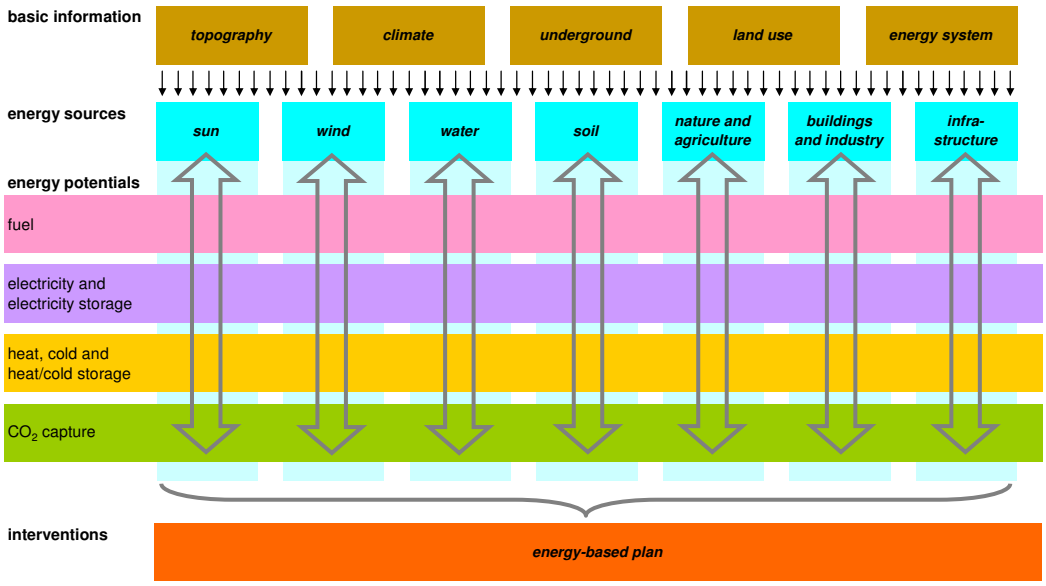

***Figure 2**: Method of Energy Potential Mapping, graphically clarified [Dobbelsteen et al., 2007]*

After the POP Groningen report, EPM was further enhanced and tested at other scales through the EPM studies for expansion plans of Almere, Schiphol Airport and Hoogezand-Sappemeer [discussed in Dobbelsteen & Broersma, 2010]. For Schiphol and Hoogezand-Sappemeer the outcome was newly presented in stacked maps, depicting energy potentials at

various heights and depths, as shown in figure 3, which enabled calculations of the maximum yield to be reapt. In the case of Hoogezand-Sappemeer, the energy produced would potentially exceed the demand, which is important as the new development then could also serve older parts in town.

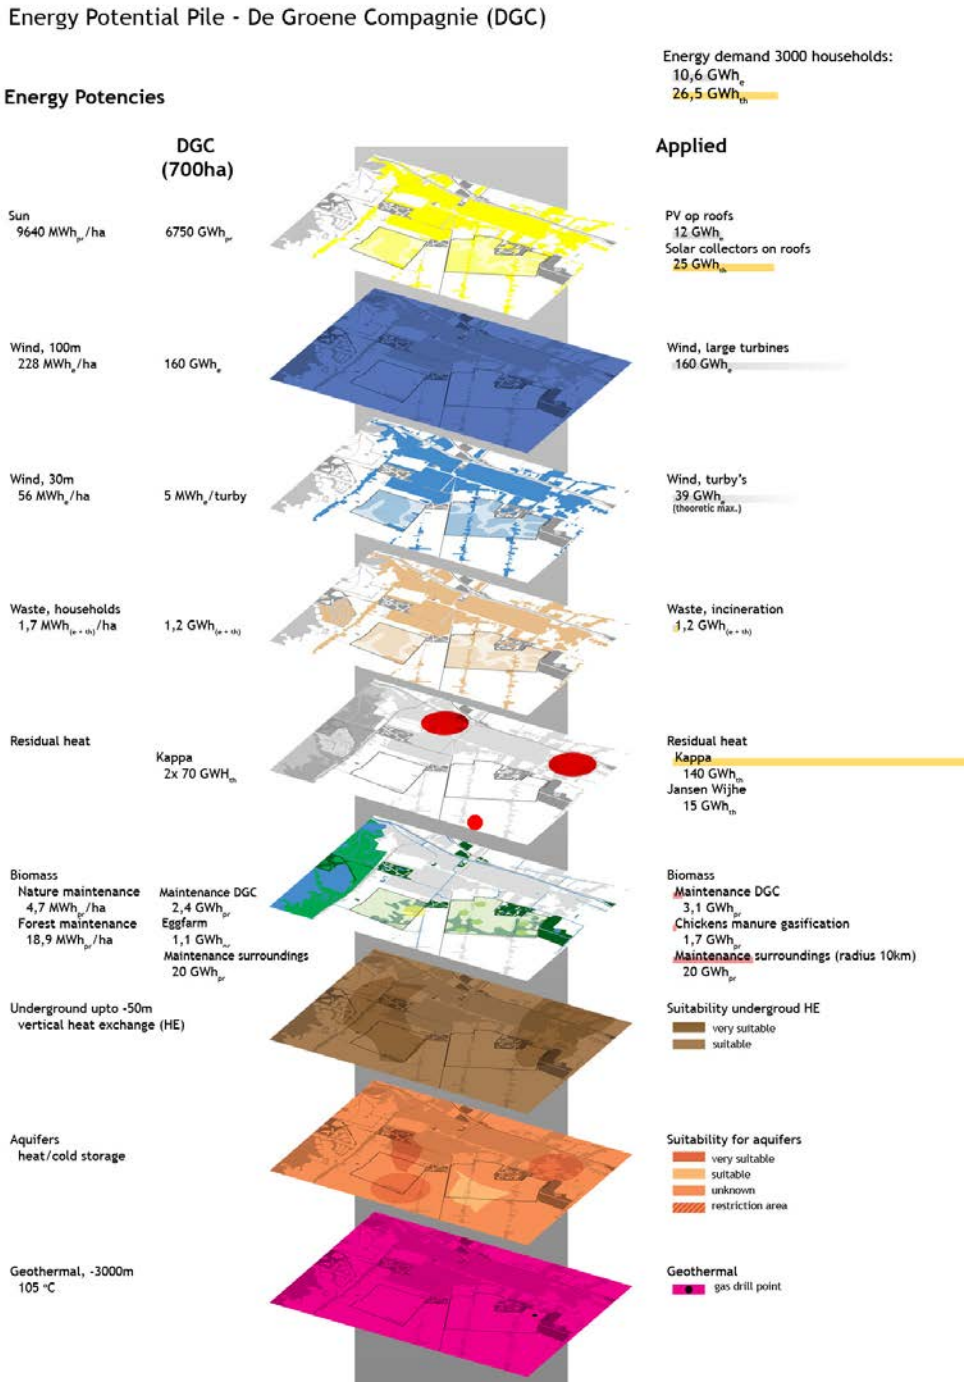

***Figure 3**: Energy potential map for the expansion plan of Hoogezand-Sappemeer, depicting energy potentials at various heights and depths, enabling calculations of the total energy yield possible [Broersma et al., 2010]*

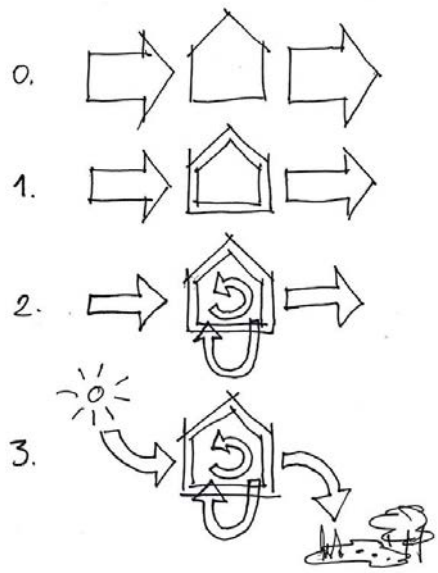
A last development in the EPM range are the heat maps made for the Netherlands [Broersma et al., 2010], focusing solely on heat and cold demand and supply, and meant to feed a national website, which will serve the realization of better exchange of energy in the built environment, or even the spatial planning of new developments.

The New Stepped Strategy



Since the end of the 1980s, approaches to sustainable building have often followed the 'Trias Energetica' [Lysen, 1996], or three stepped strategy:

1. Reduce the demand
2. Use renewable energy
3. Supply the remaining demand cleanly and efficiently

The Trias Energetica forms the guideline for a logical, environmentally conscious approach. However, in the period it has been in use it has not led to the progress required. In particular the extent of penetrated renewable energy technology, step two, is minimal. Mainly in the Netherlands one mainly concentrates on step 3, after limited efforts with step 1 and skipping step 2. No wonder the Dutch are still relying on non-sustainable energy for 96% of their demand.

That step 2 is often neglected and so little use is made of sun, wind and other renewable energy sources has a lot to do with the step abruptly following a sub-optimal reduction in energy demand and with the fact that an important intermediate step is not explicitly mentioned in the Trias.

This is the reason why, the New Stepped Strategy (NSS) [Dobbelsteen, 2008] was presented as a substitute for the Trias Energetica. This strategy adds an important intermediate step between the reduction in demand and the use of renewable sources, and it incorporates a waste stream strategy, inspired by the Cradle-to-Cradle philosophy [McDonough & Braungart, 2002]. The former last step, implying hence accepting the use of fossil fuels, is abolished. Thus, the New Stepped Strategy is as follows (depicted by figure 4):

1. Reduce the demand
2. Reuse waste streams
3. Use renewable energy sources (a) and ensure that waste can be used as food (b)

Figure 4: *Principle of the New Stepped Strategy [Dobbelsteen, 2008]*

The Rotterdam Energy Approach & Planning (REAP)

Based on the New Stepped Strategy, a team of people from the City of Rotterdam, architects and TU Delft [Tillie et al., 2009a] developed the Rotterdam Energy Approach & Planning (REAP) for a structural approach to urban areas. Therefore, the three steps of the NSS were not only connected to buildings yet also to clusters or neighbourhoods, districts and the entire city. Figure 5 graphically clarifies the principle of REAP method.

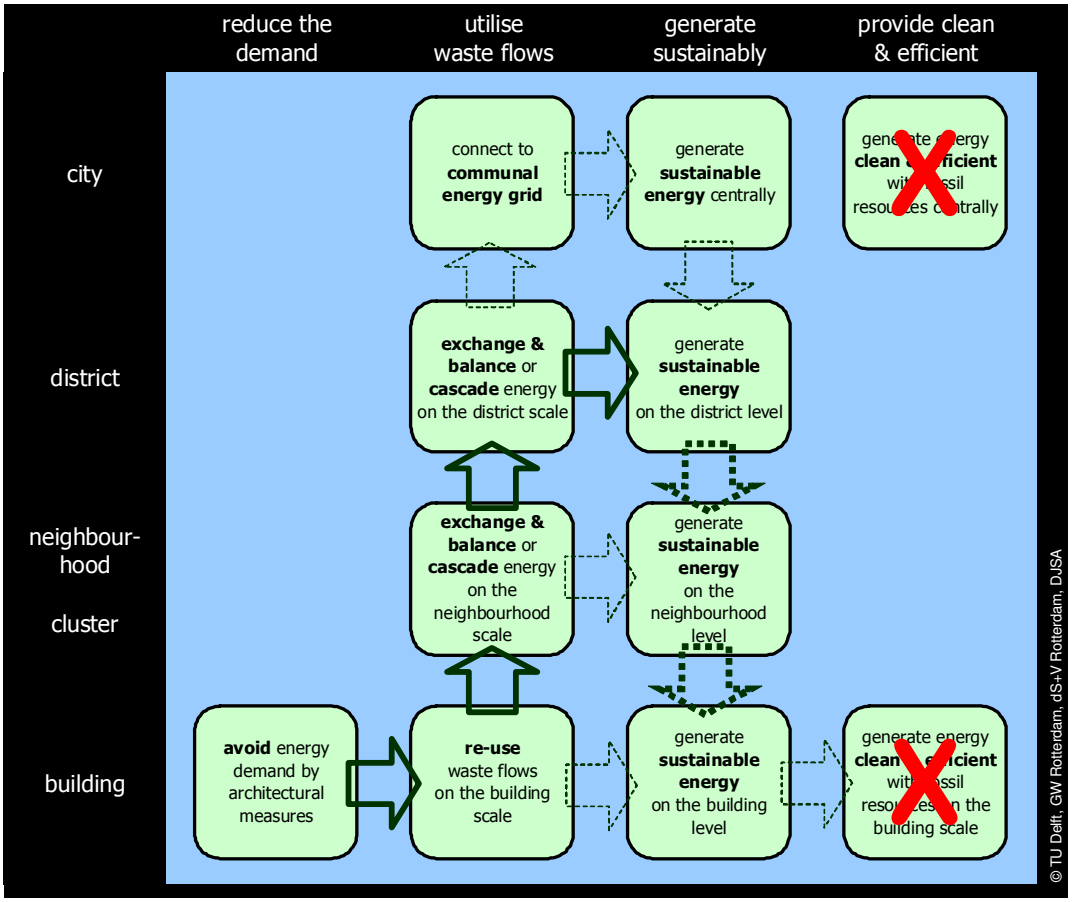


Figure 5: *Principle of REAP for urban areas: the New Stepped Strategy that starts with buildings but expand to neighbourhoods and district for optimal balancing of supply and demand before the question of sustainable generation is tackled [based on Tillie et al., 2009a]*

REAP was tested on, or actually evolved with a study of, the district of Hart van Zuid ('heart of south'), for which the City of Rotterdam wanted to explore the possibility to become carbon neutral. The largest harbour city of Western Europe has the ambition to become 50% carbon neutral by 2025, so interventions in the existing urban landscape will be necessary. REAP demonstrated that Hart van Zuid could become carbon neutral without devastating demolition of existing building, however with smart exchange of waste energy streams from different urban functions, as well as some additions of greenhouses, green facades and roofs.

The essential novelty in the REAP method is the explicit step of exchanging, balancing and cascading of waste energy in an urban context (figure 6). Earlier approaches had neglected this yet unreapt energy potential in cities.

Figure 6: *Urban functions have totally different energy patterns for heat (W), cold (K) and electricity (E). This image shows that a logical connection between specific functions can be made that require heat or cold, since the generation of cold produces waste heat, which can be used elsewhere but usually is emitted into the air [Tillie et al., 2009a]*

Since its presentation in a Dutch and English language book [Tillie et al, 2009a], it was handed to the Dutch minister of the environment, got coverage on national tv and radio, was published in a scientific journal [Tillie et al., 2009b] and inspired other cities to work accordingly. One of them was the city of Amsterdam.

THE AMSTERDAM GUIDE

Amsterdam Guide to energetic urban planning (in Dutch: Leidraad Energetische Stedenbouw, LES) must become the manual that will support urban area (re)development towards energy neutrality [Kürschner et al., 2011].

Outline of the Amsterdam Guide

The Guide clarifies the local Amsterdam energy potentials, both natural and anthropogenic, and gives an extensive overview of measures and data to be used for the sustainable provision of electricity, heat and cold. This is presented in a very tangible manner, practical to urban planners and architects, housing corporations and project developers, public institutions and politician. Figure 7 gives an overview of measures (in simplified icons) in the Amsterdam Guide, divided between heat and cold versus electricity, with the potential improvement of energy performance added.

Figure 7: *Overview of the Amsterdam Guide to energetic urban planning, according to the New Stepped Strategy and with a division between measures (simplified in icons) for heat and cold (thermisch) versus electricity (Elektra); big printed numbers and percentages below are the potential improvement in energy performance*

Amsterdam potentials

The Amsterdam Guide commences with an inventory of all energy potentials of the city, in accordance with the method of Energy Potential Mapping. Thus the booklet gives all potentials of natural energy sources and anthropogenic functions that produce waste streams. This latter is of course necessary for the second step of the New Stepped Strategy.

Factsheets

Where REAP was merely a method for an approach to energy-neutral or carbon-neutral cities, the Amsterdam Guide is presented as a handbook, guideline for urban planning within the objectives of the Amsterdam climate goals. The method is set within the municipal managerial system of PLABERUM (translated in English: 'planning and decision making of spatial measures') and gives practical data regarding financial and technical-spatial measures. Figure 8 gives apart of the overview of measures of thermal energy.

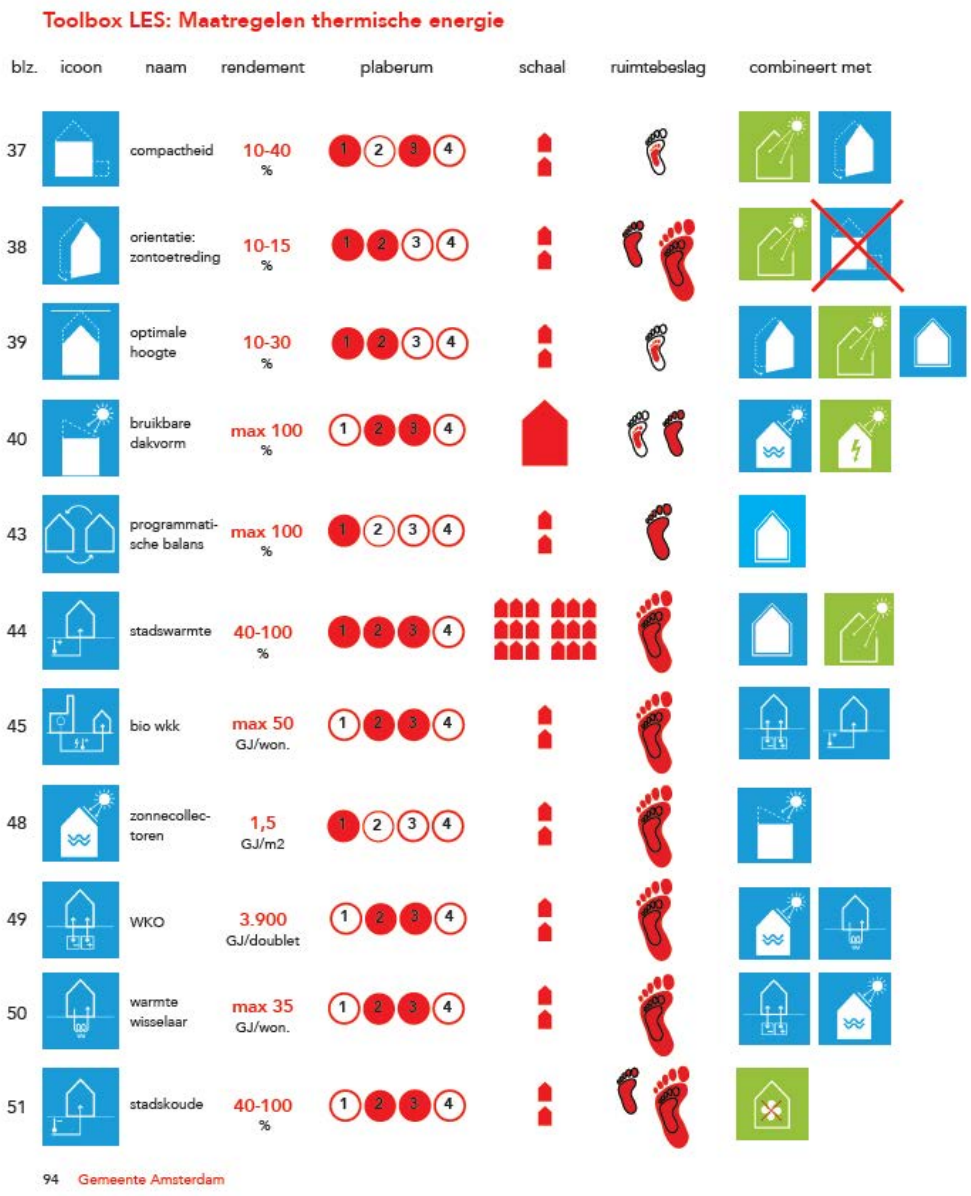

Figure 8: *Overview of the Amsterdam Guide to energetic urban planning, according to the New Stepped Strategy and with a division between measures (simplified in icons) for heat and cold versus electricity; figures in the column 'rendement' are the potential improvement in energy performance*

Measures are presented in factsheets, of which figure 9 gives two examples, one for heat and cold, one for electricity. These factsheets are meant to be practical and helpful for urban planners and other stakeholders involved in the process of making Amsterdam climate neutral.

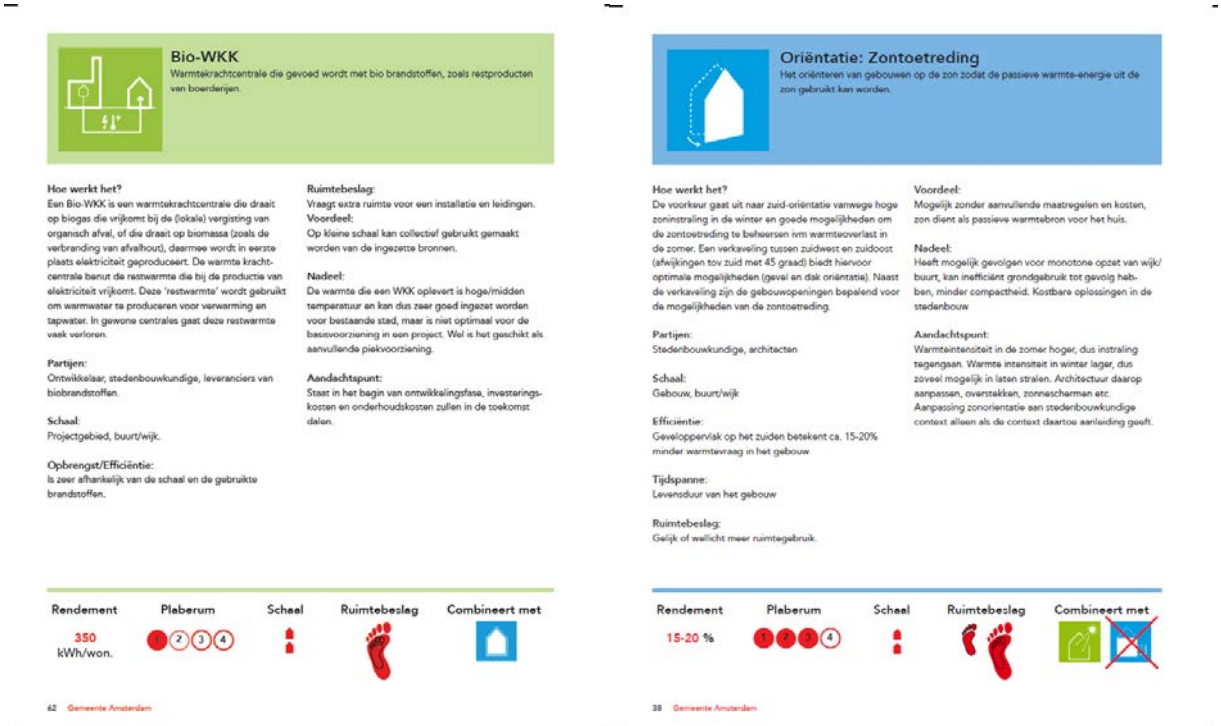

Figure 9: *Two examples of factsheets within the Amsterdam Guide, on the left hand side bio CHP for heat production and on the right hand side solar access for power generation*

Case studies

The Amsterdam Guide has been tested on two sites, one to be newly constructed (in northern Amsterdam) and another to be redeveloped (in western Amsterdam). With a mixed team of urban planners. energy experts from energy companies, housing corporations, project leaders and the authors presentations were given about the Amsterdam Guide about how to use it, showing what options planners have. After that each group worked on of the areas in an iterative design process planning and energy options were tested in the design and a reality check was performed directly with the stakeholders at the table. After this an energy performance was calculated via an excel sheet of the Amsterdam Guide. The outcome was direct feedback in the ongoing process. This incremental approach proved worthwhile, enabling energy neutrality in both cases. The Guide has incited discussions on both short-term actions and long-term visions needed to facilitate real climate neutrality in the city of Amsterdam. Both urban areas could be made energy-neutral according to the steps of the Amsterdam Guide.

Implementation

Before being finally presented, the Amsterdam Guide was discussed with a response group of

people who would have to work with it or who had profound knowledge of the matter. These meetings were used to improve the model. The concept version of the booklet was presented and discussed with the Amsterdam alderman for spatial planning, and finally it was presented early 2011 to colleagues of the departments of spatial planning and environmental & building regulations, hence the people who need to work with it in practice. The response to this was positive and everyone was asked to test the model in concurrent projects and get back with comments or suggestions for improvements.

DISCUSSION AND PERSPECTIVE

The Amsterdam Guide to energetic urban planning, just as REAP, so far have only been theoretic, though practical, methods that could help urban development towards energy, carbon or climate neutrality. Useful as they may seem, the proof is in tasting the pudding, so ongoing projects within the cities of Amsterdam and Rotterdam will have to show whether the models actually work.

In Rotterdam a REAP follow-up study recently started to investigate not just the technical consequences, yet also the legal, strategic, social and spatial consequences. The test-case this time will be a real project to be elaborated by the municipality, giving it a proper meaning and insight to: What energy scenarios are possible at this local level; what are the building blocks used, to make combinations between scenarios; what are the back up systems and what are the legal, spatial and social consequences.

In Amsterdam, several areas are under study, paving the way for a new approach according to the Amsterdam Guide. The year of 2011 will provide the first findings of working according to the method, inevitably leading to necessary improvements to version 2.0, expected late 2011.

Abstract

A changing climate can have a large influence on the living quality of houses. A case study was carried out on the level of awareness of housing associations. This study forms the start of a research project on governance strategies for adaptation in residential buildings. A content analysis on climate change related topics was pursued on the policy plans and the most recent annual reports of the 25 largest Dutch housing associations. They were classified according to their level of awareness. Based on the results of the analysis it is concluded that the housing associations fall within the lowest category of awareness. In order to reach higher levels of awareness, governance strategies for adaptation have to be developed. The nature of possible strategies will depend on the level of awareness of the housing association. The definition of strategies will be studied in the future.
This research provides basic information on 'climate change awareness' that is valuable for governmental and non-governmental policymakers on the national, regional and local level, who are dealing with climate change issues.

Keywords: Awareness, Climate Change, Adaptation, Social Housing, Energy Efficiency

INTRODUCTION

There is clear scientific evidence of a changing climate on the global and the national level. The Intergovernmental Panel on Climate Change (IPCC) states that "Warming of the climate system is unequivocal". It reports that during a period of twelve years - between 1995 and 2006 - eleven rank among the warmest years since measurements started in 1850 (IPCC (2007a). The Royal Dutch Meteorological Institute (KNMI) found out that the long term mean temperature in the Netherlands has risen by 1.7˚C since 1900, while the global increase was 0.8˚C. In the time frame 2003-2008 three years were part of the top-10 warmest years since measurements started in 1706 (KNMI, 2008). These evidences determine that policy makers have to start facing the consequences of changing environmental circumstances. Scientists commonly agree that climate change is a fact, and they are now investigating the precise impact of it on the living quality in our cities, offices and houses, and how we can prepare for and adapt to these impacts.

In the international debate on climate change, opinions diverge. Internet forms a broad base for blogs and blog posts from adopters, who actually believe that the climate is changing (Gore, 2010) and skeptics, who don't believe that climate is changing [i, ii, iii]. The discussion even entered into the Dutch political system, when errors were discovered in the Fourth Assessment Report of the IPCC early 2010. This was a motive for the Dutch House of Representatives to ask the minister of Housing, Spatial Planning and the Environment for an evaluation of the report. This was carried out by the Netherlands Environmental Assessment Agency (PBL) which concluded that the report did not contain any significant error. It did confirm, however, that more transparency is required in the Fifth Assessment Report (due in 2013), concerning both the sustenance of the findings and the benefits of climate change (PBL, 2010). In this paper we follow the line of the PBL. We trust the work of the thousands of scientists, who have collaborated on composing the IPCC report, until there is scientific evidence that they drew the wrong conclusions. The skeptic voices have sharpened our critical attitude which will help us presenting the most realistic results and solutions for effective adaptation strategies. After all, we know that housing associations will not take all scientific evidence for granted.

With the intention to reduce the effects of climate change (mitigation), policies have been adopted on the international and the national scale. For example, the European Commission has approved Directive 2002/91/EC, known as the Energy Performance of Buildings Directive (EPBD) (EP, 2002). In the Netherlands, this EPBD is applicable on existing buildings. Moreover, for new buildings legislation on energy performance is operative. Because a building can only be built when it complies with the building code, property owners and the building industry are automatically aware of the legal mitigation measures. However, even if it is possible to stabilize greenhouse gas emission, the changing process and its corresponding effects will continue developing (IPCC, 2007). Consequently, measures have to be developed for adaptation, which is defined as "any action, either intentional or accidental taken to minimize the adverse effects of climate change or to take advantage of any beneficial effects" (Crown, 2006). Policy on this theme is being made on a regional and a national scale. The European Union has shown adaptation awareness by firstly launching a Green paper on Climate Change in 2007, which set out ideas on adaptation measures, (CEC, 2007), followed by a White Paper on climate change in 2009 (CEC, 2009), proposing legislation on the matter. On the level of national governments, adaptation strategies are ready or in progress in countries such as Denmark, Finland, France, Germany, Hungary, the Netherlands, Romania, Spain and the UK (Biesbroek et al., 2010). On a local scale, information is more diffuse, but adaptation strategies are implemented or under development in cities such as Cape Town, Durban, Quito, Tokyo, Walvis Bay and Windhoek (MIT, 2011). The conference '*Resilient Cities 2011, 2nd world congress on cities and adaptation to climate change*', will strongly contribute to awareness among all participating cities (ICLEI, 2011). The engagement of the 'Hotspots'/Stakeholder cities in the Climate Proof Cities project in the Netherlands (Knowledge for Climate, 2010) indicates that they are also aware of a changing climate. The sense of urgency for adaptation has emerged as plan development field in the new Millennium (Biesbroek, 2010). As a result, much effort is still put into the setting up of adaptation programs, which can eventually lead to legislation. As a consequence, the awareness of adaptation is not as widely spread as awareness of mitigation, especially on the level of the property owners and the building industry.

In order to find out if the awareness of adaptation has already reached the operational level of policy making, we carried out a case study among housing associations in the Netherlands. They own and manage 2.3 million dwellings, which is approximately 32% of the total Dutch housing stock (CFV, 2010). Their successful involvement in the adaptation of the built environment will not alone provide living quality for the social stock, but will certainly help

to reach a substantial part of the existing housing stock and provide tools for private owners to follow similar actions. Knowing the state of awareness of the housing associations, appropriate governance strategies for adaptation can be developed. This study on awareness is considered as a starting point for a larger research on the application of climate change adaptations in social housing.

DUTCH HOUSING ASSOCIATIONS

Housing associations have legal duties on six performance fields, being: the quality level of the dwellings, renting of the houses, tenant-participation in policy making and management, financial continuity, livability, and housing and care (BBSH, 2011). Focusing on the quality aspect, it is their task to be aware of the changes that might challenge the living quality of their tenants and to provide housing with future value, which includes climate change resilience.

Energy efficiency

Since January 1, 2008, it has been compulsory for housing associations to hand over an energy label at the transaction moment of a dwelling. This obligation follows from the implementation of the EPBD. In the Netherlands, the energy label is merely a communicative instrument because of a lack of law enforcement possibilities and/or sanctions, and because a required minimum energy performance level is missing. However, it does give an insight in the energy performance of the dwelling. As most housing associations have 'labeled' all units in their possession, they know the current energy performance status of their building stock (Tambach et al., 2010). This insight, complemented by the housing associations' statutory performance requirements on livability and its sense for Social Corporate Responsibility (SCR), has opened possibilities for the introduction of the 'energy efficiency'-theme in the strategic asset management. By implementing energy saving measures, the associations fulfill their task of providing affordable housing, as they slow down the influence of the rapidly increasing energy costs on the overall operating costs. They also improve the living quality of the building, as for example an insulated wall or window not only saves energy but usually also contributes to noise reduction; humidity decrease and cold air flow reduction (Smid and Nieboer, 2008).

However, it is not only the 'social incentive' (livability, SCR) that makes the housing associations more alert on energy saving. The Dutch government has set up energy saving goals as the consequence of the ratification of the Kyoto Protocol. In order to reach these goals they approach the housing associations as one of the key actors, since the social housing stock is considerably large, with a projected emission of 137 Mton CO2 in the period 2009-2020 (adapted from: Rooijers et al., 2009). The so called 'Covenant Energy Saving Housing Association Sector' was set up, where housing associations and government have agreed on mutual efforts to improve the energy efficiency in the period 2008-2020. During the course of the covenant, housing associations have to invest in energy saving measures, targeting for an energy reduction of 24 PètaJoules. The measures to reach this reduction are: pursue to reach energy label B or raise 2 label steps (for instance from F to D) when performing high level renovation interventions and reduction of energy use of newly built dwellings with 25% from 2011 and 50% from 2015 (reference year 2007). In turn, the government is committed to introduce the valorization of the energy performance in the 'dwelling evaluation system' (MinVROM, 2008). This is a system used in the Netherlands to rate the quality of the dwellings in the rental sector. The height of the evaluation score determines the maximum rent a housing association is allowed to ask for the dwelling. If the

association improves the energy label, the evaluation score and maximum rent will increase accordingly. In this way, applying energy saving measures provides extra income for the housing associations.

CLIMATE CHANGE IN THE NETHERLANDS

As exemplified in the foregoing, the current national and local governance strategies focus mainly on mitigation rather than adaptation. This can be seen in the ambitions of CO2 reduction and energy saving measures of the existing building stock. However, policies are to a large extent based on responsibilities of actors, building owners and contractors, and on market mechanisms. These last appear not to work well enough to reach the intended goals in the Netherlands (Daniels and Kruitwagen, 2010). Together with the unstoppable changing process of the climate (IPCC, 2007), adaptation measures are inevitable to withstand the upcoming effects of climate change.

Climate change adaptation

The temperature in the Netherlands has risen significantly in the last decade, as described in the introduction. Also the overall precipitation has increased with 18% over the past century and the multi-day precipitation amounts augmented, especially in winter (KNMI, 2006). Moreover, the summer rainfall values in the coastal zone (between 0 and 30 km's from sea) are higher than in any other part of the Netherlands, which is expected (but not scientifically proven) to be influenced by the rising water temperature of the North Sea (KNMI, 2008). The effects of climate change in the Netherlands are numerous. The sea level will rise (KNMI, 2006), threatening the lower parts of the Netherlands and the major rivers will have more run-off in winter (Bessembinder, 2008), threatening the areas close to this rivers. All together, the risk areas for sea and river flooding cover 55% of the surface of the Netherlands (PBL 2011). Another thread comes from intensified peak precipitation, which can cause local flooding (Bessembinder, 2008). The increase of temperature will affect the natural environment (PBL, 2009) and the climate in the cities (Salcedo Rahola et al., 2009).
In order to create a base for planning and policy making, four scenarios have been developed by the KNMI showing the prognosis of the state of the climate in 2050 (see table 1) and in 2100. Although there are some different trends in various scenarios, the average temperature is expected to rise in all scenarios, as well as sea level and peak precipitation (KNMI, 2006).

		G	G+	W	W+
Global temperature rise		+1°C	+1°C	+2°C	+2°C
Change in air circulation patterns		no	yes	no	yes
Winter [3]	average temperature	+0.9°C	+1.1°C	+1.8°C	+2.3°C
	coldest winter day per year	+1.0°C	+1.5°C	+2.1°C	+2.9°C
	average precipitation amount	+4%	+7%	+7%	+14%
	number of wet days (≥ 0.1 mm)	0%	+1%	0%	+2%
	10-day precipitation sum exceeded once in 10 years	+4%	+6%	+8%	+12%
	maximum average daily wind speed per year	0%	+2%	-1%	+4%
Summer [3]	average temperature	+0.9°C	+1.4°C	+1.7°C	+2.8°C
	warmest summer day per year	+1.0°C	+1.9°C	+2.1°C	+3.8°C

Table 1: *KNMI'06 climate scenarios for 2050 (source: KNMI 2006).*

Risks affecting the social housing stock

As climate change shall inevitably threaten the well being of their clients, housing associations need to withhold climate change from decreasing the living quality of their building stock. With the current knowledge, key issues to focus on are discomfort caused by heat and consequences of flooding, as these have a direct influence on the living quality of the tenants.

Heat effects

The main heat effects are directly related to human health issues, rather than the financial damage on properties caused by natural catastrophes such as flooding. Expected effects are heat stress, summer smog, and allergies and viruses. A positive effect of a warmer climate is the reduced illness and mortality in winter (PBL, 2009).

As 62% of the social housing stock is located in urban areas (with a density > 1500 addresses per sqkm, VOIS, 2011), special attention is paid to the 'Urban Heat Island'-effect. This is the effect where the urban structure accumulates heat and consequently is warmer than the surrounding countryside. The highest temperature differences occur at the end of the day and can reach up to 10˚C (Salcedo Rahola et al., 2009). The 'Urban Heat Island'-effect is caused by several factors, being absorption of sun radiation, air pollution, 'street canyons', anthropogenic heat (cars, air conditioners, industrial processes etc.), heat storing materials, decreased evaporative surfaces, and reduced wind speeds (Kleerekoper et al., in press)

Water effects

The risk of flooding caused by sea and major rivers will be tackled to a large extent if the national government executes the measures proposed by the 'Delta Commission' (Deltacommissie, 2008). The focus for housing associations will be to contribute to the reduction of flood risk caused by precipitation.

Adaptation measures

None of the above named effects of climate change can be controlled by the housing associations alone. They are dependent on co-operation with other stakeholders as water boards and municipalities etc. However, housing associations do have the possibility to

contribute to the climate robustness of the living environment of their tenants by applying adaptation measures to the houses, preferably during maintenance and renovation activities. They could for example apply light colors on their building façades in order to reflect radiation and reduce the inner-temperatures. In the case of allergies, they could be more alert on which type of vegetation they plant in the common gardens of e.g. apartment blocks. The reduction of the harmful effects of flooding caused by extreme precipitation can be established by applying adaptation measures to retain water temporarily, such as 'green roofs' or to ensure effective drainage as open pavements so that the peak load on the sewage system is topped off. Another effective measure is to use the materials that are not negatively affected by water so that the consequences are less intrusive if, despite all protective measures, flooding happens in case of extreme circumstances (Pitt, 2007).

Whatever measures will be applied on the different scales, it has to be taken in to account that collaboration and a multi-scale approach can be beneficial. For the housing associations, the local authorities and the tenants are the first stakeholders to deal with when addressing climate change adaptations. Moreover, the type of measures will bring more benefits when they focus on climate resilience than on climate robustness. For example, in the first case, flooding in extreme situations would be accepted and the extra water would temporarily be buffered in a designated natural area, which would benefit the quality of the landscape in general when not flooded; while in the second case, measures could be to simply raise the height of the dikes (Pijnappels and Sedee, 2010).

However, before measures will be taken, the actors have to be aware of the task that lies ahead. This research determines to which extent housing associations are aware of this task. Only after their level of awareness is known, effective strategies can be developed for adaptation to climate change.

RESEARCH METHODOLOGY

In order to obtain a clear view of the awareness of Dutch housing associations towards climate change and its threads, a content analysis (Bryman, 2008) was carried out, searching for climate change related topics in their policy documents.

The research question for the content analysis was: How much do housing associations express their awareness to climate change in their policy documents? The sample consisted of the 25 largest housing associations in the Netherlands. Together they own 881.000 dwellings, which is 37% of the social rented housing stock (ABF, 2008). The housing associations are divided through the Netherlands (see figure 1), but mainly in the western part, where most people live. From the sample, 24 associations had their annual reports available for analysis and 18 associations their policy plan. The reference year for the awareness is 2010.

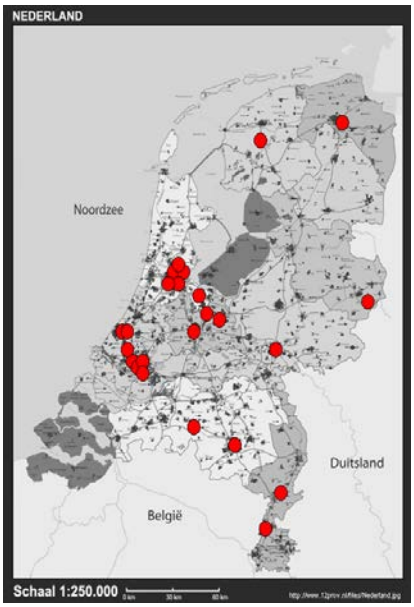

Figure 1: *Distribution of the 25 housing associations*

Two types of documents have been selected for this survey as they would evidence the associations' implemented projects and general strategies. The first type of documents analyzed was the annual report describing the associations' projects and activities executed during 2009. The second type was the corporate policy plan. In this document the housing associations have described their strategies for a time span of several (3-5) years. The oldest plan dates from 2006, looking forward to 2010. The newest plan dates from 2011 with a vision till 2015. Additionally, the policy plans especially addressing sustainability issues were searched. However, as many housing associations are drawing them up at the moment of writing, the number of available documents was only 6. They were, however, analyzed in order to discover if they would differ much from the general policy plans and annual reports.
The topics that were searched for were divided into three groups. The first is 'Adaptation', containing the topics *Climate*, *Climate change* and *Climate change adaptation*. The second group is 'Mitigation', containing *Energy*, *CO2* and *Operating costs* (in the sense of all costs related to live in a house, i.e., rent, energy costs, local taxes etc.). The topics that literally belong to one of the two groups, but do not refer to climate change, were left out of the results presented in this paper. For example, the topic *Climate* in the sense of "inner climate" or "social climate" was excluded.

Four stages of learning
In order to define effective approaches for governance of adaptation, four awareness categories have been created, in analogy with the four stages of learning model, which describes the process of learning. See table 2. The housing associations will be attributed to one of the awareness levels.

Level	Stages of learning (Hughes, 2002)	Awareness levels of housing associations
1.	*Unconscious incompetence* One is not even aware that he or she lacks knowledge or	*Unaware non-adapted* The housing association doesn't show awareness to climate change adaptations in

	skill (that is, one lacks an awareness that certain know-ledge or skill even exist)	its strategies and projects
2.	*Conscious incompetence* One is aware that he or she lacks a knowledge or skill	*Aware non-adapted* The housing association shows awareness to climate change adaptations in its strategies
3.	*Conscious competence* One acquires the missing knowledge or skill and applies it in articulated or codified ways	*Aware adapted* The housing association shows awareness to climate change adaptations in its strategies and projects
4.	*Unconscious competence* One's knowledge or skill becomes second nature, applied seemingly without thought or effort	*Unaware adapted* The housing association shows awareness to climate change adaptations in its projects

Table 2: *Four levels of awareness of housing associations*

RESEARCH FINDINGS

The annual reports of the 24 housing associations were analyzed, and the results are presented in Figure 2. In the reports, hardly any attention is given to the 'Adaptation'-related topics. Out of the 24 reports analyzed, 14 (58%) do not mention *Climate*, whereas only one association (4%) mentions the topic more than 10 times. Zooming in on the topic *Climate change,* this only appears twice, being mentioned only once by 2 associations. The topic *Climate change adaptations is* not mentioned at all. The 'Mitigation' topics, however, showed up far more frequently in the annual reports. *Energy* appears in all (100%) annual reports analyzed. The number of topics range from 4 to 88, with an average value of 31.0. The related topics *CO2* and *Operating costs* were also frequently mentioned, both by 19 (79%) housing associations.

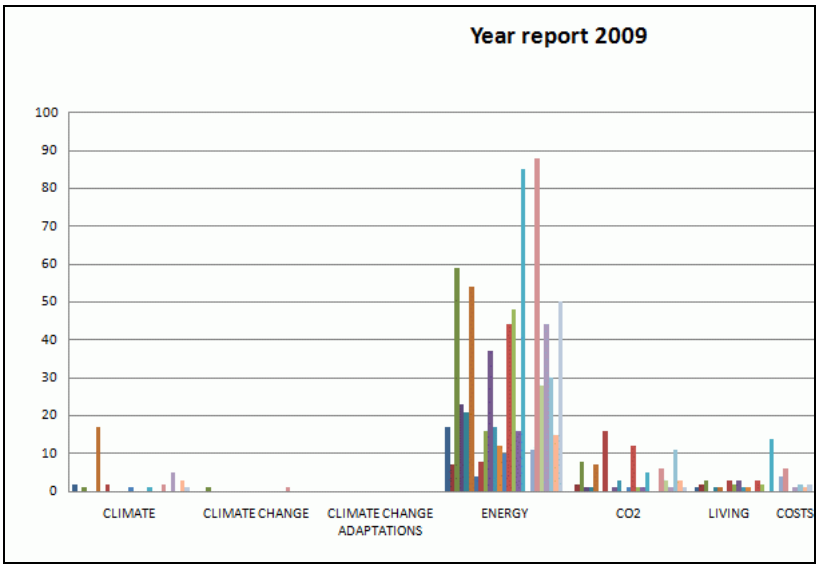

Figure 2: *Content analysis results for the annual reports of 2009.*

Figure 3 presents the results of the document analysis of the 18 policy plans. The 'Adaptation' topics appear on a very small scale. *Climate* is used in only 3 documents (17%). *Climate change* and *Climate change adaptations* appear in none (0%) of the policy documents. The 'Mitigation' topics appear more than the 'Adaptation' topics. *Energy* appears in 15 (83%) of the policy documents analyzed, whereas *CO2* and *Operating costs* appear in 8 (44%) and 13 (72%) documents, respectively

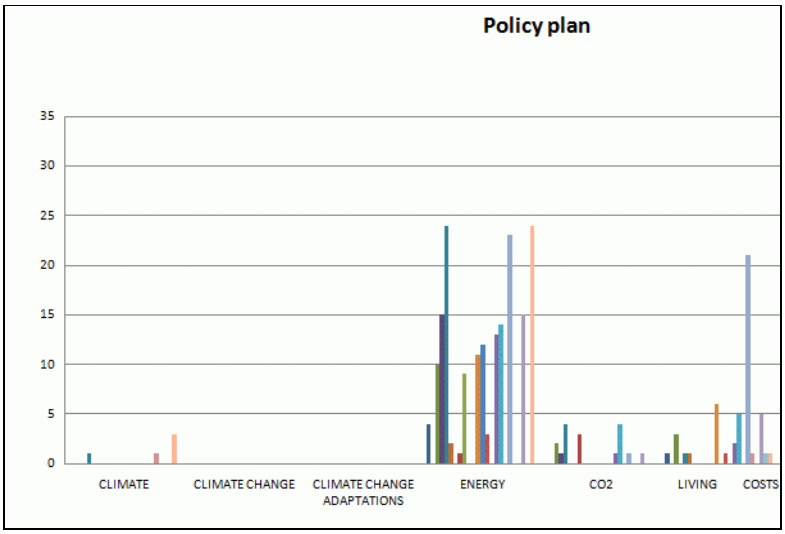

Figure 3: *Content analysis results for the policy plans.*

Energy

The Dutch housing associations reported on in this paper show little awareness for the threats posed by climate change. The governance on implementing mitigation measures, however, seems to have been effective judging from the fact that many housing associations show awareness of the *Energy* topic. Figure 4 demonstrates that this awareness has increased since 1 January 2008, when a new law came into force obliging the social housing sector to provide energy labels for their housing stock. The policy plans with a scope from 2009 onwards, which were drawn up in 2008, show an increase in energy attention. However, even though the action of taking energy saving measures not only serves the goal of compliance with the EPBD, but also improves living quality and provides cost savings for the tenants, it is the regulatory measure by the government that appears to have been the impetus for taking action.

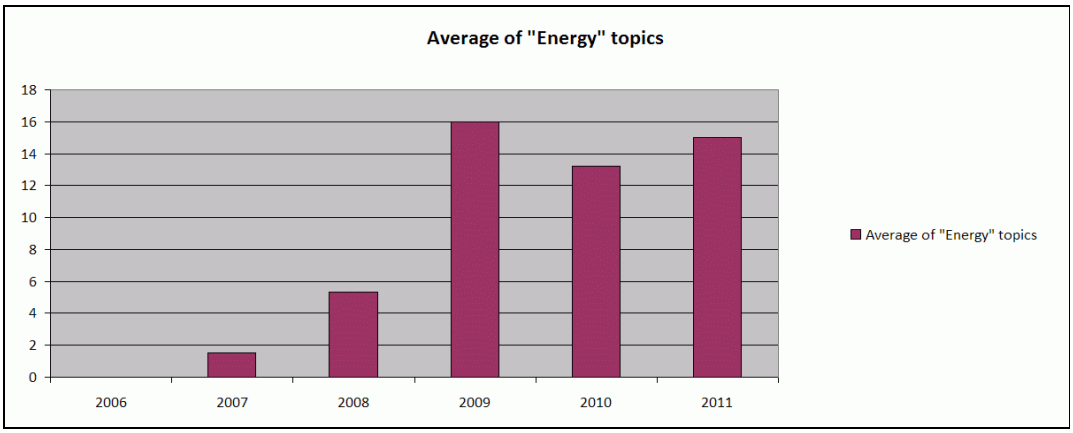

Figure 4: *Development of "Energy" topic.*

The attention for energy-related issues is also reflected in the energy policy documents available for analysis. The topic *Climate* is referenced in 83% of the documents, *Climate change* is referenced in one of the documents (17%), but *Climate change adaptation* is not referenced at all. The focus on energy topics becomes clear in the 'Mitigation' group, whose topics (*Energy, CO2 and Operating cost*) are all mentioned in all documents. The highest number of *Energy* topics is 174, in one document (see Figure 5).

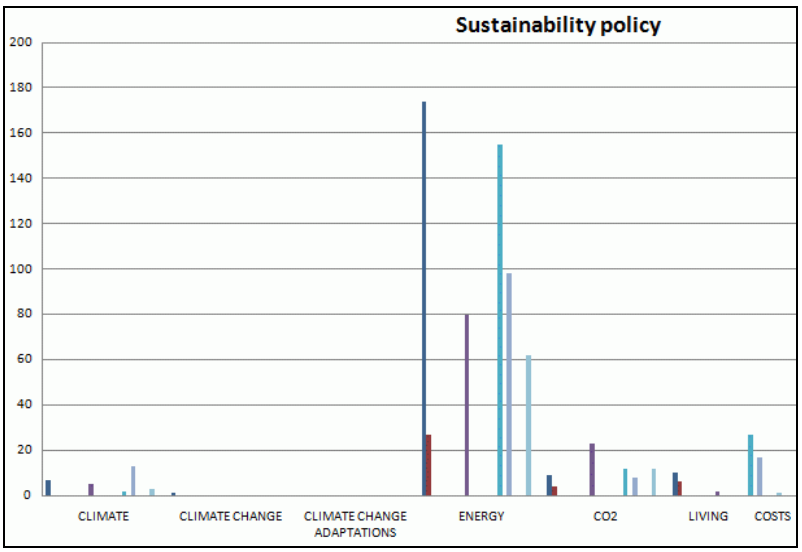

Figure 5: *Content analysis results for sustainability policy.*

Further proof of the attention given to energy can be found in the projects developed by the housing associations concerning energy efficiency or sustainable energy. Among the remarkable projects initiated in this area are: a geothermal heating system [iv], use of CO2-capturing materials (olivine) on roofs [v; vi] a tenant-oriented website for energy information [vii] and a 'Green Deal' between a housing association and an energy company [viii].

DISCUSSION AND CONCLUSION

Based on the content analysis of the two types of documents, it can be concluded that, to date, awareness of housing associations with regard to climate change adaptations is still very limited. All housing associations of the sample can be categorized into the lowest awareness level, "unaware non-adapted". The topic *Climate change adaptations* was not mentioned, neither in their strategies nor in the projects they executed. In order to validate the results presented in this paper, we would recommend analyzing other documents, such as the strategic asset management plans, using the same topics, or analyzing the same documents using a larger number of topics related to climate change adaptation measures.

The categorization of the housing associations according to their level of awareness allows for differentiated governance strategies for adaptation. As it is expected that not all housing associations will shift to higher levels of awareness at the same time, a differentiated framework with strategies focusing on each level would seem to be more effective than one general approach. What the results of this study have made clear is that the governance strategies for adaptation need to be further studied, taking into account the impact of the

governance strategies for mitigation. They appear to be effective for awareness raising on both the strategies and the projects level.

Abstract
Building sector contributes a large part of total energy consumption. Building Energy Efficiency Retrofit (BEER) is an effective approach to save energy & reduce emission of CO_2 and improve sustainability of existing buildings. Energy Performance Contracting (EPC), a market oriented mechanism provided by Energy Service Companies (ESCOs), has been widely used to improve energy efficiency in developed countries. EPC mechanism has been introduced in China since 1990s and implemented in different energy efficiency improvement projects. However, EPC mechanism is still unimplemented in some existing building retrofit projects. This research takes hotel buildings as example aims to identify the barriers to implementation of EPC mechanism into hotel buildings retrofit in China. Qualitative research methodology is employed in this research. In order to identify these barriers, a set of interviews are conducted. After that, a qualitative analysis of feedback information is discussed. Finally, a series of corresponding measures for remove identified barriers are proposed.

Keywords: Energy Performance Contracting, ESCOs, Building energy efficiency

INTRODUCTION

Existing buildings require over 40% of the world's total final energy consumption, and account for 24% of world CO_2 emissions (IEA, 2006). Buildings also represent an important and increasing component of China's energy consumption. For the past 20 years, Building energy consumption in China has been increasing at more than 10% each year. In 2004, building energy consumption alone constituted 20.7% national energy consumption (Jiang and Yang, 2006; Liang et al, 2007). Currently, there are nearly 40 billion m^2 buildings in China and the urban building area is up to 14 billion m^2. 95% existing buildings in China are "highly-energy-consuming". Building Energy Efficiency Retrofit (BEER), such as upgrading to newer, better-performing equipment and building's renovations, is a great way to save on energy bills over the long term. Building Energy Efficiency Retrofit (BEER) supports excellent opportunities to reduce energy consumption in buildings as well as encourages environment protection, rational resources use, and occupants' healthcare.

Although there are many benefits and large potential energy-saving of energy efficiency program in existing buildings, many energy efficiency projects are still unimplemented. The

reasons for delaying projects may vary, most energy efficiency projects stall due to one or a combination of the following perceived barriers (Zobler and Hatcber, 2003): (i) Lack of money, (ii) Lack of time or personnel to design and plan the projects because of other higher priorities, (iii) Lack of internal expertise to implement the projects, (iv) Lack of policy support within the decision making process. Besides above general barriers, there are other special barriers to building energy efficiency retrofit in China: there isn't the energy consumption baseline of different types of buildings in China, which should be established though lots of surveys; the ownership rights of many buildings are not clear; most people have low consciousness to energy efficiency project; new technologies for energy efficiency retrofit should also be further explored (Jia and Zhou, 2008; Yang et al., 2006; Lv and Wu, 2007).

Energy Performance Contracting (EPC) is a market mechanism to deliver energy efficiency projects. EPC mechanism is emerged in US in 1970s and was introduced into China in 1990s (Shen, 2007a). Energy Performance Contracting (EPC) is financing package provided by Energy Service Companies (ESCOs) that include energy savings guarantees and associated design and installation services for energy efficiency projects. EPC mechanism has great advantages for building clients to conduct building energy efficiency retrofit projects and improve sustainability of existing buildings. Energy efficiency projects under EPC mechanism has been widely implemented in nation's industrial, construction, and transportation sectors. However, EPC mechanism is still unimplemented in some existing building retrofit projects. There are significant barriers to implementing EPC success, and these differ by country, sector and other circumstances. This research takes hotel buildings as example aims to identify the barriers to implementation of EPC mechanism into hotel buildings retrofit in China.

ENERGY PERFORMANCE CONTRACTING (EPC) MECHANISM

Energy Performance Contracting (EPC), also known as energy service performance contracting is financing package from Energy Service Companies (ESCOs), which includes energy savings guarantees and associated design and installation services for energy efficiency projects, which was emerged in America in 1970s after the first oil crisis. Energy Performance Contracting is a mechanism for procuring and implementing energy efficiency improvements today that are self-funded over time through guaranteed operational savings. Performance Contracting uses operational savings and avoided capital expenditures to fund repayment of capital for building/infrastructure improvements. However, EPC principle not only is a financing tool, but also a market mechanism. Energy Performance Contract in the ESCO business may be broadly defined as a contract between an ESCO and its client, involving an energy efficiency investment in the client's facilities, the performance of which is somehow guaranteed by the ESCO, with financial consequences for the ESCO (Taylor et al, 2007). Under an energy performance contract, the ESCO will provide financing for a specified set of energy efficiency retrofit measures, along with associated design, engineering, and installation services, the owner or user can achieve high energy efficient facilities and get potential savings with little or even no front investment. The Basic concept of energy performance contracting is shown in Figure 1. The first bar represents the total utility costs of one facility before performance contract. In the second bar, after retrofitting the energy savings are shared by client and ESCO during performance contract period. After performance contract, all the cost savings belong to client after the performance contract period, shows in the third bar.

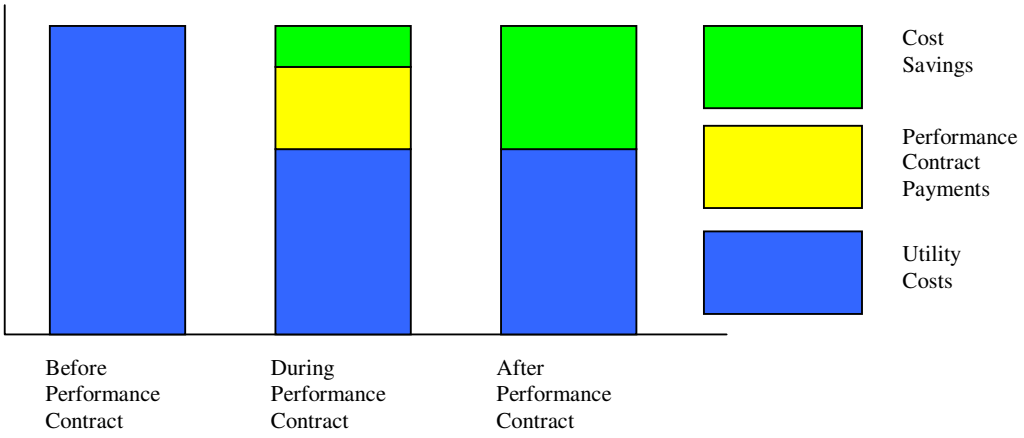

Figure1 *Basic Concept of Energy Performance Contract*

EPC was introduced to China in 1996 in partnership with World Bank and Global Environment Fund, The program aims to introduce EPC, improve energy efficiency, reduce greenhouse gas emissions, and protect global environment in China. The program is divided into two phases (Shen, 2007a). During Phase I (from 1998 to June 2003), three pilot energy service companies (ESCOs, also called energy management companies in China-EMCs or EMCOs) were created: Beijing ESCO, Liaoning ESCO, and Shandong ESCO. They altogether have established client-provider relationships with 405 users, implemented 475 projects, and invested 1.33 billion RMB. The project has brought in both energy conservation and environmental benefits: capacity of an annual energy saving of 1.49 million tce plus capacity of an annual carbon dioxide reduction of 1.45 million ton-c. Phase II refers to the period of 2003-2008. The objective of Phase II is to promote the adoption of EPC energy saving mechanism, foster and develop energy conservation service industry, expand investment in energy efficiency projects, and reduce carbon dioxide emissions and other pollution. Phase II includes two subprojects: 1) A Loan Guarantee Special Fund was established to help EMCo secure loans from commercial banks to implement energy efficiency projects. 2) The Energy Management Company Association (EMCA) was created in April 2004 to facilitate the operation of EPC and development of energy conservation industry in China (Shen, 2007a). Investment in energy conservation projects using energy performance contracting in 2007 up to over USD 1 billion was four times the 2005 level. Meanwhile, EMCA members increased from 59 to 308 (including 185 ESCOs) in the end of 2007 and implemented many energy conservation projects in the nation's industrial, construction, and transportation sectors (Taylor, 2009).

There are many ways to structure an EPC model. Two common EPC models are shared savings contract and guaranteed savings contract (Rezessy, et al; Han, et al. 2006; Bertoldi and Rezessy, 2005; Hui, 2002; Hansen 2003, Poole and Stoner 2003). The shared savings contract means the ESCO designs, finances and implements the project, verifies energy savings and shares an agreed percentage of the actual energy savings over a fixed period with the customer. This is also referred to as the "Full-Service ESCO". In guaranteed savings contract, the ESCO designs and implements the project but does not finance it, although it may arrange for or facilitate financing. The ESCO guarantees that the energy savings will be sufficient to cover debt service payments (Bertoldi and Rezessy, 2005; Hui, 2002; Hansen

2003). Besides the two main models, various models of EPC process have been implemented according to energy efficiency projects in different areas. The general process of EPC mechanism may be similar, which is comprised of three phases: Phase I Selecting contractor; Phase II Make an EPC agreement; Phase III Implementing EPC agreement. The common process can further be divided into the follow seven steps: Identify Project; Planning assessment; Select a contractor; Project design; Arrange financing; Negotiate EPC Contract; Construction and Implementation; and Measurement and Verification of Savings.

EXISTING RESEARCH ON BARRIERS TO EPC/ESCO

Despite the business concept of EPC is very attractive from a theoretical perspective, there are many barriers to EPC mechanism and ESCO industry. Vine (2005) made an international survey of barriers to ESCO industry faced in different countries, and listed the key barriers to EPC from end user aspect, which include: Financing, Perception of risk, Information/awareness/knowledge, EPC expertise, Access to energy-efficiency equipment and technology, Administrative, Reliability, and Credibility/confidence/ trust etc. Painuly et al. (2003) classified the barriers to ESCOs growth in developing countries into three categories: market barriers, institutional barriers and financial barriers. In developed countries, European Commission's Energy Service Company in Europe (Status report 2005) and the International Energy Association's Demand-Side Management Implementing Agreement's Task X identified some major barriers: lack of information and understanding of the opportunities that energy efficiency offer; lack of culture for project financing; public procurement rules that prevent the use of ESCOs; "low" price of electricity; safety and reliability concerns that hinder the introduction of new technologies; burdensome administrative procedures that allow only very large projects to be carried out; limited understanding of energy efficiency and performance contracting by financial institutions; administrative hurdles persist; limited government support; lack of motivation; and Measurement and verification protocols for assuring performance guarantees are not understood(Westling, 2003; Bertoldi and Rezessy 2005).

The development of EPC is later in China. China is a large developing country. Many barriers encountered in the development of EPC industry in China are discussed in previous studies (Fu, 1999; Wang, 2009; Yang et al, 2004; Xie, 2008; Shen, 2007; Wang, 2008; Zhang, 2008). Table 1 summarizes barriers to EPC in China.

Table 1: *Barriers to EPC in China*

Barriers	**Sources**
Information/awareness	Wang (2009), Fu (1999), Yang et al (2004), Xie (2008)
Financing	Wang (2009), Yang et al (2004), Xie (2008), Shen (2007b), Wang (2008), Zhang (2008)
Measurement/verification	Yang et al (2004), Wang (2009), Zhang (2008)
Institutional barriers	Wang (2009), Fu (1999), Yang et al (2004), Xie (2008), Shen (2007b), Wang (2008), Zhang (2008)
Risk	Yang et al (2004), Xie (2008)
Credibility/trust	Shen (2007b), Yang et al (2004), Zhang (2008)
EPC expertise	Yang et al (2004)

Previous researches, both in developed and developing country, mainly focus on barriers to the EPC/ESCO industry development. This research wants to pay more attention to explore barriers to implementing the EPC mechanism at project level. The following parts of this paper describe a qualitative research on barriers to implementing EPC into hotel buildings sectors.

EXPERT INTERVIEW

Above section has summarized barriers to EPC industry development. In order to explore barriers to implementing EPC in hotel retrofit projects, a series of semi-structured interviews with the industry practitioners have been carried out. The interviews involved talking to project managers, managers of engineering department in hotels, executives of hotels, contractors (ESCOs), and researchers. Altogether 15 interviewees were conducted. The details of the interviewees are shown in Table 2.

Table 2: *Details of the interviewees*

Sector	**Personnel interviewed**	**No. of interviews**
Hotel	**Manager of engineering department in hotels:** *South Union Hotel (H1)* *Golden Coast Lawton Hotel(H2)* *Haikou Huitong Hotel(H3)* *Ye Hai Hotel(H4)* *Haikou Tower Hotel(H5)* *Leaguer Resort Sanya Bay(H6)* *Xinyuan Hot Spring Hotel(H7)* *Sanya Beautiful Spring Spa Garden Resort(H8)*	8
	Executive manager of hotel: *Bohua Harbour View Hotel(H9)*	1
ESCO	**Project manager of energy service companies:** *Bard Energy Saving Engineering Ltd.(E1)* *Yangpu Oasis Energy Saving Ltd. (E1)* *Shenzhen Guoneng Power Investment Company(E1)*	3
Academics	**Researchers in sustainable construction and green building***(A1-A3)*	3

Because the interviewees were senior personnel, the interviews were not purposefully structured to facilitate free flow of ideas. At beginning of interview, I explained this framework to each expert in detail. Then the interviews were discussed around 5 issues: 1) Understanding of Energy Performance Contracting mechanism, 2) Difficulties to implement EPC mechanism, 3) Why do clients use or not use the EPC mechanism? 4) Problems in EPC process, 5) How to clear barriers mentioned above? Questions were open and interviewees

were encouraged to add any details that they considered relevant. The interviews were conducted between April and July 2010. They lasted from 1 to 2 hours and were taped and fully transcribed.

RESULT AND FINDINGS

All the barriers mentioned above are discussed by experts during interviews. This research focuses on hotel sectors. Most important barriers and special barriers for this type of project are discussed as follows:

Hotel leader's awareness

From above review, customers, suppliers, engineering companies, banks, finance sector, industry lack awareness and information of EPC. According to collected information from interviews, most leaders of hotel have willingness to reduce energy consumption. However, only few of them have heard about EPC.

> *I never heard about the EPC (H6, H8).*
> *I know about the EPC, I think it is another method for sales promotion of energy-saving production (H4).*

Hotel managers' lack of understanding and interest in EPC is a barrier to implementing EPC in hotel retrofit.

> *I think clients' awareness to EPC should be improved, they don't believe we can provide a win-win retrofit plan based on EPC mechanism (E1).*

Measurement and Verification (M&V)

Measurement and Verification (M&V) is one of most important part of EPC procedure, which is to identify the project result and energy savings. There is not a standard guideline to do this job in China. Sometimes hotel clients and contractors couldn't reach an agreement on how to measure project energy savings because of lack of measurement equipment and baseline data in hotel industry.

> *We had made a success retrofit in last year, I think it very important to identify the energy consumption baseline before conduct the retrofit (H2).*
> *It is very difficult to measure the energy saving accurately. Energy consumption is impacted by many factors, such as working hours of equipment, weather, and others (H7).*

Credit/trust

Both experts from hotels and ESCOs worried about their partners' credit. There is still lack of credit history for ESCOs and customers in China. This will impact project financing from the third party institute. Lack of credit and trust during project organization even causes project failure. Because there is not a standard for M&V, it is also difficult to agree with each other about the result of energy saving, if they don't trust each other.

> *ESCOs like to get up to tricks on M&V. Maybe big contractors certified by National Development and Reform Commission are much better (H3).*

Qualified staff and equipment
Shortage of qualified staff for ESCOs and hotels is another barrier mentioned by experts.

> *As contractors, ESCOs should give a technical support during the retrofit projects, however, sometimes I found the skill of their workers is worse than ours' (H3).*

Besides, some poor quality equipment is used in retrofit projects, which cause these projects failure.

> *……equipment quality cannot meet the preliminary requirement, there is a phenomenon called "saving energy but not saving money" because of short life of poor quality equipments (H1).*

Small scale
Two experts from ESCOs indicated their companies consider prefer industry retrofit projects rather than hotel retrofit projects. Because hotel retrofits projects are usually small with high relative transaction costs. In China, governments have provided many funding supports for energy efficiency projects. Also because of small scale of these projects, these projects cannot reach the requirement of support policies.

> *To be honest, the business of our hotel is not good. It is tight budget for us to update our energy consumption system. I have studied the support polices to these projects. Because of small scale of these projects, we cannot meet the requirement for getting a support funding from government (H7).*

Have sufficient fund
Some hotels have sufficient funds to implement energy efficiency upgrades themselves. They don't want to hire an expensive adviser and be bound to running a multi-year service contract. This will impede ESCOs to enter this market.

> *As a manager, I pay more attention to the operating performance of hotel. Benefit from energy saving affect little to the operating performance. Investment needed in energy efficiency retrofit takes up a small part of total operating cost. In our hotel, we prefer to conduct retrofit ourselves rather than contracting with an EPC contractor (H1).*

Operation status
Experts from ESCOs worried about the future operation status of hotel. Performance contract is a long term service contract. ESCOs invest project and get payback from future saving. Bad operation status of hotel is big risk for ESCOs.

> *Another risk for me is the operation status of hotel. If the business of the hotel is not good, the operating hours of equipment I supplied will be shorten. The energy saving and benefit share is calculated based on the operating hours. So the payback period will be longer (E1).*

> *We don't consider hotels with bad operating status. You know EPC is a long term contract. If the hotel is bankrupt during the contract period, we cannot get back our investment (E3).*

Above 7 barriers to EPC in hotel retrofit are most usually cited by interviewees. Besides these 7 barriers, other barriers such as financing, risk, and institutional barriers and so on are also

mentioned by experts. These barriers are commonly for development of EPC industry and have been discussed by previous research. This research focuses on barriers to hotel retrofit projects, the common barriers will not be discussed detail in this study. Having identified the barriers to hotel retrofit, so what are the possible solutions or recommendations to eliminate the barriers? Some suggestions we obtained during the interviews are given in Table 3.

Table 3: *Suggested solutions to the barriers*

Barriers	**Possible solutions**
Leader's awareness	Information and demonstration programs, training, education programs
M&V	Accurate measurement technology and equipment, M&V protocols
Credit	Accreditation system, standardization of contract procedures
Qualified staff and equipment	Education programs, training, quality regulation
Small scale	Reduce transaction costs, policy incentive
Have sufficient fund	Information and demonstration programs, education programs
Operation status	Fast payback retrofit measures, contract strain

CONCLUSIONS

This research aims to explore barriers to implementing EPC mechanism into hotel buildings retrofit in China. This research reviewed EPC mechanisms, and current existing research in this topic. After that, 15 expert interviews were conducted. This resulted in the barriers to EPC in hotel retrofit. The interviews further resulted in solutions to clears the identified barriers.

Seven barriers to EPC in hotel retrofit are summarised based on information collected from interviews. These are Hotel leader's awareness, M&V, Credit, Qualified staff and equipment, Small scale, Have sufficient fund, and Operation status. In order to clear the encounter barriers, some solutions are suggested as follow: education program, information and demonstration programs, training, policy incentive, accreditation system, standardization of contract procedures, and so on. The findings in this research are collected based on hotel buildings retrofit. Implementation of EPC mechanism in other type of energy efficiency projects should be also explored in future research.

ACKNOWLEDGEMENTS

This paper is support by research fund provided by The Hong Kong Polytechnic University. The authors are thankful to all those who contribute in the interviews.

Abstract
Construction technology utilizing prefabricated concrete elements is known as a 'precast concrete system'. In Western countries, this system has been widely used in constructing bridges, office buildings and residential buildings. A precast concrete construction system provides the advantages of construction effectiveness, high levels of quality control, saving of construction time, minimisation of skilled labour, reduced manpower requirements on site, and saving in formwork requirements when compared with the traditional construction method (cast-in-place concrete). In Thailand, cast-in-place is the traditional construction system that has been mostly used to this point. Precast concrete floor slabs are the only a prefabricated elements used widely in Thailand. Only a few parties in the Thai construction market have adopted fully precast concrete systems. However, many factors have an impact on the adoption of precast concrete system. This paper presents and analyses a conceptual model that accommodates the numerous factors impacting the effectiveness of the adoption process. The results of a survey of 160 construction industry professionals in Thailand are presented and the significant factors which impact the adoption of precast concrete systems are determined through statistical analysis. The paper concludes with an analysis of the significant factors in the adoption of precast concrete elements and system.

Keywords: Precast Concrete System, Conceptual Model, Thailand

INTRODUCTION

Precast concrete elements are one of the most remarkable developments in the construction of concrete structures. In recent decades, precast concrete elements have been widely used for architectural and structural buildings. The construction method is mainly divided into two stages: manufacture of mass-produced components in a permanent construction facility, and assembly of components on the construction site. The use of precast concrete elements has increased in recent years because these precast concrete elements provide the advantages of construction effectiveness, high levels of quality control, saving construction time, minimisation of skilled labour, reduced manpower requirements on site and savings in formwork requirements. Numerous researchers have studied the adoption model within their individual fields of study. It should be noted here that although some adoption models have been developed particularly for the field of marketing, the author is not aware of any comprehensive model developed specifically for the precast concrete construction industry. This study attempts to model the various factors that influence this industry's effectiveness in adopting precast concrete elements. These factors can be broadly defined as enablers and include the product characteristics, communication channels, management support and

environmental impact. The performance and interaction between these enablers influence the degree of adoption achieved. Factor analysis was used to confirm and refine grouping of significant factors.

LITERATURE REVIEW

Adoption of the precast concrete construction continues to be a key stimulant to industrialization and economic growth in developing countries, particularly in the fast-growing Asian countries such as Thailand, China, Vietnam (Prilhofer, 2007; Schultes, 1995; Yeung, 2002). In recent decades, many researchers have studied the adoption model in various areas particularly marketing, but none have targeted their study on the adoption model of the precast concrete construction industry. A literature review was undertaken in this study, which closely examined existing models developed across all industry sectors with a view to developing a conceptual model specifically designed for studying the significant impact factors of adopting precast concrete systems (Brand and Huizingh, 2008; Obra and Melendez, 2006; Wu, 2004).

Table 1: *Enablers and level of adoption*

As a result of the literature review, several variables were identified and grouped as either enablers of adoption or indicators of level of adoption. The enablers were divided into four main categories: product characteristics; communication channels; management supports and environmental impacts (Table 1). The performance of these enablers contributes to the level of adoption in the construction business sector. The level of adoption, which is significantly impacted by these various factors can be divided into five degrees: awareness; interest; evaluation; trial and adoption (Table 1).

'Product characteristics' concerns how the use of precast concrete components will provide significant benefits to the investor and environment. 'Communication channels' deals with how information about the benefits of adopting precast concrete technology will be transferred to architects, engineers, project owners and other users. 'Management support' addresses the industry's policy to improve the knowledge base of customers. 'Environmental impacts' is concerned with product quality to support the customer's choice. 'Level of adoption' concerns the individual customer's satisfaction when planning to adopt the precast concrete construction system.

A conceptual model of factors impacting the satisfaction of precast concrete components has been developed (Figure 1). The relationship between the above-mentioned constructs is represented by four hypotheses, described below:

- H1: Appropriate product characteristics enhance the level of adoption;
- H2: Effective communication channels enhance the level of adoption;
- H3: Appropriate management support enhances the level of adoption; and
- H4: A supportive environment enhances the level of adoption.

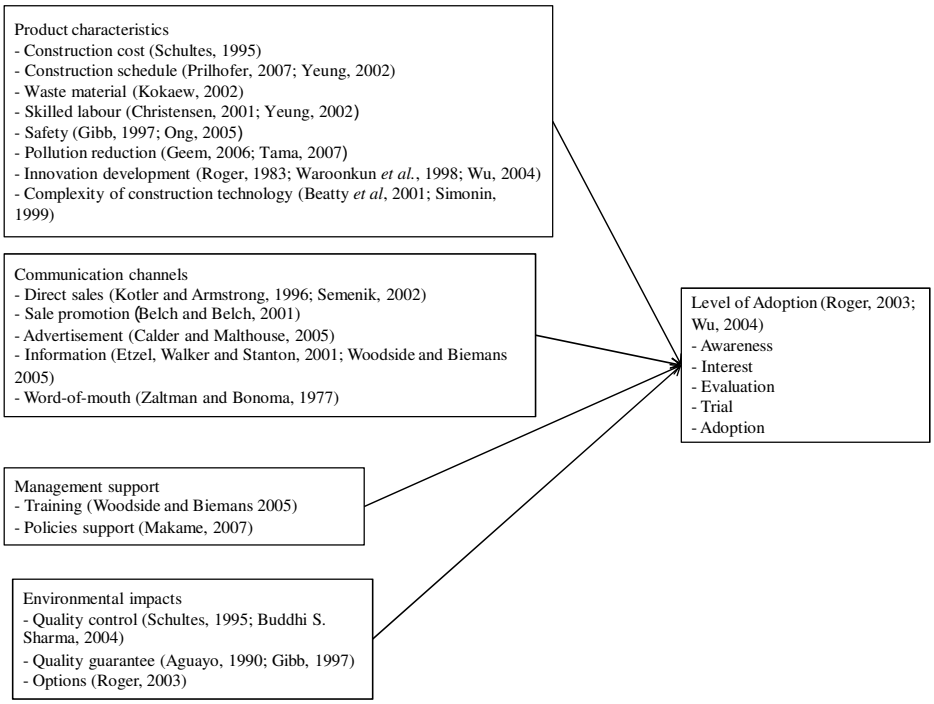

Figure 1: *Conceptual model*

RESEARCH METHOD

During April-May 2010, data collection for this study was undertaken with construction professionals in Bangkok and Chiang Mai, Thailand. The target group of respondents included design and construction professionals from construction projects involving precast concrete systems. In total, 525 surveys were distributed and 160 were returned, representing a response rate of 30 per cent which exceeds the minimum 1:5 ratio requirements for factor analysis (Hair *et al.*, 1998). The objective of this study was to refine and confirm the conceptual model, and identify the numerous factors which impact the level of adoption. Factor analysis was undertaken to summarise the information contained in a number of original variables into a small set of new factors (Hair *et al.*, 1998). Results from this analysis were used to identify the significant factors. The survey questionnaire contained two sections with a total of 29 questions representing individual variables in the conceptual model. Part 1 focused on measuring the level of adoption in the following degree: awareness; interest; evaluation; trial and adoption. Part 2 included questions relating to the enablers influencing the level of adoption, including: product characteristics; communication channels; management supports; environmental impacts. Other background information such as, years of experience, position, education, etc. was also solicited from respondents. This section was included to ensure that information was received from valid sources.

Each question in the survey required the respondents to provide a rating of the impact of enablers and the level of adoption. The question in Part 1 asked respondents for their opinion about the level of adoption, ranging from 'strongly disagree' to 'strongly agree'. Part 2 of the survey questionaire sought to ascertain respondents' perception of the factors influencing satisfication with precast concrete components, based on their experience. The scale in Part 2 of the survey questionaire ranged from 'strongly negative' to 'strongly positive' and the results were utilised for the majority of the statistical analysis because they enabled causal links between variables to be established.

DATA ANALYSIS AND RESULTS

Descriptive Statistics

Respondents were classified into five categories: designer (63%), construction manager (21%), project administration (9%), builder/contractor (5%) and project owner (2%). The respondents' level of education was classified into five levels: bachelor degree (64%), master degree (28%), diploma degree (4%), PhD degree (3%) and high school (1%). Respondent age was also noted: under 25 years (2.5%), 25-35 years (52%), 36-45 years (29.5%), 46-55 years (12%) and over 50 years (4%). The breakdown of respondents' construction experience was 0-5 years (25%), 6-10 years (27%), 11-15 years (15%), 16-20 years (28%) and over 20 years (15%).

Analysis of variance (ANOVA) was performed to ensure that respondents of different age, different education level, different positions and different length of experience could be considered as a single sample. ANOVA confirmed congeners between education levels at the 0.05 level of significance (Black *et al.*, 2000). However, when age, position and past experience were considered together, there was one variables in (use of precast concrete beam in construction) which had a significantly ($p < 0.05$) different mean value for three age

groups (36-45 years, 46-55 years and > 55 years). The mean values for this variable within their respective groups suggest that respondents aged 55 years and up do not trust precast concrete beam construction, it can be describe that the construction technology was developed rapidly during 20 years ago during the period of respondents' age around 36-45 years.

Table 2 shows the mean and standard deviation value for the respondents' level of satisfaction in adopting precast concrete construction systems. The overall mean and standard deviation values for the respondents' satisfaction were 3.58 and 0.47 respectively, which suggests that all questions representing the level of respondent satisfaction in the conceptual model were understood and respondents had a high level of acceptance in adopting the precast concrete system as part of construction projects.

It was found that the respondents were highly aware of and intended to adopt the precast concrete system but when it was implemented in a construction project as part of a structural or architectural building, the respondent's satisfaction level declined slightly. This may be explained by the fact that few past construction projects in Thailand were designed to be built entirely with precast concrete elements: precast concrete is normally utilized only for the floor in Thailand. This suggests that the owners of precast concrete factories should produce a variety of products and arrange courses to promote and teach about the precast concrete products.

Level	Description	Adoption Level of Precast Concrete System		
		Number	Mean	Standard Deviation
1	Awareness	160	3.48	0.62
2	Interest	160	3.54	0.69
3	Evaluation	160	3.84	0.62
4	Trial	160	3.26	0.86
5	Adoption	160	3.76	0.64
Level of Adoption Mean = 3.58; Std. = 0.47				

Table 2: *Mean and standard deviation of adoption level*

Factor Analysis

Table 3 presents the factor loading, eigenvalues and explained variance for the final four-factors solution. The enabler variables that were significantly low on the factor loading from analysis included: making precast concrete technology comply with the traditional method (A7, 0.48) and complexity of construction technology (A8, 0.48). The enabler variables of factor loading should be appropriate for analysis by exceeding the 0.5 threshold level (Coakes, 2005; Hair *et al.*, 1998). In the final four-factor solution, factor 1 was determined to be the most important explaining 38.42 percent of the total variance, most variable loading exceeding 0.5 and the initial eigenvalue of 6.91. Factor 4 is the lowest significant of variance, explaining only 6.09 percent of the total variance with the initial eigenvalue of 1.10. Generally, factors with initial eigenvalues lower than 1 have a poor contribution to the model (Hair *et al.*, 1998).

Factor	Description	Loading
1. Product characteristics	A1 (Construction cost)	0.56
Variance = 38.42%;	A2 (Construction schedule)	0.70
Eigenvalue = 6.91	A3 (Waste materials)	0.72
	A4 (Skilled labour)	0.76
	A5 (Safety)	0.76
	A6 (Pollution reduction)	0.62
	A7 (Innovation development)	0.48
2. Communication channels	A8 (Complexity of construction technology)	0.48
Variance = 10.88%	B3 (Advertisement)	0.50
Eigenvalue = 1.95	B4 (Information)	0.63
	D1 (Quality control)	0.66
	D2 (Quality gurantee)	0.61
	D3 (Options)	0.77
3. Management support	B5 (Word of mouth)	0.59
Variance = 7.27%	C1 (Training)	0.65
Eigenvalue = 1.31	C2 (Policies support)	0.87
4. Environmental impacts	B1 (Direct sales)	0.82
Variance = 6.09%	B2 (Sale promotion)	0.61
Eigenvalue = 1.10		

Table 3: *Varimax rotated factor loading for the final four-factor solution*

Regression

The conceptual model shown in Figure 1 was tested using single regression analysis. Table 4 details the single regression analysis results from the survey questionnaire. The result obtained through single regression provides some indication on the relationship between model factors and the contribution of each factor to the predictive power of the model (Hair *et al.*, 1998; Hatcher, 1994). The higher value of R^2 produces greater explanatory power of the regression equation, and therefore a better prediction of the independent variable (Hair *et al.*, 1998). The *t* value and the significance value both explain whether the addition of the predictor variable has a significant contribution to the model. A higher *t* value suggests a higher contribution to the model.

The combination of the independent variable explained 61.2% of the variance in the level of adoption (F = 23.166, p = 0.000) suggesting that the combination of variables does a reasonable job of predicting the respondent's adoption. Two main independent effect variables including Product characteristics and Communication channels ((t = 3.904, p = 0.000), (t = 3.408, p = 0.001)), were strongly significant in the model as well as Factor 3 (Management support) and Factor 4 (Environmental impacts) were less significant in the model. Each hypothesis will be addressed in the following details.

H1 predicted that appropriate product characteristics would enhance the level of adoption. This study showed that product characteristics were significant as a predictor to increase the adoption level (t = 3.904, p = 0.000). Thus, H1 is supported.

H2 predicted that effective communication channels would enhance the level of adoption. The results show that effective communication channels did significantly enchance the level of adoption (t = 3.408, p = 0.001). Thus, H2 is supported.

H3–H4 predicted that both management support and environmental impact should lead to enhanced respondent adoption levels. These two factors were shown to be less significant in term of effect on the respondent's level of adoption ((t = 0.257, p = 0.798), (t = 0.489, p = 0.626)). Thus, H3 and H4 are only partially supported.

	Beta	*t* value	Sig. level
R = 0.612 R Square : 0.374 (F = 23.166) (Sig = 0.00)			
Independent Variables			
Factor 1 (including A7)	0.270	3.904	0.000
Factor 2 (including A8)	0.257	3.408	0.001
Factor 3	0.012	0.257	0.798
Factor 4	0.025	0.489	0.626

Table 4: *The single regression analysis result*

SUMMARY

This paper details a conceptual model of factors impacting adoption of precast concrete systems. The research study described herein was undertaken with the aim of examining the validity of the model factors and sub-factors, and finalising the conceptual model. Model groupings were achieved via factor analysis. Single regression analysis showed the significant relationship between each model factor to predict the respondent's adoption level. Future research will undertake a series of case studies to verify the reliability of quantified links. Recommendations is also advises herein.

RECOMMENDATION

This study on the physical factors affecting the level of adoption at the conceptual model had the objectives to develop the precast concrete system technology. Improving the physical factors are recommended in Table 5 as follows:

Component	Major factors of the problem	Recommendations for improvement
Product characteristics	- Skilled labor - Safety - Waste material - Construction schedule	- The precast concrete system should be designed to minimize the use of skilled labor in terms of production and part assembling. When compared to other construction systems, this precast concrete system will use machinery as its major tool which will result in a higher degree of safety. - The precast concrete system should be designed to reduce the construction time and to use the least construction material. The construction time of the building structure system should be reduced by at least 60 %.
Communication channels	- Options - Quality gurantee and quality control - Information	- The precast concrete system should be used as the major channel for projects with repetitive construction patterns, especially for building structure. - The precast concrete system or the precast parts must be certified by the industrial standards and its efficiency and quality be certified by a reliable institute. - Information concerning the products and the system should be publicized.
Management support	- Policy support	- The government should support the system through its policy, for example reduction of import taxes for the production machinery.
Environmental factors	- Direct sales	- Information on construction technique related to the product must be presented by the sales representatives or manufacturer directly to the designer, project manager and the contractor to promote the use of the pre-cast concrete system.

Table 5: *Recommendations for improvements of the factors*

Abstract
What is obsolescence? Numerous older housing blocks have been knocked down because of being obsolete. There is a general understanding that buildings, like machinery and durable consumer goods, should be replaced when they become obsolete. But is this true?
Obsolescence is a serious threat for built property. Given its immobile, long lasting and capital intensive character and its societal and cultural significance on the one hand and the high uncertainty about their future lives on the other, minimizing obsolescence is indispensible for the up keeping of the physical, economical and societal investments involved.
This article explores the characteristics and symptoms of obsolescence, how can they be diagnosed and when and to what extent is demolition an unavoidable consequence?
Due to the limited availability of empirical sources, the approach is mainly inventory and conceptual, based on literature search supported by previous empirical work.

Keywords: building management, building pathology, decision making, life cycle extension, obsolescence

INTRODUCTION

What is obsolescence? Numerous older housing blocks have been knocked down because of being obsolete. The recent discussion about the demolition of Ringo Starr's birthplace illustrates on the one hand the emotional character of the subject, but also that there is a general understanding that the life span of buildings, like machinery and durable consumer goods, is determined by becoming obsolete with demolition as a necessary end (Taylor, 2011). But is this true? Not for monuments and other structures with heritage or other intrinsic values that may not be demolishes, not for empty out of service structures on valueless land that no one will demolish, and even not for obsolete worn down property as long as the owners and users love it and it does not harm its environment. Even if obsolescence is defined as a condition that justifies demolition, there are other solutions like renovation, reuse and transformation to extend the service life of buildings. On the other hand, obsolescence is not a necessary condition for demolition, and pretended obsolescence is not necessary always the true reason for pulling down existing building (Thomsen and van der Flier, 2009b).

Obsolescence is a serious threat for built property. Given its immobile, long lasting and capital intensive character and its societal and cultural significance on the one hand and the high uncertainty about their future lives on the other, minimizing obsolescence is indispensible for the up keeping of the physical, economical and societal investments involved.

Since the awareness of the fundamental paradigm change from the massive new construction in the 20th century to the sustaining of the existing stock, the significance of careful maintenance and adaption is undisputed but still often ignored (Thomsen, 2010). The awareness of the huge ecological burden and the consequential need for physical and social sustainable improvement of the built environment further underpins the significance of useful life cycle extension of the building stock.

Obsolescence is not a natural phenomenon but a function of human action. Buildings are complex man-made artefacts and can only survive by means of regular reinvestments during its long service life. As a result the total life cycle costs will generally be a multiple of the initial building costs (Boussabaine and Kirkham, 2004; Woodward, 1997). These high costs demonstrate the relevance of avoiding and minimizing obsolescence and the need for knowledge how to achieve that.

However, the available knowledge about the prevention and management of obsolescence is scarce. Libraries are filled with publications about the initial phase of building; resources on the service life are scarce and on the terminal phase almost inexistent. Bibliographic search machines show an abundance of hits on obsolescence and demolition, but they are mainly casuistic and descriptive. The available theoretical knowledge is limited, empirical data are scarce and evidence based applicable expertise is hardly present nor accessible.

This article explores the characteristics and symptoms of obsolescence. Based on the available literature and following previous research, answers are explored for three research questions:

1. What is obsolescence, what is its role in the life cycle of buildings and its effect on the built environment?
2. How and to what extend can it be avoided, diagnosed and cured?
3. What is the relation to end of life phase of buildings, and to what extent is demolition an unavoidable consequence?

Goal is an inventory of usable and evidence based knowledge to prevent unwanted, unnecessary obsolescence and to optimize the sustainable use of building stock by life cycle prolongation and reduction of demolition.

Due to the limited availability of empirical sources, the approach is mainly inventory and conceptual, based on literature search supported by previous empirical work.
The structure follows the research questions and concludes with recommendations for further research.

OBSOLESCENCE AND THE END OF LIFE PHASE, A THEORETICAL APPROACH

What is obsolescence?

The Oxford Dictionary defines the adjective obsolete as 'no longer used or practised; outmoded, out of date', or 'worn away, effaced, eroded; worn out, dilapidated; atrophied', and the noun obsolescence as 'the process or fact of becoming obsolete or outdated, or of falling into disuse', or more specific 'the process whereby or state at which machinery, consumer goods, etc., become obsolete as a result of technological advances, changes in demand, etc. (OED, 2010). Merriam-Webster's Dictionary adds to the adjective 'no longer current, old-fashioned' (M-W, 2010).
In practice, the term obsolete is mainly used to point at the discarding of all kind of subjects. A search on Google Scholar resulted in about 300,000 hits, commonly articles like "Is xxx obsolete?", with xxx varying from market mentality to vectorcardiography and prisons, but of the first 250 none about buildings (GoogleScolar, 2010). Housing and property obsolescence is nonetheless a significant design and management issue. The degradation over time should be regarded as the fourth dimension in building as it largely determines the performance, usability, occupants satisfaction and life cycle costs of built facilities (Iselin and Lemer, 1993). Given the immobile, long lasting and capital intensive character of built property and its societal and cultural significance on the one hand and the high uncertainty about their future lives on the other, minimizing obsolescence is thus an essential professional skill of designers, developers and facility managers.

Obsolescence of building stocks

Obsolescence can have a wide range of causes. The fact that buildings are composed of a multitude of elements and materials with different life cycle characteristics makes an extra confusing complication. This is mirrored in the available literature, showing a confusing variety of categorisations like physical, economic, financial, functional, locational, environmental, political, market, style and control obsolescence, all focussing on a specific causal factor and subsequent explanatory and problem solving concept.
One main causal factor, inherent to the word obsolete, is overall acknowledged: the factor time i.e. age. But age alone is not a decisive clarification, considering the huge diversities in occurrence of obsolescence between and within buildings and building types. Why are some age old houses still very popular while others are demolished before the trees grow to maturity? For more clarity and a better understanding it is first necessary to order the subject by distinguishing the major characteristics: the nature of causes and effects, the different levels of scale, the building category and building type, and the kind of tenure and control.
Most categorisations of obsolescence are based on the nature of causes and/or on the effects.
Regarding the causes the most acknowledged and widely applied distinction is between physical factors, related to material processes, and behavioural factors, related to human actions, and the interactions between them. Where most of the attention was originally pointed at the physical decay of the buildings and building parts, the awareness of the behavioural and environmental impact has gradually grown (Nutt et al., 1976) and is nowadays acknowledged as decisive for most processes of obsolescence (van Kempen et al.,

2006). The effects are commonly divided in technical and economical obsolescence (Iselin and Lemer, 1993).
Regarding the scale, obsolescence can appear separately or combined on the level of building materials, parts and elements, constructions, separate buildings, blocks, quarters and neighbourhoods. It can be regarded as a range of diseases, spreading over and mutually affecting different levels of scale, i.e. timber blight and lacking maintenance can corrode the market position of dwellings and trigger filtering processes, while reversely the inflow of more vulnerable residents can seriously hamper maintenance investments.
Regarding the building category, there are essential differences between residential and non-residential buildings. Apart from differences in purpose, use, funding, management and legislation, housing is a rather stable function with a long life cycle expectancy, where non-residential functions like office, retail, leisure, trade and industry often have a short cycle of usage and adaptation and consequential different vulnerability for obsolescence. Building types, shapes and functions are often interrelated, sometimes very strong as e.g. water towers and churches, posing strong restrictions for reuse and transformation; sometimes less curbing or in contrary facilitating a wide range of functions, like manor houses converted in offices and back again in residences, and warehouses converted in apartments, the origin of lofts, space and structure being the main determining factors (Markus et al., 1972).
Tenure is decisive for property management and control. In this regard there are essential differences between rented and owned property, as well as between profit and non-profit and between single and joint ownership. (Itard and Meijer, 2008). This holds in particular for residential property, as social and institutional landlords are as a rule organisations with skilled professionals but limited control on usage and care, whereas single owner-occupiers generally lack any proficiency but have in principle full control on usage and care. Small landlords and condominium owners take a middle position, with limited control on usage and care and often lacking professional support. Similar relations can be found in non-residential property like shopping centres.
In relation with building category and tenure, building type has a strong influence on the usage and the appreciation of property. Detached, terraced, multi-storey, high-rise etc. have a significant influence on the property value. The inventory above is not exhaustive; real estate agents will immediately add size, location, situation, architecture, services and facilities (Isaac and Steley, 1999), illustrating the complex influences on property value development as itself a determining variable of obsolescence.

Obsolescence, a conceptual model.
Often used categorisations of obsolescence distinguish on the one hand internal and external factors (Iselin and Lemer, 1993) and on the other hand physical and behavioural factors (Nutt et al., 1976). Assembled in a quadrant matrix, similar to the one used for building evaluations (Leaman, Stevenson, and Bordass, 2010) results in figure.1.

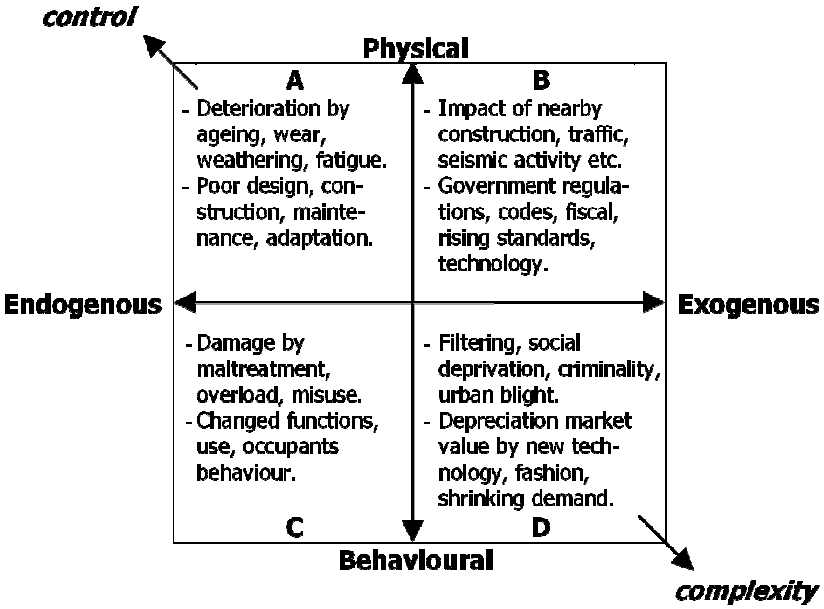

Figure 1 Obsolescence, conceptual model

Internal or endogenous factors are related to processes typical for the building itself. The processes can be physical, like degradation and deterioration over time, caused by ageing, wear and weathering or fatigue of materials and structures, or by poor design, construction, lacking maintenance and adaptations (quadrant A in figure 1). They also can be behavioural, like damage by maltreatment, overload, misuse or by changes in functions, use and occupants behaviour (quadrant C in figure 1). External or exogenous factors are related to influences from outside. They can have physical effects, like the impact of changing conditions in the environment by nearby constructions, traffic, pollution, noise, seismic activity etc., or by changes in government regulations, building codes and fiscal conditions, rising standards and functional requirements and new technologies (quadrant B in figure 1) They can also have behavioural effects like filtering and social deprivation processes in the neighbourhood, criminality, urban and planners blight, or like depreciation and loss of market position and value as a result of new technology, changing fashions and user preferences, the availability of better alternatives or simply a shrinking demand (quadrant D in figure 1).

The diagonal line from quadrant A to D also depicts the increase of complexity regarding scale and participants and the corresponding decrease of control. The physical factors in quadrant A are relatively uncomplicated and can be well controlled and managed by the proprietor. The mainly use related factors in quadrant C are more complex and less easily controlled, while the mainly environmental factors in quadrant B are generally beyond control of the proprietor, as well as the highly complex factors in quadrant D. From the opposite direction, threats coming from the exogenous behavioural corner can have very serious effects. Where direct control fails, proprietors answers have to be found in timely anticipation and intervention.

Many of the aspects in figure 1 are interrelated (Grigsby et al., 1987; Prak and Priemus, 1986). The interrelation can be demonstrated by looking at the actual environmental challenge of energy efficiency. The energy performance of buildings is on the one hand determined by the energetic quality of the physical design and construction (quadrant A)as measured in the EPBD (quadrant B), but on the other depending of the users behaviour (quadrant C). A low EPBD rating and high energy bill can weaken the market position (quadrant D) and consequently have either have a negative impact on the chances for

improvements in the direction of C, B and A, resulting in increased obsolescence, or be a stimulant for improvement actions. A similar reasoning can be applied on social deprivation, being another major contemporary threat.

1.1. Obsolescence and the life cycle of buildings.

Obsolescence is commonly regarded as the beginning of the end-of-life phase of buildings. Sources about the life cycle of buildings show a variety of terms. The building and development trade commonly refers to the development cycle, consisting of the development phase, including the design and the construction phase, and the usage phase, consisting of the actual use and the reuse or end-of-life phase (de Jonge and Arkesteijn, 2008). Sources regarding the life span, building pathology and mortality of buildings more often refer to the physical life or real life, being the period of physical existence, including the usage and end-of-life phase. This is in line with most national building stock statistics that in general only state withdrawal from the residential stock, in some countries subdivided by withdrawal by demolition and/or disaster, merging with other buildings and loss of function (Dol and Haffner, 2010).
The usage phase has now a formal definition: the service life, being 'the period of time during which a building or its parts meet or exceed performance requirements' (ISO, 2000). Bradley and Kohler state that the end of the service life can be the end of the physical life but can also be just the indication of the expected time horizon. They also refer to the economic life, being 'an assumed period of time over which the costs and benefits of buildings are assessed for purposes of making decisions about design and management', adding that this term when used for accounting or fiscal or other legal requirements is not necessary related to the likely service life time (Bradley and Kohler, 2007).
Analysing the influence of decay, several authors depict the life cycle as a function of a building's performance capacity over time (Awano, 2006; Iselin and Lemer, 1993; Markus et al., 1972; Miles, Berens, and Weiss, 2007; Nutt et al., 1976; Vroman, 1982). Following Markus cs., Iselin and Lemer illustrate obsolescence as the extending divergence over time between the declining performance and the steadily rising expectations. Miles cs. more specifically look at the economic performance of buildings, from the first investments in the development phase, the regular operation in the stabilization phase, the growing obsolescence in the decline phase through the final end of life. Combining these concepts results in figure 2, showing the effects of maintenance and reinvestment.

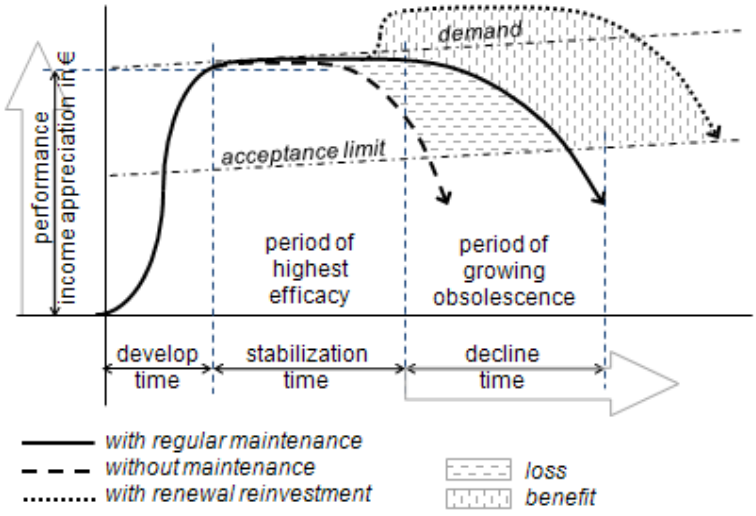

Figure 2 Obsolescence and service life (not to scale)

Maintenance is required to maintain a building's initial performance capacity. Without maintenance the performance will not meet the demand and eventually drop below the limit of acceptance of users or residents and the expected service life will not be reached, resulting in serious loss of efficacy.
In practice, both the demand and the limit of acceptance will gradually rise over time as a result of improved technology, rising standards and growing prosperity. Improvement and renewal are required to answer the accordingly rising expectations. By adding performance capacity the period of highest efficacy can be considerably extended and the service life prolonged. Assessment of the loss and benefits of alternative interventions in this way is part of nowadays professional property and facility management (Boussabaine and Kirkham, 2004).
Apart from proficiency, financial ability and insight of urgency play a decisive role. For some building categories and functions with a short life cycle like retail and industrial facilities, regular refurbishment and adaptation are accepted preconditions to uphold its market position respectively accommodate to changing needs. But in many other cases renewal and improvement is less obvious, due to lacking means and/or urgency. For example in the residential sector, only non-profit landlords maintain and improve their stock in a regularly planned way; most private landlords lack the means for substantial reinvestment, institutional landlords lack the urgency as they generally will sell their dwellings before they need major improvements, while the majority of owner-occupiers lack both means and urgency (Oxley, 2004; Thomsen and Meijer, 2007). As a result major improvements in the owner-occupied sector are generally combined with the purchase and financing by a new owner.
In the last decade, sustainability and more particularly energy efficiency is of growing importance for the market position of built property. Improving the energetic performance has become a strong rationale for additional investment in structural improvement of buildings and dwellings, imposing threats as well as opportunities for the existing older stock (Thomsen and Van der Flier, 2010).

Obsolescence and life cycle management: prevention, diagnosis and cure
Though highly theoretical, the conceptual models of figure 1 and 2 give in a nutshell the basic ingredients to analyse, avoid and cure obsolescence. In practice, the development of

obsolescence is much more complicated and the range of methods and instruments to avoid and cure obsolescence likewise broad.

Given the long life and capital intensive character of buildings, prevention is the most effective and efficient approach to avoid obsolescence. Prevention consists of systematic periodic analytic anticipation on all influences that are potential threats for the performance of buildings. Lijbers et.al. found four circumstantial factors for decay and obsolescence in the Dutch early post-war housing stock: design, construction, use and management, of which the design was by far the main causal factor (Lijbers, Thijssen, and Westra, 1984). A variety of surveys on different stock in different countries came to the same conclusion. They emphasize the importance of on the one side appropriate functional and circumstantial analyses underlying the functional program, including future developments (Iselin and Lemer, 1993), and on the other the building's spatial and structural flexibility to accommodate future changes (Brand, 1994; Maver, 1979; Till, 2009; van Nunen, 2010). Prevention should thus start in the earliest initial stage with an open eye to anticipating on changes, but should in fact never stop.

The diagnosis of obsolescence follows prevention as the next step in the systematic periodic analyses of stock performance. In the same way as prevention it requires in the first place an open eye for early symptoms and trends that may foster negative effects on all quadrants of figure 1, being the base of systematic maintenance and management. This implies in quadrant A the systematic periodical inspection of the property, to be implemented in maintenance schemes (Harris, 2001; Straub, 2008; Watt, 2007), but also in quadrant B, C and D as indications for possible improper use, changing circumstances and conditions, and last but not least evaluated and fed back as preventive input to be used when programming new development.

Apart from physical decay, obsolescence is more and more related to exogenous factors on a larger scale like unattractiveness of the neighbourhood and/or the availability of more attractive alternative options (Wassenberg, van Meer, and van Kempen, 2007). Nutt et.al. paid in their then breaking analytic models for housing obsolescence much attention to the allocation and movement of residents (Nutt et al., 1976). In the rented housing sector, but also in the retail, leisure and hotel sector, regular market analyses are necessary both for assessing the core business as for monitoring the buildings as main capital assets (Gruis and Nieboer, 2004).

Based on an international comparative evaluative survey of the regeneration of larger social rented housing estates, Van Kempen et.al. developed a comprehensive framework for the diagnosis and cure of decay and obsolescence (van Kempen et al., 2006). Though based on residential property, it gives a clear basis for housing as well as for non-residential property management.

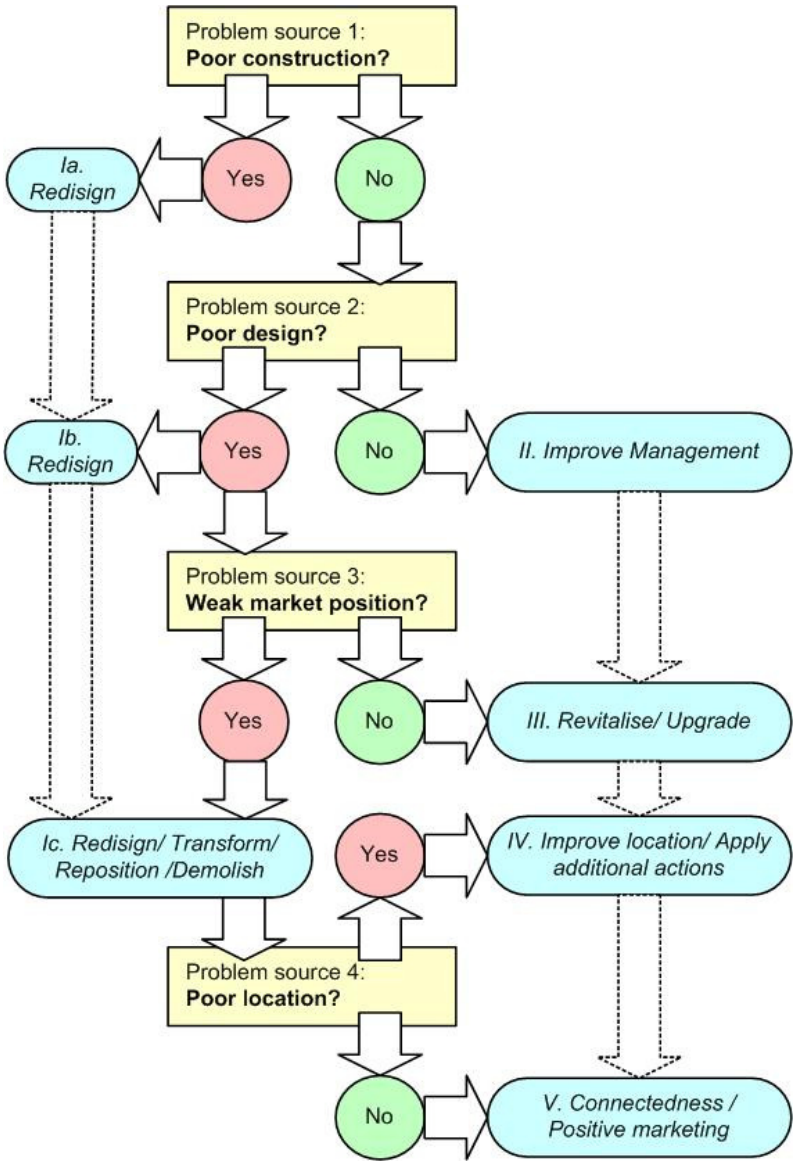

Figure 3 Managing housing obsolescence, analytical model (source: van Kempen 2006)

Obsolescence and demolition

The end of life phase is a normal part of the life cycle of buildings. Without adequate cure, obsolescence will eventually result in the end of the service life, generally by demolition. Exceptions are monuments and other structures with heritage or other intrinsic values that no one may demolish, and empty out of service structures on valueless land that no one will demolish. Even if obsolescence is defined as a condition that justifies demolition, there are other solutions like renovation, reuse and transformation to extend the service life of buildings. On the other hand, obsolescence is not a necessary condition for demolition, and pretended obsolescence is not necessary always the true reason for demolition. Apart from obsolescence, there can be many reasons to -or not to - demolish. To what degree these reasons become decisive motives depends on the interests and disposition rights and the capacities of the party involved.

Despite an abundance of case studies and descriptions (LibraryofCongress, 2010), empirical knowledge about the decision-making in the final phase of the life cycle of buildings and the underlying motives is scarce and fragmented. Data about demolition of non-residential property are generally not included in the statistics nor available from other resources. As a consequence, quantitative data are only available from the residential stock of the 19 out of the 27 EU members that supply any, of which only 9 on an a rather complete annual base, while the qualitative knowledge comes almost exclusively from the social rented stock and/or urban renewal areas of these 9 countries. Furthermore the definition of what is included in the records varies considerably.
Looking at the available data as shown in Figure 4, the rate of demolition differs considerably between countries, varying from 0,05% and below in France, the UK and Sweden to over 0,3% in the Netherlands.

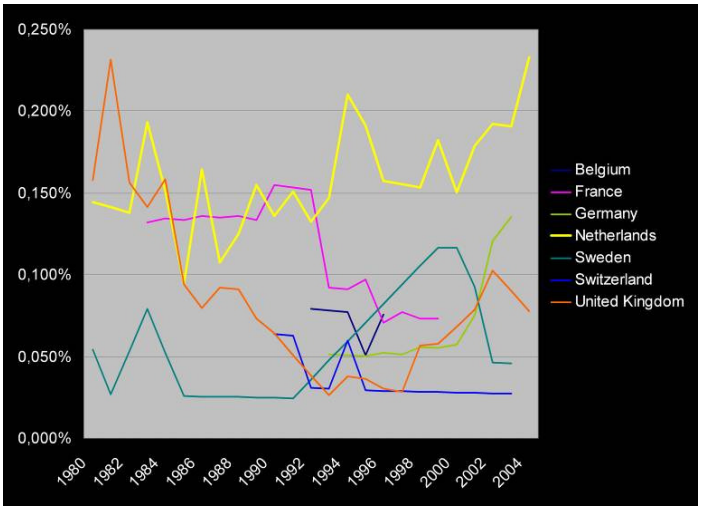

Figure 4 Demolition rate Western-Europe.

According to a survey of demolition by housing associations in the Netherlands, over 60% of the demolitions were motivated by functional and structural obsolescence, in the pre-war stock even over 90%. Including economic motives and oversupply, 87% of the demolitions were attributed to a kind of obsolescence and 13% to urban planning (Thomsen and Andeweg-van Battum, 2004). Additional questioning and information showed though that the decision making was also strongly influenced by social problems and more hidden profit driven motives like the land value, urban and asset policy and deals with the municipality and was biased by prejudices about the quality and costs of renewal versus new construction (Thomsen and van der Flier, 2009b).
Empirical data about demolition motives in the private owned stock are almost absent. The available information shows that, apart from acquisition for urban redevelopment, almost all of the demolition in the owner-occupied sector concerns detached dwellings after purchase by a new owner. The explanation is simple: residing owners do not likely pull down their homes and accordance between multiple owners in apartment blocks to do that is a rare exception; this in contrast with new owners who either decide to replace instead of refurbish the original dwelling, or are just in search of land for new construction.
The conclusion is all together that obsolescence does not necessary lead to demolition, nor that demolition is necessary preceded by obsolescence. It can certainly be a motive or at least a trigger for the decision between demolition or life cycle extension, depending on the interests, motives and capacities of the proprietor.

Recent studies point at the unwanted environmental, social and economic impact of demolition and conclude that life cycle extension by improvement, renovation and renewal is a better and more sustainable solution (Itard, Klunder, and Visscher, 2006; Power, 2010; Thomsen and van der Flier, 2009b). Though based on housing, the outcomes for non-residential stock with regard to environmental sustainability, e.g. building waste and energy use, will probably not be different. The conclusion is as yet that the limited building replacement capacity, being anyhow insufficient for mass replacement (Thomsen, 2010) should be used for life cycle extension of the existing stock. This underpins on the one hand the need for appropriate life cycle management as described above, but also the relevance of careful decision-making before the execution of final destruction.

Knowledge about the decision-making in the final phase of the life cycle of buildings and the underlying motives is scarce and fragmented. It is generally regarded as a black box, in which a complex range of interrelated and often conflicting interests and expectations of different parties are blended with the interests, considerations and expectations of the proprietor, with the latter as decisive condition for the outcome. Following a more elaborated analysis of the decision process and underlying motives of proprietors, physical quality and market demand can be considered as the main decisive variables, with tenure and asset management as main conditional factors (Thomsen and van der Flier, 2009b). Though explanatory in the Dutch setting, comparative findings are not yet available and use for forecasting or influencing the outcome is as yet beyond reach.

CONCLUSIONS AND RECOMMENDATIONS FOR FURTHER RESEARCH

This article explores the characteristics and causes of obsolescence resulting in a conceptual model of causes of obsolescence and effects. It distinguishes between on the one hand physical and behavioural factors and on the other endogenous and exogenous factors. It shows the inverse relation between the increase of complexity of types of obsolescence and the decrease of possibilities to manage it. Obsolescence as a process is described as the growing divergence between the declining performance of buildings and the rising expectations of users and proprietors. Obsolescence is often regarded as the start of the end-of-life phase of buildings. However, obsolescence is not an inevitable natural phenomenon but a function of human action, read decision making. It does not necessary lead to demolition as demolition is not always preceded by obsolescence.

Obsolescence is a serious threat for built property. Given its immobile, long lasting and capital intensive character, its societal and cultural significance, and the high uncertainty about its future lives, minimizing obsolescence is important for the preservation of the physical, economical and societal investments involved. However, facing the paradigm change from new construction to maintenance and adaptation and the resulting huge task to improve the performance of the existing stock, the knowledge about the management of obsolescence is insufficient. Further research about the causes of obsolescence and about decision making about life cycle extension or demolition is therefore required.

Concentrating on the residential sector different questions should be investigated about the owner occupied sector and about the non-profit rental sector and different research designs are appropriate. Although the causes for obsolescence in both sectors of the housing market can be the same the decision making in both sectors varies resulting from different objectives and capacities of owner occupiers and professional housing managers. The availability of knowledge and data about management and decision making in both sectors differs too, as relevant knowledge about the owner occupied sector is very scarce compared with the non-profit rented sector.

For the owner occupied sector a twofold research strategy may be appropriate. On the one hand the collection of basic quantitative data about numbers of demolition and possible causal factors by means of surveys using the model, depicted in this paper and on the other hand explorative case studies to elaborate a conceptual scheme about the decision making in this sector. Different from the non-profit sector the decision making by residents in the owner occupied sector seems to be related with their housing career: decisions are often related to change in household composition or to a move to another dwelling. The capacities of owner occupiers are also much more limited than the capacities of professional housing managers.
In the social rented sector more quantitative data are available so it is possible to start testing assumptions about causes and effects of obsolescence and about relations with interventions by housing managers. Different from the owner occupied sector the decision making in the non-profit sector seems to be mainly related to asset management and policy objectives. Starting from the knowledge about the structure of decision making in this sector it may be fruitful to compare decision making between non-profit housing providers in different housing markets or countries to test the effect of external factors like housing policy, housing culture and housing market. This could be achieved by international comparative research as described by (Thomsen and van der Flier, 2009a).

A PARADIGM SHIFT OR CHOKE?
THE FUTURE OF WESTERN EUROPEAN HOUSING STOCKS

ANDRÉ THOMSEN
Delft University of Technology, OTB Research Institute for the Built Environment
The Netherlands
A.F.Thomsen@tudelft.nl

Abstract
The 20th century saw an enormous worldwide growth of the housing stock. In particular the building boom after WW-II, during which the housing stock in most countries was multifolded, focussed the attention of the housing sector primarily to the planning and realisation of new construction; the consciousness of the enormous maintenance and management task to come was still a far cry.
The begin of the 21st century shows a completely different situation that urges for a paradigm shift.
New construction in most western countries has faded down below an annual production of 1% of the existing stock, and often well below. Parallel to this, the ageing existing stock draws growing attention. The necessary investments in major repairs, renovation, adaptation and redevelopment count at present for a total turn-over well beyond that of new construction. Improving the energy efficiency to the required standards of tomorrow will give these investments a strong extra boost.
Though the change from new addition to the adaptation and transformation of the existing stock is well under way, large parts of the construction and real estate practice seems hardly aware and to stick to business as usual: new constriction, if not in greenfields then in brownfields. The knowledge about how and when to successfully maintain, manage, adapt, transform and redesign has still a way to go. At the same time, the awareness grows that housing problems are only partly related to the physical supply side and solving them requires more than bricks and mortar.
The paper illustrates the paradigm shift in Western Europe and explores the consequences for the future management of the housing stock.

Keywords: housing stock management, paradigm shift, construction market, life cycle extension, housing pathology

INTRODUCTION

The 20th century saw an enormous worldwide growth of the housing stock. In particular the building boom after WW-II, during which the housing stock in most western European countries was multifolded, has shaped nowadays housing stock. As figure 1 shows, two-third of the western European housing stock is built after WW-II; in most western European countries over 60% of the stock - in some countries like the Netherlands and Finland even over 75% - is younger than 50 years and over half is younger than 30 years.

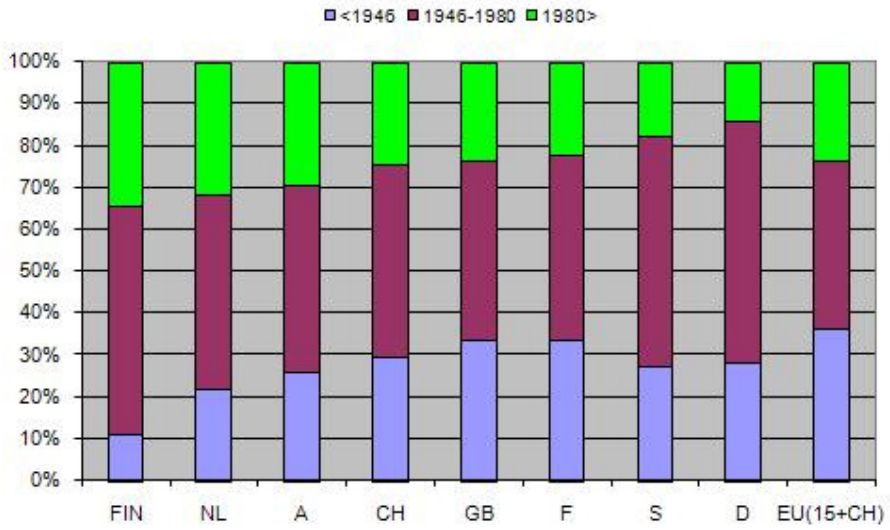

Figure 1, *Western-European Housing Stock, by age (8 W-EU Countries + CH)*
Edited from source: (Dol and Haffner, 2010)

The causes for the building boom were, like in the Netherlands, generally 4-fold: a production backlog due to the economic crisis of the 30'ies, loss by severe war damage of roughly one third of the stock, an unprecedented baby boom resulting in an explosive growing housing need, gradually followed by rising housings standards and dwelling space consumption (Vreeze, 1993). As a result, and despite massive new construction, crude housing shortages in the Netherlands continued till after 1990. In other countries like Denmark, the United Kingdom and France, war damage and the post war baby boom were less dramatic and/or resulted in a less massive housing production, and consequently in a relative older housing stock. But also in these countries the attention and attitudes of the housing and construction sector were primarily focussed to the planning and realisation of new construction; the consciousness of the enormous maintenance and management task to come was still a far cry.

The begin of the 21st century shows a completely different situation. As figure 2 shows, new construction in most western countries has faded down below an annual production of 1% of the existing stock, and often well below. As a consequence, the influence of new construction on the composition, quality and suitability of the existing stock is little and no longer a practical means to satisfy changing needs.

Though still relative young the existing stock is ageing. In particular the older part of the stock is increasingly facing deficiencies and shortcomings, large parts do not satisfy residents needs and preferences, are far from energy efficient and many post-war neighbourhoods are

in trouble. Reliable comparative data about the volume of the qualitative backlog are scarce, but the available data show an ongoing need for reinvestment, in particular in energy efficiency(Itard and Meijer, 2010). In the Netherlands, the total turn-over of major repairs, renovation, adaptation and redevelopment count at present for well beyond that of new construction(CBS, 2010). Improving the energy efficiency to the required standards of tomorrow will give these investments a strong extra boost.

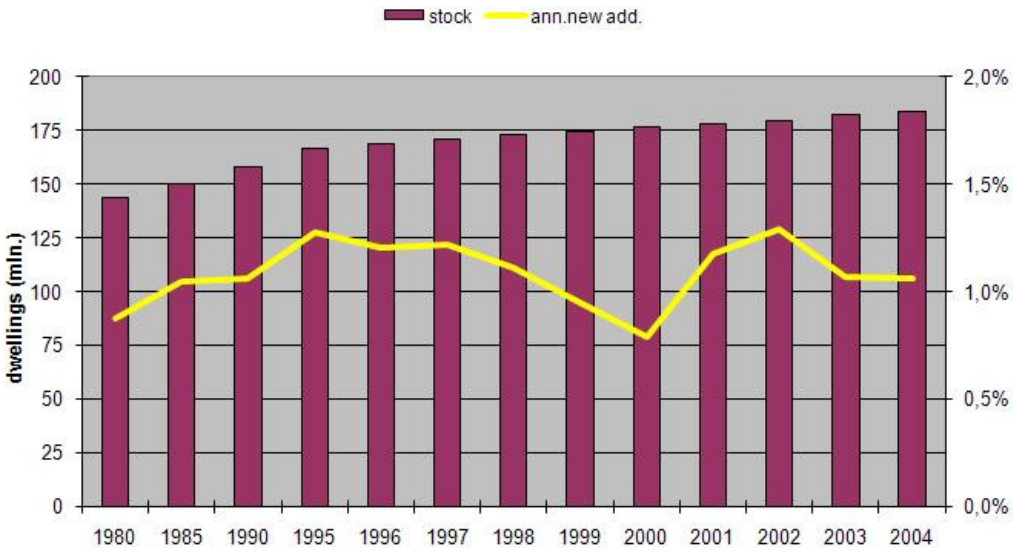

Figure 2, *Western EU housing stock, % annual new addition (8 W-EU countries + CH) Edited from source: (Dol and Haffner, 2010)*

Though the change from large scale new construction to maintenance and improvement of the existing stock is well under way, the knowledge about how and when to successfully maintain a healthy housing stock has still a way to go. At the same time, the awareness grows that housing problems are only partly related to the physical supply side and solving them requires more than bricks and mortar. This shows the relevance of housing stock (and building stock and land stock) management as a vital assignment of both proprietors and governments.

This paper gives some backgrounds of the housing production and housing stock development in Western Europe, explores the consequences for the future management of the housing stock and discusses what it indicates for the next future. As previous coherent research on this topic is hardly available, the content has an explorative character, based on an abundance of only partly cited sources. It also bears the limitations of a macro approach: an average water depth of 1 cm gives no guarantee against drowning.

BACKGROUNDS

The declining housing production in the past decades can have a variety of causes on the demand side, the supply side or the conditional context of the housing market. Though housing markets are largely specific, depending of country and region, most West-European countries show the same declining production, most probably due to the same or similar developments.

The following description is in broad outlines based on the Dutch situation and sources(ABF-Research, 2010; CBS, 2010), but if not otherwise mentioned applies also to most other West-European countries (except Ireland) (Ball, 2010; Eurostat, 2010; Oxley, 2004). Housing production is defined as the annual gross completion of new dwellings. This does not cover the annual growth of the housing stock, as a part of the new addition will compensate the annual loss by demolition, merging, loss, change of use and other subtractions.

Demand side causes

On the housing market, which is mainly a stock market, rising demand is the strongest thriving force for additional construction. In the past, the demand was mainly determined by demographic variables: at first the growth of the population, the main cause of the post war building boom; later after the family size started shrinking the growth of the number of households kept fuelling the demand up to now. In most West-European markets rude housing shortages have come to an end though, and some regions face even a shrinking demand.

Apart from the demographic side, an additional more hidden cause is economic prosperity, enabling a growing housing - land as well as floor space - consumption. Although partly included in the family size reduction, the effect of dwelling stock reduction by merging or replacement is of growing importance, even in shrinking markets and declining populations. The housing need in most West-European countries has nevertheless declined to a much lower structural level than in the previous century, and if not, high land and property prices suppress the effective demand.

The disastrous effect on the building production of the recent economic crisis shows the building trade's vulnerability for fading consumers' confidence and purchasing power.

Supply side causes

Supply side causes play another main role in the declining annual housing g production.

In the first place, a nominal stable annual number of newly produced dwellings will mathematically result in a declining relative growth of the stock. But the number of completed dwellings was not stable but instead declined, as secondly the quality and character of the building production gradually changed. Due to increased building standards of e.g. energy efficiency, the quality of new dwellings improved substantially. And due to changed policy and market conditions, the character of the housing production changed from often subsidised, modest priced mass greenfield production, to increasingly differentiated and generally substantial larger and comfortable market directed production, increasingly in existing urban areas. As also the size of building plots grew and land prices increased, the average building costs swell accordingly and not seldom doubled. So even with a nominal stable investment budget the number of dwellings to be completed within that budget had to shrink drastically. Instead, most national housing budgets were drastically reduced, government subsidies cut and, as the market did not fill the gap, the housing production declined.

A third and perhaps most critical limitation lies in the limited available building production capacity, in particular the availability of adequately skilled construction workers. The last decades saw a steadily decline of new hardhats entering the West-European labour market, a development that puts its shadow over at least the next decade and is only partly compensated by supply from new EU member states.

A fourth and up to now hardly investigated macro-economic limitation is the maximum available total payment capacity of a population for housing. According to a recent survey, the housing costs of Dutch families - tenants and owner-occupiers - have risen to the highest level in the EU(Ward and Özdemir, 2009). This at least indicates the likelihood of substantial

failing demand. Though in fact a demand side cause, the way housing developers anticipate on declining demand has direct negative supply side consequences.
A fifth cause often mentioned by the building trade are institutional hindrances by governmental regulations and bureaucracy, like building and planning regulations. On the one side the growing building and planning bureaucracy incontestably effects the progress of building production, on the other side it reflects the increasing complexity and public concern of the built environment with inevitable issues as sustainability and urban sprawl. Regarding the limited building capacity it is doubtful though to what extend these hindrances do cause a factual loss of production. New ways of integrated and digitally supported planning processes and decision making can otherwise considerably simplify procedures and shorten the procedure time.

Contextual conditions and constraints
Following the energy crisis of the mid-seventies of the last century, the eighties saw a wide spread policy shift in Western Europe, shortly summarized in the slogan "less state, more market". This shift marked the end of large scale subsidised mass - mainly social - housing programs. As already mentioned above, this resulted in a much lower market directed production. But not only subsidies faded away, also the government's policy attitude changed from active steering to a more reactive market approach.

All together these causes make clear why and how the housing production declined as it did. As the decline went very gradually and generally took place simultaneously with a range of other changes in the housing and planning field, the effects did not get much attention up to now. The following section gives an overview on these effects and impacts.

SOME CONSEQUENCES

The declined housing production has a range of consequences. The following overview, based on a wide variety of only partly mentioned sources, gives only an approximate indication.

Housing provision, housing quality and housing stock management
Compared with an annual dwelling production of over 3,5% like once in the Netherlands (1975), a production of 1% or less in the first place implies a crucial reduction of the changeability and adaptability of the existing stock by new addition and/or replacement,. As the volatility of the housing market demand is generally higher than 1%, changing market demands regarding quantity, quality, availability and suitability cannot anymore be solved by providing new additional dwellings but have to be accommodated in the existing stock. While the adaptability of the existing stock by renovation, transformation, addition, reuse and redistribution is much larger than often assumed (van der Flier and Thomsen, 2005), the opportunities for substantial addition of extra dwellings by e.g. transformation and reuse of non-residential buildings is very limited. This as a matter of fact underlines on the one hand the strategic importance of new production, but exemplifies on the other that qualitative improvement by integral stock management is the only viable way to improve the condition of the existing stock and - with the exception of very bad substandard and/or unwanted obsolete stock - a generally better choice than replacement by new construction (Thomsen and van der Flier, 2009).

A second effect of the declined new production is the steadily ageing of the existing stock. Though still relative young, in particular the older part of the stock is increasingly facing deficiencies and shortcomings. Reliable comparative data about the volume of the qualitative backlog are scarce, but the available data show an on-going need for reinvestment, in particular in energy efficiency (Itard and Meijer, 2010). In the rented sector, large parts do not satisfy residents needs and preferences and many post-war neighbourhoods are in trouble (van Kempen et al., 2006). The quality development of in particular the older owner-occupied sector needs growing attention and the energy efficient is still far from the Kyoto goals. On the longer term, in a few decades many parts of Western Europe will face a declining population, which in combination with an aged population and aged housing stock will have wide spread economic, social and environmental effects.
Although the addition of new construction is often reasoned as to improve the availability and suitability of the stock by offering residents a free choice, this is only valid in an open demand driven market with sufficient supply. Even if effective in some markets, an annual production of 1% of the stock or less largely limits this inefficient way of stock management. In general, redistribution by interference on the housing market, either direct by letting regulations or more sophisticated area directed instruments, may be a better and on the longer term more effective and efficient solution.

Building and construction sector
The shift from new construction to accommodation of the existing stock has indispensable - and eventually structural - consequences for the building and construction trade, two main causes being the character of the work and the commissioning.

As mentioned above, the total turn-over of major repairs, renovation, adaptation and redevelopment in most Western-European countries counts at present for well beyond that of new construction, causing an essential shift in the building construction practice. Compared with large scale new construction, working in often occupied existing dwellings requires completely different and difficult skills regarding technical, social and managerial craftsmanship, as well as the type, size and organization of the company. Typical renovation, maintenance and repair contractors are generally small to medium sized companies with flexible work units, increasingly staffed with independent shop keeping craftsmen. Large new construction companies are not suited for this kind of business, though some of them have started a specialized subdivision for large scale maintenance and renovation projects. On the side of designers, developers commissioners and government, the situation may even be worse as, with the exception of an increasing number of specialists, the knowledge about how and when to successfully maintain, manage, adapt, transform and redesign older stock has still a way to go.
Also, though the building construction sector as a whole acknowledges the need for a change, in practice many large scale new construction contractors try to maintain a conservative business-as-usual course, if not in greenfields then in brownfields. Together with a large share of housing associations and real estate developers they up to now propagated new construction as being better, cheaper, easier and less risky than renovation and pushed large scale brownfield redevelopment by acquisitions. Mainly as a result of this, the Netherlands saw a considerable increase of demolitions (van der Flier and Thomsen, 2006). Similar advances are visible in e.g. Austria, Ireland, Germany, The UK and Switzerland.

While most new housing construction is commissioned by developers, construction work in the existing stock is largely a consumer market, commissioned by either owner-occupiers or with decisive tenant involvement. The building production is in fact more and more divided

in two different segments: on the hand large professionally commissioned and managed projects of mainly new construction, and on the other hand small privately commissioned, hardly professionally managed works of mainly repair and renovation. While roughly covering an equal total turnover, the first covers less than 20% and the latter over 80% of formal building permit applications(Dutch data), (Van der Heijden, 2009).
In particular in the owner-occupied stock, most work consists of small to moderate maintenance and refurbishment jobs, often without assistance of an architect and partly without a building permit. A substantial share of the turnover involved takes place in the informal market of moonlighters and semi-DIY. The same happens to some extend in countries where tenants have refurbishment rights like in the Netherlands, the UK and Sweden and where as a result the average refurbishment investments of tenants have been estimated on over one third of that of owner-occupiers (REF). In case of substantial refurbishment and renovation by landlords, particularly with a rent increase, tenants usually have involvement and co-decision rights, entitling them to e.g. decide about the main design, finishing and furnishing.

The shift to a consumer market in particular effects the supplying industry. The building material industry - the mainstream of whose production is now directed to the replacement market(Thomsen, 2002) dominated by DIY and C&C markets - is increasingly converting into a multinational industry, serving a competitive end-user driven market and supported with substantial research, development and marketing budgets. As they more and more outshine the traditional building contracting trade, a growing part of the providing industry is intervening in the building market by appealing directly to the consumers with dealer networks, licensed contractors and franchise trades, including marketing, advertising, after sales services and guaranties, provisions that as a matter of fact are regular in most other markets. A further development may be the partly or total takeover of contractors - being the assemblers of their products - by the providing industry, as in some specialized branches is already emerging.
Within the building contractors branch, some promising recent developments show the rising growing awareness of the paradigm shift. In the Netherlands a group of maintenance contractors launched a model for performance based long term maintenance contracts for residential property. This initiative not only acknowledges the physical and economic importance of long term quality care but also implies a shift in tasks and responsibilities between property managers and contractors(Straub, 2009).

Governmental steering and legislation
Last but not least, the paradigm shift has consequences for governmental planning and control on different levels. In many Western-European countries, the main legal steering structure on building and planning dates from the building boom era, and is insufficiently fit for the changed circumstances. Improvement of the legislation is under pressure of a strong undercurrent of liberalisation and reduction of bureaucracy.
Traditional instruments for spatial planning are mainly restrictive, to prevent unwanted developments, while nowadays spatial problems require active steering, provoking wanted improvements. The fact e.g. that traditional zoning instruments are insufficient for the renewal of existing urban areas is meanwhile well noted, but the understanding that this more and more applies for environmental planning as a whole is not yet widespread (Houterman and Hulsbergen, 2010). New more effective intervention instruments are often expensive and/or - like some PPP (public-private-partnership)-constructions - on the edge to where public commitment legally and democratically may go. Renewal and revitalisation of existing areas will anyway need an area directed approach using a mix of spatial, physical, social and

fiscal instruments(Thomsen and Meijer, 2007). On the larger scale, urban sprawl, confined or shrinking cities and regions will need growing attention. Confined cities like The Hague have no expansion space left within their borders. To prevent uncontrolled speculative acquisitions as well as hardly less unlikeable public interventions, new legal instruments are indispensable. The same - but quite differently - applies for shrinking areas. In a few decades many parts of Western Europe will face a declining population, which in combination with an aged population and aged housing stock will have wide spread economical, social and environmental effects.

Regarding building regulations and enforcement, the above mentioned two separate segments of the building production lay a very different burden on the governmental bureaucracy. According to the Dutch situation, the one part of large, professionally managed projects, covering less than 20% of building permit applications, requires extensive and intensive expert interference, but the governmental burden can substantially be reduced by privatisation and certification(Van der Heijden, 2009). The other part of private hardly professionally managed small works, covering over 80% of building permit applications, requires a totally different approach with an emphasis on facilitating and supporting safe, healthy and sustainable solutions, increasingly by means of web-based applications.

On the subject of governmental steering and legislation, but in fact on all the consequences as discussed above, the conclusion is all together that the new paradigm comes with on the one side new problems and public assignments, but on the other side declining means for public planning, steering and enforcement. This is not only true where it comes to new requirements like energy reduction and sustainable development that need new approaches (Sunikka, 2006), but touches the core of the new paradigm: it requires new ways of policy development and in particular of understanding and cooperation between the parties involved.

CONCLUSIONS AND DISCUSSION

The turn of the last century showed a drastic reduction of the production of new dwellings. Though this reduction went slowly and silently, the underlying causes and consequences are structural and urge for a paradigm shift in the way the housing stock is maintained and managed.

Up to now this development draw little political attention. Coherent overall research is up to now only scarcely available. This may be partly due by the fact that the consequences were apparently limited on the short term, but they will be crucial on the long term.

The underlying causes can be divided in demand side, supply side and contextual causes and constraints. They each apart and all together underpin the structural decline of the housing production.

The consequences are manifold and widespread. With respect to housing provision and housing stock management, new construction is no longer a solution to solve quantitative nor qualitative shortages. Instead, qualitative improvement by integral stock management is the only viable way to improve the condition of the existing stock and - with the exception of very bad substandard and/or unwanted obsolete stock - a generally better choice than replacement by new construction. With respect to housing quality, the ageing of the stock requires increasing attention and an ongoing need for reinvestment, in particular in energy efficiency.

The shift from new construction to accommodation of the existing stock has also structural consequences for the building and construction trade. Compared with large scale new

construction, working in often occupied existing dwellings requires completely different and difficult skills regarding technical, social and managerial craftsmanship, as well as the type, size and organization of the company. This also applies to the side of the designers, developers commissioners and governments, who's knowledge - with the exception of an increasing number of specialists - about how and when to successfully maintain, manage, adapt, transform and redesign older stock has still a way to go.
The fact that work in the existing housing stock is almost entirely a consumers market drastically effects the market approach of the supplying industry and eventually the structure of the construction industry. Nevertheless many large scale new construction contractors and developers maintain a conservative business-as-usual course by propagating new construction as being better, cheaper, easier and less risky than renovation and refurbishment.
Regarding governmental steering and legislation in particular, the conclusion is all together that the new paradigm comes with on the one side new problems and public assignments, but on the other declining means for public planning, steering and enforcement.

For the next future, much will depend on the way how governments, property and building markets will acknowledge the need for a paradigm shift. And if they do, how the parties involved will find new ways of understanding and cooperation. After all, housing and planning policies are only partly related to the physical supply side, and finding solutions requires more than bricks and mortar. Housing is not a purpose at itself but serves a basic need that is conditional for the quality of human life. The awareness of this is not always ruling the decision making. Particularly in the building and property market, self-interest - either by clear and open price negotiations or more hidden by influencing policy, goals and conditions - is a natural mainspring that not seldom biases the outcomes. As an example, the decision making between renovation or demolition of older dwellings may serve as a touchstone regarding its crucial role in the future approach of the housing stocks. A range of recent research findings show that, from a social and physical sustainable viewpoint, life cycle extension is preferable above demolition and replacement by new construction(Itard, Klunder, and Visscher, 2006; Palmer et al., 2003; Power, 2010; Thomsen and van der Flier, 2009). Earlier findings showed a high and growing demolition rate in the Netherlands, partly attributable to profit related demolition motives of the housing associations(van der Flier and Thomsen, 2006). But also other parties in the decision making and building process - including municipalities - put in their influence for self-interest. Dutch municipalities for example have strong interests in new construction as in that case the municipal costs of new infrastructure will be included in the land price, while in case of renovation there is no coverage for the also necessary renewal of the infrastructure at all (Thomsen, 2005). Also, the growing scarceness and high prices of land for new development in dense urban areas puts a high and single sided pressure on the decision making about the future of older neighbourhoods(Adams and Watkins, 2008).
It will be the assignment of governments on various levels to provide checks and balances for the decision making and prevent inequitable outcomes. To facilitate this responsibility and strengthen public support, these checks and balances should include sufficient guaranties for transparency of the decision process and involvement of the residents and citizens involved.

Abstract
This paper introduces a BIM based user pre-occupancy evaluation method (UPOEM), which is applied in architectural design stage for the aim to improve the efficiency and effectiveness of the communication between designers and clients.
There are constants interactions between the clients' requirements and designers' solutions during the early design stage. However, there are some problems emerged during the designer-client communication process which may affect the effectiveness of designer-client communication, such as, inexperienced clients have difficulty in understanding 2D drawings, and the lack of an efficient method to guide the clients to review the design against their requirements.
The building information model (BIM) and BIM tools have provided a better platform to demonstrate both of the graphical and non-graphical information of the design. However the BIM tools paid less attention on facilitating clients to understand how their activities are accommodated in the building model, or helping them to express their requirements and feedback on the design. Therefore, this proposed method simulates the end users' activities in the future built environment based on building information models, so as to improve the clients' understanding on the design; a clients requirements and feedback interface is also designed to help clients express requirements and review the design. A framework of applying the UPOEM in conventional designers-users communication meetings is proposed in this paper.

INTRODUCTION

Although design process varies, the common ground is a design process always started from a briefing stage, and ended in forms of design drawings. RIBA (2000) defined the outline of work of architect in the life cycle of a building project in the book "Architect's Job Book" (Figure 1).

RIBA Outline Plan of Work 7th Edition, 2000

Preparation		Design			Pre-Construction			Construction		Use
A	B	C	D	E	F	G	H	J	K	L
Appraisal	Strategic Briefing	Outline Proposals	Detailed Proposals	Final Proposals	Production Information	Tender Documents	Tender Action	Mobilization	Construction to Practical Completion	After Practical Completion

Figure 1: *Outline Plan of Work in a Building Project*

The communication between designers and clients in the briefing and design stage is usually based on the requirements of clients and the solutions of the designers (shown in Fig 2). A project brief should define all the design requirements, and is the foundation on which the design will develop. Generally, the design process is cyclical, and there is constant interaction between the brief and design proposals (RIBA 2000).

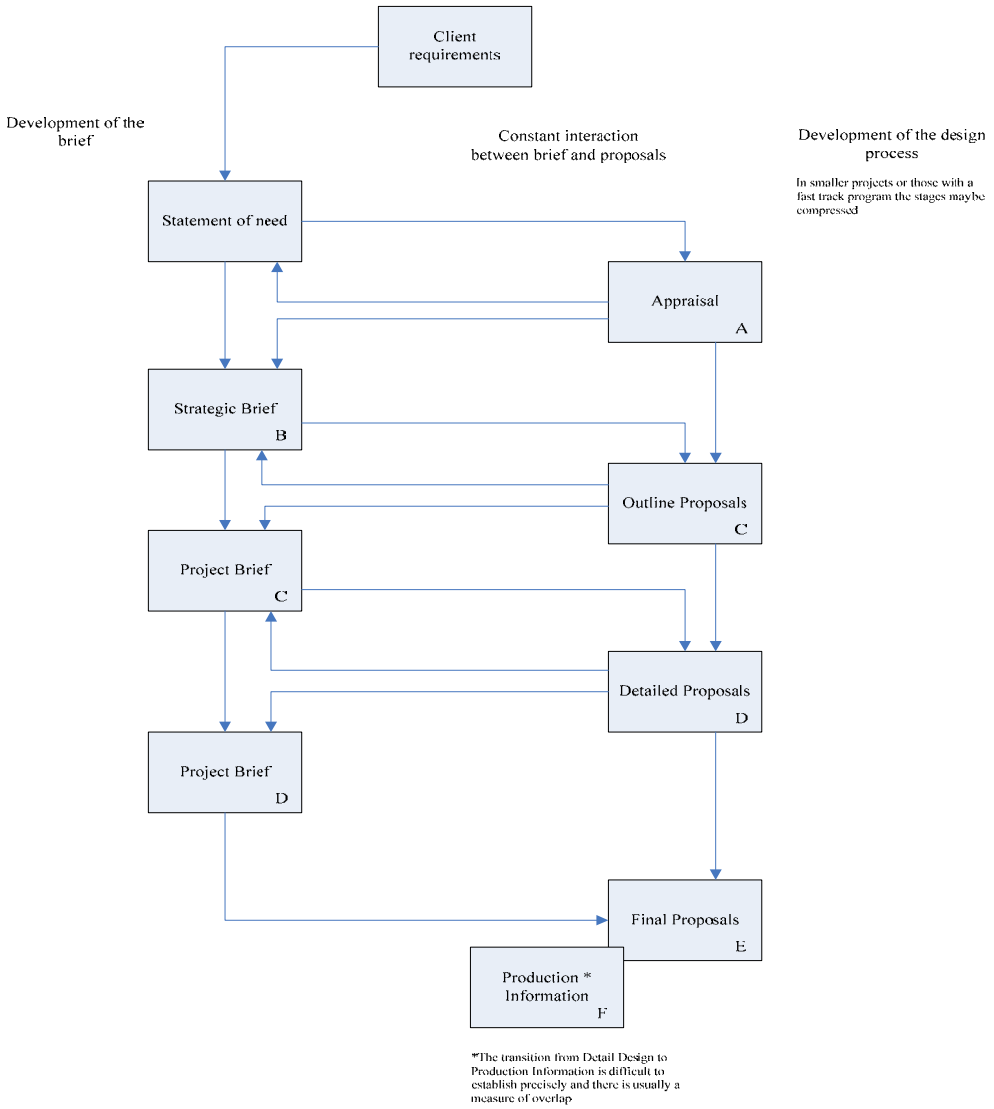

Figure 2: The process of brief and design development (Source: RIBA 2000)

A considerable gap between the designer and client is, unlike architects, users are usually not trained and their comprehension in three-dimensional space is limited. Problem usually stems from a fact that users cannot imagine how the design will be emerged after construction phase (Lertlakkhanakul, Choi, & Kim, 2008). The inability of users to read drawings also affects them to specify the client brief (Barrett, 1999).

In addition, another problem which would also affect the efficiency of designer-client communication is about the requirements management during the designer-client communication process. Kiviniemi (2005) found that there is a lack of mechanism for designers to record, manage and track changes of the clients' requirements during the design stage, which will lead to the result that the end design solution is significantly different from the clients' requirements. Then Kiviniemi designed a building requirement IFC specification

to manage requirements information during design process and provide the possibility of linking requirements to the objects of the design model. Although such requirements models were established, there is still demand for a framework/method to guide the clients to define, manage and track changes of the requirements, and facilitate them to review design against requirements in communication process with designers, especially in the context of virtual environment.

For the aim to solve the problems mentioned above and enhance the efficiency and effectiveness of the designer-client communication, in this paper, a user pre-occupancy evaluation method (UPOEM) is proposed.

First, virtual reality technologies will be applied to improve clients' understanding of their built environment. A virtual environment which can demonstrate both the building and users' activities in the built environment will be established. The reason of simulating end users' activities is that the buildings usually play a key role of accommodating user's organizations and equipment, and enable their activities. Ekholm and Fridqvist (2000) stated that, while the development of bubble diagrams in space planning process, the activities are considered as the criteria to define the size and relationship between these bubbles (representing spaces), but not the building's spaces themselves. Therefore, it is helpful to visualize the end-users' activities and provide a platform for them to evaluate to what extent the built environment could match their requirements.

Second, a *requirements and feedback interface* will be designed to facilitate the clients to manage requirements and review the design. This interface is intended to remind clients of the requirements of the given design solution, and guide them to evaluate the design against these requirements. Both the requirements and evaluation results are recorded as the attributes of each room will be saved in a database during the development of the design process.

RELATIVE WORKS

To achieve the specific objectives, the building information modeling (BIM) technology is used in the UPOEM to provide accurate building information, and the structured requirements documentation method is used to build up the pre-occupancy evaluation module. Thus this section introduces the relative works of these two aspects.

Features of BIM tools

Building information modeling (BIM) is the process of generating, managing the building data during the lifecycle of the building (Lee et al., 2006). It uses three-dimensional, real-time, dynamic building modeling software to increase the productivity during the process of design and construction (Holness, 2008). This process produces the Building Information Model (BIM), which includes building geometry, spatial relationships, geographic information, and quantities and properties of building components. On one hand, the building information model can provide "earlier and more accurate" visualizations of a design. On the other hand, it is an object-based parametric model, which contains not only the geometry and topology attributes, but also carries various properties if they are analyzed, priced, interpreted and procured by other applications. Most of the current BIM tools default to a minimal set of properties for most objects and provide the capability of adding an extendable set, so users or an application can add properties to each relevant object to conduct certain kind of cost

estimate, simulation (Eastman et al., 2008). Since the BIM tools can generate accurate building models for the demonstration of design, and the extendable object-based properties can provide a possibility to store the information generated during the designer-client communication process, the BIM technology is therefore used as the basis of the UPOEM.

User activity simulation in buildings

Lots of literature has addressed the user activity simulation models, which aim to simulate and predict occupants' activities in a given building and to evaluate the building or organization performance such as evacuation, circulation, building control system, energy saving, and space usage. In the early time, static building models including the user activities were built by Eastman and Siabiris (Eastman and Siabiris, 1995). After that, much research have studied on predicting pedestrian movements in urban planning and emergent evacuation in buildings (Kerridge, 2001; Kuligowski and Peacock, 2005).These studies have enriched the area from many perspectives, such as the environmental consideration. Zimmermann (2006) used the multi-agent technology to simulate individual's activities in a building for energy saving purpose. Lertlakkhanakul et al. (2008) built up a collaborative virtual environment for end users to interact with building models of smart houses. In order to investigate the space usage of the buildings, Tabak et al. (2007) used workflow model and activity schedule model to simulate users' activities in office buildings. Lately, Tabak (2008) has also developed a human behavior simulation system named USSU to mimic the behavior of human beings when scheduling activities. The output of this system is a movement pattern in terms of end users' activity schedule, including relevant moving routes in a building. However, the system requires a large amount of user input data, and has no connection with the building information model.

To facilitate the designer-client communication, the UPOEM in this paper will therefore establish an alternative simplified user activity scheduling method based on Tabak's work, which allows the end users to specify their activities in a new building within a relatively short time. In addition, these end users' activities are simulated within the 3D building model generated by BIM tools, and the communication is further supported by structured requirement documentation.

Requirement documentation and hierarchies

The clients' *requirements and feedback interface* designed in the UPOEM aims to connect the design solution with clients' requirements and feedback. This section therefore introduces the related requirement documentation methods or hierarchies.

Most of the time, the documentation of client requirements is in form of traditional building program, which is generated mostly by interviewing clients, owners, and end users. In many cases, the original client requirements are not clear, and designers have to turn them into more accurate requirement descriptions or requirement attributes (Whelton and Ballard, 2003). Kamara (2002) summarized several structured requirements capturing and documentation methods, including Quality Function Deployment (QFD), Client Requirements Processing Model (CRPM), Total Quality Management (TQM), and Failure Mode and Effects Analysis (FMEA). As for the research about requirements hierarchies, there are also a lot of relevant works. The International Centre for Facilities (ICF) has published several volumes documenting their standards for Whole Building Functionality and Serviceability (WBFS) since 1992 (ICF, 2009). The purpose of these standards is to help organizations to define their functional requirements for the buildings and serve as a checklist together data and evaluate the existing buildings from the portfolio management or tenant

viewpoint. Though the WBFS provides a high-level, strategic view for evaluation of building, it has no connection between requirements and design tools. On the other hand, EcoPro, a software application developed by VTT (Technical Research Centre of Finland), is intended to help building owners to define the sustainability requirements for their building projects (Kiviniemi, 2005). Kiviniemi then designed a building requirement IFC specification based on the requirements hierarchies of the WBFS and EcoPro. The research aims to manage requirements information during design process and provide the possibility of linking requirements to the objects in the design. A solution for cascading requirements which simplifies the database structure significantly is also identified. However, there is still no attention given to the clients for collecting their feedback against these requirements. In this context, Kiviniemi's requirements specification has become part of the research basis for the requirement documentation method used in UPOEM. In addition, a feedback questionnaire is used with the requirements specification together to facilitate the clients to review design solutions in this study.

DESIGN OF THE UPOEM

The rationale of UPOEM

In the conventional architectural design process, clients first specify their requirements, such as space program, and then the designer proposes the preliminary design according to this brief.

The rationale of UPOEM is to build up a 3D virtual environment not only contains the building but also the end users' activities. This integration aims to facilitate the clients and designers to understand how the end users' organization will be accommodated in the given building, such as, the location of end users' activities in the new building, or the adjacency relationship between different functional rooms. During their "daily" activities, end users can evaluate their working or living environment in a "familiar" way. So this simulation provides a platform for the clients (including end users) to conduct a post-occupancy evaluation of their built environment in the virtual reality environment.

Therefore, the UPOEM provides two more processes based on the conventional process: (1) user activity specification and simulation; and (2) pre-occupancy evaluation

Components of the UPOEM

Three components are designed in UPOEM to support the designer-client communication process (as shown in Figure 5).*Building information module:* this module's purpose is to use BIM tools to build up and update the building information model based on the design given by the designer. *User information module*: this module is intended to collect end users' information, facilitate them to specify their activities and generate the activity simulation model. *Pre-occupancy evaluation module*: this module aims to conduct a pre-occupancy evaluation based on the virtual environment and collect users' requirements and feedback.

Framework of applying UPOEM

The UPOEM is usually applied in the consultation meeting involving the designers and the end users in the architectural design stage. The timing of this meeting is usually after the

outline proposal is created by the designer. Then users are invited to discuss the design and give their feedback. The times of such interactions depend on the scope of the projects and duration of the design period, and sometimes would last until the design solution is finalized. There are four main steps for the implication of the UPOEM in practice:

Preparing the building information model: The building information model is built by BIM tools based on the drawings given by architects. When users give feedback on the design, the building information model needs to be updated for further evaluation.

Specification of user activities: By using the user organization information module, users specify their activities and the functional spaces they will use in their future working environment.

Simulation of the user activities: After preparation of both building model and user information, the activity simulation model is generated for the pre-occupancy evaluation.

Pre-occupancy evaluation: The users' feedback or further requirements are collected in this step via the pre-occupancy evaluation module.

User activity simulation

This user information module is to specify user information including roles and activities of the organization and generate the users' activity schedules. Then an activity simulation model is generated based on the end users' activity schedules (Table 1).

The activity specification method applied in this paper is a simplified and easy to use activity scheduling method based on the work of Tabak (2008). Tabak divided users' activities into skeleton activities and intermediate activities. He used different scheduling method to schedule the individual skeleton activity, interactive skeleton activity and intermediate activity. It mimicked the behavior of real human beings when scheduling activities.

Table 1: *An example of user's activity schedule*

Activity	Start time	End time	Location
Research work	09:00	11:30	Office
Teaching	11:30	12:30	Lecture room
Lunch	12:30	14:00	Canteen
Research work	14:00	18:00	Office
Leave	18:00		Exit

Activity scheduling method applied in UPOEM

In the UPOEM, the users' activities are also divided into skeleton activities and intermediate activities. But it made no distinction between planned, unplanned skeleton activities.

Scheduling the skeleton activities: all of these skeleton activities are treated as planned activities referring to users' working routines. Users are requested to arrange their skeleton activities in the new building via a user activity scheduling interface.

Figure 3 shows the interface for the users to specify their activities in the new building. End user can specify their skeleton activities including start time, end time, and location of each activity based on their daily working routines or agenda of one specific working day. They can specify their locations of each skeleton activity by inputting name of rooms directly or picking the room name from the 2D layout by clicking the button representing each room.

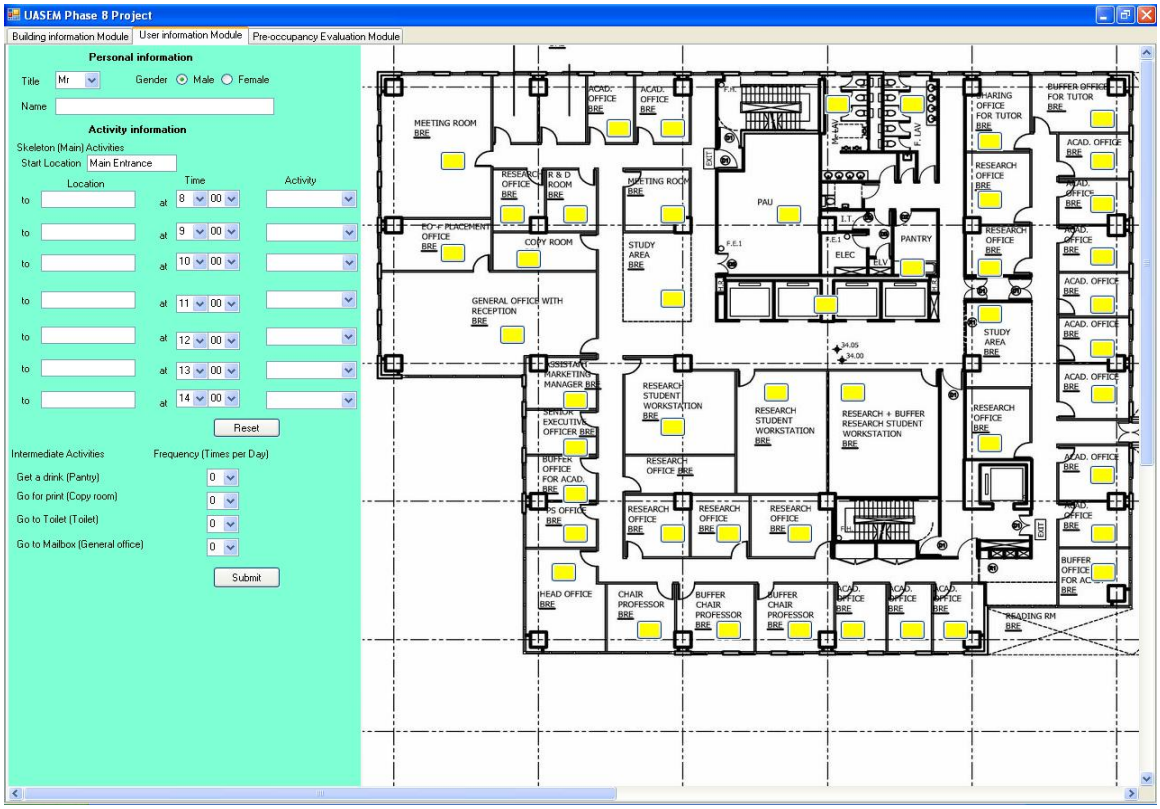

Figure 3: *Interface for user activity specification and scheduling*

Scheduling the intermediate activities: The method of scheduling the intermediate activities in UPOEM is less concerned with predicting the accurate occurrence time of each intermediate activity, but demonstrating the spatial factors of the design solution mainly (such as, adjacency relationship, circulation, walking distance and traveling time between two location in the building). The process of demonstration is usually proportionally shortened to several minutes for adoption in real life designer-client consultation meeting (e.g. 16 minutes represents 8 hours a day). Therefore a simplified intermediate activity scheduling method is proposed for this purpose. It has two features: (1) the occurrence time of all these intermediate activities depends on the time elapsed since the previous occurrence; and (2) a linear probability distribution method is used to simplify the S-curve method used by Tabak. This simplification saves the time of determining the shape of the S-curve, and is easy for the users to describe their daily activities. The intermediate activities (such as get a drink, go for print, go to toilet and go to mailbox) are described by daily frequency. And the mean duration of these intermediate activities are assumed to be a certain time for each.

The algorithm to calculate the occurrence time of a given intermediate activity in a certain time span with an N frequency is as follow:

Step 1. RC = Random (0,1.00).
Step 2. IF (PC > RC)
THEN // The intermediate activity will happen at this time.
PT = CT; // Records the activity happening time to PT.
AC = AC + 1; // Increase the activity counter.
ELSE // The activity will not happen, increase the time.
CT++ ; // The interval of time increase is set to 0:05.
GOTO Step 1;

Step 3. IF (AC = N)

THEN // The activity has happened at the user indicated frequency.

End Algorithm;

ELSE

CT++ ; // The interval of time increase is set to 0:05.

GOTO Step 1;

The parameters used in the algorithm are given the definition below:

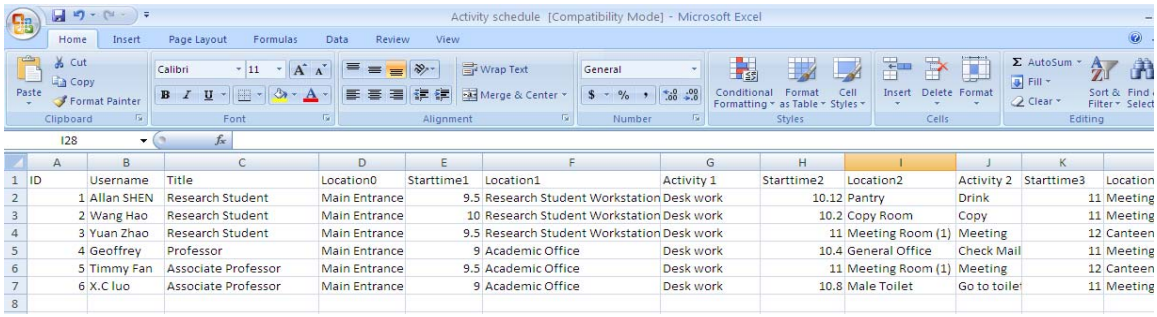
ST = The starting time of the simulation, predefined at 9:00 am.

ET= The ending time of the simulation, predefined at 17:00 pm.

CT= The current time.

PT= The time when the previous activity happened, which equals to ST at the beginning.

RC = The probability of an activity will happen at random. Ranged 0 – 1.00.



N = Frequency of the activity. (Times of occurrence of the activity take place during the simulation, and are inputted by the users.)

AC = Activity counter. Indicates how many activities have already taken place. Set to 0 at the beginning.

PC = The probability of an intermediate activity will happen in a given time. PC is calculated by the formula:

$$PC = (CT - PT) / ((ET - PT) / (N - AC)) \quad (1)$$

After determining the occurrence time, these intimidate activities are inserted into the intervals of the skeleton activities. Then the whole activity schedule including both skeleton and intermediate activities is generated and saved into the database (Figure 4). The activity simulation tool will generate the end users' activity based on this schedule.

Figure 4: *Saved user activity schedule information*

Activity simulation model

This activity simulation model demonstrates the single or groups of users' activities in the 3D environment. It is built up based on the users' activity schedules and building information model via the virtual reality software 3DVIA Virtools. A program is written for loading the users' activity schedules in the format of excel files and generating the activities in relatively short time. In this model, both graphical information (3D avatars representing different users) and non-graphical information (text instruction, activity statistical data and symbols) are provided to facilitate the demonstration and data analysis.

Graphical information to enhance users' virtual experience of the built environment

Usually the demonstration time is shortened proportionately to adapt to the communication duration. During the demonstration, users can follow the movement of the avatars to observe their daily activities in the new building according to their schedules. They can choose different end users and switch between them. Multiple observation angles are provided to observe each user's activity, such as overview (with zoom in and zoom out function), third person and first person view to enhance their virtual experience within the built environment. End users can easily change different angles to observe their working environment (Figure 5). One of the advantages of this kind of navigation is that, users can observe the design model as they already live in this building and avoid aimless roaming. This can improve the efficiency of the designer-client communication, especially when there is time constraint.

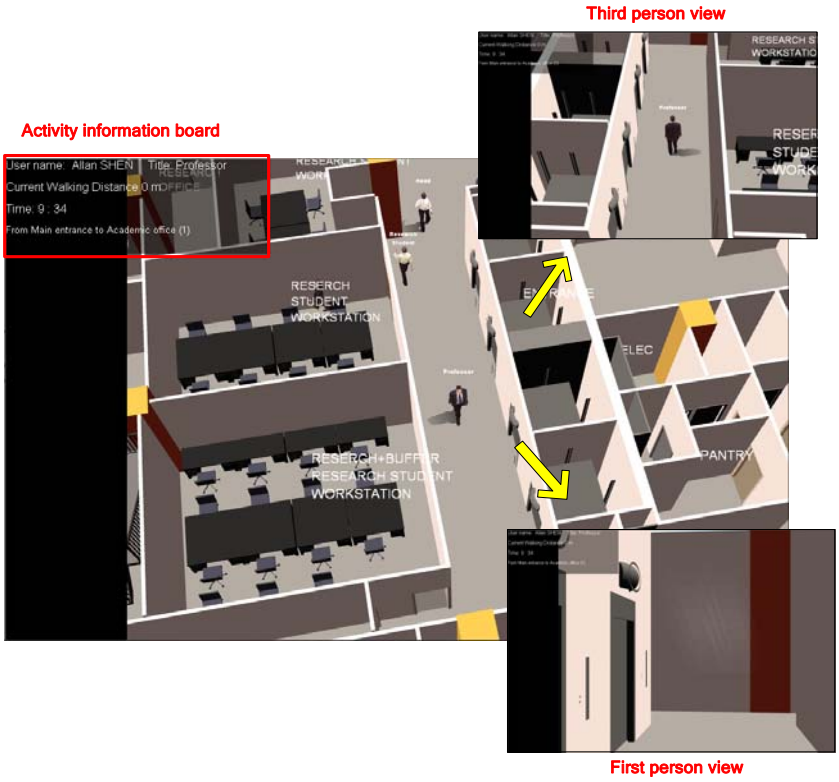

Figure 5: *The activity simulation model*

Except following the avatars, users can switch to the normal observation method as the same as those functions provided by other design (or review) software (e.g. Revit Architecture) to exam the design. The self-control walkthrough and flythrough are also available in this activity simulation model.

The activity simulation model can not only demonstrate individual user's activity but also accept multiple users' activity schedules and simulate the interactive scenarios such as meeting and teaching. Figure 10 shows five users attending a meeting according to their schedule on a certain working day. As the involvement of the avatars, users can obtain a sense of scale in the room and the "feeling" of it being crowded or spacious. They can also have the sense of distance while they are following their aviators from one location to another. The focus of this model is to facilitate users to understand the factors most related to users' movement and spatial comfort.

In the process of design development, more details are added into the building model. Then the users can understand more specific design details besides the layout, such as the interior decoration, lighting and the view outside the building, which depends on the capabilities of the building simulation model.

Non-graphical information to support the demonstration

Besides the graphical walkthrough, one of the features of this activity simulation model is that it provides statistical information to illustrate users' activities. For example, Figure 9 illustrates a normal working day of a department in a university, when one of the professors is walking from main entrance to his academic office. The activity information board on the left-up corner of the model displays the name of users, title, time, current activity and walking distance.

During the designer-client communication, questions such as "will the layout design ease the communication between employees?" or "will traffic flow easily?" are always raised by the designers, especially when users' traffic efficiency is emphasized in the design (e.g. airport and hospital projects). The users also usually concern about whether it is for him/her to travel around the building. So the walking distance or travelling time is a crucial index to measure the convenience or efficiency of the design. In this model, the distance is measured and displayed during users' movements. Other data such as the total walking distance of all the users, and the circulation time of each user can also be measured for different evaluation purpose.

Movement patterns are also important for designers to evaluate the layout. The movement path can be traced to illustrate the connection between different functional rooms (Figure 6 left). These movement tracing curves can help users to understand the adjacency relationship between different functional rooms easily. This is easy for them to specify adjacency requirements during the communication process. In the meantime, movement tracing curves with different color are used to show the movement pattern of different roles in one organization. For example, in a campus office building, the circulation of professors and research students are illustrated by different colors (Figure 6 right). This can support the circulation design in the organization and avoid disturbance between different roles.

Figure 6: *Tracking curve of user movement*

Pre-occupancy evaluation

Pre-occupancy evaluation is the application of post occupancy evaluation (POE) in the pre-construction, pre-occupancy or pre-project stage. Post-occupancy evaluation is defined as "the process of evaluating buildings in a systematic and rigorous manner after they have been

built and occupied for some time" (Preiser, 1988). It systematically evaluates the buildings in use from the perspective of the people who use them. It also assesses how well buildings match users' needs, and identifies ways of improving building design, performance and fitness for purpose. The British Council for Offices (BCO) illustrates that “a POE provides feedback of how successful the workplace is in supporting the occupying organization and individual end-user requirements” (N.A.Oseland, 2007). Virtual reality techniques have been used to conduct the pre-occupancy evaluation in some research work (Palmon, Sahar, Wiess, & Oxman, 2006).

In the virtual environment based pre-occupancy evaluation process, the evaluation objects are the building models. There are many building performance simulation tools can generate rich building information for this evaluation, such as architecture, lighting, thermal, and acoustic. In this paper, the evaluation factors focus on the spatial properties of the layout in the early architectural design stage. It is because during the designer-client communication, the functional factors (size, location and adjacency) and visual factors (appearance and view) are the basic factors most concerned by the clients.

Based on the activity simulation model, this pre-occupancy evaluation module aims to: (1) Remind the clients the defined requirements; (2) facilitate the clients to specify more requirements; and (3) collect the feedback from the end users against these requirements and save these requirements and feedback in a systematic way.

Therefore, this module aims to provide a platform to systematically manage the following information: (1) Pre-defined requirements from the brief; (2) Information from the existing design model; (3) Further requirements developed by clients during communication; and (4) Feedback from the clients on the design solution.

A database containing clients’ requirements, feedback and data from existing design model is designed to support the pre-occupancy evaluation process. The requirements of building project covers space requirements mainly including requirements on area, location, adjacency, circulation, flexibility, fixtures and etc. The extension of this evaluation method in other aspects such as site, building envelope or HVAC system will be discussed in future research.

Kiviniemi (2005) categorizes the space requirements into two main requirements objects: (1) space program instance (SPI) and (2) space program type (SPT). The space program instance contains the requirements of space such as area, occupancy type, max occupancy number, location, number of space units, adjacent spaces. The space program instance can be linked to several space instances in the design model. The space program type defines the identical requirements shared by several space instances in the requirements model. It contains the requirements about activities, function, space program fixtures, indoor climate, acoustics, lighting, flexibility, safety, comfort and etc.

According to virtual environment provided by the activity simulation model, some requirements from the space program are selected for the basis of pre-occupancy evaluation. The space program instance and space program type is also distinguished in this pre-occupancy evaluation module (Figure 7) .

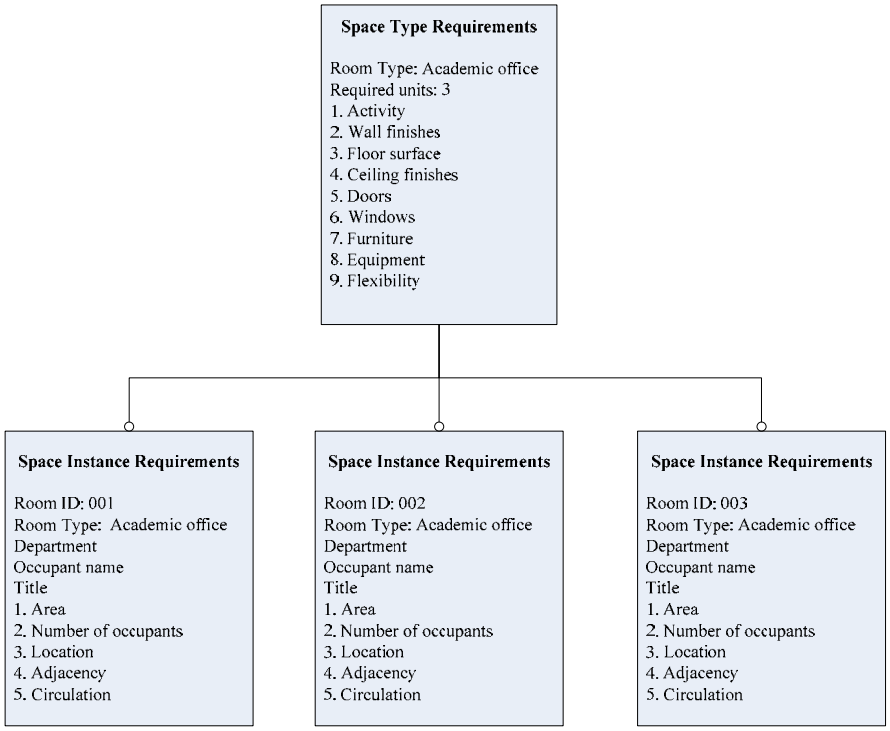

Figure 7: *relationship between space type requirements and space instance requirements*

In this way, the structure of requirements model can be simplified significantly. According to this structure, the clients' feedback of the design solution is also combined with the requirements information.

Pre-defined requirements: these requirements are extracted from the existing project brief. During the design-client communication process, new or more specific requirements may be continually generated, thus this module can record the change and generation of project requirements during the communication.

Design solutions: during the designer-client communicating, most of the design information is illustrated in the form of user activity simulation model (containing building model). Therefore clients are asked to give their feedback during the observation of the user activity simulation model. Some of the non-graphical information, such as area of each room, is extracted from the building model and stored into the database of the pre-occupancy evaluation module.

Clients' feedback: Questions about end users' spatial satisfaction are asked to obtain feedback on the design solution, for example, "Does this room have enough space to work without crowded feeling?", or "Does the layout can match your daily workflow?" The users can give response at different levels or give comments. The feedback is saved directly into the database in form of excel files. Designers can easily get access to these files and find them classified by different user names thereby facilitating the management of these files.

Design of the clients' requirements and feedback interface

On the pre-occupancy evaluation interface, users can trigger the user activity simulation model to observe the design solutions during their "daily life". After observation, they are requested to fill in the space instance requirements and feedback form of the rooms they

observed. The room ID is the link between the user activity simulation model and the requirements and feedback interface. For example, when a client observing the user activity simulation model, the room ID is shown on the top of each room, and the client can open the corresponding clients' requirements and feedback form on space instance via the interface (Figure 8). A 2D layout is used to help the clients to give feedback on each room. Clients can press the button representing each room and the space instance requirements and feedback form is popped up. The space type requirements and feedback form can be opened by clicking the space type requirements button.

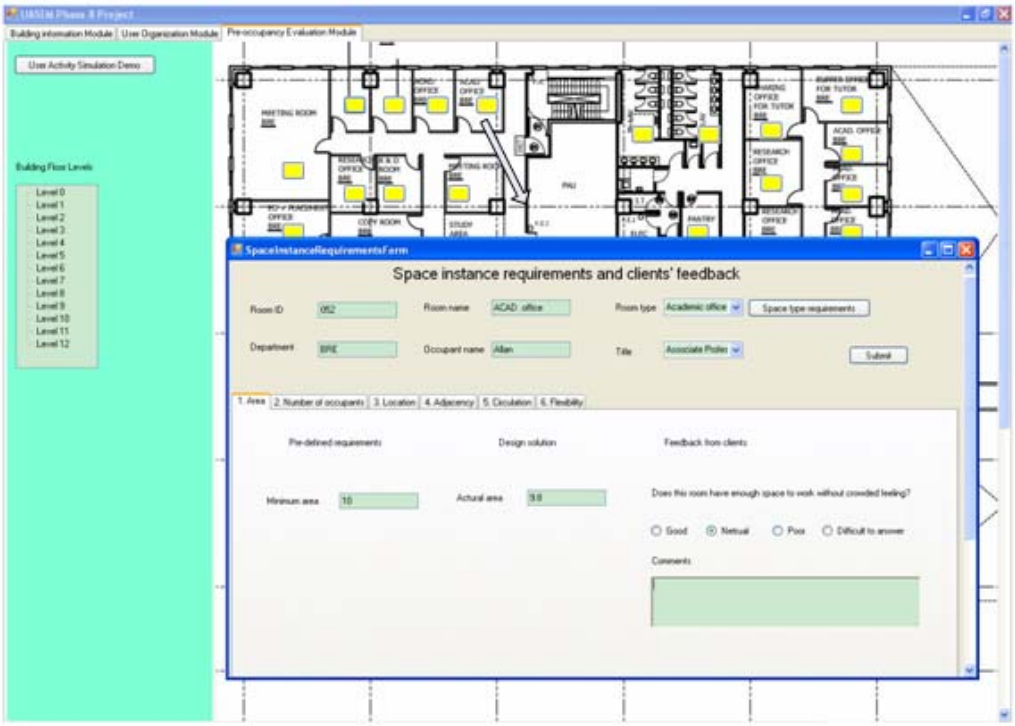

Figure 8: *Pre-occupancy evaluation module interface*

CONCLUSION AND FUTURE WORK

This paper proposed a BIM based user pre-occupancy evaluation method (UPOEM) to facilitate the design-client communication in architectural design process. User activity simulation technology is used to enhance the visual experience of the clients, and a requirements and feedback interface is designed to facilitate clients to develop requirements and review design solution. A framework of implementation of the UPOEM in real project is also proposed. It is expected that the clients can have a better understanding of their future built environment via observing the user activity simulation model. The efficiency of design review will be also improved by the support of the requirements and feedback interface.

This method will be tested in a campus project in further study, which aims to validate the effect on improving the clients' performance during the designer-client communication.

RELEASING THE POTENTIAL OF BIM IN CONSTRUCTION EDUCATION

JOHN BOON

cprigg@unitec.ac.nz

Unitec Institute of Technology
New Zealand

Abstract
When setting out to teach a group of construction students the lecturer is faced with a class who have a variety of learning style preferences and have brains with a variable ability to process information and that ability varies further with the type of processing required. They also come to the class with varying previous experience and knowledge and with varying social skills. In order to facilitate the learning the students need to be actively engaged in a task designed to cause them to interact with the information they are supposed to be learning. However learning is a complex process that requires considerable management. BIM has the potential to assist construction education in this as it can make information available in a manner that is much more accessible to visual and kinaesthetic learners (the majority of learners). It is not in itself a universal panacea to the problem of teaching construction students. The challenge for construction educators is to use this new form of information provision to enable us to move away from lecture formats and reshape our teaching delivery to a format that is better aligned with the learning styles and processes that suit most learners.

Keywords: Construction education, learning styles, learning processes, Building Information Modelling.

INTRODUCTION

For the purposes of this paper the American General Contractors (2006) definition of BIM has been adopted:

> Building Information Modelling is the development and use of a computer software model to simulate the construction and operation of a facility. The resulting model, a Building Information Model is a data rich, object oriented, intelligent and parametric representation of the facility from where views and data appropriate to various users' needs can be extracted and analysed to generate information that can be used to make decisions and improve the process of delivering the facility.

The generally accepted convention of describing construction assembly and time related modelling as 4D and cost related modelling (including the quantification of work for estimating purposes) as 5D has been adopted.

BIM at least in the sense of 3D modelling is fast becoming a reality in the commercial world (McGraw Hill 2008) including New Zealand (Boon 2009). It also has the potential to become a powerful tool in the world of construction education. At its simplest it enables construction students to see in a 3D virtual model how buildings are assembled. This in itself is a considerable advance on trying to get students to learn building construction through

interpreting 2D information. Beyond this BIM has the potential to allow faculty to radically rethink the teaching and learning process for construction students. If the BIM models provide information, that is readily understood by the student, as to how buildings are assembled, faculty should be able to spend less time "telling" students about construction detailing and thereby create more time for the students to learn by interacting with BIM models in the processes of construction planning, measurement and estimating.

This paper explores this issue by firstly looking at how people learn and then considering how BIM can be used to enhance the students learning experience in construction education. The latter is done firstly from a theoretical perspective and then by way of case studies of the authors own experiences.

EDUCATIONAL THEORY

This section is written from the perspective of a construction educator attempting to understand the process they are engaged in rather than as an expert in teaching and learning. MacKeracher (2004) makes the point that *"Learning is something done by the learner rather than something done to or for the learner. Learning proceeds independently of (and sometimes in spite of) education and schooling"* (p5) Understanding how learners approach learning and process information is therefore critically important. This brief review of literature is broken into three sections, learning styles, brain styles and the learning process.

Learning Styles

There is general agreement in the literature that learners vary in the way they approach learning. How such variation is categorised to form a typology of learning styles differs between authors.

MacKeracher (2004) refers to Curry's (1983) three layer onion metaphor as a way of analysing students approach to learning. The outer layer is composed of behaviours that are more observable, less stable and more easily influenced by external conditions. The middle layer is concerned with information processing styles that are less directly observable although modifiable by the learner adopting new strategies. These information processing styles can be categorised using tools such as the Grasha-Rechmann Student Learning Style Scale (Grasha ,1993) which measures three paired styles: social (competitive / collaborative) emotional (avoidant / participatory) and the needs for structure (dependent / independent). The third inner layer is concerned with cognitive personality styles affecting an individual's approach to adapting and assimilating information. Styles in this layer can be assessed using instruments such the Myers-Briggs type indicator (Myers 1985).

MacKeracher (2004) also refers to Suessmuth (1985) typology of personal learning style preferences:

1. *Language learners* prefer to hear (auditory) language or see (visual) language. They are best at remembering information in word form.
2. *Numerical learners* prefer to hear (auditory) or see (visual) numbers. They are best at remembering and using information in numerical forms.
3. *Auditory – visual – kinaesthetic (AVK) learners* prefer to learn through personal experiencing and need sensory stimuli. They need to manipulate material and be totally involved; they may become distracted if not entirely involved. (p81)

Materna (2007) refers to the work of a number of authors to present a three part model:

1. *Auditory learners* who learn best by listening. Such learners are comfortable with traditional lectures and learn best if they have listened to information before reading about it.
2. *Visual learners* who needs to see information before they learn well. The learning of this group is greatly aided by pictures, diagrams, flowcharts as well as text information.
3. *Kinaesthetic – tactile learners* who learn best by doing. They need to be actively engaged in experiments, exercises or preparing their own material in order to learn.

Materna (2007) acknowledges that learners are capable of using more than one style and in some cases are skilled "combination learners" capable of using all three styles. However she quotes a number of authorities to suggest that "40 – 65% of learners are visually dominant, 20 – 30% are primarily auditory and 5 – 15% are primarily kinaesthetic learners" (p49).

Intelligence

Theories concerning learning styles only help to explain the manner in which a person prefers to approach the learning experience. They do not explain how the brain processes information or the nature of intelligence that enables the learning process.

During much of the 20th century theorists tended to view intelligence as a singular or general thing. The IQ test being an example of a means of measuring that singular intelligence. However in the latter part the century theorists developed the concept of multiple intelligences. Notable work includes Howard Gardiner's eight intelligences. Gardiner defined intelligence as "the capacity to solve problems or fashion products that are values in one or more cultural settings". His eight intelligences are:

1. *Logical-mathematical* the ability to compute and apply mathematical concepts and logic to complex situations.
2. *Linguistic* the ability to use language to describe, express, develop arguments, persuade and influence.
3. *Musical* the ability to understand, interpret, create and perform music.
4. *Spatial* the ability to visualise and perceive through the use of hands and other body parts. The ability to interpret and graphically represent ideas.
5. *Interpersonal* the ability to perceive emotions and respond accordingly.
6. *Intrapersonal* the ability to have personal insight and understand own emotions and responses.
7. *Bodily-kinaesthetic* ability to use parts of the body
8. *Naturalistic* the ability to understand and classify patterns in the natural environment. (adapted from Materna 2007).

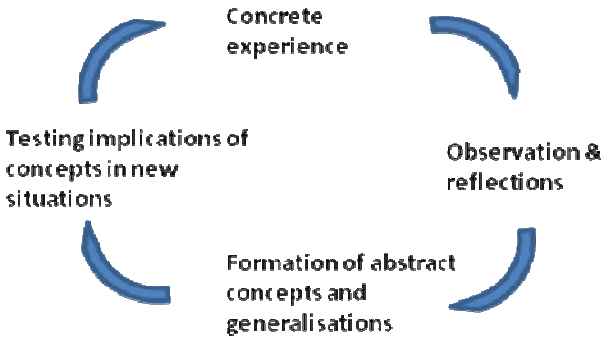
Within the context of this paper the concept of spatial intelligence is particularly interesting. It is this type of intelligence that students need to develop in order to be able to interpret drawings and understand how building components fit together. Materna (2007) makes the point that within the education system generally we have promoted the development of the first two intelligences to a much greater degree than the others.

Whilst agreeing with the concept of multiple intelligences Sternberg (1988) does not classify them in terms of specific abilities in the way Gardiner does. Sternberg argues that successful intelligence is a mixture of analytical, creative and practical thinking behaviours. He defines these as:

1. *Experiential intelligence (creative)* the ability to deal with different situations and develop new ideas for dealing with situations

2. *Componential intelligence (analytical)* the ability to process information effectively using abstract thinking and logical reasoning.
3. *Contextual intelligence (practical)* the ability to adapt to the environment, street smarts and ability to change behaviours in a new environment.

Sternberg's analysis seems to provide a different perspective. It can be argued that in order for a person to be competent in the area of construction technology they need to bring all three dimensions of Sternberg's intelligences to apply to develop their spatial intelligence in Gardiner's terms.



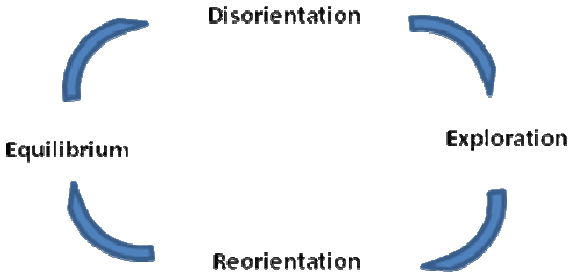
Materna (2007) also refers to the work of Perkin's (1995) who supports the concept of multiple intelligences but focuses on three dimensions.

1. *Neural intelligence:* Efficiency and precision of the neurological system.
2. *Experiential intelligence:* Accumulation of life experiences in different areas.
3. *Reflective intelligences:* Metacognitive abilities or personal strategies for problem solving and self management.

This analysis provides additional insights into the learning process as it identifies both that learners bring all their past experiences to the process and that the learner needs to process the information in accordance with their own reflective intelligence abilities and preferences.

The Learning Process

There seems to be a reasonable consensus that learning is an iterative (or circular) process. Authors such as Mackerchar (2007) refer to the "Kolb Cycle" although David Kolb (1984) refers to the "Lewinian experiential learning model "(p21).



The Lewinian Learning Cycle from Kolb 1987 p21

The implications of the model include that the learner needs some kind of experience as a start point which they can move on from, to reflect on and then conceptualise in an abstract sense and then further experiences in increasingly challenging situations in order to test and affirm their concepts and generalisation. Kolb is of the view that as part of the learning process the experience and the observations and reflections should be shared with others.

Taylor (1987) provides a useful alternative that aligns with the author's own experiences. She argues that the experience can start with *disorientation and confusion* when the learner is confronted with a new situation. This can result in a loss of confidence and unless the learner can find a way forward (with or without assistance) they may stay in that situation for a protracted time. If successful in moving forward the learner enters what Taylor calls the *information phase* within which the individual becomes engaged in searching for information to solve the problem. Taylor argues that when learners have gathered enough information they usually withdraw to think things over. Following this period of reflection Taylor says the individual enters a *reorientation phase* within which they synthesize and make sense of ideas. It is in this phase that the learner is engaged in the act of learning. They are then able

to proceed to the *equilibrium phase* within which they refine and elaborate on their understanding. It is normally necessary to engage in discussion with others in order to complete this phase.

Taylor's learning Cycle (adapted from Taylor 1987)

Gavin and Taylor (1992) have elaborated on the dangers of the learner struggling in the disorientation phase and suggest that the learner may instead of moving forward enter a "decremental cycle of learning" in which they will seek to blame others, build a case to support their negative feelings and may even exit the learning process altogether, rather than seek to understand the disorientation they are experiencing and enter the exploration phase.

Cross (2009) acknowledges that learning is not necessarily a linear process. Some people learn in an incremental (step by step) process whilst others may appear to make no progress and then move forward in large and apparently unpredictable ways.

Learning as a Social Constructivist Activity

The final piece of theory of relevance to this paper is the notion of learning as a social constructivist activity. Within educational theory there are two schools of thought; objectivist and constructivists. Feyton and Nutta (1999 p50-51) summarise these as:

> *The objectivist (also known as behaviourist, instructivist, rational, or directed learning) viewpoint assumes that the role of the teacher or instructor – is to transfer or transmit knowledge to a student, who is a more or less passive recipient. In this model, the content of "what is to be learnt' is considered to be a stable entity that can be organised into a structure involving a series of steps or subcomponents that are often followed in a sequence. The teacher – directs the process of transmitting the sequence of structured content.----*
>
> *In contrast, the constructivist approach incorporates the notion that learners build a knowledge base through personal experience. Knowledge is not viewed as something to be poured into an empty vessel. Constructivists maintain an emphasis on learning by problem solving and apprenticeship in real-world contexts (Brown, Collins and Duguid 1989).*

Cross 2009 describes constructivist's theories as being concerned with "knowledge creation within individual minds and through social activity" (p31). In order for the learner to learn they have to actively reconstruct the knowledge in their own minds. Cross uses the work of Vygotsky to look at the social aspects of learning, suggesting that when a learner interacts with a "more knowledgeable other" progress can be made with a task that is beyond the current ability of the learner. However Cross extends beyond interaction with the expert to emphasise that the "social" dimension of "social constructivism" includes the need for other people interacting with the learner to observe in action, engage in discussion or provide emotional support. Cross uses the metaphor of scaffolding to support the learning activity in

progress (the authors of this paper, as members of the construction industry feel "propping" would have been a better term). Learning is seen by Cross as a transition that needs support. Once the new knowledge is integrated into an existing framework of knowledge in the learners own mind the scaffolding can be removed.

Cross (2009) describes the role of the teacher within the concept of social constructivism as being to design tasks and activities, integrate appropriate assessment, provide relevant feedback and act as facilitators of dialogue during the learning process.

Summary of Educational Theory

This overview of education theory suggest that when setting out to teach a group of construction students the lecturer is faced with a class who have a variety of learning style preferences and have brains with a variable ability to process information and that ability varies further with the type of processing required. They also come to the class with varying previous experience and knowledge and with varying social skills. In order to facilitate the learning the students need to be actively engaged in a task designed to cause them to interact with the information they are supposed to be learning. The task should enable them to move through the type of cycle described by Kolb (1984) and Taylor (1987). This cycle includes a period of reflection that each student will hit at a different time and need a different period of reflection. Repetition through the cycle with increasing levels of complexity is necessary. As they move through the cycle the learner needs some (but a varying) degree of interaction both with people with expertise (the lecturer) and fellow students. If the task is too challenging the students may experience disorientation and if not able to move out of this situation (with or without assistance) may become negative and even withdraw. How students engaged with the learning experience presented to them depends on their earning style, past experiences and prior knowledge. If they succeed in moving through the learning cycle they will learn something but not necessarily what the lecturer intended.

EXPERIMENTS IN USING BIM IN THE LEARNING PROCESS

From the theoretical discussion above it is possible to conclude that an ideal process for learning construction subjects such as technology, scheduling and measurement should:

- Present the subject matter in a visual manner with some verbal explanation but allow those who wish the freedom to explore for themselves.
- Should be delivered in an environment that allows social (informal) interaction, student – teacher and student – student.
- Allows students to proceed at their own pace.
- Gives the teacher the ability to identify those experiencing disorientation and time to work with them to move them to the next phase.
- Gives students time to reflect when they need to.
- Provides repeat experience.

To a certain extent construction subjects have always allowed elements of this approach. Technical subjects are inherently visual and students learn by doing (drawing, scheduling, measuring etc). BIM has the potential to improve this process particularly in regard to the first bullet.

At Unitec we have been teaching our architectural technology students drafting of 3D models for about five years. However it was only in early 2009 that we started to take a serious

interest in the wider issues of BIM and consider its potential as a teaching tool for construction management and quantity surveying students.

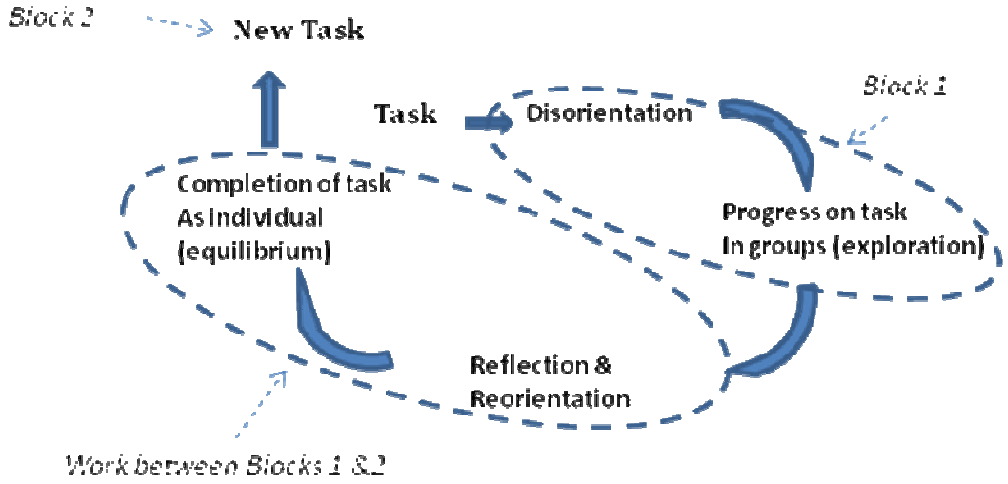
In order to build our understanding of the potential of BIM beyond basic 3D models we formed a small development group of recent graduates and senior students and tasked them with:

1. Creating some 3D models
    a. A very detailed model of a house
    b. An industrial building
    c. A four storey teaching block. In this case separate architectural, structural and services models were produced.

    These were created by obtaining 2D drawings and redrawing them as 3D models.
2. Learning to connect the 3D model to a M.S. Project schedule to produce an animation of the construction sequence (basic 4D modelling).
3. Use additional software to compare the architectural, structural and services models for the purposes of coordination and clash detection.
4. Use software to measure and estimate in accordance with quantity surveying practice and rules, directly from 3D models (5D).

From this exercise we gained:

1. An initial stock of 3D models to use as teaching tools
2. Confidence that it was possible for the students to integrate the models with limited assistance.
3. An understanding of how to link model to schedule and produces a sequence animation.
4. Confidence that students would be able to use software to measure from 3D models.



From this exercise we also learnt that what was possible to achieve by way of scheduling and measurement was limited by the way the 3D model was built, by the information that had (or had not) been placed in the drop down boxes that are associated with each object in the 3D model and the limitations of the interrogating software both integrating software and 5D software, to read the information in the boxes. Our learning caused us to undertake substantial rebuilding of the 3D models.

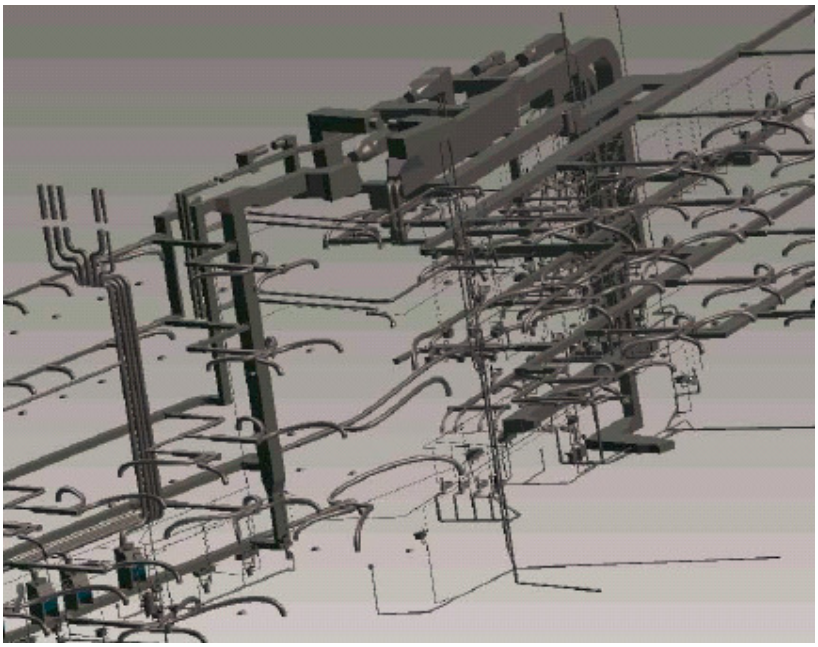
In parallel with the activities described above we experimented with the use of 3D models to assist a year one measurement class. In this case the students were required to measure from simple 2D drawings (as in previous years) however a 3D representation of the drawings was also prepared and set up to run as a rotating model on the projector in the classroom. It was also made available to students through our online teaching support system (Blackboard). This seemed to significantly enhance the students understanding of and ability to interpret the 2D drawings and enable them to make progress with their measurement (avoid disorientation). Whilst this experiment barely tapped into the potential of BIM it did make us realise just how much students struggle with understanding 2D drawings.

Our second experiment was with third year construction economics students on the Bachelor of Construction programme. The aim of the course is to teach students measurement and pricing of building services. We decided to incorporate the use of measuring and estimating software that extracted information directly from 3D models for the first time, thereby introducing the concept of 5D modelling into the programme. The course is a final year

course delivered as a Block course in two blocks each of two days mainly to part time students. It was delivered in a computer lab to approximately 25 students. To assist in delivering the course we obtained the assistance of a specialist from the software company and staff from a QS practice with expertise both in services and the software.

We have been teaching block courses for a good number of years now and have evolved a pattern of delivery that was influenced by an interest in "problem based learning" based on the work of authors such as Boud and Feletti (1997) and Savin-Baden (2004). The pattern has many individual variations dependent on the subject matter and inclinations of the course lecturer however its generic form is as illustrated below. This seems to accord with much of the educational theory presented above, providing for loop learning, social interaction, and engagement through a variety of learning style preferences etc.

Generic format of block course delivery used by authors with reference to Taylor's (1987) learning cycle



The building used for the course assignments was the four storey teaching block which we had modelled in 3D described above. Most of the students were already familiar with the building and the 3D model as it had been used in a services technology course they had taken the previous semester. This course had also included a site visit. This coordination with the previous course and 3D model reduced the possibility of the students becoming disoriented through being unfamiliar with the services they were required to measure and price. It was also their third course in measurement and pricing so they were familiar with the basic approach and processes.

Delivery of the course was designed around a 3 part assignment requiring the students to:

1. Produce an early stage estimate based on gross floor area
2. Produce an elemental cost plan
3. Produce a schedule of quantities based on the New Zealand standard method of measurement and an estimate of the cost of the work.

Designed in this way the assignment provided three learning loops with increasing complexity. The first was done entirely within day one of the first block and enabled the student to become familiar with using the software. The second was started within block 1 and completed as an individual assignment before block 2. The third was started in block 2

and completed before the end of the semester. Students also had to complete an end of semester examination.

Screen shot of 3D model of services

The first block started with a short formal teaching session on using the software. The students were then required to work at their own pace working in collaborative clusters as much as it suited them. The lecturer and industry experts circulated and coached the students through difficulties as they encountered them. From time to time presentations were made to the whole class on common difficulties. The industry people also gave short presentations on issues such as dealing with inadequate and inaccurate information, quality assurance and sources of pricing information.

Overall the course went well. Significant student collaboration was observed particularly they helped each other when they become stuck (typically with the use of the software). Their interaction with the industry people increased as they became more familiar with them. Two students displayed noticeable symptoms of disorientation as they struggled to master the software. One worked their way through the difficulties and successfully completed the course. The other entered a decremental cycle and did not.

There were significant issues with the 3D model. Some confusion was created where we had used generic models of objects such as pumps, heat exchanges, sanitary fittings etc, taken from an object library, which were not a good likeness to the actual equipment specified. This problem will be overcome in the future as more manufacturers provide online libraries of their equipment as BIM objects. In addition the model had errors in it and little specification information had been entered into the drop down boxes (equipment type, capacity, etc). Whilst it can be argued this represents a ‘real world experience” (the drawings are always incomplete and contain mistakes at the time of estimating) it does increase the learning challenge to students. They have to struggle with the “what” as well as “how” to measure and price. This must increase the chances of disorientation and therefore seem desirable to avoid. To improve this situation it is necessary for us to embed in the model significant amounts of

specification information that currently resides in a separate specification document. Whilst the process of entering the data into the drop down boxes that are associated with each object in the 3D model is straight forward it is labour intensive and for a resource lean academic institution provides considerable challenge. However once this is done it is easy to envisage that the students will have the ability to better connect in their own minds text based specification information (contained in the drop down boxes) with the 3D object they are looking at.

A further noticeable impediment to the students understanding was the issue that whilst the literature on BIM tends to imply there is one single model, whereas at the current stage of evolution of BIM there are in fact several models. The students therefore had significant difficulty in understanding where in the building (as depicted in the architectural model) the services (contained within a separate model) were actually located. These difficulties were at a fundamental level concerning issues such as whether the piping was in an exposed situation, contained in a duct or run between ceiling and floor slab. This limited their ability to describe the difficulty of installation and reflect that in their estimating. Until BIM models become fully integrated, this problem will remain with us.

CONCLUSION

Learning is a complex process that requires considerable management. BIM has the potential to assist construction education in this as it can make information available in a manner that is much more accessible to visual and kinaesthetic learners (the majority of learners). It is not in itself a universal panacea to the problem of teaching construction students. The challenge for construction educators is to use this new form of information provision to enable us to move away from lecture formats and reshape our teaching delivery to a format that is better aligned with the learning styles and processes that suit most learners. Specifically BIM models if constructed in sufficient detail and they contain sufficient embedded specification information, can empower the student to visualise the building component they are attempting to understand and then access specification information relevant to that component. If this is done successfully much of the disorientation that can occur in the early part of the learning process arising from not understanding the building components they are dealing with can be avoided.

Moving beyond the experiences we have described here we see the next step is for us to use BIM's 4D capabilities to enable to students to better understand the assembly process through the production of assembly animations. We envisage that in time this will extend to include temporary work such as formwork, propping etc.

EXPLORING DIFFERENT COMMUNITY ATTITUDES TO SUSTAINABLE TECHNOLOGIES

Abstract
The adoption of sustainable technologies to mitigate high energy use by home owners has not been extensive. As a result of legislation there are a number of initiatives to help resolve this situation, some which recognise that communities could be a good site of influence to effect this change. Communities have different socio-economic backgrounds, which may constrain their choices. This affects their attitudes to sustainable technologies, and how they might go about adopting them. This paper refers to pilot research studying attitudes in two socio-economically different communities in Birmingham, aiming to inform a larger study about successful interventions. These communities underwent the adoption of sustainable technologies via different interventions, here defined as an identifiable activity bringing sustainable energy technologies into an area. The interviewees presented a positive attitude to the intervention in their area, but displayed a difference in their perception of a sense of community. Socio-economic data raises important questions about a community's capability to intervene which was supported by the interviewees. The pilot suggests that interventions can enable interactions which allow positive information transfer necessary for increasing acceptability of sustainable technologies, which will be explored in the larger study.

Keywords: communities, sustainable technologies, attitudes, intervention.

INTRODUCTION

In 2008, the UK Government passed the Climate Change Act, obliging the UK to cut its greenhouse gas emissions by 80% by 2050, to mitigate against potentially dangerous climate change. As part of this, there has been some UK policy encouraging the generation of energy from renewable technologies (DTI, 2005). There is also a role for community based generation of energy (Hain *et al* 2005).

However, change has been slow. Information campaigns have not lead to as wide an uptake of sustainable energy technologies or energy efficiency measures as governments had hoped (Owens & Driffil 2008), and it is often difficult for governments to know which will be the best intervention and best use of resources, especially in times of economic hardship.

This research is a pilot for a larger study which aims to look at the success of interventions using communities to direct change in sustainable energy behaviours in individuals, and was designed to inform the larger study. The pilot aims to identify some important areas of study,

to establish what can be found out from individuals about successful interventions, and to establish whether the style of intervention is important. Individual attitudes are related to the process of an intervention; if people have a positive attitude to sustainable technologies themselves and the process of sustainable technology interventions in their area, interventions are potentially more likely to be successful. This is important if we want to see the widespread adoption of such technologies in order to address climate change. This paper will look at the responses of individuals from two different communities: residents of Moseley, who are benefitting from a community-led project; and residents of Northfield, who benefitted from a top-down intervention. This pilot was useful to inform a larger study looking at how different types of intervention in different contexts can encourage positive attitudes towards sustainable energy technologies.

The Communities

Moseley is situated to the south of Birmingham city centre, and is one of the more affluent neighbourhoods of the city. It is a well educated area, with a reasonably high average income, and a skilled workforce (see figure 1). The neighbourhood has a strong sense of identity that became evident in 1978 in retaliation to the threat of a relief road that was planned to run through the centre of the 'village'. The local residents succeeded in stopping this road, and formed the Moseley Society in 1979. Since then a number of groups and associations have arisen in the area including Moseley Forum, of which Sustainable Moseley (SusMo) became a working group in 2007 (Moseley Forum 2010).

SusMo are working to cut carbon emissions across their neighbourhood. In January 2010 they became one of 14 communities across the UK to win a British Gas Green Streets award. With this they will install photovoltaic (PV) panels on a number of community buildings and one home, as well as other energy saving measures such as condensing boilers, loft insulation and solar thermal panels in other homes. For this project, SusMo formed partnerships with the local Mosque, St Mary's Church, Moseley Church of England School, and MaDAHAL Allotments, and developed close working relationships with all of them. This project will be referred to as a community-led intervention for the purposes of this paper.

	Moseley	Northfield
Education		
No Qualifications	24.06%	34.64%
Level 1 (1 -4 General Certificates of Secondary Education or equivalent)	10.09%	18.45%
Level 2 (5+ General Certificates of Secondary Education or equivalent)	14.04%	19.47%
Level 3 (2+ Advanced levels or equivalent)	8.73%	6.79%
Level 4/5 (First Degree, Higher Degree or equivalent)	39.33%	13.34%
Other (Level unknown)	3.75%	7.32%
Income		
Average weekly household income	£500	£450
Occupation		
Managers & Senior Officials	14.45%	11.19%
Professionals	28.12%	9.69%
Associate Professional & Technical	18.10%	12.63%
Admin & Secretarial	10.80%	15.91%
Skilled Trades	6.03%	12.87%

Personal Services	5.36%	8.05%
Sales & Customer Services	5.17%	7.01%
Plant & Machine Operatives	5.20%	10.35%
Elementary	6.75%	12.30%

Figure 1: *Table showing education, income and occupation statistics for Moseley and Northfield. Office for National Statistics 2011*

Northfield has a very diverse cross-section of financial situations, with pockets of deprivation and vulnerability. It has a varied education profile (with a high proportion of people with no qualifications), a slightly lower average income than Moseley, and a more varied skill level among the workforce (see figure 1).

Birmingham Energy Savers is a large project being run by the local authority, Birmingham City Council (BCC). It aims to cut carbon emissions as well as create local jobs and help fuel poor or vulnerable households. During the pilot phase over 50 households (mostly within Northfield), 6 business premises and 2 social enterprises were fitted with PV panels, paid for by BCC. BCC will recoup the outlay by taking the Feed in Tariff – a mechanism whereby an amount (approximately 40p) is paid per kWh generated to the owner of the technology, as an incentive for generating energy renewably. This project will be referred to as a top-down intervention for the purposes of this paper.

LITERATURE REVIEW

There are many descriptions and theories of how society might change so that people will readily adopt more energy efficient technologies (Geels, 2005). Although change in individuals is required, the extent of the change needed to address global warming needs to be more widespread and comprehensive. Thus, the debates and theories need to address the fundamental problem of the way individual agents act in a wider social and structural situation. Theories of community (e.g. Bourdieu 1986, Wenger 1998) argue that individuals are overpoweringly influenced by history, identity and norms such that they are obliged to act in particular ways. However, theories of psychology (Ajzen 1991) see individuals as independent agents with attitudes, motivations and behaviours continually interacting with other individuals. In practice, most conceptions work with individuals, groups and their context simultaneously, and therefore we need to explore individual attitudes at the same time as exploring the way in which individuals see communities, technology and different types of intervention.

Attitudes

Attitudes and behaviours need to be modified if sustainable energy technologies are to be widely adopted. Attitudes towards these technologies will be influenced by many things, including the amount of factual knowledge a person has access to (Stutzman and Green 1982), their evaluation of the outcome of this behavioural choice, and the likelihood of that outcome (Kaiser *et al* 1999). However it is a paradox that apparently pro-environmental attitudes are not reflected in behaviour (Owens & Driffill 2008). Kaiser *et al* (1999) refer to the theory of planned behaviour (Ajzen 1985) in trying to explain this. As well as attitudes, a person is influenced by social norms (the expectations of significant others) and values when thinking about whether or not to behave in a certain way, such as adopting certain technologies. If both attitudes and social norms are conducive to this, an intention to perform

a particular behaviour is formed. This intention is then affected by contextual factors outside one's control.

A definition of 'attitude' throws up another interesting point. Allport (1935) defines attitude as a learned predisposition to respond to an object in a consistently favourable or unfavourable way. Just as people may have attitudes about sustainable energy technologies, so too may they have attitudes about governance arrangements. People may have negative attitudes towards a local authority (Frith and Bennetto), or towards particular community group members (McAreavey 2006, Derkzen and Bock 2009). This will affect the success of different types of interventions.

Communities

Most research on communities is focussed on their emerging internal conditions in relation to wider social norms, whether to do with crime, health or enterprise. This often relates to the breakdown in communities and the reduction in social capital (Putnam 2000). However the theory of social learning postulates that we acquire and evaluate our activities from our social context (Bandura 1977). This provides a much more positive role for community in determining meaning, identity and action of its members, giving opportunities for action and change. The Government would like to move responsibility and empowerment to communities which would then become important locations of decision making and action (DEFRA 2008). Therefore, policy issues of subsidiarity, collaborative management and ownership in common are starting to surface (Krishna 2003). The role of communities as agents of management and ownership or as givers and receivers of social capital has been studied within the social capital discourse (Bourdieu 1986; Shorthall 2004; 2008). However some commentators are sceptical of the abilities and capacities of local communities to deliver effectively with local action being far more complex and conditional than the theory suggests (Upton 2009; Andersson and Gibson 2006).

An understanding of socio-economic status (SES) can help to understand why particular interventions (for instance, community action) are confined to certain contexts. As Liberatos et al (1988) explain: "According to Weber, differential societal position is based on three dimensions: class, status, and party (or power). Class is assumed to have an economic base. . . and is indicated by measures of income. Status is considered to be prestige or honour in the community [and implies] 'access to life chances' based on . . . factors such as family background, lifestyle, and social networks". Therefore, occupation, education and income are used most often to measure SES. Income as an indicator clearly falls into Weber's economic or class realm, influencing opportunities for education, and providing access to certain lifestyles. Occupation is a good indicator of SES since different occupations are perceived differently in terms of prestige, require different amounts of education, and give different monetary pay-offs. Education confers differential status and provides the qualifications to acquire differential occupations and income, and so is a useful proxy for economic variables (Liberatos et al 1988). The idea of social and human capital (Coleman 1988) is also useful here – resources achieved through social connections (social capital) and nonmaterial resources as education (human capital) are readily connectible to processes directly affecting well-being, and access to life's chances (Bradley & Corwyn 2002).

Thus, different communities will not respond in the same way. Interesting questions arise as to what gives communities cohesion and whether communal action can arise other than neighbourliness. Yet there are many examples of communities operating successfully in different ways, whether in top down interventions through some authority structure, or

bottom up using the collective action of members. It is their 'success-in-context' in achieving the aim of sustainability that is of interest here. In particular, there is the potential for concerns about sustainability and energy issues to provide a new cohesion and meaning to communities (Wals 2007), providing a locus around which the community can work together.

Technological Change

In an attempt to conceive of the problem of the lack of transition to energy sustainable technologies, researchers have used concepts of socio-technical regimes. Theories of technical change had hitherto been based in a techno-economic view of the world, whereby the non-adoption of proven energy efficiency technologies is the result of social barriers – usually consumer ignorance or market distortions (Guy & Shove 2000). However, Rip and Kemp (1998) have shown that firms and technologies are embedded within wider *social* and economic systems: "socio-technical regimes". Smith et al (2005) show that the current socio-technical regime of energy production is dominated by rules and practices relating to long established centralised, large-scale power technology, and high voltage alternating current grid infrastructures, which make it difficult to make individual choices about how the energy one consumes is produced. In this regime, people have relinquished responsibility to gain convenience and dependability. However, transition from a regime of energy production based on fossil fuels to a different regime is necessary, given the legislation described above. This requires individuals to accept responsibility, and the technology and the way it is introduced needs to encourage this.

The interface between people and technology is therefore complex; people make choices about and use energy sustainable technologies as individuals in a social world. Owens and Driffill (2008) show that a large number of social factors come into play to influence energy behaviour, such as trust, habits, cultural norms, as well as financial constraints and these become important concerns in any intervention.

Interventions

Local and central governments are best placed to make large changes to the contexts in which sustainable technologies may or may not be adopted. Smith et al (2005) point out that governments have a role in guiding transitions of socio-technical regimes. Foxon et al (2008) explore this further by looking at the different pathways such guided transition could take. Hischemoller et al (2006) also suggest governments as key players in governing the transition to sustainable technologies. However interventions are not always successful; Owens and Driffill (2008) point out that government messages that driving contributes to climate change are difficult to act on when price signals provide a powerful counter-incentive to getting the train (HM Treasury 2010) and these continue to remove responsibility from individuals.

However, increasingly there is a role for communities to govern that transition in their localities, sometimes with government support (Walker et al 2007), or in partnerships with other agencies (Shucksmith 2000). Partnerships often come with their own difficulties for the community members, who may feel unable to put their priorities on an equal footing as the priorities of professional agencies (Mayo and Taylor 2001). However, this is not always the case – Mackenzie (2006a, b) gives the example of the North Harris Trust, a community trust that owns the North Harris Estate, and has installed a wind turbine.

METHOD

Studies of such complex situations and their change are difficult to undertake, thus requiring detailed studies of individuals, communities and their contexts. Thus, pilot studies are needed to determine what can be found and how best to find this. This investigation sought to determine differences in attitude in the communities and the impact of the interventions on this. A social constructionist approach was adopted where social life is understood to be constructed rather than objectively determined (Easterby-Smith et al 1991). This approach was taken in this pilot study because whether or not an individual decides to sign up to a project like BES or Green Streets, and adopt a sustainable technology, is a personal choice made on the basis of personal perceptions. Thus the focus is on individuals and their experience. This approach seeks to unpack these perceptions; to better understand why individuals respond in the way they do to sustainable energy projects.

In this pilot study, in-depth interviews were used to explore how we can find out about individual attitudes, as well as they way individuals see their communities, technology and different types of intervention. Four interviews were carried out with beneficiaries of different sustainable technology projects – two Northfield residents who had benefitted from BES, and two Moseley residents who had benefitted from SusMo's Green Streets project. Of the Moseley residents, one was having PV installed on his own house; the other was speaking as a representative of the mosque which was having PV installed on its roof. The sample size was small since this was a pilot, but this allowed the attitudes and experiences of each interviewee to be properly explored. Interviewees were asked to explain how they became involved in the projects they were benefitting from, if they had noticed a change in their energy bills (where applicable) and how they felt about energy. Interviewees were then asked to discuss their views on climate change, and whose responsibility they considered it to be to do something to tackle it. They were then invited to talk about their community in general, before moving onto perceptions of and attitudes towards the agencies (SusMo or Birmingham City Council) who were delivering the projects they were benefitting from, including if there had been any change in these.

RESULTS

The Moseley residents were both involved in SusMo's Green Streets project. As the technologies were not yet installed only provisional energy attitudes were explored. One interviewee explained that his family was not wasteful with energy at all, but were looking forward to being able to spend even less on energy. The other interviewee felt that once the PV was installed on the roof of the Mosque, people would be able to see it, making it easier to educate them about saving energy. Both interviewees were concerned about climate change, and explained what they personally were doing to combat it. Both were members of SusMo; one was starting to encourage food growing initiatives at the mosque, and the other was going to attend a course on energy advice. Both interviewees noted a sense of community in Moseley which seemed to cut across ethnic and religious groups:

> *"There's a strong sense of community in Moseley, it's diverse, people get on".*

Both interviewees knew their neighbours well, as well as the wider Muslim community. They perceived the wider community of Moseley to be fairly well informed about climate change, and to be doing their bit. One interviewee was impressed with SusMo members for

giving up so much of their time for Green Streets, which had in a way negated the need for any local authority initiative in the area, the other explained how SusMo had to do this kind of work, since the local authority had fewer financial resources and were moving too slowly.

> *"Nowadays, the government don't have money for anything, what can they do, just give you money to do these things, but now they haven't got any money to give, so it's up to us"*

The Green Streets project has changed the Moseley interviewees' attitudes towards themselves and their role within the community;

> *"I'm a completely different person to how I was last year. I did have all these things in the back of my mind, these are the things that you do when you retire, but this year I said, you know you don't have to wait until you retire, you do them now"*

and their attitude to sustainable energy:

> *"we have these habits [of not being wasteful], but it's nice now to incorporate the environment, and put these habits to a greater cause"*

The Northfield residents were both council tenants who were at home during the day. They both noticed a saving in their energy bills. Both interviewees thought that climate change was an important issue, and that something should be done about it. Both interviewees saw a very strong role for the council in providing facilities that allowed the opportunity for green behaviour, such as recycling facilities, water butts and composters, or PV panels, as was the case here.

> *"well things should be done about [climate change] cos it can't go on like this forever can it? . . . . but somebody's got to start the ball rolling for other people to get involved"*

They also saw a role for the local authority in helping those who could not afford to 'be green' even if they wanted to;

> *"at the end of the day if I didn't get the solar panel fitted on the roof I couldn't have afforded to do it on my own".*

Neither Northfield interviewee noted a particular sense of community in their local area, were not close to their neighbours, nor members of community groups. However there may be an opportunity to change this as a result of BES – with their experience of the technologies the beneficiaries could act as trailblazers, and discuss the technologies with other members of the community – enhancing social capital as more links are made between individuals. The interviewees mentioned the difficulty of getting started without such prior knowledge:

> *"for a community that gonna come together without the actual experience of the solar panel, it's harder, but like us as a community then that have it fit in, it's good for us to be involved"*

The interviewees mentioned that people were asking them about their PV panels since they had been installed:

"Oh I've had them knocking on the door! . .and stopping me in the street asking me for phone numbers and that [to find out how they can get panels aswell]"

The Northfield interviewees do see a role for individuals, but their discussion of that role was set in the context of council facilitation;

"it is, [laziness] . . . it's like when you see bits of furniture and everything lying all around, they've only got to make a phone call to the bulk rubbish [a council service] and they come and fetch it, it's what you pay your poll-tax for!"

Both interviewees were pleased with the local authority for having instigated BES, which allowed them to have the PV:

"They're doing something really worthwhile".

Both interviewees also discussed issues of trust – they trusted BCC to do a good job, to use reputable companies, and to deal with any problems that would emerge with the technology. Both feared 'dodgy' or 'cowboy' companies, and felt that a company being registered with the council was a stamp of approval.

"The council would never take up for instance a dodgy company to come here and do certain type of job. Normally when they came here, you know it's a proper company that register with BCC. So BCC wouldn't send like a dodgy company come to your house and stuff like that so I would feel more comfortable doing it with the council"

DISCUSSION

According to the interviewees, both the Northfield and Moseley interventions although different, were successful. The pilot suggests that success could best be defined for the larger research study as having a positive attitude to the intervention, saving energy, and having the potential to induce a wider, community based change in behaviour. The pilot also suggests that the style of intervention is important. Thus, an in-depth study needs to investigate how the style of intervention in different contexts can lead to positive attitudes towards that intervention, and hence greater adoption of sustainable energy technologies.

Moseley residents believed that in difficult economic times, BCC must target its resources where they are most needed. Moseley, being a more affluent area, cannot benefit from BCC led interventions. Therefore Moseley's only option is a community-led intervention. This pilot raises an interesting question about why community led interventions are possible in Moseley and directs us to look at the 'capability of the community'. This can be characterised by socio-economic status (SES), which if measured by education, occupation and income (Liberatos et al 1988), can be said to be high, certainly higher than that of Northfield. Nearly 40% of Moseley residents have a very high level of education, and nearly a third of its residents are professionals, of which nearly a half are teaching and research professionals (Office for National Statistics 2011). Bradley & Corwyn (2002) consider capital (social, human and financial) to best embody the meaning of SES. Moseley clearly has a wealth of capital (as shown by its large number of community groups made up of

active, capable and resourceful individuals) particularly so within SusMo itself (many members participate in multiple groups). SusMo's committee is made up of individuals with high levels of education and sustainable technology related experience (human capital), and its members can support each other and share skills within the group (social capital). This capability enabled SusMo to inspire the two residents interviewed here, and include them within SusMo itself. This led to a positive attitude to the project between the interviewees, and therefore a willingness to adopt the sustainable energy technologies.

The community of Moseley is diverse – there is a strong Muslim community, and numerous other communities of interest based around community groups. SusMo's Green Streets project by formally partnering with the mosque, the church, the local allotment association, the school, was able to incorporate all of these communities and build a community of place cutting across faith and interest groups. Therefore the in-depth study should also investigate the potential of interventions in such areas to draw sub communities together and create 'community cohesion' which enables further activities. Moseley does indeed have a strong sense of place and having won awards for its farmer's market and 'Moseley in Bloom', it has become a place that people are proud to live in and be part of. This is reflected in the ability of SusMo's project to interest all faith and interest groups, and more generally in the large number of community groups to be found in Moseley (which provide social capital for their members). Such support enables residents to become involved in projects such as Green Streets, and act on their own initiative to tackle issues around climate change. This can also lead to human capital, further facilitating such projects as residents become more able to become involved, and learn the skills needed to organise and run them.

SusMo's intervention in this particular context (of a capable community) has clearly led to positive attitudes amongst residents amongst the Moseley residents interviewed here. The two interviewees are well informed about climate change, and saw individuals as having a key role to play in its mitigation. Both interviewees explained how they *personally* were 'doing their bit', by reducing their consumption of energy by changing their behaviour, and by becoming involved with SusMo both as beneficiaries and as committee members. It is clear that SusMo provided these residents with the opportunity to be involved in the management and running of a climate change project leading to positive attitudes towards the technologies and the process of intervention. The suggestion for an in-depth study would be to investigate how the style of intervention here can lead to positive attitudes and thus 'success in context'.

BCC's Birmingham Energy Savers is specifically aimed at communities in need and is well positioned to intervene in communities like Northfield. The SES of Northfield as a whole is diverse, and residents have a wider spread of educational attainment, but with a much larger proportion of people with no qualifications at all. Since educational achievement can influence occupational level, it is not surprising to see many residents in lower skilled jobs, with not such a large proportion of residents in one particular highly skilled area. However, the financial status of the Northfield council tenants interviewed here is straightforward – they must be of a lower socioeconomic status, and have lower financial capital in order to qualify for a council tenancy. In such circumstances, these residents would ordinarily be unable to adopt sustainable technologies, being constrained as they are by their financial context.

The two Northfield interviewees had varying levels of understanding about climate change, but saw a strong role for the local authority in mitigating its effects. This is unsurprising,

these tenants would not have been able adopt such sustainable energy technologies as PV without council aid. BES was the only opportunity these residents have to choose to do something about climate change in such a manner. As council tenants they also rely on the council for the maintenance of the technologies, as they rely on the council for the maintenance of the rest of their houses. Therefore they trusted the council over any other agent to install these panels.

This pilot gives evidence that the BCC intervention in this particular context led to a positive attitude to sustainable energy technologies in the two people interviewed here and thus 'success in context'. The residents trusted the council over other organisations to install the technologies, saw a strong role for the council in leading this type of project, and saw them as doing something "worthwhile". They were therefore willing to be a part of Birmingham Energy Savers and agree to the installation of the sustainable energy technologies. Neither Northfield interviewee noted a particular sense of community in their local area, were not close to their neighbours, nor members of community groups. This suggests that as a result, they had little structure through which they could act together with others and little opportunity to gain access to any skills or knowledge that other residents may have had about issues of climate change and sustainability.

The suggestion for an in-depth study would be to investigate how the style of intervention here (top-down) might be most appropriate to engender positive attitudes towards sustainable energy technologies and facilitate their uptake. The pilot also suggests that it would be interesting to further explore how a top-down intervention could also lead to an increase in community groups and action (social capital) and hence draw communities together in the future. The BES beneficiaries here, with their experience of the technologies could act as trailblazers, and discuss the technologies with other members of the community – thus increasing community cohesion and thereby the capability of the community as a whole.

CONCLUSION

The value of exploring attitudes to sustainable energy interventions in this pilot study has been to identify some important areas of study, to establish what can be found out from individuals about successful interventions, and to establish whether the style of intervention is important. This pilot does indeed suggest that the style of intervention is important to establish 'success in context', and this requires further study. It also raises important questions for further study about how interventions encourage 'community cohesion'; involving sub communities working together to interact and affect each others' attitudes.

The Northfield council tenants, having financial concerns and feeling less of an identity with the community, had 'success in context' from a top down intervention from a trusted body - BCC. An in-depth study would provide more conclusive evidence for whether top-down or community interventions are more appropriate in helping communities that are unable to act unsupported, and whether or not the local authority is the most appropriate and trustworthy body to suggest the take-up of these technologies; thereby effecting a positive attitude towards them.

The Moseley residents, being from a more affluent area, were unable to benefit from Birmingham City Council's project, but were more able to make use of their connections with friends and neighbours in the community in order to self organise. An in-depth study

would provide more conclusive evidence for whether or not community interventions are appropriate in these communities since residents are skilled and can support each other to make such interventions work, and inspire the rest of the community. This is not to say that top-down interventions in communities like Moseley would *not* be successful. Therefore an in-depth study would also provide more conclusive evidence for whether or not community interventions in communities like Moseley (who can afford to be more critical of their local authority, being less dependent on them) can lead to *more* positive attitudes about sustainable technologies and the process of interventions, than would a top-down intervention. It would further refine whether the 'capability of the community' is necessary for 'success in context' here, and whether this can be developed in less cohesive communities as part of the intervention.

In a study looking for more successful interventions, it is important that we find out about individual attitudes, as well as they way individuals see their communities, technology and different types of intervention. This pilot study highlights some areas for investigation within top-down and community-led interventions. Potentially an in-depth study could also look at a third approach to interventions: the *facilitation* of a community-led intervention.

ETHICAL AND SUSTAINABLE EMPLOYMENT IN CONSTRUCTION: THE CASE OF BLACK AND MINORITY ETHNICS' (BME'S) ENGAGEMENT

PAUL MISRA
VIAN AHMED
The Universtiy of Salford, Salford.
United Kingdom.
p.missa@edu.salford.ac.uk and v.ahmed@salford.ac.uk

Abstract
The instability of employment resulting from fluctuations in demand and the widespread use of contracting systems poses major problems of attractiveness to the construction industry. This practice has considerable negative impact on the industry. Therefore, as much needed investment is cut from training in the sector, the issue of skills shortages can be very devastating in the event of an upturn which is indeed certain. Consequently, it is anticipated that the construction industry should look to expand its recruitment base to become progressively multicultural and reflect the diversity of the population. As a result, this review of literature on the sustainable aspects of increasing the engagement of the BME population who, hitherto, have been underrepresented aims to highlight the situation. It is worth noting that the white population has been seen to be aging while BMEs have quite a younger age profile making it sustainably intelligent to proportionally engage them for the future of the industry. Furthermore, it is ethically prudent to involve the sections of the population whose involvement has, until now, been very minimal. It is probably, for instance, a recipe for bitterness and resentment where religion becomes a tool for marginalisation in the industry.

Keywords: BME, ethical, sustainable, diversity and employment.

Introduction

Demographic changes have resulted in societies becoming more and more ethnically diverse and as a result organizations around the world cannot afford monolithic blocks of workforce and still compete on the global scene. Therefore, an unparalleled impetus for a relatively large number of studies on the effects of diversity at work has been created and the construction industry is no exception. The need for the inclusion of minorities for the industry to be representative of the larger population is, in effect, paramount and has been covered in several studies (Caplan et al, 2009; Ahmed et al, 2008; Caplan and Gilham, 2005; Sodhi, 2004; Steele and Sodhi, 2004; Egan, 1998; Agapiou et al, 1995; Harrison, and Davis, 1995; Latham, 1994). However, studies into diversity at the workplace have generally yielded mixed results with some demonstrating that diversity can have negative effects by giving rise to communication difficulties thus affecting group cohesion and resulting in dysfunctional conflict (Jackson, Joshi, & Erhardt, 2003; Williams & O'Reilly, 1998). Yet, others (e.g., Caplan, et al 2009; Ahmed et al, 2008; Dinsbach, 2005; De Vries & Pettigrew, 1998; De Vries, 1992) indicate otherwise and hence see no reason why such problems should occur.

According to (Schaafsma, 2008) little attention has, so far, been paid to why inter-ethnic relations may be more harmonious in some work settings but rather more problematic in others as indicated by Jackson et al. (2003) and Milliken & Martins, (1996) while asserting that generally, relations between workers with different ethnic backgrounds have only been explored as potential mediators of the effects of diversity on work group outcomes. There is, as a result, little research into the experience of ethnic minority and majority employees and managers about how working in a diverse environment involving different ethnic groups can

have positive or negative impact on productivity. Therefore, this review seeks to fill this gap by bringing to the fore the possible barriers that need to be understood and surmounted in order to create a positive inter-ethnic work relationship in construction. How do ethnic minority and majority members compare in dealing with inter-ethnic relations at work? And, whether either report on more positive or more problematic inter-ethnic relations. Is the former group over-blowing their experiences or is the latter covering up incidents of discrimination and how such issues are dealt with?

Ethnic minorities in The UK: Background and socio-economic Consideration

With a trend increase in immigration of more than 100,000 per year, the past four to five decades have seen Britain change from being a country of net emigration to one of net immigration (IPPR, 2010). Notwithstanding that improved economic performance in the UK relative to overseas has tended to increase immigration and rising UK inequality has had an even larger effect. Additionally, immigration policies at home and abroad have also helped to increase net immigration, particularly in the 1990s. According to the Labour Force Survey, some 4.5 million individuals living in Britain in the year 2000, 9% of the population, were born in another country (LFS, 2001). Many of these individuals of foreign origin work, and contribute to economic prosperity and well-being. And as supported by several studies, (e.g. Zimmermann, 2008; Dustmann et al, 2003; Shields and Wheatley Price, 2002; Dustmann and van Soest. 2001) differences in education, the demographic structure, culture, and skills of foreign-born individuals may have advantages in some labour market segments, but disadvantages in others and construction is classed in the latter category.

However, these disadvantages may diminish depending on the changes in the underlying factors and over time, immigrants may adjust in many respects to their UK-born peers, from the accumulation of skills, collection of information, and adoption of new habits. It is worthwhile to note that understanding how labour market performance of immigrants differs from UK-born, and from each other, how these differences relate to observed characteristics, and how they change over time is an important pre-requisite for migration policy. Also, it is significant to note that while adaptation and labour market performance of immigrant populations has been subject of intensive research in the US, Canada, Australia, and also in some European countries, according to Dustmann et al (2003), relatively little is known about the absolute and relative performance of the immigrant community living in Britain.

Notwithstanding, it is generally the case that when immigrants arrive in the destination country, their labour market productivity is likely to be different from that of their indigenous counterparts; a situation attributable to different levels of education, socio-economic characteristics, and different demographic composition. But even if an immigrant is compared, for example, with a UK-born of the same education and age, they may differ in labour market outcomes, like wages and participation. One important reason for this is that the skills immigrants have acquired in their home country are often not directly transferable to the host economy. Furthermore, immigrants may also lack certain general skills immediately after arrival in the host country especially fluency in communicating in the host's language as well as the observance of certain cultural practices. However, they may adjust over time to a level commensurate with the skills requirements of the labour market and in most cases acquire new skills. At this point, they may match or even do better in the level of local economic performance as well as assimilate into the hosts culture and hence the community.

Also, as Dustmann et al, (2003) note differences in demographics, education, or skills may but only be some of the reasons why immigrants differ in their labour market outcomes as they tend to settle in areas of more economic prosperity to take advantage of high levels of employment and wages and in most instances close to their predecessors and relations of similar origins. Consequently, this leads to selective settlement, as is the case in the South East and London regions and may cause a less even spread of immigrants and hence concentration in particular industries. This could result in more favourable labour market outcomes of immigrants and so underestimate the differences in economic outcomes between the hosts and immigrants and their descendants. Apparently, this ideal situation does not usually apply to immigrants as labour supply outstrips demand causing in its wake further unemployment thus worsening their plight.

The Recession and Future Skills Requirements

As has just been hinted in the preceding paragraph, it is usually the case that in an efficient labour market where the supply of skills is aligned with labour market demand, the supply and demand matching processes are seen to be deficient where there are mismatches between demand and supply for skills. Therefore, it is easier to assume that skill shortages, skills gaps and general unemployment have been controlled in the current situation. This fact is consistent with the Construction Trade Survey (2009), where organisations across the construction industry all reported a considerable decrease in skill shortages to a record low. For instance, the recent Construction Products Association Trade Survey (Q3, 2009) reported that only 6% of building contractors had difficulties in obtaining the main site trades, a complete contrast to two years earlier when it was 78%.

Yet, looking at the recruitment activity, one in ten employers (10%) felt that there had been times when they lacked the number of skilled workers they required (ibid). Again, around half (52%) felt that they had been operating at around full capacity given the number of skilled staff they employed and still a third had not had enough work for their workforce (ibid). Also, it is worth noting that a more recent review of the Migration Advisory Committee's (2009) recommended shortage occupations listed civil engineers, mechanical engineers and welding trades while noting that although falling employment and vacancies and a high redundancy rate indicate that the labour market is in turmoil, it should not be assumed that all labour shortages disappear upon the acknowledgement that the removal of some construction-based occupations from the original list is in response to changing economic circumstances. Table 1 below shows the recent unemployment rate for construction as it compares with all other industries in the UK.

	Construction Industry	All Industries
England	8.3%	6.9%
Wales	10.3%	7.2%
Scotland	9.1%	5.8%
Northern Ireland	11.8%	5.6%
UK	8.6%	6.8%

Table 1: *Unemployment rate in Construction Compared with All Industries by nation (UK: 2009).*

Source: Office for National Statistics, Labour Force Survey (2009)

As the data highlights in table 1 above, the construction industry has been significantly affected by the economic downturn, with the unemployment rate not only higher nationally, compared to the figure for all industries at 8.6% against 6.8% but it is even higher in each

country as indicated in the table above. Here it is significant to note that the unemployment rate across the Northern Irish construction industry is twice as high as the rate for all industries.

Therefore, it must be stressed that the impact of the recession across the construction industry has radically affected the mismatches between demand and supply. While on the one hand skills shortages and skills gaps have decreased dramatically, this has contributed to worsening unemployment. Although skills shortages are currently at an all time low, lessons need to be learnt from the previous recessions. One of the biggest risks to the recovery of the construction industry, according to the ConstructionSkills (2009) is a shortage of skills as people made redundant seek new careers outside the industry and new entrants unable to get jobs, look elsewhere.

Employment and Participation

Unemployment has been a serious cause for concern among first generation immigrants as generally, most literature in the UK on employment and participation differentials compare outcomes of whites with those of ethnic minorities in general. This practice calls for further cause of concern as the distinction between immigrant and UK-born minorities, if drawn could have given a different picture of the level of unemployment in either situation for redress. In this way the pool of labour resource is easier to identify. Exceptional to this is the work of Blackaby et al. (1997) who based on the 1991 UK Census of population, investigated the incidence of unemployment and found that foreign-born ethnic minorities have a higher unemployment rate than UK-born minorities. Also, they found no evidence that the latter perform worse than white UK-born majorities. Additionally, Blackaby et al. (1997), also confirmed by Dustmann and Fabbri (2002), based on data from the Fourth National Survey on Ethnic Minorities (FNSEM) and the Family and Working Life Survey (FWLS) survey found substantial differences between different ethnic groups, for instance the suggestion that Pakistanis and Bangladeshis have particularly low employment probabilities compared with the other Asian counterparts (Modood, T. and Berthoud, R. (1997). Conversely, a comparative study by Wheatley Price (2001) based on the Quarterly LFS data for the years 1993 and 1994 found that white and non-white immigrants have initially a lower probability of being employed, compared to white UK-born individuals but this disadvantage decreases over time, although it does not completely disappear. In similar sequence, an analysis of ethnic minority immigrants and UK-born ethnic minorities, base on the FNSEM and the FWLS by Dustmann and Fabbri (2002) found that minority immigrants have lower employment probabilities compared to white UK-born individuals and minority UK-born individuals, a disadvantage which falls slightly over time.

Also, with respect to earning differentials, the first study on wage adaptation of UK immigrants by Chiswick (1980), analysed the 1972 General Household Survey (GHS) and found no significant earnings gap between white immigrants and white UK-born individuals, but a 25 percent gap between white UK-born individuals and non-white immigrants. Also, Chiswick (1980) found neither evidence for adaptation of non-white immigrants nor wage gap between white and non-white UK-born individuals. Pooling 20 consecutive cross-sections of the GHS (1973 to 1992), Bell (1997), through a more recent study performed a more exhaustive analysis, which distinguished between West Indian, Indian, white and Old Commonwealth immigrants and found different adaptation rates and entry wage differentials across these groups. While ethnic minority immigrants have an initial wage disadvantage that slowly decreased over time, white immigrants have initially higher wages which adapt downwards, a negative adaptation trend attributed to the possibility that white migrants who

remain in the UK are negatively selected, results confirmed by Denny et al. (1997), also using GHS data (from 1974 to 1993). Of particular significance is that, they found a large wage differential between non-white immigrants and white UK-born individuals, however, there was no wage gap between white UK-born individuals and white immigrants.

Self-Employment

Dustmann et al, 2003, has stressed the scanty work on self-employment of immigrants on the whole. However, Borjas' (1986) analysis of self-employment probabilities for immigrants in the US and UK-born individuals and subsequently extending this analysis to assess self-employment probability differentials among different ethnic groups in a separate study (Borjas and Bronars 1989) stands out. For the UK, Clark and Drinkwater (1998) used the General Household Survey (GHS) and the FNSEM (Clark and Drinkwater 2000) and found that ethnic minority immigrants are more likely to be self-employed than ethnic minority UK-born individuals or their white counterparts. This revelation supports a justification of attempts to create their own employment where they fail to progress in finding one while reinforcing the means of escape from discriminatory practices. However, contrasting with findings by Borjas (1986) they also found that ethnic regional concentration affects self-employment rates negatively as a result of mismatch between supply of labour and demand for it.

Language and Level of Education

Again, according to Dustmann et al, (2003), few studies in the UK analyse the determinants of immigrants' language fluency, and the effect of language on economic outcomes. Studies by Shields and Wheatley Price (2002) based on the FNSEM found that higher education levels are associated with higher degrees of language proficiency, and that longer migration duration has a positive influence on language fluency. They further found out, by analysing the occupational success of non-white immigrants, that those who are fluent in English language have, on average, wages about 20 per cent higher than non-fluent individuals. This was further confirmed by Dustmann and Fabbri (2002) using results from both the FNSEM and the FWLS who further established a positive relationship between language, employment and earnings although this relationship did not necessarily indicate a causal effect of language on earnings (Dustmann and van Soest (2001).

Further afield in Continental Europe, studies have evidenced a high level of discrimination thus hindering the integration of ethnic minorities in the labour market (Zimmermann, 2008). A recent study in Hungary reports that members of the Roma minority are more likely to lose their jobs than Hungarians (Kertési, 2004). According to the Bureau of Democracy, Human Rights, and Labour report of 2006, most Roma people in Hungary live in abject poverty and their unemployment and inactivity rate is as high as 70%, ten times more than the national average. Also, in Slovakia the Roma suffer a permanently higher ratio of long-term unemployment than the majority Slovaks (Vasecka, 2001). In fact, there is evidence that in 1999 the number of unemployed Roma stood at 80.5 thousands out of a total population of about 400 thousands, and among the unemployed 83% Roma people had no educational qualification. Similarly, differences in earnings and in the duration of unemployment between the Latvian majority and non-Latvian minority reported an enormous ethnic wage gap in 2005 of 9.6% (Hazans, 2007; Hazans et al., 2007). These studies found that in 2002-2005 the median duration of unemployment period was 3 months longer for the non-Latvian minority and in almost all cases the basis for such gaps have been the level education, language proficiency and low level of integration.

Even so, regardless of the factors mentioned above, higher education does not guarantee a better labour market placement of ethnic minorities for over-education by BMEs in the UK has been reported (Battu and Sloane, 2002; Alpin et al, 1998). In some EU member states, like the Netherlands, Germany and even the UK, higher education in the country of origin does not pay off during the early years in the labour market (Hartog and Zorlu, 2007). While language requirements for higher level jobs and non-transferable skills may explain this finding, discrimination is certainly said to be the latent contributor. Moreover, economists often find inexplicable differences in the labour market outcomes of ethnic minorities and the majority population to which they attribute discrimination as the sole factor (Kertési, 2004; Hartog and Zorlu, 2007). Citing a level playing field, Caille (2005) render a more positive outlook for France in respect of the finding that among pupils in 6th grade in 1995, immigrant children had a higher probability to complete high-school than non-immigrant children. The table below gives a picture of the situation in some selected EU countries.

Country	Minority/Majority Group	Participation Rate	Unemployment Rate	Hourly Wage
Denmark	Total Population	76.3	4.5	278.3
	Turks	62.2	17.8	170.7
	Iraqis	37.7	26.9	138.4
	Bosnia-Herzegovinians	7.2	12.9	177.4
	Other non-Western	55.8	28	164.8
Hungary	Hungarian Majority	40.47	9.84	
	Africans	48.13	10.0	
	Arabs	48.14	5.21	
	Chinese	65.01	0.68	
	Croatians	41.37	7.25	
	Polish	53.07	6.81	
	Armenians	51.13	5.68	
	Rutheneans	48.27	8.11	
	Serbs	40.44	8.17	
	Ukrainians	47.95	8.39	
The Netherlands	Dutch Majority		9.0	10.4
	Turks		21.0	7.1
	Moroccans		27.0	6.9
	Surinamese		16.0	8.5
	Antilleans		22.0	8.0
Romania	Romanian Majority	41.6	11.5	
	Hungarians	38.0	11.3	
	Ukrainians	42.8	11.1	
UK	White Majority Population	81.8	3.8	11.8
	Indians	80.1	6.4	12.2
	Pakistanis	55.2	12.8	10.2
	Bangladeshis	48.7	19.4	10.1
	Other Asians	75.1	8.3	10.2
	Black Caribbeans	81.0	11.0	11.4
	Black Africans	77.7	11.8	9.9

Table 2*: Labour market situation of selected ethnic minorities Compared with the Majority population in Denmark, Hungary, the Netherlands, Romania, and the UK*
(Sources: Zimmermann et al, 2008)

As shown in table 2 above, the rate of unemployment disparity between majority and minority populations is significantly high in all the countries listed. Although this refers to the whole economy of which construction is a subset, it helps to give an idea of the need for inclusion in the various sectors of the economy. In the case of the Netherlands, this has been attributed to the policy of integration adopted. Initially, attempts to integrate the different ethnic groups have been a source of considerable debate as these discussions centred on the socio-economic integration of ethnic minorities. For example, compared to other European countries such as Germany, France, and the UK, the labour market position of non-western minority members is relatively unfavourable (Koopmans, 2003). Although employment among ethnic minorities has increased over the past few years, the average unemployment levels among ethnic groups still hovers around 4 times higher and the net participation rates are lower than the Dutch native population. Additionally, long-term unemployment is relatively high among non-western minority members and many of the employed occupy lower job levels (CBS, 2007; SCP, 2003). By and large, this can be explained by factors at the level of the different ethnic groups themselves, as already indicated earlier involving their lower levels of education, their often one-sided work experience and limited social networks. This said, however, institutional factors basically underlying conscious or unconscious discrimination by employers also play a major role (SCP, 2003; Veenman, 2001).

Generally, the integration of ethnic minorities into Dutch society has been described as a failure and it has been argued that the adoption of a multicultural approach in the 1980s is largely to blame for this contrary to the approaches in other countries with a multicultural policy like Sweden and The United States. For example, multicultural rights were ascribed to ethnic minorities where the use of mother tongue for instruction in primary schools was permitted. This is said to be a major setback and did not actively promote Dutch language training thus reinforcing immigrants' image as a problematic and low-skilled group, with a concomitant disadvantage in employment (Koopmans et al, 2005).

Consequently, the low level of participation among Black and Minority Ethnics in construction and their high unemployment levels generally have been blamed on their educational standards and efficiency in communication here in the UK and elsewhere in Europe. This said, however, the incidents of over-education among ethnic minorities cited in the UK with the accompanying high level of unemployment does not justify this fact. Furthermore, ethnic minorities are well represented on construction related programmes in higher education here in the UK yet this is not reflected in their participation in the construction industry. It is without doubt that barriers to their participation exist in industries such as construction for in others like catering and cleaning they are known to be well represented even though they may lack the levels of skills required, they get the necessary on the job training and are able to progress with the limited communication skills they have.

CONCLUSIONS AND FURTHER RESEARCH

Finally, labour market barriers in the United Kingdom derive from a variety of sources including public perception which has been thought to be prejudiced against people of other races other than the white majority. Ethnic minority workers may be disadvantaged by their own characteristics; what might be regarded as internal barriers yet other distinct factors and external barriers are at play. Labour Force Surveys (LFS) data indicate that 16% of those whose first language is not English claimed that language difficulties caused them to have problems in finding or keeping a job. Also, data from the Fourth National Survey of Ethnic Minorities report that lack of English language fluency reduces average predicted

employment probabilities by 20-25 percentage points. In most dimensions of economic and social well being (such as income, employment, education, social class, health, housing etc.) there is a clear ethnic hierarchy with Indians and Chinese at the top, Black Africans and Caribbeans somewhat lower down and Pakistanis and Bangladeshis at the bottom.

Therefore, United Kingdom policy interventions and existing national legislation should focus on removing racial barriers to labour market integration; while it is clear that the weak labour market outcomes for ethnic minorities are due to a number of other causes as well that cannot be are beyond legislative control. In particular, in the United Kingdom, policy is driven by the 2000 Race Relations Acts that focuses on extending the duties required in the public sector to the private sector and as construction is mainly in the latter but heavily controlled and financed by the former, a lot of improvement of policy initiatives in place when properly implemented and monitored may help stem the tide as recent positive stance on ethnic minority issues is encouraging.

These developments make further study on interethnic relations at work all the more warranted and targeting construction as the driver of most economies will go a long way to achieve the desired effect. In the workplace, people may have to interact with members of ethnic out-groups who they would perhaps avoid in their private lives. This may result in tensions, however if the workplace is oriented to a context in which people inculcate tolerance it may help to develop more positive attitudes toward each other as well as the common objective of fulfilling assigned tasks. There is also the need to consider whether the conditions of minorities are hyped and if some members of the native majority do not suffer similar fate yet shy at reporting it.

ABSTRACT

The structure and purpose of urban areas varies over time. For 50-100 years ago it was often desired to have closeness between the city centre and adjacent industries and infrastructure, e.g. the harbour and railways. Today these land areas are coveted for housing and commercial interests. In the beginning of the 21st century the municipality of Helsingborg in the southern part of Sweden decided to convert the south industrial harbour area in Helsingborg into housing and offices. The purpose of this paper is to elucidate the factors that can influence future relationships between various stakeholders in urban redevelopment projects, special attention will be given to efforts made in early stages of how to manage and organise the project from an overarching vision into an action plan for project implementation. Interviews with participants in the project management team for the development of the H+ area in Helsingborg and with involved municipal officials lead to mapping the expectations for the future development. Partial results shows that open communication between involved stakeholders and public officials give a good base for participation and engagement. Transparency and goal definition along the project planning characterise a well performed property development process. Thus, creating an interest by developers to invest and establishes a baseline for stakeholder management in forthcoming phases of the project.

KEYWORDS: Property Development, Urban Planning, Project Management, Relationships

INTRODUCTION

Cities of today are often segregated considering both aspects of economy and immigration (Andersson, 1999). Sweden is not an exception, but in a global perspective Swedish cities are less sharply divided along the socioeconomic dimension. The Swedish housing policy focus first and foremost on counteracting socioeconomic segregation (Bolt, 2009). The ethnic segregation seems as a consequence of poor integration on the labour market with results of socioeconomic divided cities. The aim of Swedish authorities is to achieve a social mix in

neighbourhoods with a variety of housing solutions, and not only for distressed neighbourhoods (Bolt, 2009). Andersson (1999) claims that improving the living conditions and accessibility to strategic resources for people residing in certain areas is necessary but it not the only measure in order to achieve an undivided city. The undivided city is an alluring mirage, but though urban development the gap between the reality and the mirage can be reduced. Although, it may appear as though land use changes and development takes place automatically in a city it requires a public support and approval from city planning officials in order for such change to take place (Nallathiga, 2010). Similarly, to stimulate urban redevelopment, policy-makers must address the economic problems and fears faced by land-owners, who are major stakeholders for achieving success (Hayek et al., 2010). Adams et al. (2001) divide landowners into active and passive. Active landowners are those who develop their own land, enter into joint venture development or make their land available for others to develop. Passive landowners take no particular steps to market or develop their land, even though they may intend to do so in the distant future. There is a delicate balance between public activities, for instance, the control of land use and the right of landowners to develop land according to their own wishes (Larsson, 1997).

How the structure, purpose and socioeconomic status of urban areas varies over time and how this change affects housing policies is a relevant area to study. For 50-100 years ago it was often desired to have closeness between the city centre and adjacent industries and infrastructure, e.g. the harbour and railways. Today these land areas are often coveted for housing and commercial interests and due high development costs often built with expensive solutions with little room for a social mix.

Renewal of the city has to, according to Hulsbergen and Stouten (2001), be anchored in the urban environment and neighbourhood problems have to been solved before a socioeconomics change can be possible. Residents and local entrepreneurs are important stakeholders in this process. By allowing the public to be a part of the planning process a link is created between the built environment and public concerns (Clark, et.al, 2010). According to Meen and Andrew (2004) a social mix can be achieved, in communities, through planning decisions. Graaf and Dewulf (2010) pointed out three characteristics of urban planning, analysing internal and external environments, stakeholders' participation and implementation. Internal environment can be controlled and influenced by the organisation. The external environment cannot be controlled, instead to deal with it the organisation has to reduce the level of uncertainty. Stakeholder participation and networking is needed to ensure effective implementation of plans. Implementation is about finding solutions and practical alternatives in urban planning policies, although urban policy is about achieving changes that will benefit localities, this goal probably will not be fulfilled if people cannot voice their needs or take action to effect change on their own (Seyong-Kyu 2001). To ensure stakeholder participation, especially by stakeholders from an external environment, various analysis and mapping techniques are available (e.g. Olander and Landin, 2005, Bourne and Walker, 2005, Olander, 2007).

The purpose of this paper is to elucidate the factors that can influence future relationships between various stakeholders in urban redevelopment projects, special attention will be given to study efforts made in early stages of how to manage and organise the project from an overarching vision into an action plan for project implementation. In this sense every project has several outputs, a product or a service delivered for internal or external customer and project knowledge which is related to the outcome (Kasvi, et. al, 2003). A project is temporally limited and the people involved and the lessons learned are dispersed when the

project ends. People often even change during the course of the project. Sometimes it may be hard to find people that have been involved in the project from the beginning. In combination with employee empowerment and information decentralisation Kavi, et al. (2003) states that knowledge will be fragmented with loss of organisational learning as a result. Thus there is a need to study how knowledge within an organisation is transferred from project to project, not at least when it comes to communicating with stakeholders, in an internal as well as external environment. How a project is organised is one relevant factor in order to achieve a successful stakeholder management process (Olander and Landin, 2008). No actor in the development process pursues strategies, interests and actions entirely on their own, to a greater or lesser extent, the performance of each actor is linked to that of others and is set within a broader structural context (Adams et al. 2001). All participants in an urban development process must be able to make informed decisions about their costs and benefits (Hayek et al. 2010). For the urban renaissance to be sustainable it is going to be necessary to ensure that as many stakeholders as possible is involved in its performance and that its benefits are more widely distributed (Ward, 2003).

The information in the research presented here is acquired from four interviews during the winter of 2010. Two of the interview respondents are working at the municipal office of Helsingborg, one of them as development director and the other one as city planning manager. The other two of the interviews belong to the project organisation responsible for the development area H+ in the south city centre, which today is a large extent an industrial area. The representatives from the project organisation were the project manger and the project coordinator. The project is currently in its early stages working with the depth layout plan. In the early stages there is uncertainty as to how the project will be affected by external factors such as stakeholder influence. However, there is the clear possibility in this stage for various stakeholders to affect project outcomes (Olander et al. 2010), which can enable project managers to find effective solutions to specific problem raised by stakeholders. During the course of the project this opportunity will gradually decrease. Thus, the aim with the interviews was to visualise the forthcoming views and structure of the development process for the current project. The interviews are limited to officials at the municipality of Helsingborg in order to provide a picture of their vision of the development process for the project and their vision for the future outcome of the development. Despite their limited financial resources, municipalities can foster local support by creating a common vision for an area and can create a demand for reusing sites by helping the public understand the benefits (Hayek et al. 2010).

REDEVELOPMENT OF THE SOUTH HARBOUR IN HELSINGBORG (H+)

Helsingborg is a city placed in the expansive Öresund region (the south-west of Sweden and eastern Denmark). Helsingborg is a segregated city with a clear division between the north and the south parts of the city centre. Around the millennium shift the first thoughts about H+ arose. It is an extensive project with an area about one million square meters, which is similar with 140 soccer fields, situated south of the ferry terminal in the city centre of Helsingborg. During the same time the municipality of Helsingborg began the project, ‘South of change’. The Project ‘South of change’ began in year 2001 with the purpose of making the south part of the city centre of Helsingborg more attractive in close dialogue with the city residents. During this dialogue a vision was created of linking the city with the water in the south parts of the city centre. Ten years earlier had the railway in the north part of the city been buried in a tunnel and the result was a success for the urban development in these areas.

In the Swedish planning process, the municipalities have, by law, significant control of land development within their boundaries. It is the municipalities that exclusively decide which property developments to approve and can with a development agreement control the outcome of such developments. Additionally, vague national rules and legislations concerning the planning process add to the uncertainty perceived by property developers (Riksdagens revisorer 2001, Olander and Landin 2008). The risk is that the municipality uses its advantage in the process to force the developer into an unbalanced development agreement (Kalbro 2002) that adds costs to the property development project.

Up-coming ideas for urban development in the city of Helsingborg

During the second half of 19th century the city became industrialized with the result of a population growth and around the year 1900 the city had 24 670 inhabitants. This created a need of workers housing. The earlier undeveloped area south of the city centre had rapidly grown to become a neighbourhood for the working class, often overcrowded and with low standards. These workers largely worked in the new industrial area, the South harbour. The north part of the city was now to a large extent the living area for the wealthy citizens with a higher socioeconomic status. Today this segregation has to some extent persisted and clearly defines the city of Helsingborg from a socioeconomic perspective.

The current redevelopment named H+, stands for more than just changing the structure of the buildings and activities in them. The name stands for urban renewal with the purpose of connecting the north and south part into one city and thus builds off segregation. H+ can be compared with an integration project, by physical changes as well as by creating a psychological change among the city residents. The intent is to raise the image of the south part of the city and by overcoming both the physical as well as psychological barriers between the north and the south part. Although the municipality adopts a variety of methods, they see the physical changes as a way to speed up the process of achieving these goals. The results from the project 'South in change' has become the basis for the H+ vision, which is, that everyone should feel welcome, the area will offer housing, businesses, trades, leisure activities and meeting points.

During the year 2006 the city council made a decision to begin the planning process for the H+ area. Two years later the process took a new direction after a structured competition for the design of the area. The results from the competition have formed the basis for the later work of planning the redevelopment of the area. Before the juridical process concerning the planning of the H+ area there has been an extensive process of understanding the value creating capacity of the development project from a number of various stakeholder perspectives. It is during these periods' ideas, models and visions that later on will form the base for the performance of the planning process in terms of efficiency, cost and time.

Today the municipality owns 60 % of the properties in the area and the other 40 % is owned by business practitioners and developers. It is a clear trend that developers buy properties in the H+ area with expectations of future developments. The harbour area is built of infill lots and no one today knows the degree of the impurity and the extent of cleaning-up that is needed before any new development can start. First after this analysis is ended the clean-up process can begin. Another condition that has to be solved before the development of the H+ area can begin is the railway south of the city. Today the railway build a barrier between the south harbour area and the south parts of the city centre. A necessary prerequisite for the success of the H+ development is the construction of a railway tunnel to overcome this barrier. The development area is divided into seven smaller parts and the expansion scheme

between these parts is important for the attractiveness of them. An organic city growth will tried to be obtained and the construction process will start in the most attractive parts of the development area. A mixed urban fit is sought with a variety of housing, tenancy and ownership solutions together with variety of trades and businesses. The university is already located in the H+ area which is of strategic importance for the future of the H+ development, further the municipality hope that the university will be a help in improving the attitude of city residents towards the future H+ development. The construction of the railway tunnel is calculated to begin in 2012 and first after the tunnel is completed the development above the ground can take place. The first stage is calculated to 2016 and the whole H+ area will be completed in year 2035.

Project organisation

For the municipality to manage this type of large-scale urban redevelopment project, a separate project organisation has been formed with the purpose of managing the whole redevelopment project, including the construction of the railway tunnel. The project organisation is directly subordinate the municipal board as an independent department. One reason for the choice of project organisation is that the municipality's permanent urban planning department can maintain focus on other development projects in the city parallel to the H+ development. Otherwise, there is a risk that the majority of their efforts will focus on the largest project, in this case the H+ development. The project organisation´s tasks are stakeholder management, time planning and cost control while the urban planning administration stands for the juridical process in consultation with the project organisation. When a project organisation is established it is important not to create parallel organisations, everyone needs to know which tasks the different organisations have responsibility for. To avoid parallel organisation, in this case, workshops are organised once a year. During these workshops the previous year will be evaluated and the coming year´s work planned for. This approach is considered to be inspiring and developing for the ones involved in the project as well as a critical success factor for the project. However, at the end of day the outcome will largely depend upon the persons involved in the project.

Visions

The survival and development of the city of Helsingborg is one of the core values in the development process of H+. The municipality sees the development of the H+ area as self-preservation. Through the development of the H+ area, important values are created for the city and its residents. The city will attract new inhabitants and businesses and improve the academic and cultural image of the city. The values for the city residents are a more attractive city to live in addition to a participative urban redevelopment process with input from a variety of stakeholders. A significant driving force for the redevelopment is to decrease social and physical barriers and thus reduce the segregation between the north and south parts of the city centre. Through the development an opportunity for city growth opened-up, and the municipal also hope to increasing the number citizens with academic degrees, which is today below the average level in Sweden.

Communications

One important task for the H+ project organisation is the communication with the city to raise the awareness among its residents and businesses. The project organisation use different channels to reach out. Everything from social networks, competitions for children and students, exhibitions and a coffee shop in the area to attract visitors is conducted. The communication goals are both to attract future contractors and residents. Communication is core task in the project, dialogue and interaction with the city created the first vision for the

development and the communication will permeate the H+ project until the last contractor leave the area in year 2035. Completed stakeholder analysis shows that 60 % of the city residents knows and are positive to the city development of the H+ area. However, in the forthcoming implementation of the development project there will be a need for further stakeholder analysis on various levels of the project, in order to achieve a good base in the decision-making process.

DISCUSSION

Helsingborg is a city where the difference between the north and the south part of the city centre is strong and clearly defined by perceived socioeconomic status; this creates a mental line that strongly affects the city resident's image of the attractiveness inherited of different parts of the city. It will not become easy to change this image, but the redevelopment of the south part will be a good beginning in this process. Helsingborg is an attractive city but to make the city to become one united city which it is not today will raise the attraction even more. Also to change the city from a worker city to a more mixed city with both contractors and academic life will attract a larger public. Replacing industrial areas by the waterfront and replacing them with attractive housing and businesses is one step in this direction.

The idea about the redevelopment of the H+ area came originally from the residents in the south part of the city. The municipality and the project organisation claims that this is a project raised from the city residents and this atmosphere should influence the project during the whole process. The H+ project is a long going process there both informal and formal ideas have elaborated and been processed with the final aim to becoming an asset for the city and its residents. In accordance with arguments from Meen and Andrew (2004) and Graaf and Dewulf (2010), redevelopment of urban areas can be used as tool for attitude change. Here is H+ an example where the municipality of Helsingborg is trying to achieve this goal.

To maximise the outcome of the H+ redevelopment the municipality use the city residents' thoughts and ideas as a relevant input. This idea is in line with the thoughts of Clark, et.al (2010) about involving the population to arise an interest by the public for their own city. Seyong-Kyu (2001) highlights the importance for people to raise their voices to achieve changes in the urban environment. In the end if the city residents' are not satisfied with the outcome of an urban redevelopment the project cannot counts as successful. Olander and Landin (2005), Bourne and Walker (2005) and Olander (2007) mention various analysis and mapping techniques which can be useful to ensure that the city residents and the city businesses interests are taken in account throughout the redevelopment process and like Ward (2003) point out a high participation from the external stakeholders is of weight to ensure a successful outcome. They are the ones who in the future will be active and enjoy the redevelopment area so by embracing their opinions it can create the future value for the H+ area.

The municipality of Helsingborg has for a long period worked out a strategy to obtain the best possible outcome of the H+ project. The project carry so much more than just a redevelopment of an earlier industrial area. This project also represents the city´s future and survival. The project organisation responsible for the H+ development was formed to create a clear focus on project outcomes by coordinating questions raised by stakeholders, time schedules and cost control. To create an independent project organisation send signals to the surrounding environment that the project is relevant and important. By creating an

independent project organisation keeps, according to Kasvi, et. al., (2003), the knowledge alive and will enable opportunities for knowledge transfer between project stages throughout the life of the project. An urban redevelopment of this scale is an ongoing process for a long period in time and the people involved may change several times during this period. However, by implementing the project with a consistent organisation the possibility of knowledge stay in the organisation and hopefully enable knowledge transfer for forthcoming urban redevelopment projects, thus increasing the value of project outcomes and experiences. Kavi et al. (2003) also argues that the project result never can be better than the project team members. This emphasise the importance for the municipality to create a leading project organisation that has the ability to create interest and involvement both among the city residents and forthcoming property developers.

Today the redevelopment of the H+ area is in an early stage. Next step in the research will become to explore the developers point of view with the project and which the confidence they have. Are they already today making planes to be a part of the development and which are their visions with the H+ area? It is up to the future to show if the project organisation produces a successful process and also if the redevelopment of the H+ area will counts as successful. Relevant factors to study in the ongoing development process are the level of transparency and how the project organisation will succeed to create an interest by different stakeholders.

Abstract
The major subject of this paper is the actual situation of large infrastructure projects in Germany based on a literature review of experiences in this field all over the world. The results of a field study show that many clients and contractors are dissatisfied with the current situation and wish for a change. To start with this change a guideline for partnership between clients and contractors in infrastructure projects was developed at the chair of Project Management at the University of Kassel by working groups of practitioners and scientists. This guideline contains a preamble and seven elements referring to clear project specifications, defined processes for project changes, fair risk handling, common data systems, regulations for responsibilities and decisions, contractual alternative dispute solutions and contractual incentive regulations. At present this guideline is in the testing phase to improve it, if necessary, and to collect experiences for a possible binding implementation in infrastructure projects in Germany.

Keywords: Partnering, collaboration, cooperative contracting, incentive based project optimization

INTRODUCTION

All over the world the situation in large construction projects seems to be very similar. Many projects have a cost and time overflow and the relationship between client and contractor is not cooperative. The project participants often complain about too many disputes and litigations. The typical situation in the German construction and plant market and the market in other countries has been characterized by Girmscheid (2005), Ingram and Bennet (1997) and Spang (2009) as follows:

Dissatisfied clients and distrust between client and contractor/s

- Decrease of know-how due to “lowest price-principle”
- Increasing expenses for claim and anti claim management
- A growing number of disputes and litigations between clients and their contractors

- Low rate of return and high risk of business failure for contractors.

Starting from United Kingdom, the United States and Australia in the nineties various partnering and alliancing models for the relationship between the main parties have been developed in the last years. There are for example: the early contractor involvement in the UK, the alliance contracting in Australia or the construction management in the US to enumerate the most common ones. Changes towards more partnership between client and contractor can be seen, especially in the private sector. However, the international construction market is rather different in matters of market conditions, the legal situation and public authorisations. In Germany the situation is still not satisfying at all, especially in the field of public infrastructure sector. Even though many people wish a change it is however difficult to introduce fundamental changes in the relationship between client and contractors. The current legal situation in public tendering and public financing restricts the options of a change very much. This applies as well to the strict and very citizen related provisions for the legal authorizations for infrastructure projects in Germany (”plan approval”). In spite of these very challenging preconditions, a change of the client-contractor-relationship towards more partnership is necessary and without alternatives.

THE RESEARCH WORK

Initiated by the Chair of Project Management at the University of Kassel a group of researchers, practitioners and public clients started a research project towards partnering in infrastructure projects in 2005. The research is sponsored by the German Federal Ministry of Transport, various public clients, contractor organizations and several contractors. The principal target of the project was to develop a partnering model for public infrastructure projects respecting the specific conditions of public financed road and railway projects in Germany. Following this target the detailed project objectives were defined as:

- Reduction of conflicts
- Avoiding litigations
- Optimisation of the project in sense of value engineering
- Raising the level of efficiency and finally
- Reduction of construction time and saving of money

Literature review

A global literature review should show how large and complex infrastructure projects are managed in other countries. In the beginning of the nineties the situation in the British construction market was very similar to the current situation in Germany. Hence, “Her Majesty’s Stationery Office” assigned Sir Michael Latham to analyze the reasons for the dissatisfying situation. In his report “Constructing the team” (Latham 1994) he demands for a rethinking of the tendering system, to evaluate the contractor not only by price criteria but also by quality criteria. Beyond he demands to establish preconditions to achieve a win-win situation between client and contractor, to be managed through a partnering approach. Some years later Egan (1998) recommended in his report “Rethinking Construction” that the construction industry should use best practices from other industries and implement them in their processes.

Furthermore clients and contractors should work together to achieve a common goal. To reach these goal, he also demanded for a partnership between clients and contractors. Especially in complex projects with limited budget the traditional way of project handling seems to be insufficient (Sakal 2005). The idea of a new concept was born in the early nineties with the Andrew Project of the Oil and Gas Company BP. The project had so many uncertainties that the project success was not sure. For that, a new way of contracting had to be established. Contractors were now chosen not only by price criteria and the goals of the further project handling were fixed with a fair risk sharing between all parties, better and faster solution of conflicts without court processes and a pain and gain regulation for exceeding respectively failing the project targets. The outcome was the first form of an alliance contract, which leads to a satisfactory project for the client with savings of more than 20 % (Rooney 2006).

This good result was the impulse for the Australian construction market to adapt and to develop this way of contracting. In the meantime, until today, alliance contracts are used in Australia in the private and public sector more than anywhere else in the world (Ross 2009).

Bennett and Jayes (1998) identified three levels of partnering:

- First Generation Partnering – Project Partnering
- Second Generation Partnering – Strategic Partnering
- Third Generation Partnering – System Partnering

The distinction in three different levels of partnering is due to the sometimes difficult preconditions in creating a project atmosphere which allows a collaborative way of working. To reach higher levels of partnering is even harder. Tyler and Matthews (1996) and Black et al. (2000) analyzed these preconditions. Thereby they identified the following important elements, which have to be fulfilled: Trust, common goals, communication, defined problem resolution, clear understanding of roles, commitment from senior management and incentives.

Analyzing the benefits of partnering is a big challenge, because it is hard to define how the changes contributed to the improvements (Bresnen and Marshall 2000/a). Black et al. (2000) analyzed it by a survey in the construction industry. They identified the following benefits:

- Less adversarial relationship
- Increased customer satisfaction and better understanding of each other
- Improved time-scales, quality and reduced costs (improved return on resources)
- Risk sharing

Bresnen and Marshall (2000/b) analyzed nine partnering projects in the UK contracted in different ways like long-term agreements, project alliances or construction management contracts. They found a very high level of satisfaction of the parties not least because all projects were finished in time and did not exceed the planned costs. Pakala et al. (2007) compared various innovative partnering models all over the world and found similar results, such as higher client satisfaction, reduced time of construction and a better cost control. Chan et al. (2007) compared partnering practices between Australia and Hong Kong. They found that partnering leads to a stronger teamwork with more cooperation, which results in a better overall performance. Manley (2002) conducted an international survey of eight Australian and ten international road agencies. The general feedback concerning their partnering experiences was good, and most of them would like to extend their engagement in partnering projects.

The above mentioned results should not suggest that problems do not occur in partnering projects, there are examples for problems as well. In the nine projects, analyzed by Bresnen and

Marshall (2000/b), problems were solved without claims or litigations. Lu and Yan (2007) state that partnering is not always the master key to project success. It is necessary to evaluate for each project if partnering is applicable and useful.

The positive outcome of partnering can only be achieved by contributions from both parties but the benefits of this way of working will overweigh the efforts. It is really not satisfying, that reliable methods for evaluating the effect of partnering do not exist, but it is very difficult in respect of the uniqueness of projects in general. A research work in respect to this subject is in preparation at the University of Kassel.

Field Study

Based on the results of the literature review a field study about the relationship between clients and contractors in the German construction industry was initiated (Spang et al. 2009). Half of the 130 respondents were clients respectively contractors which allows a good comparison between the answers of clients and contractors. The study showed clearly, that clients and contractors rarely feel 'partnership' in their projects, that they do not feel comfortable with the current situation and that they mostly do not see one party as a winner, which will be described more precisely below.

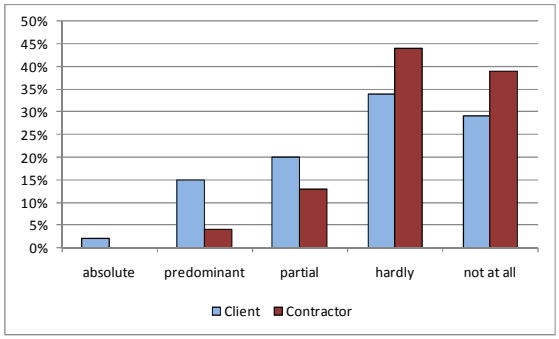

Figure 1: *Satisfaction with the current situation (Spang et al. 2009)*

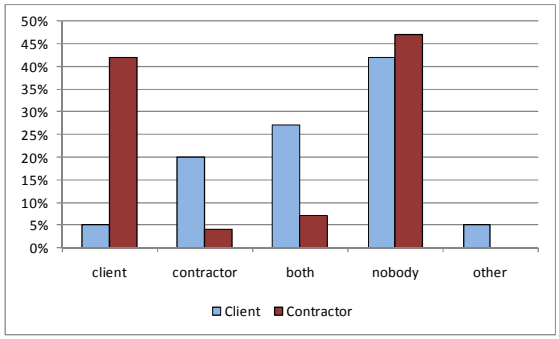

Figure 2: *Winner of the current situation (Spang et al. 2009)*

Figure 1 shows the results of the question "Are you satisfied with the current situation?" More than 80% of the contractors and more than 60% of the clients state that they are dissatisfied. Only 17% of the clients and 4% of the contractors are content with the current situation. In general the contractors are more dissatisfied with the current situation than the clients. This may be due to the strong public clients, which can impose conditions and prices to the contractors. This imbalance of power may be still amplified by the big numbers of companies in the German construction market.

The dissatisfaction of the clients may be based on the more and more intensive claim management of the contractors, which try to improve their insufficient price levels by this way. Most of the disputes and litigations are consequences of disagreements about the contract and about claims and a loss of trust.

Another reason for the dissatisfaction of both parties may be found in the answers to the question "Who is the winner of the current situation?" (Fig. 2). About 45% of all participants think that neither the client nor the contractor is the winner, whereat client and contractor have the same perception. About 42% of the contractors answered that the clients are the winners and - in contrast - just 20% of the clients see the contractors as winners. Only 7% of the contractors, but 27% of the clients see both parties as winners. But especially the benefit

for both parties, so called ‘win-win-situation’, is essential for working in partnership. Thus, a relationship, where so many participants see no winner or the other side as the winner, is not a reliable base for a successful project. The reasons for this situation may be based partly on the principle-agent-theory, but otherwise on the lack of common objectives and of accepting a win-win-situation.

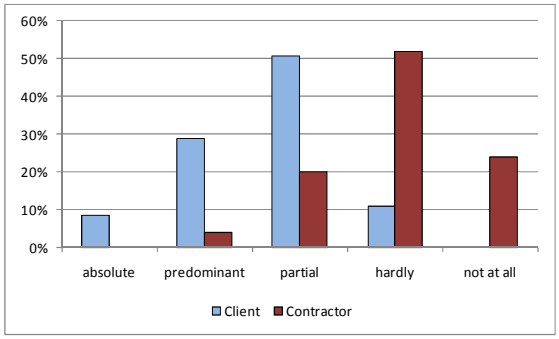

Figure 3: *Fair risk allocation (Spang et al. 2009)*

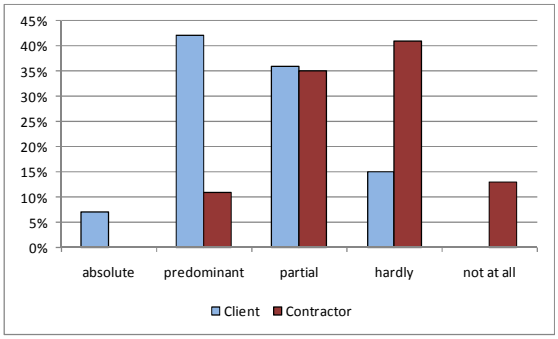

Figure 4: *Clearness of the contractually agreed scope (Spang et al. 2009)*

Further results can be seen in Figure 3 and Figure 4, where the answers of clients and contractors dispersed most, for example concerning the risk allocation. About 35% of the clients stated, that the risk allocation is at least predominantly fair. Another 50% see it partially fair. In contrast 75% of the contractors believe that the risk allocation is hardly fair or completely unfair. An explication for that might be that clients often try to shift all the risks to the contractors. This could be no problem for the contractors if they could consider the risks in their bid. But in the very competitive German construction market there is no space for the consideration of risks. Therefore contractors often are responsible for the risks without achieving a higher “risk-margin” or the risks are cached in the tender documents. The different point of view at the clients side my due to their mentioned strong position.

Concerning the clarity of the contractually agreed scope the distribution of the answers is similar. The majority of the clients believe that the contractually agreed scope is well described, while the majority of the contractors stated the opposite. The clients are convinced to have a perfect scope based on a design of high quality and the contractors see lacks and space of interpretations. There is no mutual understanding of the scope and this will be the initial point of most of the disturbances and disputes in the projects.

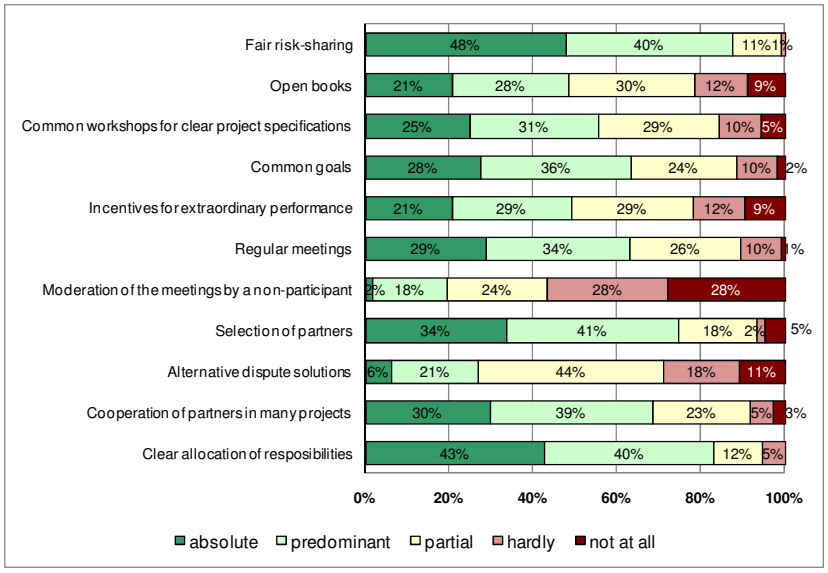

Figure 5: *Contribution to partnering (Spang et al. 2009)*

Furthermore the participants of the study were asked about possible contributions to partnering (see Figure 5). The given propositions have been deduced from the literature review. The results show that these facts are considered predominantly to be important for working collaboratively. Fair risk sharing and a clear allocation of responsibilities were mentioned to bring the most contribution to collaboration. In contrast, the participants state that moderation of the meetings by a non-participant and alternative dispute solutions are less important, but both are not really common in construction projects in Germany and so the benefits cannot be seen. Other elements, like common goals, common workshops or regular meetings contribute in a medium to high level to establish a collaborative work atmosphere. Cooperation in many projects and selection of partners seem to be well accepted, but they can not be used in public projects in Germany. In general, it must bee seen, that most of the participants did not have any experience in partnering projects.

In respect of the results of the study (more results will be found in Spang et. al., 2009) a clear wish for a change towards more fairness and partnership in construction projects ca be concluded.

The partnering guideline

The results of the field study and of the literature review were used for the development of the guideline, which will now be described.

With these results of the literature review and the filed study working groups were formed for specific topics, which are identically with the intended elements of the guideline. Each working group consisted of representatives of clients, contractors, lawyers and the chair of Project Management. Every group established one element of the guideline. The intermediate and final results have been discussed in workshops with higher representatives of the participating organizations and companies (“advisory board”). The final result of this process was the “Guideline for partnership between client and contractor in German infrastructure projects”. The guideline contains – starting with a preamble - seven elements. It contains regulations for clients and contractors for working together in partnership regarding the specific preconditions of public financed infrastructure projects in Germany.

Preamble:

The preamble aims for creating an environment that allows clients and contractors to work in partnership. To achieve this goal, basic principles like trust, willingness for cooperation and open communication are described. The preamble has to be signed by leading persons from both parties. The signatures shall be a sign for their willingness to follow the above mentioned facts and to follow the rules set in the guideline. Furthermore the companies will commit themselves to create a company culture which supports their employees to respect the guideline in their daily work. Clients and contractors should start the project with a leap of faith.

Element 1: Clear project specifications

As one result of the field study and the literature review it could be shown that a not well and comprehensively described scope is the main reason for disputes. Hence, element one provides regulations for the design-, the tendering- and the construction phase to enhance the quality of the project specifications. Special regulations for the pre qualification of the planner, exploring the subsoil and the design quality management are some examples of the suggested sub elements. Giving the contractor enough time during the tendering phase allows him to check all documents and ask questions, if necessary. Furthermore a site visit is compulsive during tendering in order to give all potential bidders the opportunity to take a look at the site and its environment, to point out possible problems and to ask questions

During the execution phase, it is advised to implement the conceptual designer in the team of the contractor to do the detailed design. If this is not possible, a minimum solution is to hire the conceptual designer as a consultant in the design-team of the constructor to guarantee a good know-how transfer from the design phase into the execution phase.

Beyond that special review workshops with representatives of the client and contractor are prescribed, which should help to learn from the project and in the project and to share knowledge not only in the own company but also between client and contractor. This knowledge can also be used to help to improve future projects, if it is introduced in a knowledge management.

Element 2: Defined processes for project changes

Even with a good scope quality, differences between the contractually scope and the necessary works will occur. Reasons may be irregularities in the underground and other site conditions, changes by the client or, which is unavoidable for complex construction projects, an incomplete design. To control this process it is necessary to have a defined model with clear and defined specifications. All stages which have to be passed in the change process are mentioned and described to specify “who has to do what in which way until when”. So, the responsible person, the action he has to do, the contents of his actions (like for example documents and its contents) and the time period are fixed in the process-model.

In the beginning of every project the time regulations have to be adjusted for the special circumstances. If these procedures are not respected by one party, the other party can relate to element six of the guideline to find a solution.

Element 3: Risk management

Infrastructure projects are, in addition to the common risks arising in every (construction-) project, fraught with many special risks like underground-uncertainties or high complexity. Hence, it is particularly necessary to identify the risks and establish a qualified risk handling process. Starting in the design phases all risks, identified and not completely cleared, have to be collected and described with their consequences in a risk register. This risk-register will be attached to the tender documents and the bidders have to complete it and implement the described risks in their offer. In the construction period client and contractor will meet in a fixed interval in a so called "risk-committee" to discuss the status of the collected risks, check if the handling of them has to be adjusted and to find out if there are any new risks. For the identified risks client and contractor together have to find ways how to handle the new risks and have to decide who is responsible for them.

Element 4: Common data

In big and complex projects many documents, drawings and information have to be used by both parties and exchanged between them. To handle this data-volume and to assure that everybody deals with the same, actual documents, a common project server with data, such as plans, documents, pictures and time schedules is installed. Moreover this data-server offers a platform for an open communication between the parties. This allows a faster and more comfortable handling of the project data. Thereby a double effort can be avoided and everybody uses the same documents and can be sure to use the newest version. There is access to the project data from everywhere. The common use of the data reduces the potential of conflicts.

Element 5: Regulations for decisions and authorizations

Many conflicts arise or grow up because of unclear responsibilities and late or wrong decisions. Sometimes staff members of the related parties do not have the entitlement to decide about a problem or the other party does not know the right contact person for their concern. For example only 40% of the participants of the above mentioned field study (Spang et al., 2009) state, that they clearly or at least predominantly know the right contact persons. That is why responsibilities and authorisations have to be clearly defined and clearly described in order to be able to take quick decisions, including client and contractor. Decision processes and standards for relevant documents are prescribed as well.

Element 6: Conflict solution

Conflicts or differing points of view are often arising in projects. If there are no quick and adequate solutions for these conflicts they may lead to a deterioration of the climate between client and contractor with a lower willingness to collaboration. Often the consequence of conflicts is a reduction of efficiency and additional works and costs. In the worst case a blockade of the project may occur as a consequence of missing decisions.

Hence conflicts should be solved as soon as possible. Especially disputes concerning money can take a long time or even end up in litigations. This is cost and time intensive and not suitable for the client contractor relationship. To handle and solve the conflicts as early as possible a stage model was created.

On the first, the operational level, the project managers of client and contractor try to find a solution for the conflict. If they don't succeed in a predefined, adequate time, every party has

the right to invoke the next level. On this strategic level, branch managers or managing directors (depends on the size of the organisation) of the two parties look for a solution of the problem. If they also do not find a solution the dispute will be given in an arbitration process. One or three arbitrators will start consultations with both parties in order to find a suitable solution. Subsequently they will formulate an arbitration award, which is binding for all parties until it is cancelled by a formal court decision. Going to court cannot be denied in Germany. Decisions by arbitrators are usually much faster and often cheaper than court decisions. Furthermore the defined process should influence the parties to find suitable solutions in the operational or the strategical level.

Element 7: Contractual incentive regulations

Generally the contractor has to realise the project as contracted. He is not motivated to find special solutions or to optimize the project with advantage for the client. But a project optimization or value engineering can often create a win-win situation for client and contractor – the client gets a better building or traffic line and the contractor gets physical advantages. In each case the chance for a common optimization creates often an atmosphere of trust.

In the first case, the contractor suggests a change or an improvement, with is equal to the contractual solution but cheaper. When he can prove the equivalency of his suggestion and the client agrees with it, he will participate in the savings in a contractual agreed proportion. This could be 50/50 but also 60/40 or 70/30. That means the contractor obtains a bonus and the client saves money for an adequate solution.

In the second case the contractor suggests an improvement with enhancing of the quality but without increasing the costs. When the suggestion is agreed between client and contractor and the target quality is reached, the contractor will get a bonus and the client gets a better work.

In the third case, the contractor finishes his work earlier than contractually agreed. In this case he will also get a bonus for the time of earlier finishing. So the contractor gets a bonus and the client finishes his project earlier.

All of these cases have to be agreed upon between the parties before execution. In each case the client must have an interest in this optimization. He must not accept the proposition; the contractor has no entitlement for the acceptance of his proposition. So, this incentive element has two effects. One is the project improvement for the client, combined with an additional revenue for the contractor, a real win-win situation. The second is the creation of an atmosphere of trust as a precondition for finding such win-win situations.

Du to the very strong boundary conditions for public financed infrastructure projects in Germany, the space for changes is restricted, so a “revolutionary step forward” was not possible. Some of the formulated specifications in the guideline are not new and do already exist in Germany. Others are new, at least for public financed infrastructure projects, as the common project reviews (element one), the common risk handling (element three), the common database (element four), the arbitration process (element six) and the incentive arrangement (element seven). Even when it is no revolution and the model goes not so far than models in other countries, this guideline may be the first step for a collaborative project management in large infrastructure project in Germany.

TESTING THE GUIDELINE

At present the research project is in its second phase – the testing phase of the guideline. During this phase the research results, fixed in the guideline shall be validated and the guideline is to be tested on its practicability. Thus the guideline is actually applied in two pilot projects. The first project is an upgrading of a highway from one lane in each direction to two lanes in central Germany. The whole site is 1 km long and has total investment costs of about 4m €. The project is just terminated. The second project is a construction of a new motorway in eastern Germany. It is about 8km long with total investment costs of ca. 45 mio €. The contractor consists of a consortium of three companies for the subsoil, bridge and pavement works, so there are more possible interactions between client and contractor. The project started in autumn 2009 and will be terminated in spring of 2012 due to a very hard and long winter period in 2010/2011. Further projects are in preparation.

To collect many information and experiences in applying the guideline, the chair of Project Management is strongly involved in these pilot projects. Thus the clients are strongly supported in terms of the guideline and all observations, results and particularities of the project are to be collected for the evaluation of the pilot phase.

The first findings of these two pilot projects are mostly positive and can be described as follows:

- More collaborative way of working together
- Open communication between client and contractor
- Fair risk allocation, no hidden risks
- Fast solving of problems without litigations
- Optimisation of the whole project (not only monetary, but also qualitative)
- Higher satisfaction of the participants, but also
- Backslides towards confrontative working from time to time,
- Upcoming mistrust because of violation of agreements
- "Bad prices" and "old" organisational structures obstruct the success of partnering.

The review workshops, which have been conducted in both projects, showed a big step towards partnering, because client and contractors participated commonly. The workshops showed as well, that there have been significant changes in the communication and in problem solving as well as in proactively risk handling towards partnering.

After finishing the research project, there will to be discussed, if the public authorities will prescribe this guideline as binding for specific infrastructure projects.

CONCLUSIONS

As shown above, the current situation in the German construction market is affected by dissatisfaction on both sides – client and contractor. Neither both, nor one of the parties is the 'winner' of the current situation. With the guideline a first step to a more collaborative way of working is achieved. The results of the testing phase with the adoption of the guideline in pilot projects has shown big progresses, but structural problems as well. As a result of the different workshops in both pilot projects, it could be seen that all elements of the guideline

act together in a way that the communication between client and contractor became more open and the atmosphere changed for the better. So far all problems could be solved either on the operational level or, in just a few cases, on the strategical level. Till today, the arbitrators have not been contacted. Element seven of the guideline contributed to savings of money for the client. Simultaneously the contractor got some extra money for his ideas. Another step forward to start working in a collaborative way.

Further pilot projects will show if this positive impact will continue. In this case there will be a good chance that the guideline will become a fixed standard for infrastructure projects in Germany.

Abstract
Today in many of our neighbouring countries 'working together in integrated project teams', using groupware and BIM, is the future way of process thinking in the building practice. Everyone is convinced that 'teams outperform individuals'! Especially when diverse skills, judgement and experiences can enhance the project's outcome.
This paper contains the first phase of a comparative study of IPD processes, ways of enhanced collaboration and communication between the different stakeholders in the supply chain of projects abroad, to solve the problems occurring in traditional construction processes used in Belgium. Before the search for solutions can start several questions need an answer first. 'Which types of building processes are being applied in Belgium today? From which problems do stakeholders suffer? Do all stakeholders understand the problems? Why do Belgians keep following these traditional processes? Are they already aware of the progress in innovative processes made in our neighbouring countries? Is there economical, professional, legal or political support for them?'

Keywords: innovation, collaboration, integration, comparative, Belgium

INTRODUCTION

This paper is written as a part of a PhD research. The first phase of this research contains an exploratory study to be able to clearly define the problems occurring in the traditional Belgian building processes. The aim of the PhD research is making a comparative study of diverse integrated building processes, ways of enhanced collaboration and communication between the different stakeholders in the supply chain of projects abroad, to solve the problems of the traditional construction processes at home.

RESEARCH QUESTION

Integration

Today in many of our neighbouring countries 'working together in integrated project teams', using groupware and BIM, is the future way of process thinking to achieve best practice in building. Everyone is convinced that 'teams outperform individuals'! (Wright, 2009) Especially when diverse skills, judgement and experiences can enhance the project's outcome. (Katzenbach, 1993) In the process of integrated project delivery (IPD) people, systems, business structures and practices are integrated into a process that collaboratively harnesses the talents and insights of all participants to optimize project results, increase value to the owner, reduce waste and maximize efficiency through all phases of design, fabrication and construction. (AIA, 2007) The integrated team has to be formed at the inception of the project. Next to the owner and the advising architect, the contractor is also involved from the first draft of the design on. He is often individually invited from the architect's former experiences. The contractor contributes through his knowledge of materials, details,

managing and timing the execution phase, and he advises the project team concerning technical and financial feasibility. This results in the best quality/cost combination for the project. There exists a continuous communication between all the team members, which will lead to improved learning, more informed decision making and increased effectiveness. The building information is non-stop shared through new ICT tools. Working intensively together will result in a lower cost, earlier delivery and higher quality within the scope agreed at the outset of the project. All team members will probably need to sacrifice a part of their own interests, they will have to make trade-offs to reach the overall goal of the project (Bovens, 2009a). Everyone has to share in the risks, through intensive meetings the uncertainties are defined and the best owner will be selected. At the same time they share in the profits as well, the better they work together, the more risks they can avoid or transfer, the greater the shared potential profits will be at the end. This is the ultimate way of stimulating ownership and commitment of all the stakeholders. Transparency among the partners involved is the key to success.

Tradition

Nevertheless building partners in Belgium stick to the traditional design-bid-build method, in which the responsibilities of assigning, designing and executing are strictly divided and follow each other chronologically (Bruggeman et al., 2010). In this way of procuring, lots of problems occur. Experience learns that every day, projects suffer from overruns in time and costs and perform under quality. The stakeholders can't cope with the new prescriptions in terms of sustainability, energy-efficiency and whole life performance. Poor communication between the stakeholders makes it all even worse. The more parties involved in the building process, the more information that gets lost during design and execution, the more risks occur. Mistrust is growing. Incentives to create involvement and ownership and to perform more efficiently are lacking.

A belief

All the positive elements of integration in construction processes cited above can never be part of exact science, it's more a belief. However it is interesting to examine whether this belief in integration could bring solutions for the problems encountered in the Belgian building processes. Before this search for solutions can start several questions need an answer first. 'Which types of building processes are being applied in Belgium today? From which problems do stakeholders suffer? Do all stakeholders understand the problems? Why do Belgians keep following these traditional processes? Are they already aware of the progress made in our neighbouring countries? Do they plan any action in the future? Is there economical, professional, legal or political support for the stakeholders involved in projects?' Subsequent to the questions concerning the Belgian situation being answered, this belief in integration abroad enquires for a critical view. What is stated in literature, 'Working in integrated project teams is necessary to achieve best practice!' (see paragraph 1) will need further investigation in a second phase of the PhD research to verify whether integration is already implemented in building practice abroad or is still only theory.

EXPLORATORY STUDY

To be able to clearly define the problems occurring in the Belgian building processes, two methodologies were applied. With the questions listed in the previous paragraph a questionnaire was drawn up to base interviews on among the different stakeholders in the construction process. Together with an analysis of the existing literature in Belgium on the

implemented processes today in construction, a clear picture of the organisation of building projects in Belgium is established.

Implemented processes

Traditional

The traditional building process of design, bid, build is still the overall used process in Belgium. In this building process the owner (customer or developer as representative of the end-users) has thoughts, needs and requirements concerning a project that he/she would like to execute on a certain site (Bruggeman et al., 2010). In Belgium an owner will begin by searching for an architect, to discuss his plans with, to get the brief of the project clear. Important in choosing an architect is selecting and appointing one, whose ideas or maybe already his/her first design meets in a substantial way with the outcomes the owner has in mind, this to spare time. When owner and architect have reached an agreement on the design, the architect can finish the drawings and prepares all the documents to acquire the building permission from the authorities. While waiting for the building permission to return the architect starts making a bill of quantities together with a description of the building specifications of the project. With these documents the procurement can start. General contractors can bid for the whole job or subcontractors are bidding for separate packages. After a certain period the bidding procedure will be finished and the offers can be compared (Van der Heyden, 2010). During the design phase the architect made several estimations of the building cost, based on studies he made or asked for, to assure the project is designed within the owner's budget. The contractor with the best quality/cost combination will be assigned for the project. When the building permission is delivered by the authorities, the execution on site can start. The architect will plan, manage and inspect the construction phase, because he will be partly responsible for the outcomes to be achieved within time, cost, quality and scope.

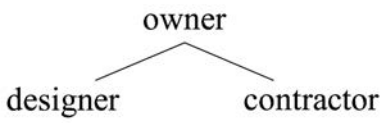

Figure 1: *contractual relations in traditional process as well as in building team in Belgium*

Building team

Working together in building team avoids the chronological fragmented organisation of the traditional building process and replaces it by a multidisciplinary coordination of design and execution (Breesch and Versele, 2009). All building professionals are involved from the very early beginning and contribute through sharing their knowledge on construction, this increases the buildability of the project. Risks and problems are detected by the multi professional team during the design phase, to avoid complications in execution It is a more integrated way of organising the building process, although abroad this building team model is still categorised as a variant of the traditional method (Wamelink et al. 2010). This because the sharing of risks and responsibilities, costs and profits of IPD, which generates optimal involvement, ownership and stimulates whole life cycle thinking is not incorporated in this model. The contractual relationships remain unchanged (fig.1), caused by the legal incompatibility in the relationship between architect and contractor and the deontological requirement of total independence of the architect at all times. (Art. 6 Architectenwet, 1939) All stakeholders are involved from the very beginning, the rest of the process remains equal

to the traditional process. Nevertheless using building teams proved their use already in several projects in Belgium, mainly in industrial and office buildings and residential projects.

Traditional versus building team
Verheyen (2009) states: 'traditional building is everything except a sustainable building process, after the project is executed we have to confess that every party's concern was achieving as much as possible its own interests, being the budget for the owner, the creative concept for the architect and the profit to be made for the contractor'. This is everything but what the integration thought requires. (see paragraph 1) Timing, costs, quality and scope should be shared interests! 'An ethical charter should be signed by all parties to outline the common goal of this temporary cooperation.'

From the chart Ceyssens (2008) drafted, it can be deduced that a 20% profit can be achieved in timing as well as in cost by working intensively together in building team compared to the traditional design-bid-build method.

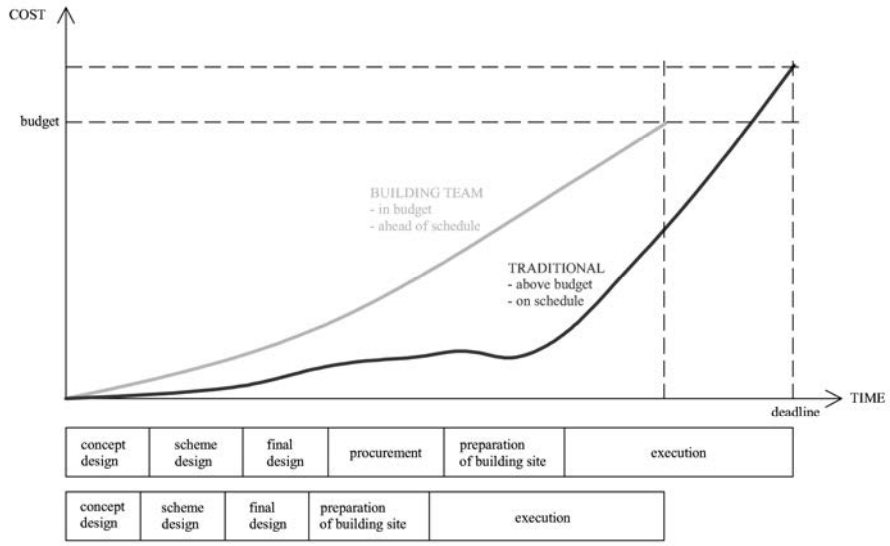

Figure 2: *traditional versus building team (Ceyssens,2008)*

Breesch and Versele (2009) argue that Belgium continues to work traditionally cause the building sector doesn't obtain any administrative or legal support for working in building team. There's an urgent need for a structured procedure together with a well thought through planning of this process. Parties continue working with unsuitable contracts of traditional building process, which of course creates disputes along the process. Bellens (2009) confirms that today parties apply the building team model by trial and error, there is a great deficiency of clearly formulated rules, manuals, standard contracts, documents, …

Knowing that this is only a small step into integration compared to what our neighbouring countries intend to implement, Belgium should be able to systematize this better.

Interviews to define the problem
The three main building partners included in the interviews will be the clients, the advising architects and the contractors. The group of clients can be divided in public authorities and institutions, private institutions, companies, developers and private owners. For the advising architects the attention can be drawn to all individual architects or architects offices. Together

with the Board of Architects (a legal authority in charge of defining the statement of ethics for architects and guarding whether Belgian architects comply with this code) and the two major professional organizations for architects, NAV and BVA, it's possible to get a entire view on how the problems of traditional building is encountered on the architects' side. On the contractors' side, two main federations the Confederatie Bouw (federation of Belgian contractors) and more specific the FABA (federation of Belgian general contractors) could be a guide to find interesting co-operators for the interviews. Knowing that this target group is to vast, aiming for a more narrow scope is a must, a selection need to be made to continue the research.

The target group was narrowed down from an architect's point of view. As an architect I experienced the traditional building process in practice myself, therefore a focus on the architects first seemed a reasonable next step. The purpose of the first interview with the chairman and director of the NAV (largest professional organization for architects) was to get a clear picture on which type of architects offices suffer from which problems in the Belgian building sector. And subsequently analysing whether these problems were caused by the traditional way of building. The list of problems was long, going from never been able to deliver a project within the budget or on schedule to the unfair obligation for the architect to take a ten year professional liability insurance for each project, compared to the contractors who don't have any legal obligation in this matter.

Size matters

NAV statistics show that the type of problem suffered depends on the size of the office. Offices of 1 to 3 people struggle the most with the fact that in small scale projects in Belgium there is ascertained that the owner's search for an architect is not because he needs his advice but because of the legal obligation to work with an architect to get a building permission from the authorities. Those owners are only looking for a signature for the least payment. This attitude decreases the value of the architect's profession (Bellens, 2009a), but was shaped by the Belgian architects' act of 1939 and still in use, that protects the title and profession of architects. This act describes the compulsory services of the architect, containing: making the design, delivering the plans and documents for the building permission and periodically inspecting the execution phase on site, what created a monopoly status for the architect in Belgium. These offices apply the traditional building process cause it still suits well for small scale projects. According to Van der Heyden (2010) working in building team is an investment in time and energy, this need to be in balance to the benefit possible to make. For offices between 5 and 10 people the major concern is that they are not big enough to be able to invest in retraining their staff into a multi professional team, they have difficulties in coping with all the new regulation that is written according to sustainability and whole life cycle costing, energy efficiency, safety, … The work package of the Belgian architect grew to a great velocity the last ten years. Creative designing only takes a small piece in the daily agenda of the architect, 52% of the architect's work package exists of administration. This, together with the increasing responsibilities and being the only building professional who is legally obliged to have a professional liability insurance, with the deep pocket approach as a consequence (owners will always try to involve the architect in construction disputes), leads to the following disturbing figures: 36,2% of Belgian architects consider a change of profession in 2009, compared to 25% in 2008! (NAV survey, 2009). The 'Wet Laruelle' (2006) encountered the heavy liability of a Belgian architect, what was called an explosive cocktail by Mrs. Body (2004), to some extent by offering architects the opportunity to practice their profession in a corporation with limited liability. But what still remains is that the owners are not aware of the overwhelmed work package of the architect, resulting in

difficulties in asking for extra remuneration. Informing the clients should be everyone's primary concern.

The search for the right focus group continued within the G30 (an association that represents recognized architects' offices in Belgium). The members of this association are the top of the Belgian building market, their portfolios comprise a great percentage of the major projects executed the last 15 years in Belgium. The main ideas that drive the G30 are: 'bringing together leading architecture firms in Belgium and represent them, promoting best practice in the field of architecture and urbanism towards clients and contributing to improve the conditions of practice of the profession in Belgium and Europe. Through the interviews within the G30 it became clear that these offices are ready to question the overall used traditional building process and are interested in the challenges of integration. Analysing their projects in the future will enable finding the right people on the clients' and contractors' side to meet.

Problem listing
As a result of the interviews a list of the most frequently occurring problems in construction projects according to the Belgian architect was drawn up. A division is made in problems caused by the fact projects appear through implementing a traditional building process and problems that don't have their roots in the traditional way of building but sure do have their influence on it.

Caused by traditional process
- Overruns in time and budget, underperformance in quality
- Low document quality for the bidding procedure
- Division in too many work packages > many bidding procedures > time consuming
- No transparency in cost/quality balance > fixed price
- No whole life cycle thinking
- Poor communication, no team work
- Low involvement > low ownership
- Risk averse attitude of everyone, no sharing in the risks
- Lack of trust and mistrust

Caused by other factors, but have consequences for the traditional process
- New regulations on sustainability, energy-efficiency, whole life cycle costing
- Heavy work package > lack in delegating
- Job hopping > project management changes > no relations of trust
- Unfair obligation of the professional liability insurance
- No ICT tools available at decent prices

The problems that returned in all interviews were the quality of the documents for the bidding procedure in traditional building processes. The scope and specifications of the project should be described enormously detailed for the contractor to understand every part of the construction, because he never saw the design before, this is time consuming. Alongside this the legislation concerning energy-efficiency and preserving the environment, and according to that the work package of the architect, is changing very quickly in Belgium. As a result the architect can almost not assure the owner that the documents delivered are complete. Secondly the architect often tries to shift some of the risks and responsibilities to the contractor by ordering special studies or research in the bidding, together with the construction contract becoming frequently fixed price, transparency in the prices disappears.

The contractor from his side is searching for the blanks or errors in the bidding documents, the selling unit of the different articles will go up and down depending on the commercial judgement of each contesting contractor, cause they can make profit out of it. They try to anticipate on the uncertainties of the studies made and the changes they expect the owner will ask for, e.g. articles which are likely to disappear will get a negative margin resulting in achieving a lower bidding price (Bovens, 2011). This created an enormous mistrust in the past up till now between clients and contractors. Clients experience the use of competition in the bidding procedure as the only way to ensure cost control. When it comes to choose between contractors, the client repeatedly decides to work with the cheapest one instead of the one with the best quality/cost combination. Finally a project is often divided in several work packages as: foundations, main construction, windows and doors, roof, finishing,… which means a bidding procedure for each individual package will be necessary. This takes much time in collecting and comparing prices, also in communication and managing during the building process. The more parties involved, the more information that can get lost during the execution, the more risks can occur. To conclude, there's often no existence of collaboration between the building partners. Which comprise the poor communication, the low involvement, the risk averse attitude, … This unhealthy building environment has to be taken on!

Heard from IPD?
The interviewees that had foreign projects before knew of the existence of integrated project delivery, but none of them ever implemented it. This isn't too strange knowing that for instance in the Netherlands and the UK the majority of projects are still constructed through the use of traditional building processes as well.

When considering public assignments in Belgium like PPP-projects, what should represent that all building partners work together in a temporary venture to design, build, finance and maintain a project, partnerships are never established, it is only of a structured way of collaborating. The public CBO-procedure (Constructieve Benadering Overheidsopdrachten) resembles the design & build method, but again doesn't mean that designer and contractor share the responsibility and risks of these projects. These models are restricted in use because of the monopoly status of the architect in Belgium and together with that, the prohibition of a cooperation between architect and contractor because of the potential conflict of interests that would occur. Meaning that the Belgian architect, as an adviser and representative of the owner, at all times has to preserve his incompatible relation with the contractor, cause he can't control and work together with the contractor at the same time.

Support?
To the question whether architects felt supported in their search for solutions to the problems they experience in their profession, the answer was disappointing. Although all Belgian architects are obliged to register at the Board of Architects to provide their services, you would think they will be represented by them, like in many other European countries. Unfortunately none of the interviewees could enumerate a positive experience. Nevertheless the Board of architects should have an important role in promoting the profession and informing the sector for instance on new, more integrated building processes.

CONCLUSIONS

From the search for the applied processes in Belgian construction projects, the problems of the traditional building process and the little progress made through implementing building teams, the following can be deduced: 'Belgian architects aren't aware of the positive elements of integration yet.' What they do realize is that the loads of problems in construction today, make it impossible to guarantee a project being delivered within time, budget, quality and scope. Through the interviews a clear checklist of the problems arising was made, some relate to the traditional building process, some have an influence on it. Although Verheyen (2009) stated that time, budget, quality and scope should be shared interest, new enhanced ways of collaborating will be necessary to achieve this goal.

FUTURE CHALLENGES

After this exploratory phase, where the problems of the traditional building process from an architects' point of view has been analysed and how those problems emerge in the Belgian construction market, time has come to go through some case studies on G30 projects, to get into contact with the other building partners. Once the picture on how everyone involved in construction encounters the problems of the traditional building process is tangible, looking for solutions in building processes applied in our neighbouring countries can commence. Figure 3 illustrates the future steps, where the research is heading for in the coming years.

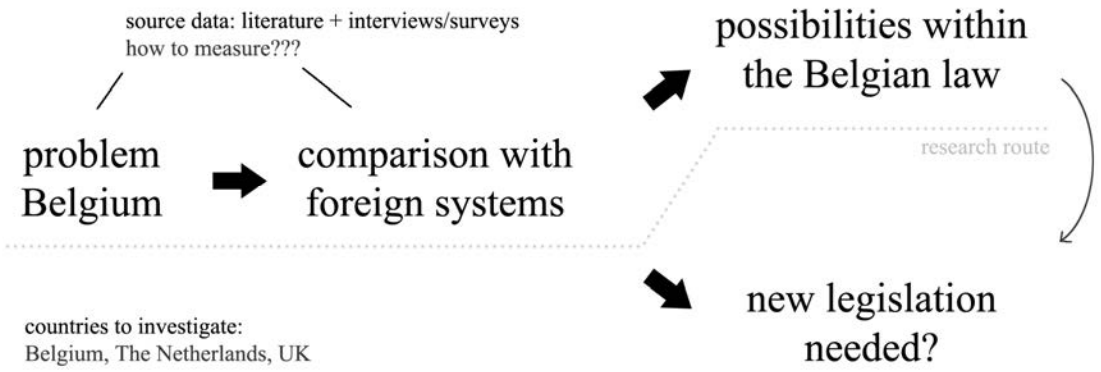

Figure 3: *Research route*

Comparison with foreign systems & possibilities within the Belgian law
Today integrated project delivery methods are used together with adjusted contracts to enhance the building processes in the Netherlands and the UK. They intensively use building teams, integrated contracts like design & build and turn-key, public private partnerships, alliances, SPE's, … The restriction of the monopoly status of the architect in Belgium together with preserving at all times his incompatible relation with the contractor will be considered first. The following questions will guide the research in the future: 'Which future perspectives can Belgium have? What kind of integrated methods are successful in our neighbouring countries? Are there any possibilities to implement them within the Belgian legislation or is a profound revision inevitable? Will an evolution be enough or is a real revolution to be expected? …'

STANDARDIZING KNOWLEDGE: A DIALECTIC VIEW ON ARCHITECTURAL KNOWLEDGE AND ITS MANAGERS

PERNILLA GLUCH
Construction Management, dept of Civil and Environmental Engineering, Chalmers University of Technology
e-mail: pernilla.gluch@chalmers.se

ABSTRACT
Many organizations within the construction industry are currently developing standardized practices. Increased standardization involves new ways of organizing construction projects, changing interrelations between professional groups, setting a new culture, i.e. challenging the institutionalized way of being. It, for instance, leads to a concentration of key knowledge into specific knowledge networks and artifacts. This in turn creates new and/or strengthened roles of expertise within the organizations leading to a reallocation of knowledge, as well as power, from the project setting to centrally organized functions, specialist consultancies and knowledge networks. Based on a case study of one Architect Company, this paper examines the tensions and paradoxes inherent in these 'new' roles. In the study, 13 persons were interviewed; actors responsible for changing practices, developing tools and ensuring learning among employees. The study contributes to theory building within a research field that examines the emergence of new roles and practices in construction and the contradictions which arise leading to tensions and possible conflict. Many of the assumptions that underlie these new practices run counter to the established norms and local practices as well as to construction practitioners' 'intuitions'.

Keywords: social practices, roles, knowledge management, standardization, construction process, architect company

INTRODUCTION

Many companies within the construction industry have today adopted strategies and procedures in order to operate in a more standardized and industrialized way. Knowledge Management related to standardized and industrialized building has been the focus of several recent studies. Most studies have focused on the procedural processes (eg. Höök and Stehn 2008, Koskela 2000) or ICT tools (eg. Persson et al 2009, Ekholm and Wiberg 2009). A few studies have had a more organization oriented perspective focusing on supply-chain relationships (Engström et al 2009a), quality control (Johnsson and Meiling 2009) and business barriers (Pan et al 2007). Conclusions are made that the industry's interest to adopt these new ways of building is still limited and suggestions are that to make it happen the project culture must change (Höök and Stehn 2008, Roy et al 2003), the client's power need to be strengthened (Engström et al 2009b) or peoples' perceptions on industrialized building need to change (Pan et al 2007). However, few have thoroughly studied these aspects. So far, much research has been 'trapped' within the theoretical frame of 'rational selection' and/or 'tool production' and thus not addressing on-going social processes related to standardization.

Increased standardization implies that strategic long-term decisions are embedded in the products and processes. This involves new ways of organizing a project, changing

interrelations between professional groups, setting a new culture, i.e. challenging the institutionalized way of being (Styhre 2009). It, for instance, leads to a concentration of key knowledge and expertise into specific knowledge networks and artifacts, such as technical platforms (Styhre and Gluch 2010) and ICT models. This in turn create new and/or strengthened professional roles of expertise within the organizations, such as production specialists, technical specialists, and BIM experts who possess knowledge that previously was to a great degree part of the professional role of an experienced project manager. This change leads to a reallocation of knowledge, as well as power, from the project setting and project manager to centrally organized functions, specialist consultancies and knowledge networks. However, results from a study of knowledge management in the construction industry (Johansson 2010) reveal that this change is not easily made. In fact it shows that individuals often mistrust the validity of the knowledge provided by experts and other professional groups. Consequently, if experts wield their power through their knowledge advantage it is perceived by practitioners as a possible threat towards the project manager's traditional role as site leader and as a disruption of institutionalized order within project practice and met with resistance (Gluch 2009).

Based on evidence from a case study of one architect company, and by taking on a dialectical perspective, on knowledge and its management (Benson, 1977; Zeitz, 1980; Seo and Creed, 2002; Omanović, 2009), this paper make an attempt to uncover paradoxes and contradictions that arise due to the ongoing change towards a higher degree of standardization in the construction industry.

THEORETICHAL APPROACH: A DIALECTICAL PERSPECTIVE ON KNOWLEDGE AND ITS MANAGEMENT

A dialectical perspective on organization views it as a multileveled phenomenon connected with contradictions that continuously challenge its existence (Benson, 1977). A dialectical perspective is thus strongly connected to the concept of on-going organizing processes, where organizations are constantly subject to change and where people continuously construct their social world. This means that the way an organization develops depends on the interests of actors and upon their ability to shape and maintain a social form. As such a dialectical model of an organization involves power and resource relations in organizational networks (Zeitz, 1980). A dialectical analysis therefore entails a search for accountants for the emergence of specific social situations. For management studies this means placing the process through which organisational arrangements are produced and maintained in the centre of analysis. It also aims at discovering ideas that are contradictory. Benson (1977) proposes four principles for a dialectical analysis: social construction, totality (context), contradictions, and praxis. It has been suggested that none of the four principles can be understood separately since they are intertwined and provide an overall perspective on social arrangements (Seo and Creed, 2002).

In this paper the first principle concerns how professional knowledge is *socially constructed* in the construction industry. This construction is influenced by actors involved in the social process of developing various ideas (Omanović, 2009). Here, human interaction, social patterns and a set of institutional arrangements are built, modified and eventually replaced. More, relationships are formed, roles are created and institutions are built (Benson, 1977). Human interaction is directed by people's interests and power (Seo and Creed, 2002) which makes these interesting to uncover in a study of knowledge and its management.

Knowledge is embedded in specific social contexts shaped by individuals taking part in this context (Fernie et al, 2003). The second principle in this paper therefore concerns how knowledge and its management are shaped by the *social context* where it occurs. Examining social context related to knowledge and its management entails linking structural networks of involved actors in their individual setting as they relate to one another and to a larger social environment. Seeing standardized knowledge and its management as part of a whole rather than an isolated phenomenon, includes studying not only new and emerging social arrangements, such as a more standardized way to manage knowledge, but also relating it to established and institutionalized social arrangements.

The third principle, *contradictions*, refers to various inconsistencies both among and within established social arrangements (Seo and Creed, 2002). Causing tensions and conflict within and across social systems, contradictions are in theory seen as possible forces of organizational change (Benson, 1977; Ceo and Creed, 2002). The direction is however dependent on human action and practice where contradictions and inconsistencies may be used to facilitate new thinking (Foldy, 2006). Thus, identifying tensions in the process of standardizing knowledge in construction may uncover change agents as well as identifying actions for change.

The forth principle of *praxis* incorporates aspects related to agency and structure in organizations. Benson (1977) uses the word praxis in the sense of a collective human action and mediating mechanism between contradictions and change. The perspective helps understand how interaction between actors, structures and artifacts forms identities and roles in a specific organizational setting (Lindgren and Packendorf 2007, Gerhardi and Nicolini 2002, Orlikowski 2002). Here this means exploring roles, interrelations and power positions of various actors in the context of increased standardization and knowledge management in construction projects.

METHOD AND CASE DESCRIPTION

The present study is based on a case study methodology of one Swedish company within the construction industry; *Alpha*. One of the principal interests of the study was to understand which instituted arenas and practices for knowledge sharing were used in the studied companies. The centre of analysis has been the process through which knowledge management practices are produced and maintained in an organisation.

Alpha, a major Scandinavian architect firm, is a nationally renowned and a prestigious firm attracting some of the most skilled and creative architects, interior designers, lighting designers, designers, and engineers in Scandinavia. Alpha works in a wide variety of areas, including housing, health care buildings, schools, landscape design and architecture, furniture design, and interior design. The company was founded in the early 1950s and has grown both organically and through mergers and acquisitions, today being one of the largest architectural firms in Scandinavia. The firm employs 500 co-workers in 10 offices. In the spring of 2008, thirteen interviews were carried out with relevant actors; such as practicing architects, interior designers, and designers.

The interviews were conducted by two senior researchers and structured in accordance with a semi-structured interview guide, lasting for about one hour and being tape-recorded. All the

interviews were conducted at the company office. During the interviews, the interviewees were asked to tell about their day-to-day work, what they were working on at present, how they regarded their profession, what kind of media they were using, and what they thought was most rewarding in their day-to-day work. In general, the interview guide was structured so as to pave the way for detailed discussion about the day-to-day practices of their professional work. The interviewees were asked about the their own professional biographies and careers, their work procedures, their preferences and beliefs regarding a range of work practices, and were encouraged to critically reflect upon their own work procedures and experiences.

All interviews were transcribed verbatim. The transcribed interview material was examined and analyzed by the two researchers individually. The analysis of the interview transcripts focused on the ways in which the different actors constructed their social world in their narratives. Key words, phrases and concepts were extracted, compared and contrasted. Representative extracts were then selected to construct the narratives represented in quotes used to illustrate specific phenomenon related to knowledge management practice. All the interviews were conducted in Swedish and thus translated into English.

STANDARDIZING KNOWLEDGE: A STORY OF BUILT-IN CONTRADICTIONS

Alpha has established a medium which they refer to as *The Knowledge Construction* (KC). KC consists of extensive networks active throughout the whole company. KC is supposed to work as a meeting place with no geographical boundaries. One major aim with KC is to make use of, bring together and promote all knowledge, skills and wealth of ideas possessed by Alpha's employees. Although open for all employees KC is govern by a set of employees assigned as *knowledge masters*. Besides leading an assigned field of expertise within KC, the *masters* are also responsible to maintain the corporate intranet. The master's are assigned this function as a side-task to their regular consultancy work. Although it varies between different masters and over time, they spent about half-a-day per week working within KC.

KC is divided into various expertise areas, for example sustainable building, ICT, public buildings, landscape, and interior design. Each master is responsible for the activities within each field of expertise. Based on personal and/or professional interest the employees can freely choose which network(s) they like to join. They can also decide to not participate in any. Although the utilization may vary there is a standardized set of activities that should be carried out within each field of expertise. These activities may be conducted internally or together with clients and partners in order to highlight relevant topics. KC has a system to arrange various activities, such as seminars, workshops and study trips. More, internal education and network meetings are arranged within the frame of the network as well as an online discussion forum. KC also supports the organization with reference documents and other 'inspirational artifacts' (checklists, texts, photos, presentations, links etc). The interviews showed that KC has a general support from the employees and, which is exemplified by the following quote:

> *KC is very important for Alpha, one of this company's strengths is that top management allocates resources on a more systematized sharing of knowledge. The industry is rather changeable and being involved in the early phases you have to sense which direction it may take.*

Contradiction 1: Masculine individualism versus a collective interest

That knowledge and knowledge sharing is an important resource for an architect company is thus evident but the interviewees had difficulties in framing what 'architectural' knowledge actually is. As professional group architects are traditionally generally located between the artistic and aesthetic fields and the engineering sciences, described as a hybrid by the following architect.

> *The role as architect is a bit peculiar; it combines the technical with the artistic, the technical side of this role possesses a more verified knowledge while the artistic side possesses a more intuitive knowledge.*

So besides their distinct architect skills and competences they are also expected to understand technical aspects as well as taking account of the demands and expectations of a wide range of stakeholders including clients and end-users. This scattered competence makes it difficult to know what should be systematized in the KC, or as one of the knowledge masters expresses it:

> *It is difficult to systematize architectural knowledge: what is it exactly? As architects we still struggle to define it, what kind of expertise knowledge do we possess actually? It is difficult to tie individuals' tacit knowledge and articulate this in seminars and discussions.*

Here, the KC network was partly working as a mean in the process of constructing what architectural knowledge is. One of the interviewees said that within the KC "we become conscious about what we do and what we see, placing wordings on our aesthetic preferences". Another said that "during these discussions I get ideas that I normally do not have time to think of. These I can 'save' for later use' ". And one of the masters said that taking an active part in the KC network forces her to "step outside my regular role and think: 'What do we want to do?' Where are we going?' ".

What complicates the framing process of architectural knowledge is the existence of a dominant view of what 'good architecture' is and what the 'right' architectural vocabulary is. The right architecture is today, according to the interviewees, a masculine view that is "taught the very first semester in architecture school, and thereafter becomes habitudinal". Considering that the world are changing we can here see a tension between two social processes that influences the role of architects, the drive towards a collective ability to handle holistic societal demands through a more systematized sharing of knowledge and the individual and masculine force to build 'good' architecture according to institutionalized norms. As a consequence some employees feel uncertain of his/her architectural preferences "when you no longer know what you believe in anymore" and/or become sidestepped due to conflicting professional interests which the following quote by a master within the environmental knowledge network illustrates:

> *They [the architects and building engineers] lack genuine interest in my expertise area; ... Therefore it is very difficult for me to learn them anything.*

The above reasoning illustrates how 'standardizing' of knowledge in this company is a social construct influenced by self-interest and traditional preconceptions of the social world. For Alpha it was clearly important to maintain the opportunities to engage their employees in the process of constructing architectural knowledge.

Contradiction 2: Stereotyped copycats opposing conformity

Within the social world, the context, there are contradictions related to the architect role. The interviewees revealed a frustration of being torn between the idealistic innovative and creative person and the stereotypical copycat. Or as expressed by the following two architects:

> *We need to stretch the boundaries a bit more, learn from other countries, in some offices in Europe it is not unusual to have about 20 nationalities in one office, here we think alike, come from the same school, has similar ideas, belong to the same networks, reads the same magazines, like the same things…*

On the same topic another architect with 22 years of experience says:

> *Over time I have become the weary architect which I mocked when I was 25.*

Although aware of this autonomous stereotyping of their role and the outcome from their work, or maybe in spite of it, there seem to be an self-assumed attitude among the interviewed architects to oppose conformity in other contexts, for example when adopting management systems and work routines. One of the more experienced architects says:

> *Creating a collective stock of knowledge is a linchpin in our office. We are convinced that we perform better together than each one individually…. [however] we have a hard time keeping up routines… we are a typical kind of organization that has difficulties in maintaining things… We lash out if it becomes too squared and institutionalized… we have to balance between a more standardized knowledge available in systems and databases and our curiosity. Otherwise we will dig our own grave and become deadly boring.*

The more standardized and systematically way to work, as prescribed by KC, is conforming to the way the employees believe is the most efficient way to work with regard to the product to be delivered, but is simultaneously conflicting with the attitude regarding the 'curious' architect.

Contradiction 3: Cross-fertilization of like-minded

To maintain business Alpha has, according to one interviewed head manager, chosen to strategically market the company as "a company that possess expertise knowledge within a range of areas". As such Alpha offer a broader but also a more specialized service, encompassing architects with focused expertise areas, such as school buildings, infrastructure, lighting, hospitals etc, as well as experts from other professional expertise areas, such as energy experts, project managers, ICT engineers. The interviews reveal that this change causes a professional identity conflict among the architects, moving away from the traditional role as the generalist that "knows everything when it comes to building a house". This strategic change involves, with KC as an intended motor, making people with various professional background but common expertise interest, meet in a more systematic way. This idea is met differently by the employees. One team manager supports the idea although the outcome from it may, according to him, be disputed. He says:

> *Top management has an outspoken strategy to cross-fertilize between different professional groupings… I encourage that my team members also work in other teams*

than my… Sometimes it gets nowhere but you have put something to stake to go beyond the predictable.

Another senior architect is of a similar view and addresses a challenge of un-locking professional barriers within the organization. She says:

One challenge is to get to that different professional groupings benefit and spur each other, and not locking-in each other in predefined boxes.

However, a contradiction to this determination to cooperate and exchange over professional and organisational boarders is that many of the interviewed also emphasise the effectiveness inherent in teams that share a long common history. Talking about a shared and intuitive collective knowledge and reference frame and the necessity of "having a professional home base" contradicts to the idea of KC. More, educational background was found to serve as basis for a very distinct grouping of employees within the company. The development of KC as a mean to share knowledge more systematically is in Alpha also obstructed by an existing and dominating culture of 'learn-by-doing and seeing'. Listening and reading, which are cornerstones in the KC framework, is not considered as ways to learn. One of the interviewed architects says: "...the most important knowledge sharing happen when you work together, not when you just listen... I learn by confronting people face to face." More, a strong individualism and prestige-mindedness were forwarded by the interviewees as a hinder for knowledge sharing. The interviews indicate that this attitude is nurtured and driven by the project based organising, where a strict economical project frame only "cover 'you' and your personal interest".

This final remark from one of the interviewees is summing up the main essence of KC and standardized knowledge sharing in Alpha illustrating the paradox of 'no matter how 'good' a system is, it is never better than the user':

KC is a great initiative; not very many architectural companies' have such an organized knowledge network to rely on. But I am quit bad using the opportunities given within it.

DISCUSSION AND CONCLUSIONS

By adopting a dialectical perspective on knowledge and its management focus of this paper has been to create a wider understanding of how architectural work practice, knowledge and context relate to the ongoing change towards a more standardized way of knowing what to do in the company. By focusing on these aspects a number of paradoxes and contradictions have been uncovered. The following discussion will be out of the perspective of contradictions as a possible force of change.

The KC idea of a more systematic knowledge sharing and the creation of a collective knowledge base and mind, were found to conflict with the institutionalized embedded perception of 'good' architecture and practice among the employees. The characteristic of 'good' architecture, as well as practice, was: *individualistic* with a practice where curious and independent creativity is favored, *masculine* with a practice inspired by male 'star' architects as role models and, *competitive and prestigious* with a culture where winning architect competitions and large contracts give credibility leading to a successful career. This

individualistic view on architect practice was further nurtured by the temporary 'bracketing' (Kreiner, 1995) of construction projects, which frame the individuals' performance in relation to short-term project goals and not the long-term objectives of the company. The collectively standardized and systematically way to work, as prescribed by KC, was nevertheless found to have support within the organisation as it conformed with the way the employees believed was the way forward towards a more efficient way to work. Simultaneously it conflicted with this attitude regarding the 'successful' architect and 'good architectural practice. In addition, the company's strategy to provide broader but more specialized service lead to shifting roles, from the traditional generalist to specialist within a targeted expertise area. In Alpha today this conflict between perceptions of architectural preferences and 'good' practices creates an identity crisis among the employees, with employees not knowing what they are and what they stand for. They wished to be innovative and creative but found them self as adaptable copycats. A stressful awareness of a present on-going process leading to a more stereotyped architect role and architecture with the risk of losing professional authority, led to that many chose to oppose conformity in situations where they were in control of their decisions, for example to not fully adopt management systems and standardized work routines.

The standardization of knowledge sharing in Alpha, by the means of the KC network, did however facilitate a continuous process of constructing what architectural knowledge is. Thus, various and sometimes conflicting views became more evident when people met leading to a reconsideration regarding one's habitual architectural practice. Participating in KC activities also permitted stepping out of their regular role which allowed them time to reflect, time seldom available in a time pressed consultancy life. However, the main basis for entering to a specific KC group was personal and/or professional interest. This might lead to that the group will consist of like-minded and even like-minded already belonging to previously established personal networks. Consequently there is a risk that KC fails creating the cross-fertilization of various professional groupings as hoped for, and instead creates sub-groupings of like-minded with a previous common history. It is therefore very important to maintain, and even enhance, the opportunities to engage within the KC network, so that a viable process of constructing modern architectural knowledge and practice is stimulated. Thus, provide a place where employees can reflect upon aspects that lie outside the every-day work. Preconceptions will be challenged, eventually leading to change. So, if the company wishes to change into the multi-professional company they constantly need to confront the reigning institutional norms of 'good' architecture and architectural practice. The KC framework show good potential in serving as mean for this change process.

In conclusion, the attempt to standardize knowledge and knowledge exchange within the KC frame in Alpha together with an attempt to broaden their market share could mean shifting from being a specialist company with hybrid employees to a hybrid company with specialized employees. Rightly used the KC could provide an opportunity to cross-fertilize professional knowledge within the organisation and also un-lock professional barriers. However, more standardized practices as well as more defined and specialized roles contradict with the current perception of what an architect is and know which resulted in that KC only existed on the periphery of regular work.

From this study it can be concluded that 'standardizing' of knowledge is a social construct influenced by self-interest and traditional preconceptions of the social world. In line with conclusions made by Fernie et al (2003) it is therefore important to consider that for a more systematic, 'standardized', knowledge sharing between organizational entities, professional groupings and individual professionals, it is necessary to facilitate a dialectic debate within

the organizations. By uncovering dominant ideas and interests in the process of standardizing knowledge the results from present study can serve as a starting point for such a discussion.

This paper should be seen as a setup for a continuing research project ending in 2013. The objective of the research is to stimulate and support development in the studied organizations (one construction company, one architect company and one prefabrication manufacturer) but also to visualise and raise knowledge and understanding concerning biases and consequences from changes made in each organisation. This means identifying opportunities and arenas where parties can share and adjust beliefs and values so that mutual knowledge sharing can take place. I also mean bridging different interrelating theoretical and practical perspectives of technology, ICT, organizational theory and psychology.

Abstract
The management of urban development projects in the Netherlands has changed significantly in recent years. These projects have become mainly 'led' by developers as they manage the entire life cycle of development projects, while public actors mainly facilitate development projects. This changes the way projects are organized and managed and might resolve in different outcomes. Therefore, this research aims at understanding the roles of public and private actors in private sector-led urban development projects and aims at determining the effects of their cooperation by conducting empirical research in different contexts. This paper provides a method for academic scholars to study the management of urban development projects, as management has been underestimated in theory as a way to influence project outcomes. A conceptual steering model is introduced which provides opportunities to describe, analyze and compare complex urban development cases. Furthermore, empirical findings from case studies in the Netherlands and England are presented and compared with each other to indicate how the conceptual model can be used.

Keywords: Conceptual Steering Model, Management, Urban Development, Method, Cases

INTRODUCTION

The way public and private actors influence the outcome of urban development projects has changed fundamentally in the last decade. By adopting more neoliberal principles throughout the European continent and subsequently Dutch society and spatial planning, the private sector gradually gained more influence over development projects. Daamen (2010) argues that 'governments have found themselves not above but between the other actors concerned, signifying a definite shift in their power to enforce and regulate particular land-uses and planning activities.' Thus, private actors, civic groups and public bodies have all become participants in the process of improving the way land is being used and developed.

It is increasingly acknowledged that this shift also affects the roles, relationships and management opportunities of public and private actors in urban projects. These projects have increasingly become 'private sector-led' as developers apply all sorts of management activities in the entire life cycle of development projects. Public actors mainly facilitate these projects by using public management tools to influence project outcomes. In this regard, Adams & Tiesdell (2010) argue that planners could be more conscious about their role as they already operate in the interest of market actors. In their view public bodies heavily rely on market investment, with the result that planners should effectively use tools at their disposal to implement public planning policies through projects. Thus, boundaries between what is 'state' and what is 'market' evaporate as both actors have become dependent on each other to develop cities and urban areas. It doesn't really matter who is who, but how planning can be implemented, or projects can be influenced.

In addition to this trend, many authors (De Zeeuw, 2007; Van Rooy, 2009) argue that Dutch urban development practice is characterized by a growing sense of ineffectiveness and inefficiency. They argue that legal and organizational arrangements could assist in solving the implementation problem. However, Van Aken (2004) and Klijn (2008) argue that it is often the actors' management of projects which makes a difference in achieving successful outcomes of projects. Nevertheless, the management of urban projects often has been overlooked in academic literature as a way to realize public and private objectives. Therefore, we focus our research on how actors can influence the outcomes of private sector-led urban development projects. Here, we use the steering paradigm applied by De Leeuw (2002) to the business management domain, which sees management as 'any form of influencing'. This is further explained in the conceptual model section.

Thus, the problem of the research is that there is limited scientific and practical understanding about how public and private actors cooperate within private sector-led urban development projects. Therefore, the research objective is to analyze organizational and managerial roles of public and private actors on a project level with the aim to design conceptual roles of public and private actors in Dutch urban development practice. Than, the main question the research tries to answer is: *what are the preferable roles of public and private actors cooperating in private sector-led urban development projects in the Netherlands?* In this paper a conceptual model is introduced that enables us to analyze these development projects, followed by the empirical findings from Dutch and English private sector-led projects. Finally, we compare and draw lessons from these practices.

THEORETICAL BACKGROUND

In order to answer the research question above, we need a conceptual model. For this research we developed a *conceptual steering model based upon the systems approach*. According to Arbnor & Bjerke (1997) the systems approach is characterized by a way to view (part of) reality as being a system. We use the systems approach to understand the mechanisms underlying the cooperation of public and private actors in order to design roles for public and private actors cooperating in private sector-led urban development projects.

Management based on the Systems Approach

De Leeuw (2002) has applied the systems approach to the field of business administration. This approach is suitable for studying urban development projects as well as this is also a goal-oriented interaction-driven discipline where actors intend to achieve individual and common goals by collaborating in urban development projects. Here we emphasize that the model is used at a project level which forms the subject of study. Hence, we are not interested in describing the complex and dynamic nature of urban development. We aim at understanding the cooperative mechanisms that take place on a project level but recognize that this is influenced by a complicated set of factors and conditions. Furthermore, by using such a structured device we are able to systematically analyze and design actor's roles within urban development projects. Thus, the model provides opportunities to prescribe solutions for problems as insight is given into relevant mechanisms underlying these problems.

Here, we must explain our view of management within the systems approach which builds upon a *steering paradigm*. Steering according to De Leeuw (2002) is defined as 'any form of direct influencing'. A steering paradigm than is a 'collection of concepts of thought about

steering and the way these can be used to make representations and models for analysis and design.' This view on steering is based on some key principles. First of all, De Leeuw distinguishes three important dimensions in steering projects; uncertainty, unpredictability and ambiguity. These dimensions are also present in urban development projects and need to be dealt with in an accurate way which depends on the changing conditions and aims of projects in specific contexts. Secondly, De Leeuw (2002) supports the contingency theory as he states that: 'There is no universally effective way of managing, the appropriate way to manage is dependent on the circumstances'. Van Aken (2002) also argues that the actual management of projects is not the objective of academic management research as this is the domain of practitioners. Academic research should try to develop useful products and models to analyze and design conceptual 'exemplars for implementation'. Finally, steering is based on three dominant aspects of managing projects; achieving objectives with people, steering a course, and problem solving and designing solutions. This is in line with our research aim.

Conceptual Steering Model

For this research we use a *conceptual steering model* based upon the *systems approach* which is represented in Figure 1. In order to understand this model some key principles need to be elaborated. First, the project *context* represents the different levels of surroundings a certain empirical object of study is part of, a context that is often subject to change. Applied to the domain of urban development the project's context for example exists of spatial policies or economical circumstances which are viewed as conditions for the way urban development projects can be organized. Second, the *organizational system* represents different aggregation levels of organizational structures, formal and informal partnerships, relationships and roles. Applied to the domain of urban development this organizational system consists of actors and the way they organize the public-private cooperation of a project. Third, the *processing system* is the subject of study. In our case this is an urban development process that needs to be managed by actors who organized themselves in an organizational system.

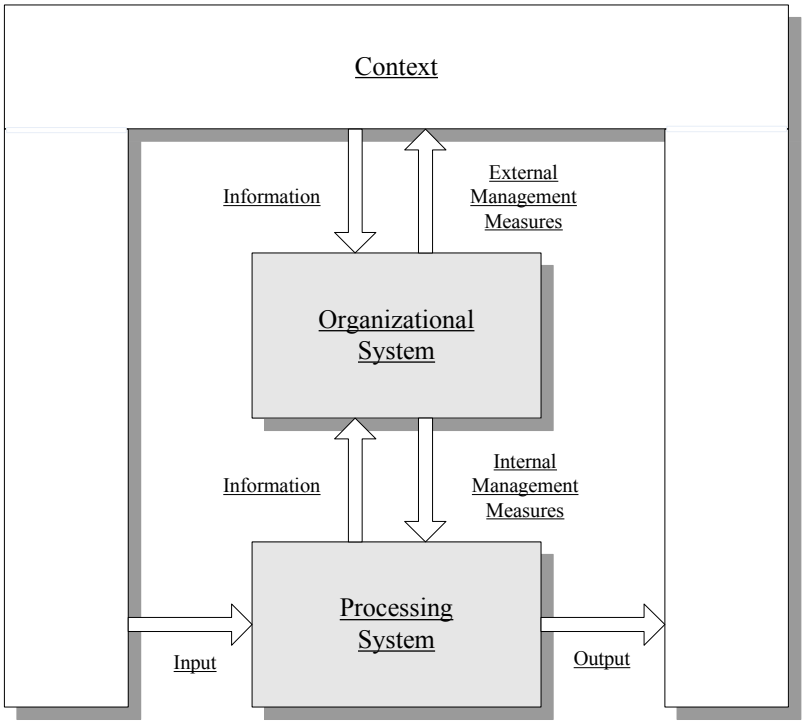

Figure 1: *Conceptual Steering Model based on the Systems Approach (De Leeuw, 2002)*

Furthermore, there are relationships between these three major components, which reflect the dynamics that exist in projects. For instance, a changing context has an impact on planning and development processes, which than is considered as *input*. For instance, changes in economical circumstances changes the way processes can be managed; i.e. the planning for delivering houses will be adjusted according to a changed customer demand. *Information* on changing processes than is 'send' to project organizations, who sometimes adjust their organizational arrangement to cope with the changes. This adjustment can be effectuated by different *management measures*, which are categorized as internal and external management measures. Internal management measures are aimed at influencing the objectives of the project itself, while external management measures are used to influence the project surroundings. For instance, internal management measures eventually are used by actors to realize an *output* or effect of the project. In urban development projects this can be the adaptation of a functional program that is more in line with contextual demands. External management measures can be used by public and private actors for instance to persuade political leaders to politically support the project. Despite the fact that some contextual characteristics are hard to manage, this research analyzes both management measures in order to see how actors are capable of influencing private sector-led urban development projects.

Analysis Aspects & Variables

Thus, this steering model is not a static representation of reality; it rather provides the ability to explain all sorts of mechanisms occurring in projects. In order to analyze and compare cases, however, a choice is made about which aspects are included in the analysis. Here, a brief description of the main analysis aspects is given based on several theoretical insights and categorized into the project's context, organization, management and effects.

In terms of context, three different contextual aspects are analyzed: *economy & politics*; *urban governance*; and *planning system & policies*. Several authors like DiGaetano & Klemanski (1999), Nadin & Stead (2008), and Adams & Tiesdell (2010) amongst others, have in our perspective indicated the importance of several contextual circumstances for actual planning implementation. In this research the economy and politics are described as a way to understand how economic situations and political landscape influences the public-private project cooperation. The urban governance situation is described as a way to understand the relationship between and roles of public, private and civic institutions that influence the project. Planning systems and subsequent policies are described as a way to understand the influence of legal rules and instruments on the project.

In terms of organization, three different institutional aspects are analyzed: *organizational*; *financial*; and *legal*. Bult-Spiering & Dewulf (2002) and Bailey et al. (1995) argue that these institutional aspects are in place in public-private cooperation and determine the inter-organizational roles of actors within different development stages of projects. In this research, organizational aspects that are analyzed are tasks and responsibilities, the financial aspects that are risks and revenues, the legal aspects are requirements and rules. Hence, all these aspects can influence actor's management opportunities in projects.

In terms of management, four different types of management measures are analyzed: *project management* activities; *process management* activities; *management tools*; and *management resources*. Here, we follow scholars like Black & Porter (2000) who indicate that management is 'getting things done with people', and De Leeuw (2002) who refers to different management measures which actors can apply to reach objectives. In this research,

project management activities are related to development stages through which influencing takes place, which are initiating, designing, planning and operating. Process management activities are related to the interaction between actors necessary to develop projects, which are negotiating, decision-making and communicating. Management tools are related to planning tools (see Adams et al., 2005) used by public bodies to influence developments, which are shaping, regulating, stimulate and building capacity. And management resources are related to the necessary assets for development, which are land, capital, and knowledge. All these management functions can be used by actors to influence the outcome of projects.

In terms of effects, three different project aspects are analyzed: *effectiveness*; *efficiency*; and s*patial quality*. These effects are important for determining the output of private sector-led urban development projects in relation to the stated ineffectiveness and inefficiency of Dutch urban development. Effects are measured qualitatively by asking interviewees to indicate whether or not these effects are realized. Effectiveness is the degree to which public and private actor's intended objectives are met. Efficiency is the extent to which public and private actors' cooperation takes place against a minimum use of time and costs. And spatial quality is the degree to which the development project satisfies user, experience and future values of the public and private actors involved.

METHODOLOGY

Hence, this research is a combination of descriptive and prescriptive research. Within the descriptive part, we use qualitative *case study methodology* to collect, analyze, and compare research data. Here we follow Yin (2003) who argues that a case study is 'an empirical inquiry that investigates a contemporary phenomenon within its real life context, especially when the boundaries between phenomenon and context are not clearly evident.' Hence, this is very suitable for the purposes of our research: a case study provide opportunities for management research as it is interested in the comprehension of the 'meaning of action' and data refers to the 'essences of people, objects or situations' (see Miles & Huberman, 1994).

Therefore, to create an understanding of private sector-led urban development projects Dutch and English cases are *described*, *analyzed* and *compared*. In the Netherlands, twelve cases of the concession model, which can be seen as the Dutch form of private sector-led projects, have been conducted. In England, two inner city mixed-use development projects 'led' by developers have been analyzed. The methods used to collect the data are literature reviews, document reviews, interviews and field work, which enables us to triangulate the data as different sources are used to collect them. The analysis of data has been structured by the conceptual steering model, which enables us to compare cases nationally and internationally.

In order to carry out the prescriptive part of this research *lesson-drawing* will be used. Janssen-Jansen et al. (2008) argue that there are three levels of transfer of lessons: inspiration, learning, and transplantation. As the objective of this research is to draw lessons from development projects in different countries and to use these lessons to create a design, our level of transfer will focus on inspiration and learning and not transplantation. Attempts have to be made to formulate context-dependent and context-independent lessons. In order to design the preferable roles, we follow the *engineering design methodology* presented by Dym & Little (2008) which consists of making a conceptual design, testing a design, and making a final design. The design is tested in an expert meeting to validate the design parameters.

DUTCH CASE STUDY FINDINGS

This section contains the case study findings from twelve Dutch private sector-led (concession) urban development projects. The main question we answer is: *How do public and private actors manage Dutch private sector-led urban development projects?*

Empirical Findings

Table 1 gives an overview of the twelve Dutch cases that have been analyzed in this research, which shows the variety of characteristics. These cases have been described and (cross-) analyzed on the basis of the components of the conceptual steering model: organization, management and effects. Hence, in this paper we focus on describing and analyzing the management component of projects.

Table 1: *Case Overview the Netherlands*

City	Project	Location	Scale (ha/acres)	Program (on April 2009)
Amsterdam	Park de Meer	Inner City	14 / 34.6	700 houses facilities
Den Haag	Ypenburg Deelplan 20	Greenfield	5 / 12.4	470 houses
Enschede	De Laares	Inner City	30 / 74.1	450 houses 2.500 m2 retail / 5.000 m2 office
Maassluis	Het Balkon	Greenfield	22 / 54.4	1.000 houses facilities
Middelburg	Mortiere	Greenfield	100 / 247.1	1.500 houses 3.000 m2 office / golf course
Naaldwijk	Woerdblok	Greenfield	30 / 74.1	900 houses
Rotterdam	Nieuw Crooswijk	Inner City	30 / 74.1	500 houses
Tilburg	Koolhoven	Greenfield	100 / 247.1	2.000 houses facilities
	Stappegoor	Inner City	50 / 123.6	1.100 houses / sport facilities / cinema 5.000 m2 retail / 20.000 m2 office
	Wagnerplein	Inner City	10 / 24.7	600 houses / parking 9.000 m2 retail / 60.000 m2 office
Utrecht	De Woerd	Greenfield	17 / 42	500 houses
Velsen	Oud IJmuiden	Inner City	12 / 29.7	350-650 houses

Management

The management of private sector-led urban development by both actors has not been mentioned in literature. Already we indicated that several management measures can be used to influence the outcome of development. Table 3 gives an overview of how these management measures are divided among or between the actors in the Dutch empirical cases.

Table 2: *Empirical Management of Public & Private Actors in Dutch cases*

Management Measures	**Management Functions**			
Project Management	Initiating	Designing	Planning	Operating
	Both	*Private / Both*	*Private*	*Public*
Process Management	Negotiating	Decision-making		Communicating
	Both	*Both*		*Both*
Management Tools	Shaping	Regulating	Stimulating	Capacity Building
	Public	*Public*	*N/a*	*N/a*
Management Resources	Land	Capital	Knowledge	
	Private	*Private*	*Private*	

In terms of *project management* activities, the cases show that local authorities in majority initiate the projects. Thereby, they establish spatial requirements for development and thus are able to influence the project characteristics. Designing plans as mentioned primarily is a private task but in more than half of the cases this management activity is carried out by both actors. Planning as management activity is a way for private actors to influence the profit margins and speed of development. Hence, the operation and maintenance of the project after delivery in all cases becomes a public task. Therefore, at the start of projects they can influence public space characteristics as they become the owner.

In terms of *process management* activities, the cases show that negotiating, decision-making and communicating are management measures that are carried out by both actors. Thus, both actors have opportunities to negotiate the incorporation of public and private objectives into the project at the initiative, design and realization stages. Furthermore, both actors influence developments based on internal or inter-organizational decision-making processes. Communicating as a management activity often is structured by different meetings and legal approvals of plans during the process. However, communication processes have influenced the development progress negatively. Public project leaders do not all have the competencies to align different municipal departments. Furthermore, developers not all seem to be aware of how to communicate with other stakeholders like local communities. Hence, housing associations in some inner cities played a key role in creating support from local residents.

In terms of *management tools*, the cases show that shaping and regulating are the main management measures used by public actors to influence development. They use indicative spatial plans and public briefs as management tools to shape developments. Furthermore, public actors use land-use plans, quality and visual conditions, and other contractual agreements to regulate development. Sometimes these briefs, plans, and conditions are highly detailed and inflexible, which results in minimum freedom for private actors to design and innovate. Hence, Dutch public actors do barely use stimulating or capacity building

management tools to influence the outcome of development. Some local authorities used subsidies to financially stimulate development, but building capacity by involving relevant stakeholders to create social or political support does not occur in the cases.

In terms of *management resources*, the cases show that land, capital and knowledge are mainly used by developers to influence development outcomes. Private land ownership on some of the greenfield sites was used a powerful resource for development. However, brownfield sites were hardly characterized by private land ownership. But as most of the developers performed the land acquisition they were able to influence development at their own interest. Hence, some of the local authorities performed the land acquisition and development in stead of developers. Thereby they managed the time and price of the land sale to developers, but at the same time created an unclear role division between the actors, undermining the principle of concessions. Capital for development was primarily managed by developers, however, their influence was limited as most of them depended heavily on bank loans. Knowledge about local market demand and project marketing mainly were a management measure used by private actors.

Conclusions

On the basis of the Dutch cases, it seems that both actors still encounter difficulties to cooperate in accordance to private sector-led urban development principles. Local authorities in some cases are not completely aware that this type of cooperating implies that they have to management projects differently. Also private actors in some cases are not completely aware that their role also imply that they take on more risks and other responsibilities than they are used to. Therefore, one of the main conclusions is that the private sector-led urban development practice in the Netherlands is not (yet) characterized as a mature way of public-private cooperation, as several problems and misconceptions still exist. In order to design future public and private roles, we need to create a better understanding of the phenomenon of private sector-led urban development by broadening our view towards foreign practices.

ENGLISH CASE STUDY FINDINGS

This section contains the main case study findings from two English private sector-led urban development projects (see Figure 3). The main question we answer here is: *How do public and private actors manage English private sector-led urban development projects?*

Figure 3: *Aerial views Bristol Harbourside and Liverpool One*

Empirical Findings

Table 4 gives an overview of two English private sector-led urban development projects that have been analyzed in this research on the basis of the components of the conceptual steering model: organization, management, effects. Hence, in this paper we focus on describing and analyzing the management component of projects.

Table 4: *Case Overview England*

City	Project	Location	Scale (ha/acres)	Program	
Bristol	Harbourside	Inner City	8 / 20	Total space	119,000 m2
				Office	45,000 m2
				Housing	44,000 m2
				Leisure/hotel	30,000 m2
Liverpool	One	Inner City	17 / 42	Total space	234,000 m2
				Office	3,250 m2
				Housing	500 units
				Leisure/hotel	ca 30,000 m2
				Retail	130,000 m2

Management

In terms of *project management* activities, the cases show that both public actors initiated the project as they were part land owner of sites; no unsolicited development proposals of private actors were handed in. Thereby local authorities were able to influence development at the merits of the projects as they set the ambition. However, developers were able to influence the project outcome by designing and planning activities, as development schemes and project planning are private matters. Hence, by operating development the developer in Liverpool was able to set 'private' requirements for the project at earlier development stages. In conclusion, project management activities in both cases mainly are private sector-led.

In terms of *process management* activities, the cases show that a lot of interaction between the actors takes place. Influencing mainly takes place in negotiations in the pre-realization phase, where public and private objectives are defined and final scheme decisions are made. At a later stage, public influence on project is limited to planning applications for separate buildings or plots which require public planning permission. Hence, communicating to key stakeholders is mainly conducted by developers. Several community involvement and public meetings were organized in which several wishes were incorporated into final schemes. In conclusion, both cases show that process management activities are used by both actors. Public and private actors negotiate and make joint decisions, while private actors in both cases use communicating as a way to incorporate other objectives.

In terms of *management tools*, the cases show that public actors use local plans, area visions and public briefs as tools to shape developments. Regulating development takes place through public instruments like planning briefs, development frameworks, development agreements, section 106 agreements, design guidelines, and even planning permission. In Bristol, the local authority stimulated development by securing public grants for cultural functions which kick-started development. In Liverpool this was not the case. Capacity building was also used by the public actor in Bristol as they facilitated a partnership between

the public and private landowners (the Harbourside Sponsor Group). In Liverpool no such network building relationship activity was used. Thus, the cases show that management tools are mainly used by public actors to influence development.

In terms of *management resources*, the cases show that private actors take the lead and influence development by using land, capital and knowledge. Although local authorities in both cases had substantial landownership, they did not use it as a resource to influence development, as land development was carried out by developers once they acquired it. Capital in both projects was almost solely private investment secured by the developers. In Liverpool, the developer also has an interest as a real estate financer. Also knowledge about market demand and development concepts was a private management resource. Developers had a variety of in-house specialists or hired specific consultants to give advice about different subjects. Thus, resources were private sector-led ways of influencing development.

Table 5 shows which empirical management measures have been used by public and private actors to influence English private sector-led urban development projects.

Table 5: *Empirical Management of Public & Private Actors in English cases*

Management Measures	**Management Functions**			
Project Management	Initiating	Designing	Planning	Operating
	Public	*Private*	*Private*	*Private / Public*
Process Management	Negotiating	Decision-making		Communicating
	Both	*Both*		*Private*
Management Tools	Shaping	Regulating	Stimulating	Capacity building
	Public	*Public*	*Public / n/a*	*Public / n/a*
Management Resources	Land	Capital	Knowledge	
	Private	*Private*	*Private*	

Conclusions

Some general conclusions from these cases are that in terms of context, urban regeneration in England can be considered as politically complex. Both cases show that the changeable nature of urban policies under different political powers also can change conditions for development, which are hard to influence by the actors themselves. In terms of organization the cases have shown that local authorities do not develop themselves, but encourage or establish all kinds of inter-organizational partnerships with other public, private or civic stakeholders in order to create support and raise funds for development. Hence, despite being mostly private sector-led at first sight, the English cases show that local authorities have different and sufficient management measures to influence development, and are aware of how to use them.

INTERNATIONAL COMPARISON

The aim of this research is also to systematically compare development projects in different international contexts. Here, we compare all findings from both empirical private sector-led urban development cases by showing some similarities and differences between all the conceptual model analysis components, presented in Table 7. Hence, we must highlight that this comparison is made on the basis of this research. These cases are not exemplary for áll private sector-led urban development projects in the Netherlands and England. Nevertheless, the table reveals some interesting points from the Dutch and English cases. The influence of the project's context in England seems to be higher than in the Netherlands; especially the political power and changeable policies influence development. Project actors have difficulties to manage these environmental aspects. The organizational role division of private sector-led projects in England seems to be stricter than in the Dutch projects, where public requirements sometimes are formulated in more detail. Management in the Dutch cases are slightly less private sector-led than in England, were local authorities and developers are more aware of how to use management measures at their disposal. The effects show quite some resemblance; effectiveness and spatial quality can be achieved, while efficiency remains difficult as time and budget overruns occur frequently.

Table 7: *Comparison of Dutch and English private sector-led urban development projects*

Aspect	Netherlands	England
Context	Moderate political influence on project	High political influence on project
	Public-private-civic project relations blurry	Public-private-civic project relations clear
	Policies stable, certainty for project	Changing policies, uncertainty for project
Organization	Blurred task & responsibility division	Strict task & responsibility division
	Risks & revenues mainly private	Risk & revenues always private
	Detailed requirements & rules	General requirements / detailed rules
Management	Project management by both actors	Project management by private actors
	Process management by both actors	Process management by both actors
	Public man. tools used unconsciously	Public man. tools used consciously
	Management tools by private actors	Management tools by private actors
Effects	Cooperation generally effective	Cooperation generally effective
	Process hardly efficient	Process hardly efficient
	Spatial quality mostly satisfying	Spatial quality mostly satisfying

CONCLUSIONS: MANAGEMENT LESSONS LEARNED

This paper showed that it is possible to systematically study urban development projects. Here, we explore what management lessons can be learned from both case study findings.

Important to notice is that despite the local authorities taking less risks and responsibilities they are well able to influence or manage development projects. Thus, private sector-led urban development involves a whole set of managing opportunities for local authorities, and not necessarily less management. Hence, they also have the awareness of how to apply these management measures more consistently then is the case in the Netherlands. Furthermore, developers in England, at least in the cases, tend to be more aware of their managerial tasks and opportunities. First, they create more civic support for development by involving local communities and businesses in the design process. Second, they are open for long term commitment to their projects as they, at least in the Liverpool case, apply long term business models in operating the project after delivery, to secure financial returns and minimize risks. Another main conclusion is that, when viewed from a management perspective, both practices do not differ that much in opportunities for both actors to influence projects.

Therefore, one of the main conclusions is that private sector-led urban developments in England can be characterized as a more mature way of public-private cooperation. In summary, we argue that in order to cooperate on the basis of a private sector-led urban development approach, other public and private management attitudes and competencies should be applied to make this type of projects successful in the Netherlands. With these lessons, conditions for designing preferable public and private roles for Dutch private sector-led projects have been established for what will be the focus of the following research stages. However, as the context for urban development has changed dramatically in recent years, we have to take this into account as well when we design these roles. These are some of the challenges that remain in the last stage of this research.

ACKNOWLEDGEMENTS

For their constant support, close reading and numerous debates I would like to thank my PhD supervisors Hans de Jonge and Fred Hobma from the department of Real Estate & Housing. Furthermore, my thanks go to other colleagues like Vincent Nadin, Tom Daamen, Peter Paul van Loon and Ineke Bruil for their well-intended scientific suggestions. Also, I thank Janet Askew, Christine Lambert and Graham Squires from the University of the West of England for helping me to gain insight into English development practice. And last, but not least, I thank all interviewees who provided me with all the necessary research data.

Abstract
The objective of this research is to analyze the function and effects of resource recycle facility in a Japanese industrialized detached house manufacturer. First, this paper analyzes the actual condition of waste disposal before the establishment of resource recycle facility. Secondly, this describes the logistics of the facility, and surveys the actual condition of waste separation with the facility. Thirdly this makes clear of the site fabrication of plaster board, and shows the trial calculation of material flow cost accounting for plaster board. Finally, this discusses the effectiveness of the facility established by house manufacturer itself.

Keywords: detached house, industrialized house, resource recycle, industrial waste disposal, waste separation

INTRODUCTION

The industrialized house is a house which applied an advanced industrial technology to the production. In Japan, the effectiveness of the applied technology has been demonstrated. However, the difference of productivity among construction projects is pointed out (Wu et al., 2008). Construction sites in the central area of Tokyo are small. There are no stock yards at construction sites. A general contractor is starting to adopt a little collection of industrial wastes from small projects (Hamada et al., 2004). The comprehensive logistics for detached house projects is necessary. Moreover, global environment problem has been more important. Some industrialized detached house manufacturers have set up resource recycle facilities for the establishment of resource recycle system.

Objectives

The main objective of this research is to analyze the actual function and effect of resource recycle facility in a Japanese industrialized detached house manufacturer, and to propose the comprehensive and efficient resource recycle system from the standpoint of economic and environmental assessment. This research surveys the kinds of waste separation and their quantities at construction sites to make clear the effort at sites for industrial waste disposal. Then, this surveys the waste separation and the recycle system at resource recycle facility and analyzes the effectiveness of the facility established by house manufacturer itself.

Research Method

This research compares the former industrial waste disposal system and the current industrial waste disposal system with resource recycle facility of house manufacturer M. First, this surveys 4 construction projects as the former system, and makes clear the kinds of waste separation and their quantities at construction site. How to dispose industrial waste outside construction sites is also surveyed. Secondly, this analyzes the operation results of the resource recycle facility built in 2009 as the current system, and makes clear the relation between site fabrication and waste quantity of plaster board. Finally this discusses the role and function of resource recycle facility established by the house manufacturer itself.

WOOD PANEL BONDING STRUCTURE AND CONSTRUCTION METHODS

Wood panel bonding structure

The house manufacturer M in Japan has built the industrialized houses on the basis of Japanese industrialized system. Figure 1 shows the structure of wood panel bonding method by house manufacture M. The structure of house is mainly composed of floor panels, wall panels and roof panels. The panels are manufactured in the factory beforehand, and are joined with glue at construction sites. Nailing and screwing is necessary as a finishing operation. After the shell of the building with the panels is erected, the desired finishes are applied to both inside and outside. On the outside, the plywood is often covered with the siding. On the inside, the fabric is often applied.

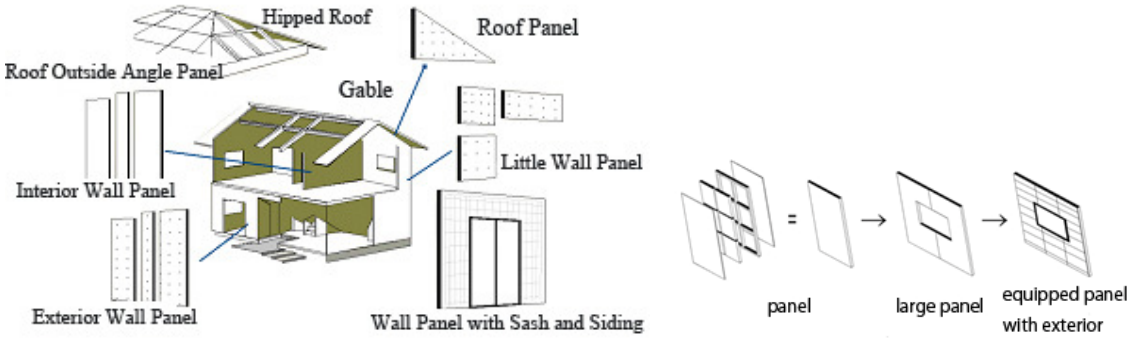

Figure 1: *Wood panel bonding structure*

Factories for wood panels and components manufacturing in Japan

The left in the figure 2 shows the location of factories of house manufacturer M in Japan. They are scattered and covers the whole area of Japan. The survey of delivery of materials from the factories investigates the distance and packing methodology of building components (Kimoto, 2009). The standard number of times of delivery by the house manufacture is 3. The objects in the first delivery are wood panels of main frame. Those in other deliveries are interior and exterior finishing building components.

The right in Figure 2 shows the location of resource recycle facility. It is established in the center of Kanto area which is comprised of 8 prefectures including Tokyo in 2009.

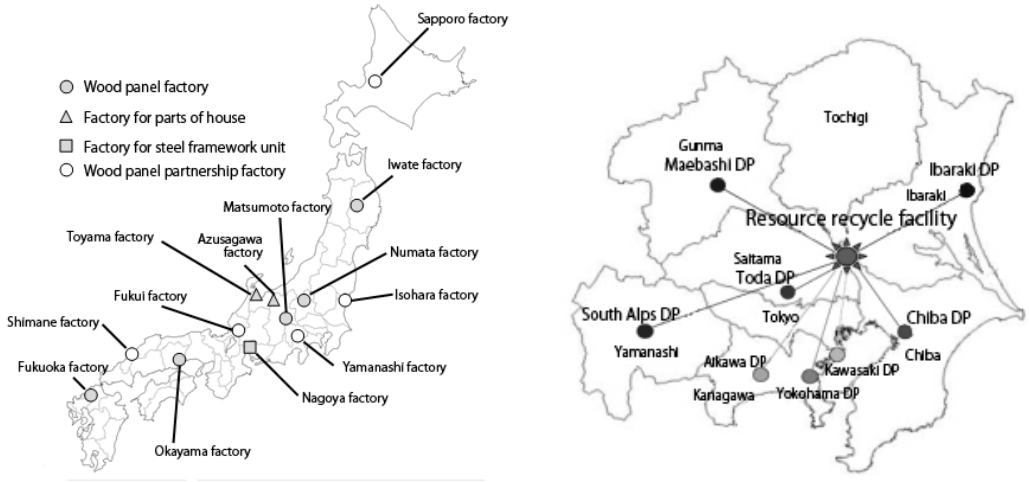

Figure 2: *Location of factories (left) and resource recycle facility (right) in Japan*

Various kinds of construction methods from the standpoint of prefabrication

In the delivery of wood panels, the adoption of pre-assembly at factory is a matter for study. Some projects adopt the pre-assembly of wood panels with the siding at factory. The left in figure 3 shows the pre-assembly of wood panels. The other projects can not adopt the pre-assembly because of small construction sites and narrow access roads. The right in figure 3 shows the delivery of wood panels. They assembled wood panels at construction sites. The adoption mainly depends on the condition of access roads. A big truck cannot run on narrow roads. A crane cannot work on narrow roads. The pre-assembly can reduce the workload at site. The supplies from the house manufacturer are relatively long-distance migration. On the other hand, the elective components by clients are relatively short-distance migration.

Figure 3: *Pre-assembly at Factory (left) and Assembly at Construction Site (Right)*

WASTE DISPOSAL WITHOUT RESOURCE RECYCLE FACILITY

Waste separation at construction sites

The survey of the collection of industrial wastes from construction sites to waste disposal facilities investigates the waste separation and the waste quantity. The survey, based on questionnaire with 25 dealers beyond the scope of resource recycle facility, makes clear the

actual condition of waste disposal. Figure 4 shows the main number of waste separation. They are different. There is one dealer that separates 10 kinds of waste. There are three dealers that don't separate waste at construction sites. There are six dealers that separate 2 kinds of waste. Figure 5 shows the main items of waste separation. Over 70 percent of dealers adopt the separation of plaster board. Nearly half of dealers adopt the separation of chips and shavings, and cardboard.

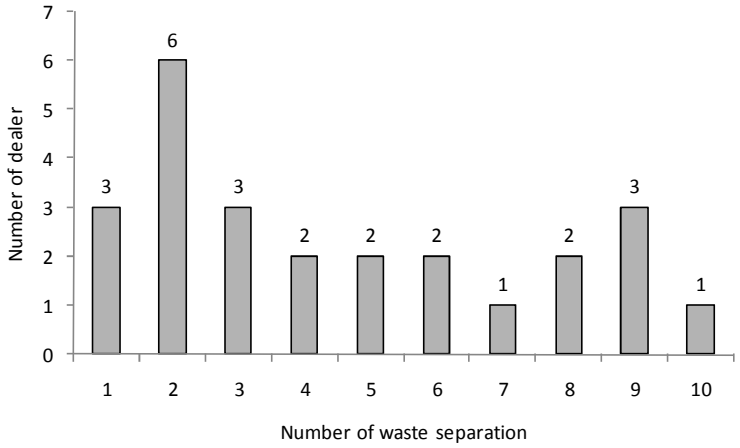

Figure 4: *Number of waste separation*

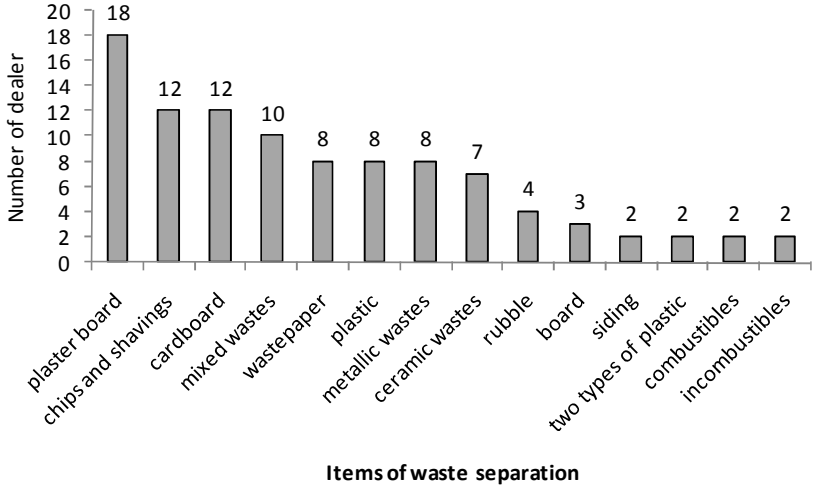

Figure 5: *Items of waste separation*

Volume of industrial waste from construction sites

Table 1 shows the construction projects for survey of industrial waste disposal before the establishment of resource recycle facility. They are located at Tokyo and the neighboring prefecture in Japan. They are detached houses, and wood panel build 2-storied structure. The size of houses is similar. S1 and S2 adopt the pre-assembly construction method of wood panels. M1 and M2 adopt the site-assembly construction method of wood panels. They carry industrial waste to intermediate process facilities. Their function is mainly the separation of wastes and the disposal of some parts.

Table 1: *Construction projects for survey*

Table 2 shows the actual waste separation and waste quantity of 4 projects at intermediate process facilities. The numbers of waste separation are different: 4 in S1 project, 5 in S2 project, 9 in M1 project, and 6 in M2 project. The intermediate process facilities in S1 and S2 measure the volume of industrial waste. The ones in M1 and M2 measure the weight of industrial waste. It depends on their systems. House manufacturers had not made effective use of the results.

RESOURCE RECYCLE FACILITY

Role of Resource recycle facility

In 2009, house manufacturer M established the resource recycle facility by itself. The expected role of the facility is to grasp the actual condition of industrial waste disposal and improve the environmental management system including the logistics and the effective utilization system of resource. It is important to grasp the actual condition of returned goods. The establishment of feedback mechanism about the above information is also important.
The facility adopts the QR code system to grasp the waste separation and waste quantity accurately and quickly. Figure 6 shows an example of QR code attached at construction site for industrial waste. It has the project information. The industrial waste at construction sites are separated to 10 kinds shown in figure 6.

Figure 6: *QR code system at resource recycle facility*

Advantageous effect of logistics by resource recycle facility

Figure 7 shows the before and after comparison of logistics of house manufacturer M. After the establishment of resource recycle facility, 10 ton trucks go around among the distribution center, the deposit center and resource recycle center. 2 ton trucks go around among the deposit center and construction sites. Special common pallets for both the delivery of materials and the collection of industrial waste are used over and over again. As a result, the material flow has rationalized.

Figure 8 shows the ratio of industrial waste collected to the resource recycle facility from May 2009 to September 2010. The ratio of plaster board and ceramic wastes is 26 % and is the highest. That of chips and shavings is 16 %. That of cardboard is 11 %. The ratio depends on the structure and specifications of houses.

Figure 9 shows the time series data of quantity of industrial waste brought from construction sites from May 2009 to September 2010. It also shows the number of commencement of construction. Roughly, the industrial waste is produced a month behind the commencement. Fiscal year of house manufacturer M is from April to March. Therefore, the number of completion of construction increases in September and March.

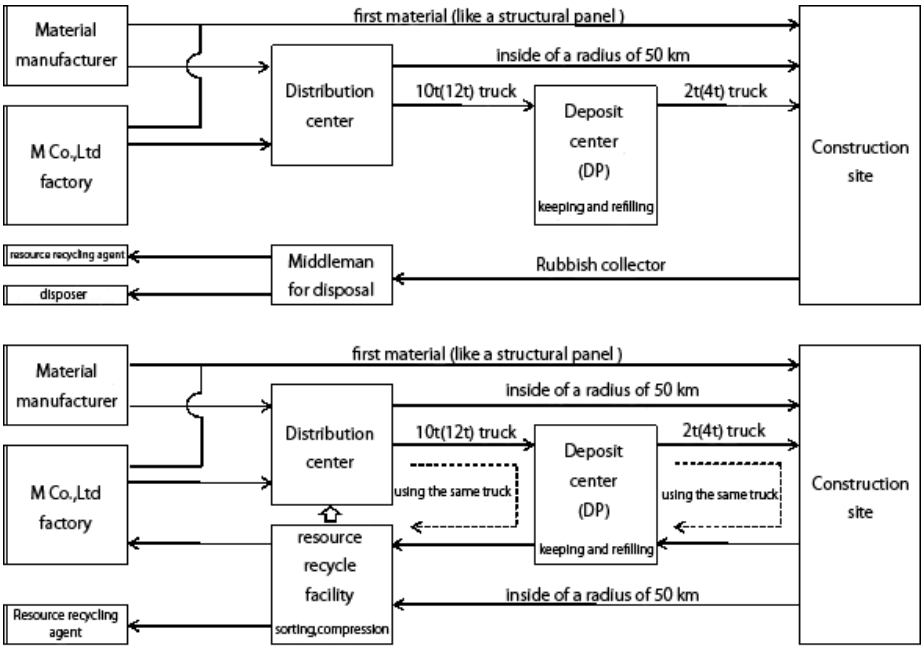

Figure 7: *Change of distribution by resource recycle facility*

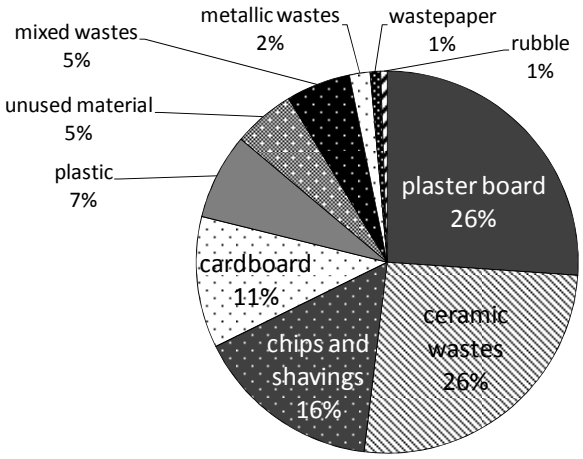

Figure 8: *Ratio of industrial waste from May 2009 to September 2010*

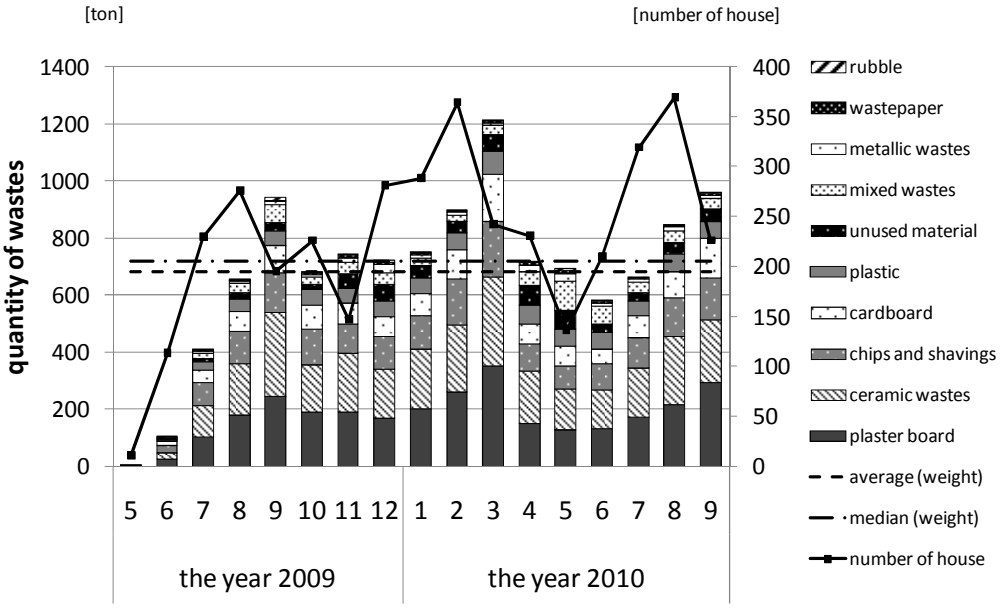

Figure 9: *Time series data of industrial waste brought from construction sites*

Figure 10 shows the industrial waste comparison among construction methods: the assembly of wood panels at site, the pre-assembly of wood panels with sash at factory, and the pre-assembly of wood panels with sash and siding at factory. The higher the ratio of prefabrication is, the less the quantity of industrial waste produced at construction site is. Of course, the quantity of industrial waste produced at factory shows countertrend.

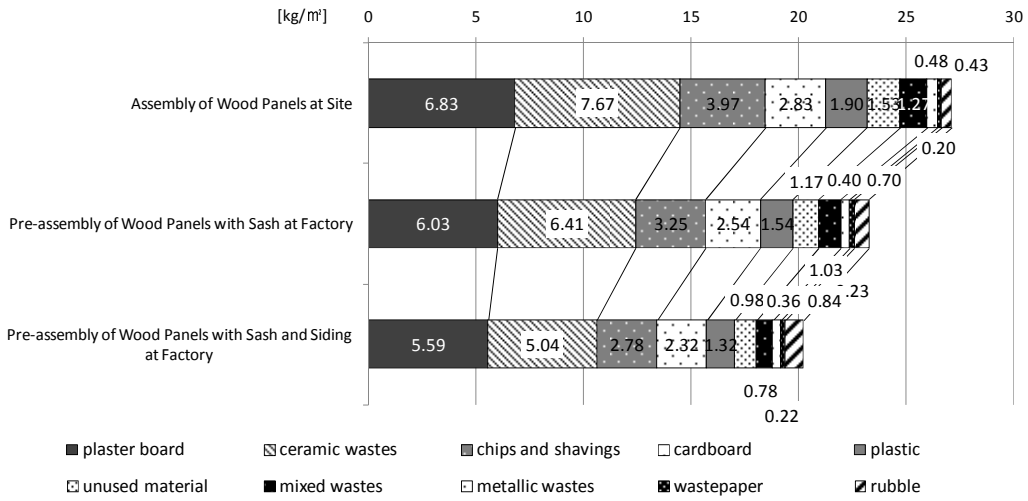

Figure 10: *Comparison of industrial waste brought from construction sites*

WASTE DISPOSAL OF PLASTER BOARD

Plaster board is the highest waste ratio in house manufacturer M. Table 3 shows the outline of construction projects for waste disposal survey. All of them adopt the pre-assembly of wood panels at factory. They are located at Tokyo and the neighboring prefecture in Japan. They are detached houses, and wood panel build 2-storied structure. The size of houses is similar.

Cutting of plaster board

The detail of cutting plaster board at construction site in projects is shown: S2 project in Figure 11 and S3 project in Figure 12. The number of cutting plaster board whose waste is the most in S2 project is 4. The average of quantity of waste is 3.15 kg. That in S3 project is 3. The average of quantity of waste is 2.18 kg. The manpower at construction site such as the cutting of plaster board is related to the adoption of precut. Less than 5 times cutting plaster board has a possibility of precut.

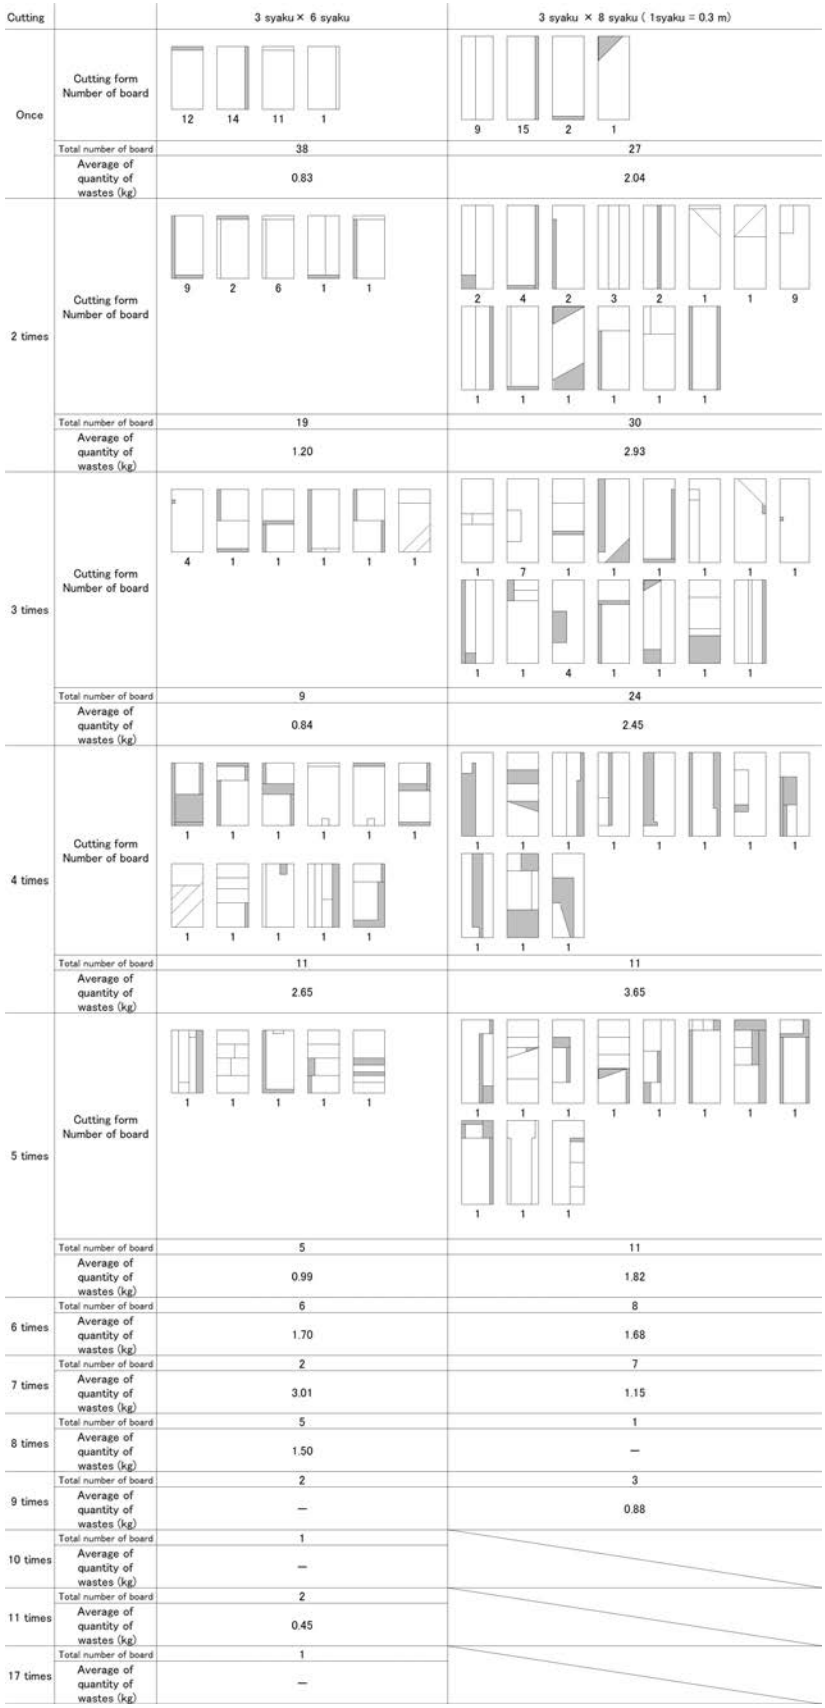

Figure 11: *Detail of cutting plaster board at construction site in S2 project*

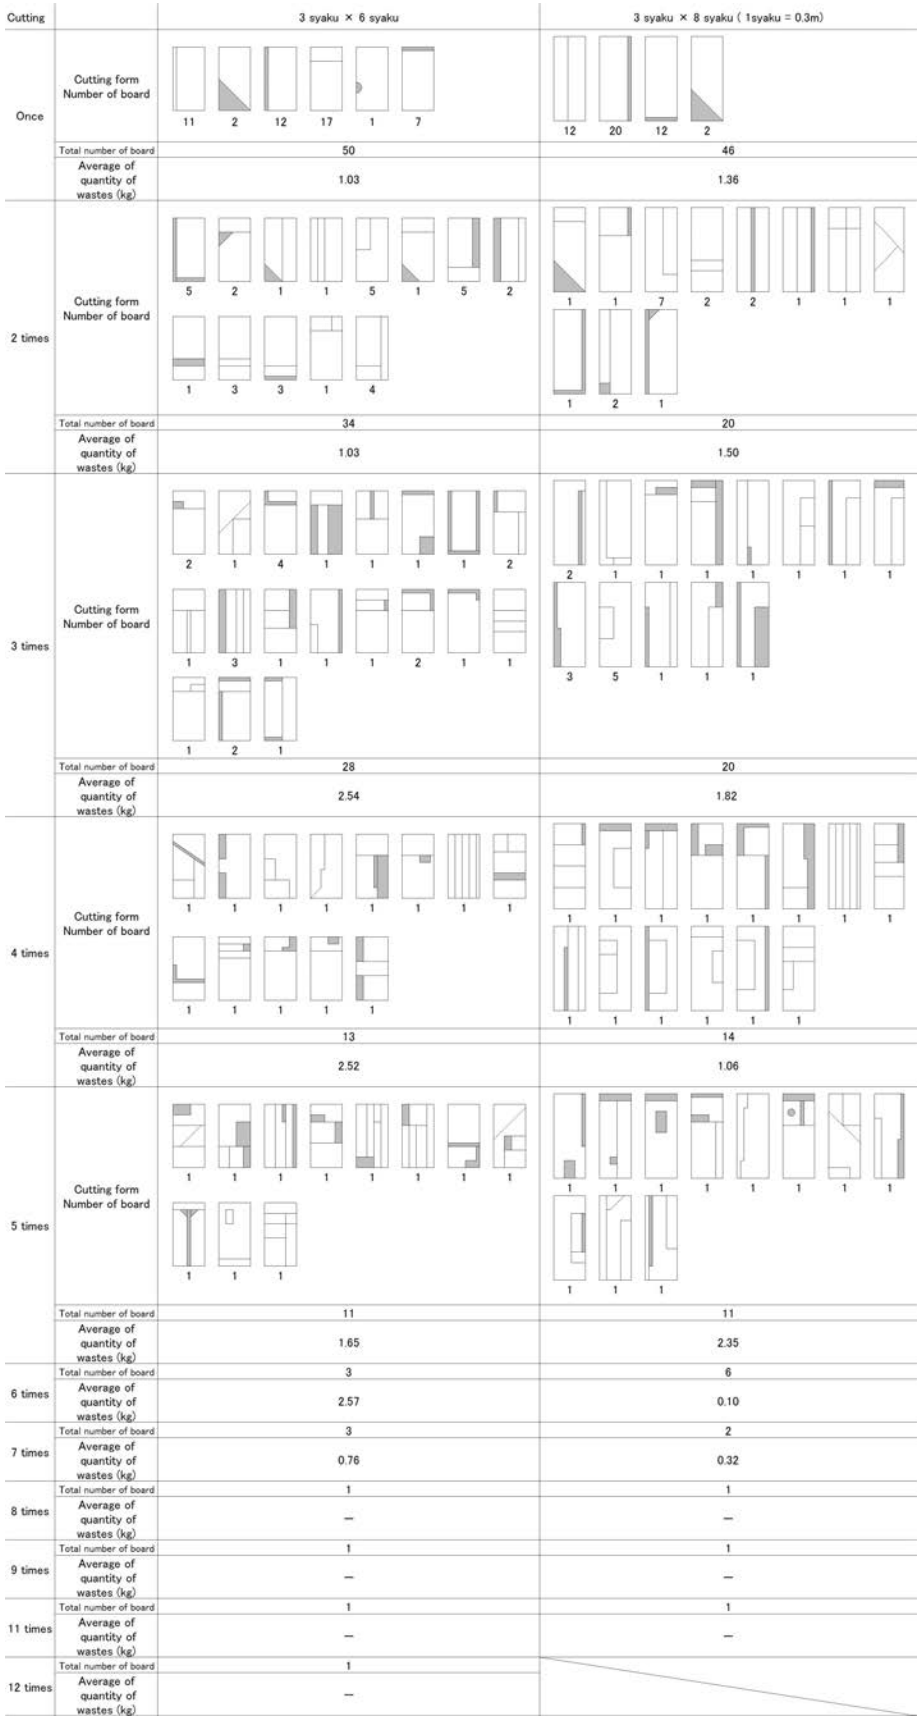

Figure 12: *Detail of cutting plaster board at construction site in S3 project*

Carry-in and carry-out plaster board

The survey weighs the plaster board in projects at the time of both the carry-in and the carry-out. Table 4 shows the result of carry-in and carry-out in S2 project. The weight of carry-in plaster board is converted with the number of sheets. That of carry-out plaster board is weighed directly with a spring scale. The number of carry-in is limited. That of carry-out is scattered. Actually they are stocked at the edge of construction site and carried out at weekly intervals.

Table 4: *Weight of Carry-in (left) and Carry-out (right) Plaster Board in S2 Project*

Month	Day	910mm × 1,820mm (Number of Sheets)	910mm × 2,420mm (Number of Sheets)
8	25	70	0
9	3	40	80
9	8	0	61
9	13	6	0
Total Number of Sheets		116	141
Weight per Sheet (kg)		13.4	17.8

Total Weight (kg)		4,064.2	

Month	Day	Plaster Board (kg)	Number of Carpenters	Work Area
8	25	74.0	2	Lathing
9	5	18.0	1	1F Wall
9	8	152.0	1	1F Wall
9	9	38.0	1	2F Wall
9	10	123.5	2	1F and 2F Ceiling
9	11	48.0	1	2F Wall
9	12	95.2	2	1F and 2F Ceiling
9	13	51.2	1	2F Ceiling
9	14	13.2	1	1F and 2F Partition
Total Weight (kg)		634.1	12	

Trial calculation with Material Flow Cost Accounting

The cost of plaster board is cheep. The reduction of material cost doesn't become incentive motivation. Material Flow Cost Accounting (MFCA) is an environmental accounting method originally developed in Germany. In addition to the cost of materials, labor cost, and other processing cost are allocated under loss cost, and waste cost is calculated by the same means as production cost. Therefore, waste is called "negative product" in MFCA.

Figure 13 is a trial calculation of plaster board work in project S4 with MFCA. The ratio of negative product is 19.8 %. The cost is 76,630 yen. It is more than three times material cost.

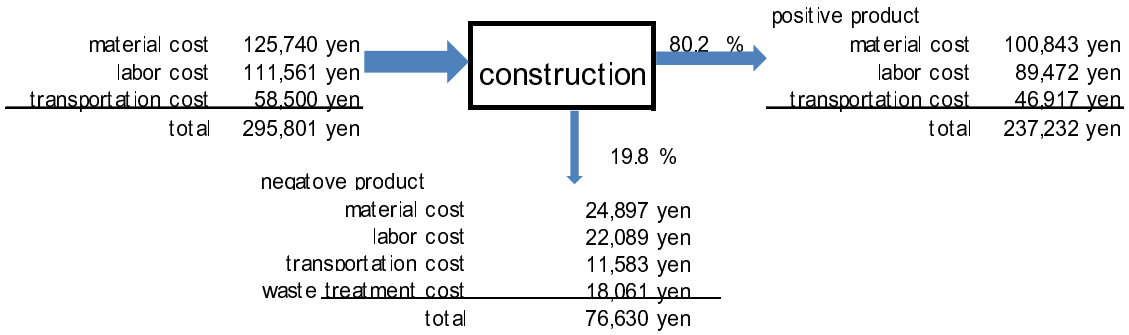

Figure 13: *Trial calculation of plaster board with MFCA*

CONCLUSIONS

The objective of this research is to analyze the function and effects of resource recycle facility in a Japanese industrialized detached house manufacturer.

First, the survey, based on questionnaire with 25 dealers beyond the scope of resource recycle facility, makes clear the actual condition of waste disposal. They are different. There is one dealer that separates 10 kinds of waste. There are three dealers that don't separate waste at construction sites. Over 70 percent of dealers adopt the separation of plaster board. Nearly half of dealers adopt the separation of chips and shavings, and cardboard. There are no systematic methodologies such as the waste disposal data analysis.

Secondly, this survey makes clear the before and after comparison of logistics with resource recycle facility. After the establishment of the facility, 10 ton trucks go around among the distribution center, the deposit center and the resource recycle center. 2 ton trucks go around among the deposit center and construction sites. Special common pallets for both the delivery of materials and the collection of industrial waste are used over and over again. This survey verifies that the material flow has been streamlined.

This survey analyzes the ratio of industrial waste collected to the resource recycle facility from May 2009 to September 2010. The ratio of plaster board and ceramic wastes is 26 % and is the highest. That of chips and shavings is 16 %. That of cardboard is 11 %. Moreover, the higher the ratio of prefabrication is, the less the quantity of industrial waste produced at construction site is. This analysis shows the difference of construction methods.

This survey also shows the time series data of quantity of industrial waste brought from construction sites from May 2009 to September 2010. Roughly, the industrial waste is produced a month behind the commencement. Fiscal year of house manufacturer M is from April to March. Therefore, the number of completion of construction increases in September and March. Moreover, the higher the ratio of prefabrication is, the less the quantity of industrial waste produced at construction site is. This time series data analysis of quantity of industrial waste shows the task of load leveling of resource recycle facility.

Thirdly, this survey makes clear of the site fabrication of plaster board. Four times and five times cutting plaster board produces more waste. The most of waste quantity is 3.65 kg. The manpower at construction site such as the cutting of plaster board is related to the adoption of prefabrication. Less than 5 times cutting plaster board has a possibility of precut. This survey also shows a trial calculation of plaster board work with MFCA (Material Flow Cost Accounting). The ratio of negative product is 19.8 %. The cost is 76,630 yen. It is more than three times material cost. This indicates the importance of rationalization of waste disposal. There is a room for improvement of waste disposal system.

Finally, this paper makes clear the before and after comparison of the establishment of the resource recycle facility by house manufacturer itself. This survey indicates that the load leveling of resource recycle facility and the adoption of construction methods such as prefabrication and precut are worthy of consideration from the standpoint of environment management. After this, the research will survey the detail of waster separation and disposal in the resource recycle facility.

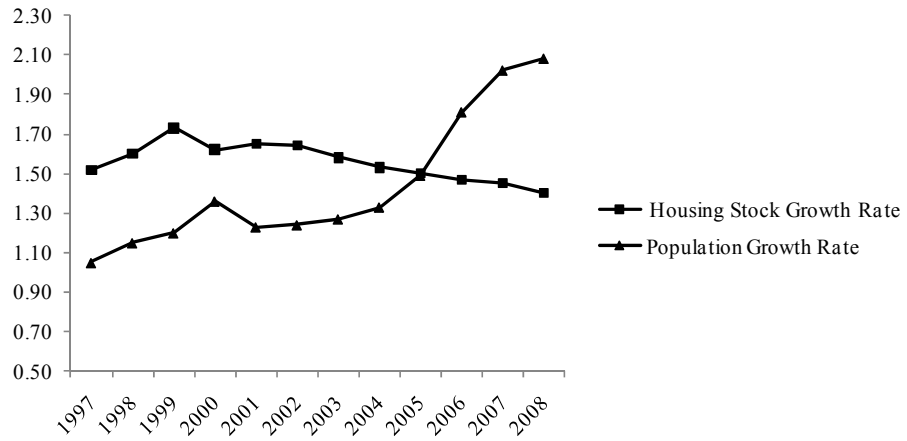
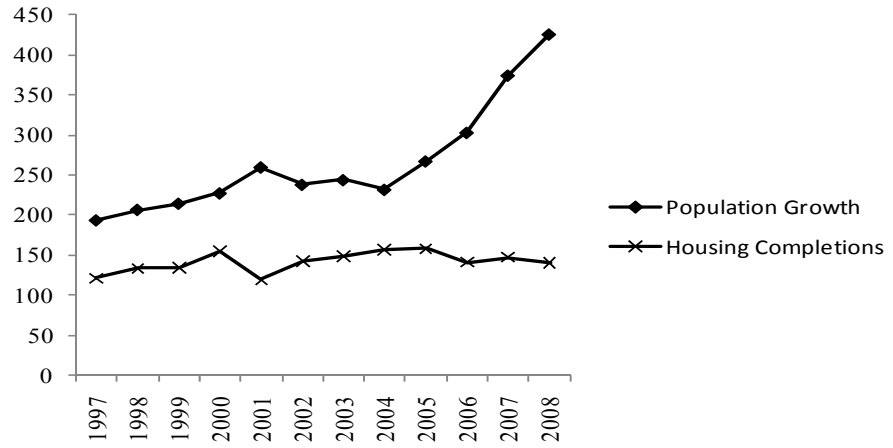
Abstract



Housing supply is one of important components of the housing sector. Compared with an increasingly strong housing demand, the growth rates of total housing stock in Australia have exhibited a downward trend since the end of the 1990s whilst the significant adjustments in the Australian monetary policy were being implemented. This research aims to estimate the nature of the relationship between housing supply and monetary policy by a vector error correction model. According to the empirical results, a transmission pattern comprised of the indicators associated with housing supply and monetary policy can be identified, which suggests that there is a significant interrelationship between monetary policy and the supply side of the housing sector in Australia.

Keywords: housing supply, monetary policy, transmission pattern, vector error correction model

INTRODUCTION



Housing supply is an essential component of the housing sector. However, Australia has been facing a challenge from inadequate housing supply since the 1990s while the demand for housing across Australia was extremely strong. The statistics from the Australian Bureau of Statistics (ABS) indicate that the growth rates of total housing stock have exhibited a downward trend accompanying a dramatic urban population growth in Australia since the 1990s. The movements in the growth rates of housing stock and urban population in Australia are illustrated by Figure 1. Urban economic theory claims that the growth of urban population is an indicator of the increase in housing demand and there should be a steady equilibrium (convergence) relationship between total housing stock and urban population (DiPasquale, 1999).

The housing literature demonstrates that the construction of new housing is a leading source of the increase of total housing stock. In Figure 2, compared with dramatic population growth, the number of new housing completion in Australia were highly stable over the past decade. It is able to be inferred from both Figure 1 and Figure 2 that a divergence between housing supply and urban population has gradually occurred in Australia. In simple terms, currently, the supply of housing can not keep pace with the demand for housing across Australia.

Source: ABS, 2009a

Figure 1: Growth rates of urban population and housing stock in Australia

Source: ABS, 2009a; 2009b
Figure 2: Population growth and new housing completions in Australia

Another statistic data regarding housing finance also indicates that the annual number of the housing mortgage for the purchases of owner-occupied dwelling in Australia increased from 412,032 to 598,566 with the increase rates of 45.3% during the period of 1997-2008 (ABS, 2009e). These data further explicitly reveal that the demand for housing in Australia is increasing. Owing to the strong housing demand and the inadequate housing supply, the annual report of the Housing Industry Association (HIA) argued that a housing shortage of approximately 110,000 had emerged in Australia in 2008 and this problem would be exacerbated in the future (HIA, 2009).

Based on the reports of the Reserve Bank of Australia (RBA), from 1997 to 2008, the growth rates of the money supply in Australia had decreased and there had been a corresponding rise in the interest rates (RBA, 2009a; 2009b). The increase in the interest rates as well as a decrease in the money supply growth rates implies that the Australian monetary policy was adjusted significantly during the period of 1997-2008. RBA's (1999) announcement supported this perspective and stated that the expansionary monetary policy that had been implemented in Australia for a couple of years would be gradually slowed down.

Monetary policy is generally defined as a process by which the central bank or national monetary authority of a country adjusts the interest rates to a target level in economy (McTaggart *et al.*, 2003; RBA, 2007a). It is a key tool for government to regulate economic activities. In housing literature, many researchers have investigated how monetary policy affects housing demand while few empirical studies were concerned with the relationship between the supply of housing and monetary policy. Thus, a research question, 'What is the interrelationship between housing supply and monetary policy?', has emerged. This paper aims to contribute to the literature by developing a conceptual model as well as a methodology to estimate the relationship between housing supply and monetary policy.

The rest of this paper is laid out as follows. Next section will review the relevant literature with respect to the relationship between monetary policy and the housing sector. Then, the *Conceptual Model* followed by the *Methodology and Data* will be described. Finally, the empirical results yielded by the econometric model will be used to analyse the linkage between housing supply and monetary policy.

LITERATURE REVIEW

Monetary policy plays an active role in the governmental interventions on economy. It is considered to be an important tool that bridges policy makers to realistic economic system. Theoretically, monetary policy can affect both the supply of and the demand for housing (Elbourne, 2008).

The response of the housing sector to the shock of monetary policy has been well considered in numerous studies since the 1990s. The econometric technique employed for these studies is either the reduced-form vector autoregression (VAR) model or the sophisticated VAR [e.g. structural VAR (SVAR) and vector error correction model (VECM)]. The early research relevant to the effect of monetary policy on the housing sector in the 1990s is the study by Baffoe-Bonnie (1998), in which a reduced-form VAR was used to analyse the dynamic effects of monetary policy and macroeconomic aggregates on the house prices and the number of houses sold on a national and regional level in the US. The quarterly data on money supply, mortgage rates, house prices and the number of houses sold were selected for modelling. The estimates suggested that monetary policy had a strong impact on the mortgage rates, which in turn triggered immediate responses of the house prices and the number of houses sold in the national and regional housing markets in the US (Baffoe-Bonnie, 1998).

Likewise, in 2004, Edelstein and Sau (2004) studied the relationships among monetary policy, house prices, wealth effect and macroeconomic situations in Singapore by a reduced-form VAR. Using the data on disposable income, interbank rates, real private and public house prices, transaction volume and real public housing wealth measure, the empirical evidence indicated that the shock of the interbank rates negatively affected the disposable income, private and public house prices and public housing wealth in Singapore (Edelstein & Sau, 2004).

Some prior VAR research demonstrated that the model misspecification is more easily triggered in the reduced-from VAR (Bernanke & Blinder, 1992; Sims, 1992). To avoid this problem, more and more studies in the recent decade identified the shock of monetary policy on the housing sector by the SVAR or the VECM. Take the research by Lastrape (2002) as an example, this study examined the impact of monetary policy on the housing market applying the SVAR. The primary interest of Lastrape (2002) was to interpret the response of the prices of owner-occupied housing to the shock of money supply across the metropolitan regions in the US. The results suggested that

both real house prices and house sales were driven up within a short-run period in response to the positive shock of money supply (Lastrape, 2002).

It is noted that Lastrape's (2002) work focused on the influence of monetary policy on house prices on a regional level. However, Aoki *et al.* (2002) investigated this issue within a national context utilising the SVAR as well. The research by Aoki *et al.* (2002) sought to explore the relationship among monetary policy, house prices and consumption level in the UK. It was identified that 0.8% decrease in the house prices in the UK was triggered after the 50 basis point shock of the interest rates within five quarters (Aoki *et al.*, 2002).

In addition to Aoki *et al.* (2002), Iacoviello (2002; 2005) and Iacoviello and Minetti (2008) explored the linkage between monetary policy and housing sector on a national level by means of the SVAR and VECM respectively. In Iacoviello's (2002; 2005) research, six European countries, involving France, Germany, Italy, Spain, Sweden and UK, were considered as an integrated entity to estimate the role of monetary policy in the inflation of house prices. Under the identification scheme of King *et al.* (1991), the results yielded by the SVAR indicated that the house prices would decrease by 1.5% following a tightening of monetary policy. On the other hand, the study conducted by Iacoviello and Minetti (2008) contributed to the literature by uncovering the credit channels of the monetary policies of such four European countries as Germany, Finland, Norway and UK. The results of the VECM suggested that an approximately 0.25% fall of economic output [Gross Domestic Product (GDP)] and 1% drop in house prices were produced by a shock of interest rates.

Recently, a research by Elbourne (2008) emerged to clarify the relationships between house prices and the transmission mechanisms of monetary policy, which include commodity prices, interbank rates, retail sales, price level, money supply and nominal market exchange rates. Empirical evidence from the SVAR suggested that the retail sales in the UK fell by 0.4% after receiving a positive 100 basis point shock of the interbank rates while house prices decreased up to 0.75% in response to 15% of the consumption drop caused by a monetary contraction.

In Australia, the research on the effect of monetary policy on the housing sector is sparse. The empirical study by Liu and Liu (2010) examined the linkage between monetary policy and housing affordability across eight state capital cities in Australia using the SVAR. In this study, the shock of monetary policy was measured by the interbank rates and the money supply (M1), and the housing affordability was associated with the house prices. The results show that the interbank rates triggered -1.28% effects on the house prices across Australia's eight state capital cities while the M1 positively affected the house prices by 1.08%.

It is able to be identified from this literature review that the past studies on the interrelationship between housing sector and monetary policy are primarily concerned

with the impact of monetary policy on house prices, GDP and disposable incomes. These variables are the components of the housing demand function (Quigley, 1999; Hui & Yue, 2006). Summarily, while there is extensive empirical literature on the relationship between monetary policy and the demand for housing, far less has been written about housing supply.

Although the literature in terms of the impact of monetary policy on housing supply is sparse, the history of this type of research can be dated back to the 1950s. An early study is that undertaken by Wolff (1957), which sought to examine the effects of the variation caused by economic characteristics of different regions on the post-war housing market in the US. The focus of this study was on economic disparities rather than monetary policy, however it briefly mentioned that the new housing construction activities in the South and West regions of the US were more sensitive to monetary policy changes than the remaining US regions (Wolff, 1957). In the 1970s, the study by Bebee (1972) divided Canadian housing markets into five regional markets and analysed the effects of economic disparity (measured by inter-regional population flows, interest rate and the household number) on the volume of dwelling unit started for construction by a simple multivariate regression model. The results indicated that monetary policy and population growth had significant influenced the housing starts in all regional markets in Canada.

In summary, the literature review in this section suggests that a number of empirical studies investigated the relationship between monetary policy and the housing sector in the framework of VAR models. Nevertheless, the majority of them concentrated more on housing demand than housing supply. In addition, the previous research by Wolff (1957) and Bebee (1972) did not explore the linkage between housing supply and monetary policy in a comprehensive context, but just discussed this issue in a simple way. The limited research scope in regard to the housing sector and monetary policy provides this paper with an opportunity for further study.

CONCEPTUAL MODEL

To empirically estimate the impact of monetary policy on Australia's housing supply, the first step in this study is to develop a conceptual model comprised of the monetary policy function and the housing supply function. These two functions will allow monetary policy and housing supply to be investigated through a series of relevant economic variables. Figure 3 illustrates the master plan of this empirical research in a simplified manner.

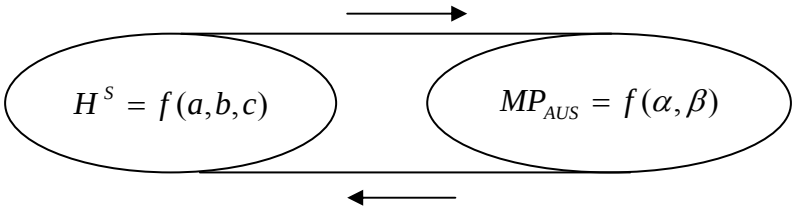


Figure 3: Simplified master plan of this research

Monetary Policy Indicators

In Australia, monetary policy is determined by the Reserve Bank of Australia in accordance with the *Reserve Bank Act 1959*, aiming to control inflation, stable currency, improve full employment and then maintain economic prosperity and people's welfare (RBA, 2007b). The RBA (2007a) stated that an inflation target is the centrepiece of Australian monetary policy.

As a country where the inflation-targeting monetary policy is implemented, the adjustment in interest rates is a key instrument (McTaggart *et al.*, 2003). Thus, interest rate is an indicator of the Australian monetary policy. However, in this research, money supply will be introduced as a variable for modelling because the interest rates and the money supply are inextricably interrelated. In Australia, a single tool left for the RBA after the removal of all direct controls on financial markets in the 1980s to achieve its objective is an open market operation (OMO). The OMO is a method used to adjust interest rates by changing money supply. Hence, employing 'money supply' for the analysis relevant to the Australian monetary policy is rational (Liu & Liu, 2010). The function of the Australian monetary policy can be written as Eq. (1).

$$MP_{AUS} = f(INT, MS) \tag{1}$$

where *INT* denotes the interest rates; and *MS* represents money supply.

Housing Supply Indicators

Quigley (1999) summarised that the supply of housing depends upon the prices of houses and new housing construction activities, thus housing supply is a function of house prices and new housing construction. Hui and Yue (2006) adopted Quigley's (1999) perspectives to study the house price bubbles in China and their empirical results supported Quigley's (1999) housing supply function.

Although the reliability of Quigley's (1999) conceptual model has been validated by Hui and Yue (2006), this function does not include the variable of construction costs. Somerville (1999) argued that construction costs are the endogenous variables of the housing supply function. Liu and London (2011) further proved that residential construction costs and housing supply in Australia are significantly interconnected. Thereby, construction costs should be incorporated in the housing supply function. In some western countries, such as Australia, UK and US, new housing construction should involve the completely new dwelling construction and the addition as well as conversion to established housing. As claimed by Baer (1986), the addition and

conversion to existing housing stock are also essential dynamics on the supply side of the housing sector in a lot of western countries. Therefore, a new housing supply function based on Quigley's (1999) perspective is developed as Eq. (2).

$$H^S = f(HP, Cost, Const^T) \tag{2}$$

where *HP* represents the house prices; *Cost* denotes the residential construction costs; and $Const^T$ stands for the construction of completely new dwelling and the addition as well as conversion to established housing.

Based on the research strategy illustrated as Figure 3, the analysis on the interactions between the endogenous variables in Eq. (1) and Eq. (2) can assist in identifying the interrelationship between housing supply and monetary policy. The interrelationship defined in this study is the causal and dynamic linkages.

METHODOLOGY AND DATA

Methodology

The econometric model used in this study for estimating the causal and dynamic relationships between housing supply and monetary policy is a vector error correction model. The VECM is useful for identifying the causal and dynamic links between the variables (Dinda & Coondoo, 2006; Liu & London, 2010).

The VECM was proposed by Engle and Granger (1987) through integrating the autoregressive and error correction representations into co-integrated systems. It is a vector autoregressive model with co-integrated restriction and error correction term. One of the most purported advantages of recognising co-integration in the VAR system is the improvement in forecasting performance (Engle & Yoo, 1987). The form of the VECM (*p*) is able to be represented as Eq. (3) and (4).

$$\Delta Y_t = \alpha\beta' Y_{t-1} + \sum_{i=1}^{p-1} \Gamma_i \Delta Y_{t-i} + \varepsilon_t \tag{3}$$

$$\Delta Y_t = \alpha ecm_{t-1} + \sum_{i=1}^{p-1} \Gamma_i \Delta Y_{t-i} + \varepsilon_t \tag{4}$$

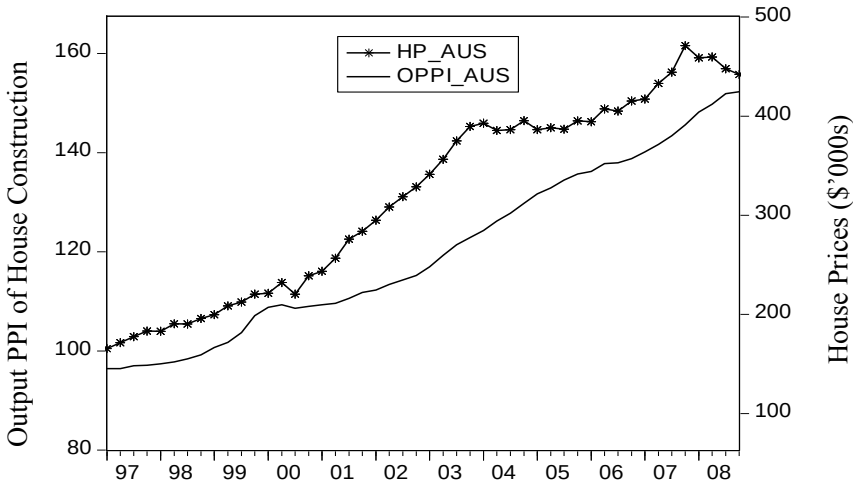
where ΔY_t is a *k*-dimensional vector in difference; $ecm_{t-1} = \beta' Y_{t-1}$ denotes the error correction term; Γ_i is the coefficient matrices; and ε_t is a vector of error term.

The causal and dynamic relationships between the variables can be detected by the Granger causality test and the generalized impulse response function under the VECM. The Granger causality is a concept proposed by Granger (1969) in the 1960s and Sims (1972) developed the test for this causality depending upon the VAR model. The Granger causality test is utilised to examine whether or not the lagged values of a

time-series variable *X* have explanatory power for the other time-series variable *Y*. If the changes in the *Y* can be explained by the lagged information of the *X*, it is concluded that *X* Granger-cause *Y*.

The impulse response function (IRF), on the other hand, is a technique used to trace the dynamic effect of a shock of the error term of an endogenous variable to other endogenous variables in the VAR or VECM. Koop *et al.* (1996) developed the traditional IRF and devised a unified method to impulse response analysis which is applicable to both linear and nonlinear models. This is the generalized impulse response function.

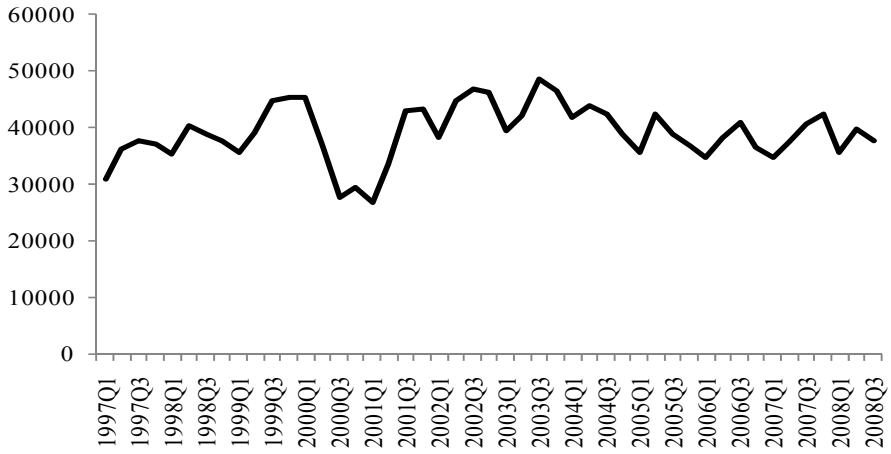
Data Collection and Description



For the purpose of estimating model, the data were extracted from several reliable sources. Firstly, the house prices selected in this study are the median house prices (HP), which are published by the Real Estate Institute of Australia (REIA).

Secondly, the output producer price indexes (OPPIs) of housing construction will be employed as the proxy for residential construction costs. The output PPIs of housing construction are issued by the ABS. It is an index measuring the rates of changes in the costs (labour input costs, plant and material input costs) throughout the procedure of housing production (ABS, 2005; 2010a). In addition, new housing construction will be measured by the housing approvals (HA) published by the ABS as well. Housing approvals reflect the total number of dwelling (house and other residential buildings) approved for construction in given periods. The data on the output PPIs and the housing approvals include the information about the construction of new dwelling and the addition and conversion to established housing (ABS, 2009d; 2010a).

Finally, in the monetary policy function [Eq. (1)], interest rates and money supply are two endogenous variables. Therefore, the interbank rates (INT) and the M1 are the ideal data for measuring these two variables (Elbourne, 2008; Liu and Liu, 2010). The interbank rate is the rate of interest charged on the loan made between banks and it is the operation target of RBA's monetary policy adjustments (RBA, 2001). Moreover, the M1 is the total amount of currency and current deposits of private non-bank sector (RBA, 2009b). Both the interbank rates and the M1 are provided by the RBA.



According to the statistics from the REIA (2009) and the ABS (2009a), the house prices and the output PPIs in Australia had dramatic movements during the period under study. Figure 4 illustrates the changes in the house prices and the output PPIs between the January quarter of 1997 (1997Q1) and the December quarter of 2008 (2008Q4) in the Australian housing and construction markets. It is discovered that the output PPIs of housing construction increased from 96.4 to 152.3 with the increase rates of 58% from 1997Q1 to 2008Q4. Meanwhile, the house prices also maintained an upward trend and achieved a peak of AUD 471,200 in 2007Q4. Then the median house prices began to move down and decreased to AUD 442,000 in 2008Q4. In

addition, Figure 5 indicates that the moving trend of the housing approval in Australia was stable. The average quarterly number of new housing (completely new dwellings and the units produced by the addition and conversion to established housing) approved for construction in the sample period was approximately 38,000.

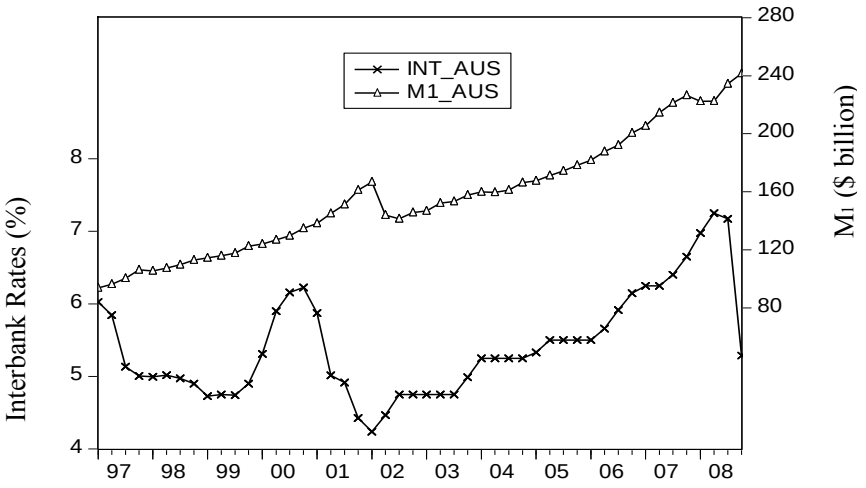

Figure 4: House prices and output PPIs of housing construction in Australia

Source: ABS, 2009c

Figure 5: Number of housing approvals in Australia

Apart from the house prices, output PPIs and housing approvals, Australia's interbank rates and money supply had also changed significantly over the past decade. Figure 6 illustrates that the interbank rates fluctuated upwards within a long-run context and climbed to 7.25% in 2008Q2, from which the interbank rates then suddenly declined to 5.29% in 2008Q4. Conversely, the movement in the M1 exhibited a smooth trend, rising from 93.8 to 241.5 billion dollars in twelve years.

Source: RBA, 2009a; 2009b

Figure 6: Interbank rates and money supply (M1) in Australia

The data description reflects that the supply side of the housing sector in Australia between 1997Q1 and 2008Q4 was exposed to the slowdown of an expansionary monetary policy. Therefore, the research question described previously is addressed again and it will be answered in accordance with the empirical results in next section.

ANALYSIS AND DISCUSSION

Unit Root Tests and Cointegration Tests

In time-series econometric modelling, the data imported must be stationary. Otherwise, a spurious regression would be triggered (Granger & Newbold, 1974). Therefore, the unit root tests will be the first test undertaken in this study. Table 1 reports the results of the PP tests of the selected variables [house price (HP), output PPIs (OPPI), housing approvals (HA), interbank rates (INT) and M1]. Based on this table, all data utilised are integrated of the order one, i.e. *I* (1).

Variables	**Level**		**First Difference**		**Results**
	Model specification (lags)	PP Test Statistics (5%, 1% sig. level)	Model specification (lags)	PP Test Statistics (5%, 1% sig. level)	
ln(HP)	Trend &Intercept (2)	-0.24 (-4.17, -3.51)	None (2)	-4.66 (-2.62, -1.95)	*I* (1)***
ln(OPPI)	Trend & Intercept (2)	-2.67 (-4.17, -3.51)	None (2)	-3.65 (-2.62, -1.95)	*I* (1)***
ln(HA)	Trend & Intercept (2)	-3.32 (-4.17, -3.51)	None (2)	-6.24 (-2.62, -1.95)	*I* (1)***
ln(INT)	Trend & Intercept (2)	-2.76 (-4.17, -3.51)	None (2)	-2.59 (-2.62, -1.95)	*I* (1)**
ln(M1)	Trend & Intercept (2)	-2.49 (-4.17, -3.51)	None (2)	-4.29 (-2.62, -1.95)	*I* (1)***

Notes: The PP Test, which is the unit root test similar to the ADF Test, contains three kinds of model specification: only intercept, trend and intercept, and no trend and no intercept. ** and *** denote the 95% and 99% significance level.

Table 1: Summary of the PP test results

The co-integration test is the second necessary step for constructing the VECM. The approach proposed by Johansen and Juselius (1990) (known as the JJ test) will be conducted after the PP unit root tests. As suggested by the Akaike Information Criterion and the Schwarz Information Criterion, one lagged term has been selected for the co-integration test. Although there are five models in the JJ test, this study is concerned with Model 3 and Model 4 (Model 3 has a linear data trend but no trend in the co-integration equation; and Model 4 has a linear data trend with both an intercept and a trend in co-integration equation) as the description on the data has confirmed that the majority of the data used in this research appears to be trending series. Table 2 summarises the results of the JJ tests, which suggest that a long-run equilibrium relationship exists among the observed variables.

Variables	Lagged difference	Model specification	Results (Trace test)	Results (Max-eigenvalue test)
ln(HP), ln(OPPI), ln(HA), ln(INT), ln(M1)	1	Model 3	1	1
		Model 4	1	1

Table 2: Summary of the JJ co-integration test results

In Table 2, one co-integration vector has been identified by both Model 3 and Model 4 under the Trace test and the Max-eigenvalue test. However, Krol and Ohanian (1990) claimed that there is a stationary deterministic trend in money supply. As a result, one co-integration vector of Model 4 will be selected because Model 4 is suitable for the situation that some of the series are trend stationary.

Causal Relationships between the Selected Variables

As the co-integration was found among the variables, the VECM can be formulated to carry out the Granger causality and the generalized impulse response function. Applying the Wald tests and joint *F*-tests, the null hypothesis that the independent variables do not Granger-cause the dependent variables is rejected at the 95% and 99% significance level. Table 3 indicates the results of the Granger causality tests. According to Table 3, a transmission pattern illustrated as Figure 7 can be identified. This transmission pattern not only confirms the interrelationship between housing supply and monetary policy, but also depicts how the monetary policy and the supply side of the housing sector interact with each other. In summary, there is a significant relationship existing between monetary policy and the supply of housing in Australia.

Dependent Variables	Directions	Chi-square	*P* values	Results
ln(INT)	ln(M1) → ln(INT)	5.63	0.02	Y
	ln(HP) → ln(INT)	0.24	0.62	N
	ln(OPPI) → ln(INT)	0.21	0.65	N
	ln(HA) → ln(INT)	2.28	0.13	N
ln(M1)	ln(INT) → ln(M1)	1.23	0.27	N
	ln(HP) → ln(M1)	5.39	0.02	Y
	ln(OPPI) → ln(M1)	0.29	0.59	N
	ln(HA)→ ln(M1)	8.83	0.00	Y
ln(HP)	ln(INT) → ln(HP)	3.91	0.05	Y
	ln(M1) → ln(HP)	0.33	0.56	N
	ln(OPPI) → ln(HP)	0.22	0.64	N
	ln(HA) → ln(HP)	1.35	0.24	N
ln(OPPI)	ln(INT) → ln(OPPI)	4.11	0.04	Y
	ln(M1) → ln(OPPI)	0.33	0.56	N
	ln(HP) → ln(OPPI)	1.90	0.17	N
	ln(HA) → ln(OPPI)	0.29	0.59	N
ln(HA)	ln(INT) → ln(HA)	2.52	0.11	N
	ln(M1) → ln(HA)	0.78	0.38	N
	ln(HP) → ln(HA)	9.22	0.00	Y
	ln(OPPI) → ln(HA)	13.09	0.00	Y

Table 3: Summary of the Granger causality test results

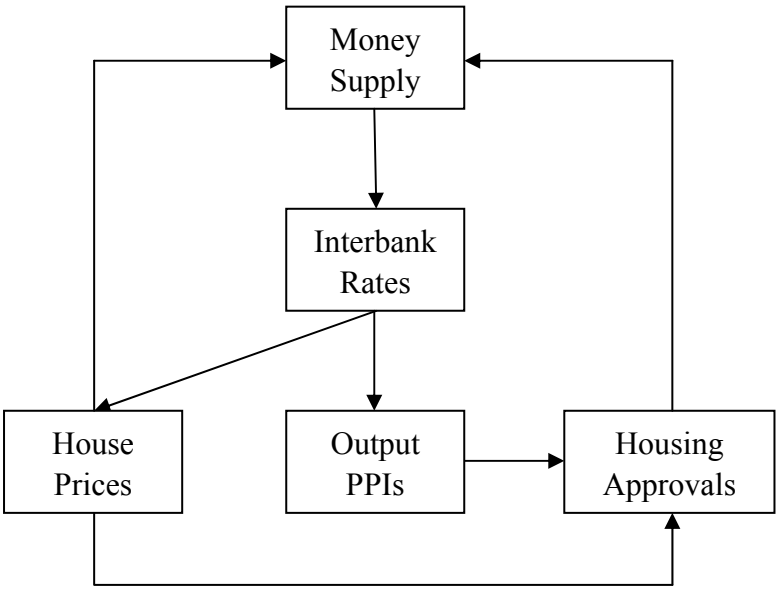

Figure 7: Transmission pattern between housing supply and monetary policy

The transmission pattern first suggests a one-way causality relationship between the money supply and the interbank rates. This finding is consistent with the reality that the RBA adjusts the interbank rates by changing the supply of money in realistic economic system. Furthermore, Figure 7 illustrates that the interbank rates Granger-cause the house prices and the output PPIs, both of which Granger-cause the housing approvals. Nevertheless, no causal relationship was identified from the

interbank rates and the money supply to the housing approvals, implying that house prices and construction costs perform as two transmission mechanisms of the shock of the monetary policy on new housing construction activities. In short, a ripple effect exists among the observed variables, and monetary policy influences new housing construction activities via house prices and residential construction costs.

The discussion previously mentioned focused on the causal links within the direction from monetary policy to housings supply. However, the empirical results also indicate that the house prices and the housing approvals Granger-cause the money supply without a feedback. Macroeconomic theory argues that the development of important economic sectors has been an essential factor in today's monetary policy decisions (McTaggart *et al.*, 2003). Hence, the changes in the housing sector can induce the monetary regime shifts.

Dynamic Relationships between the Selected Variables

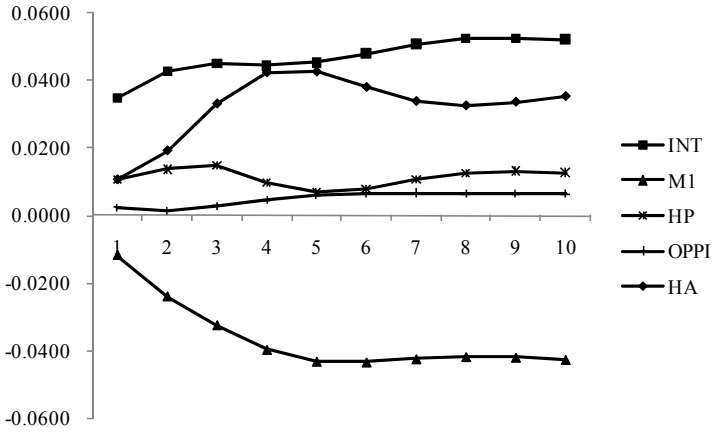
The Granger causality test has identified the causal links between the observed variables, however it is not able to explore the dynamic linkages among the endogenous variable. Thus, the generalized impulse response function (GIRF) will be adopted in the following analysis and Figure 8 illustrates the results.

Firstly, there are dramatic effects produced by the interbank rates on the house prices. It is noted that the maximum values of the response of the house prices to the standard deviation of the interbank rates achieve -1.10%. The 'negative' values here indicate that the increasing trend of the house prices in Australia had been dramatically depressed by the increases in the interbank rates during the period under study. On the contrary, the response of the output PPIs to the interbank rates is positive. Specifically, a total of 0.43% dynamics on the output PPIs is yielded by the interbank rate disturbances, suggesting that an increase in construction costs was strengthened by a rise in the interbank rates. It is knowledge that an inflation of the interbank rates increases the payments on interests, which represent a major part of the costs of the construction projects financed by the loans of banks or other financial institutions. The ABS (2009d) reports that an approximately 50% of housing construction projects in Australia is under the loans. As a result, the construction costs in Australia can be easily affected by the changes in interest rates.

Compared with the interbank rates, the house prices and the output PPIs are less sensitive to the movement in money supply. The results indicate that the standard deviation of the M1 produces less effect on the house prices as well as the output PPIs than that of the interbank rates, 1.07% and -0.21% respectively in five quarters. These two values suggest that the house prices are positively related to the M1 and there is an inverse relationship between output producer prices and money supply.

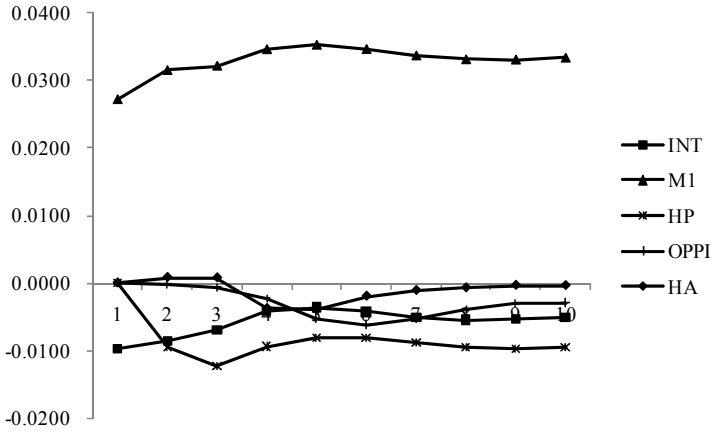
It has been described in *Introduction* that the growth rates of the money supply in Australia from 1997 to 2008 exhibited a downward trend in conjunction with a rise in

the interest rates. Thereby, the empirical results associated with the responses of the house prices and the output PPIs imply that the slowdown of an expansionary monetary policy had weakened the upward trend of the house prices but increased the residential construction costs in Australia.



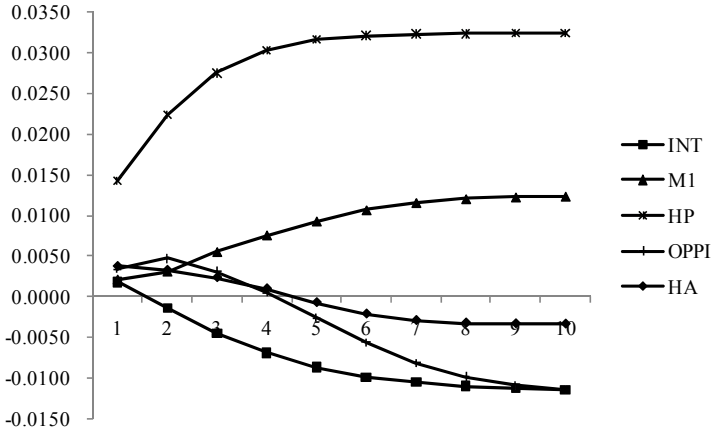
Secondly, new housing construction activities measured by the housing approvals are sensitive to the changes in the house prices and the construction costs. Overall, the house prices have a positive effect on new housing construction while an increase in the output PPIs reduces the construction for new housing. According to Figure 8, the responsive values of the housing approvals to the standard deviations of the house prices and the output PPIs reach 1.41% and -3.87% respectively in five quarters.

As discussed previously, the adjustments in monetary policy between 1997 and 2008 in Australia had depressed the house prices but driven up the residential construction costs. Due to the strong linkage between new housing construction and the changes in house prices and construction costs, the slowdown of monetary expansion surely can reduce new housing construction level across Australia. This conclusion can be supported by the results of the GIRF, which indicate that the housing approvals are decreased up to 1.65% in three quarters by the shock of the monetary policy.

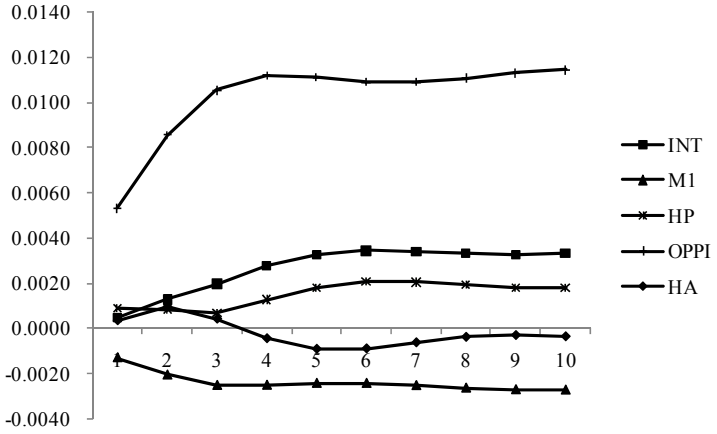


Finally, the influence of the supply side of the housing sector on monetary policy decisions can not be ignored. The empirical results indicate that the responses of the interbank rates and the M1 to the impulses of the house prices, output PPIs and housing approvals are: 1.25% and -0.85%, 1.17% and -0.65%, and 5.11% and -1.16% respectively. It is inferred from these values that Australia's central bank will decrease the money supply to increase the interbank rates when facing overheating investments in the housing sector. Conversely, if a recession occurred in the supply side of the housing sector, the central bank will lower the interbank rates to stimulate the investments on housing development. These findings comply with the conventional macroeconomic theory, thus the conceptual model and the VECM developed in this study are reliable.

Based on the empirical evidence displayed in Figure 7 and Figure 8, an overall outcome of this research is able to be summarised as Figure 9. In summary, the slowdown of an expansionary monetary policy had weakened the increasing trend of the house prices and raised the residential construction costs in Australia. Consequently, the level of new housing construction had been depressed by the price and cost changes triggered by the shock of monetary policy. In conclusion, the development of the supply side of the housing sector had been negatively affected by the monetary regime shifts during the recent decade in Australia.



Responses of the interbank rates



Responses of the M1

Responses of the house prices

Responses of the output PPIs of housing constructions

Responses of the housing approvals

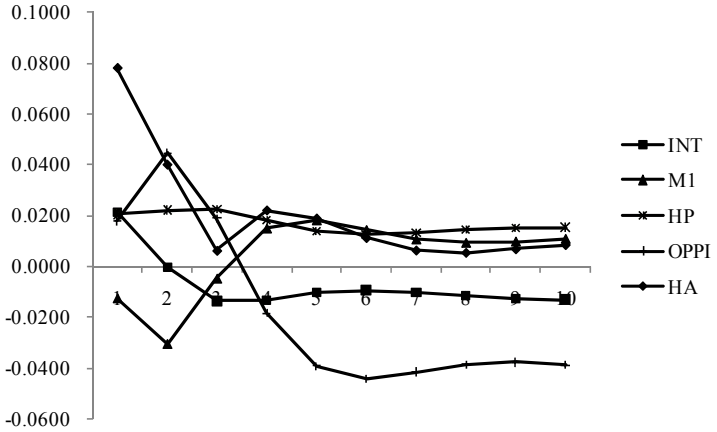


Figure 8: Results of the generalized impulse response function

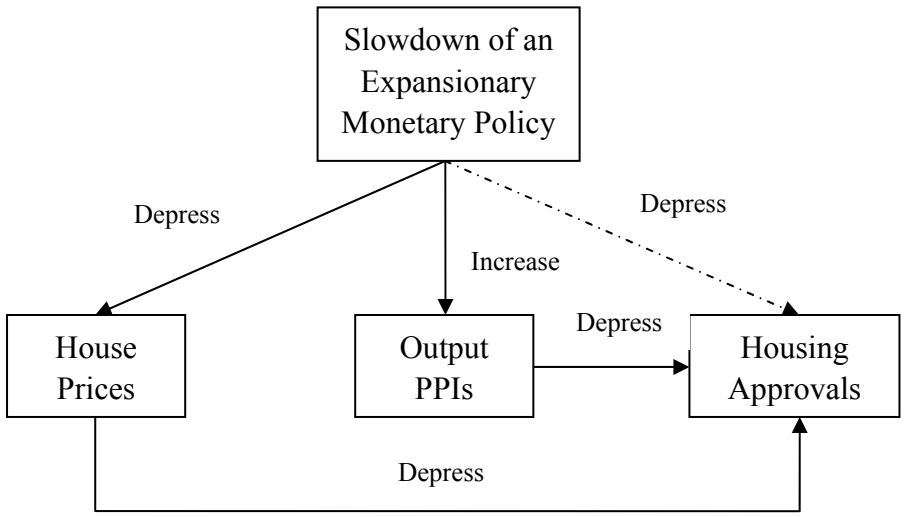

Figure 9: Impact of the slowdown of an expansionary monetary policy on the supply side of the housing sector in Australia

CONCLUSION

This empirical study has investigated the interrelationship between housing supply and monetary policy in Australia by a vector error correction model. Depending upon the Granger causality test, a transmission pattern within the framework of monetary policy and housing supply has been identified. This pattern illustrates that the interbank rates perform as an activator that transfers monetary policy makers' interventions to the supply side of the housing sector, and house prices and residential construction costs are two transmission mechanisms of the shock of monetary policy on new housing construction activities. According to results of the generalized impulse response function, it can be concluded that the slowdown of an expansionary monetary policy has significantly depressed housing supply in Australia.

This paper uncovers the negative effect of the slowdown of an expansionary monetary policy on housing supply. The models developed in this research is useful for policy makers to estimate the influence of monetary policy on the supply side of the housing sector and provides them with valuable insight to improve the housing supply across Australia. Furthermore, as suggested by the perspective of policy collaboration, some other policies (e.g. construction policies or taxation policies) in relation to residential construction can be enacted for construction industry by the Australian governments to reduce the negative impact from current monetary policy and then stimulate the investments on new housing developments. In reality, the construction policies for the supply side of the housing sector are a promising field for future study.

ACKNOWLEDGEMENTS

The authors would like to express their appreciations to the academic researchers who have contributed to this study. Additionally, the authors also extend their appreciations to the anonymous reviewers.

Abstract
Engaging the right stakeholders at the right time is a key factor to successfully complete a construction project. However, the decision which stakeholders to engage within a project can often be difficult. This research looks into the applicability of visualizations of Social Networks as a tool to support project managers to decide which stakeholders to engage and with consecutively engaging these chosen stakeholders. To provide empirical evidence for the utility of Social Network Analysis, we conducted a case study on a public-private redevelopment project in the Netherlands. The findings from this case study show that representations of social networks give project managers a quick overview of the cliques, key players, and the general position of stakeholders in the social project network. This overview helped the project managers to identify which stakeholders to engage. At the same time, our findings show that visual representations of social networks help to engage stakeholders by giving them clear insights into their respective position in the social project network. Overall, the study illustrates the utility of social network visualizations to understand and engage stakeholders on public-private construction and design projects.
Keywords: Social Network Analysis; stakeholder engagement; public-private construction

INTRODUCTION

Stakeholders are all the people, groups of people, or organizations, such as neighborhoods, institutes, or societies, with a concern for the outcomes of a certain construction project (Mitchell et al., 1997).
The influence of stakeholders on public project outcomes is traditionally high. Stakeholders can for example often rely on legal procedures to slow down or stop a project that is against their will and interests. Another option stakeholders often use to gain influence on project outcomes are political lobbies. Hence, project managers need to manage stakeholders well to achieve desired project outcomes (Achterkamp & Vos, 2007). Goals of such stakeholder management efforts are, among others, to increase support and reduce project costs and durations (Zhong et al., 2007). If stakeholders support a plan, this will prevent that time and money is spent on legal procedures and objection procedures. Another goal might be

community learning or better and more sustainable project acceptance (Innes & Booher, 1999).
As a first step in stakeholder management, project managers should start with mapping all those people and organizations with an interest in a project. This will provide project managers with a complete overview of the project's stakeholder environment. Ideally, project managers should do that early on in the project because At the very outset of a project, stakeholders have the most chance to get actively involved in the planning activities.
After identifying stakeholders, project managers have then to decide which stakeholders they like to engage in the planning process and how they like to engage them. Stakeholder engagement focuses on the participation of stakeholders, or enabling stakeholders to exert an influence on a project and its outcomes. Project managers should engage stakeholders, to reach project outcomes that are more likely to be successful in the implementation and maintenance phase. This greater success is a consequence of incorporating the ideas and opinion of a broad set of stakeholders in the eventual plans.

However, identifying and engaging stakeholders is not an easy task. Stakeholders form a complex social network that project managers need to understand to be able to engage the right stakeholders at the right moment. Further, if the stakeholders understand the social network too, this will probably grant them better understanding of the decisions project managers make regarding the engagement process. In any case, to successfully identify and engage stakeholders, project managers have to understand the social interdependencies between stakeholders within a project's social stakeholder network. The visualization of such a social stakeholder network in the form of a graph seems to be a good tool to support project managers in their stakeholder identification and engagement efforts. To explore empirically how such social network visualizations can support stakeholder management activities, we conducted a case study on a public private partnership project in the Netherlands during which we introduced social network graphs in the planning process. This paper reports the results of this case study.
The paper is structured as follows: in the next section, we will discuss the theory we used as basic knowledge for our research. In the subsequent section, we will discuss the research method we applied during the twelve weeks of research. After that, we will describe the data we collected during this research, and the results of the analysis of this data. The report will conclude with the conclusions and the limitations of the research.

VISUALIZATIONS OF SOCIAL NETWORKS IN STAKEHOLDER MANAGEMENT

If project managers set up well managed participation processes for stakeholders, this can lead to better project outcomes, reduce of costs (Zhong et al., 2007), and lead to broader support of the project. That is why it is important for project managers to identify the important stakeholders within a project. One important step during such identification efforts is to analyze the interdependencies between stakeholders in a social network. Current models for stakeholder management (Mitchell et al.,1997; Achterkamp & Vos, 2007; Bakens et al., 2005) do not provide insight in those interdependencies. Visualizations of social networks do.
To theoretically underline our work, this section offers an overview about current available models in stakeholder management and briefly discusses their advantages and shortcomings. Afterwards, this section then introduces methods to visualize social networks, and derives a number of theoretical benefits of such visualizations during the stakeholder management process.

Currently applied stakeholder management methods focus on the same basic principles to support project managers in their decisions on stakeholder engagement: identifying and categorizing the stakeholders. Identification is often done by brainstorming sessions. This is a good way to stimulate out-of-the-box thinking and produce an as complete as possible list of (potential) stakeholders of a project.
Based on the list of identified stakeholders, current methods then suggest that project managers categorize stakeholders. This categorization can be done in several ways. For example by categorizing stakeholders based on attributes they possess, such as power, legitimacy and urgency (Mitchell et al., 1997), or based on the role a stakeholder has in a project, like a client or a representative stakeholder (Achterkamp & Vos, 2007). For their own purposes, these are useful techniques. Nevertheless, the techniques do not give project managers and external stakeholders insight in the interdependencies between stakeholders in the social (project) network.

These interdependencies between stakeholders can be visualized by a social network graph that shows the stakeholders as nodes and their mutual relations as edges between these nodes. This presentation can grant project managers and external stakeholders insight in the key characteristics of stakeholders within the network: their centrality, their prestige, whether they form cliques with other stakeholders, and their relative position. Further, the graph representation can show missing ties between stakeholders. The following subsections will elaborate on how social network graphs can help to identify the above listed characteristics.

Prominence: Centrality & Prestige

Prominence of a stakeholder in a network exists in two forms: centrality and prestige. Centrality reflects the involvement of a stakeholder within many relations in the network. The centrality of a stakeholder can easily be determined by the number of relations they have within the network. Take for example a non-directed network with six stakeholders (figure 1).

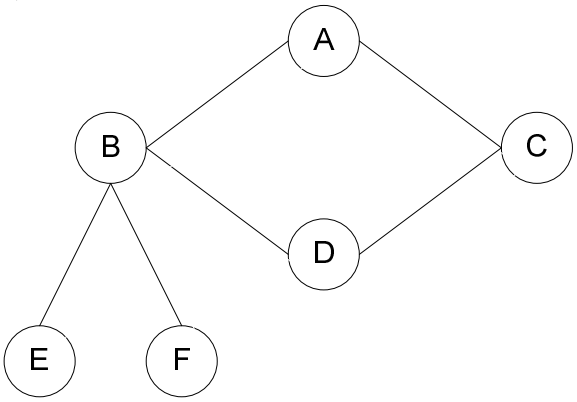

Figure 1: *Example of a non-directed social network (Knoke & Yang, 2008)*

In this network, stakeholder B is the most central stakeholder with four relations. Through this, B is the most visible to the other stakeholders and can be considered a key stakeholder. Stakeholders with many relations are likely to have a high influence on a project, as they can reach many other stakeholders in the network to convince those stakeholders of their view on a project and the desired project outcomes.
The other form of prominence in a social network is prestige. Prestigious stakeholders are receivers of many relations; i.e. they don't initiate many relations within the network, but

receive many ties from other stakeholders. The amount of such "sender-receiver" or "source-target relations", implies the control over resources and a certain amount of authority over other stakeholders by the prestigious stakeholder. Prestigious stakeholders often collect information from other stakeholders, making them interesting parties to be engaged. This makes them also a key player that should be engaged according to 'the law of the few' (Bakens et al., 2005).
The centrality and prestige concepts grant external stakeholders insight in their own position relative to other stakeholders. They can determine whether they have a strong position compared to other stakeholders ("Am I in a more central position than the others?").
Project managers benefit from the external stakeholders' better understanding of their positions through the two concepts. The external stakeholders are more likely to understand the decisions project managers make on stakeholder engagement. These decisions on stakeholder engagement can be based on the quick overview of the key stakeholders which a visualization of the social network grants project managers. This helps project managers when determining which stakeholders to engage. The key stakeholders, based on their centrality and prestige, are likely to be able to influence project outcomes and have information of the other stakeholders. Furthermore, because networks often show great variety between the stakeholders, it is time consuming for a project manager to approach every stakeholder with a tailor-made approach (de Bruijn & ten Heuvelhof, 2008).
External stakeholders benefit from the centrality and prestige concepts by knowing what their opportunities are, regarding their position in the network. They can make better decisions about what they can demand from a project manager. For example, they can try to attract a lot of attention for their interests, but if they are somewhere on the side of the network with only one tie to another remote stakeholder, they probably won't be noticed.

Cliques
Cliques give information about groups of stakeholders that are closely related to each other through their interdependencies and relational ties. Cliques consist of groups of stakeholders who have ties with all of the other members of the cliques, whereas no other stakeholder in the network has direct ties to all the stakeholders in the clique. Prerequisite is, that there are at least three stakeholders involved in a clique. Using these requirements, the boundaries of cliques within a social network can be determined. For example, see figure 2.

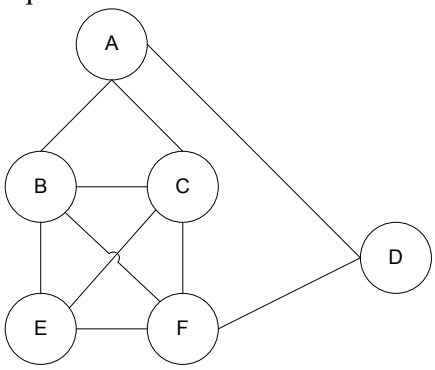

Figure 2: *Example of a clique in a social network (Knoke & Yang, 2008)*

Two cliques can be recognized in this example. There is a clique consisting of A, B, and C and a clique consisting B, C, E, and F. These stakeholders have mutual relations with each other, whereas no other stakeholder in the network has connections with all of the stakeholders in the clique. A, D, and F don't form a clique, because there is no direct tie between A and F.

Knowledge about existing cliques and prominent stakeholders within a clique is important for the project manager. Project managers can engage the prominent stakeholder that can then act as a representative for a group of stakeholders. The opposite can also be done: after determining the boundaries of a clique, the project manager can determine whether the clique has a prominent stakeholder in their midst. Furthermore, the cliques grant the project manager insight in the individual stakeholders that might be empowered by being part of a clique, and which cliques are present in the network.
Understanding about clique membership can also help stakeholders to get engaged with the project. In general, stakeholders can gain more influence as a group than individually. In combination with the technique to recognize prominent stakeholders, members of a clique can also again determine whether there is a prominent stakeholder inside their clique who can act as their representative.
Cliques are, like centrality and prestige, based on the relations and interdependencies between stakeholders in the social network. Possessing the same attributes or playing the same role in a project does not imply a mutual relation between stakeholders. Because of this, current models for supporting project managers with stakeholder management are not useful in recognizing cliques.

Insight in missing ties
The visual representation of a social network shows the relations between stakeholders. It also shows which stakeholders have no connection with each other: missing ties.
Project managers can also benefit from knowledge about missing ties. For example, through the complete oversight of apparent and non-apparent ties, the project manager can evaluate whether every stakeholder is adequately engaged in the social stakeholder network of the project. Stakeholders can also benefit from knowledge about missing ties. Stakeholders can, for example, initiate new relations to gain a more central or prestigious position in the network or to form a new clique. Another option would be to initiate a relation with a key stakeholder to get their information to the project manager.
Though project managers can use the current models to make sure every stakeholder is represented (simply by engaging all identified stakeholders), this does not grant them and the external stakeholders insight in the non-apparent relations. Because of this, external stakeholders can't use the information from the categorization models for strategic purposes.

Overview
In summary, visual representations of social networks can support project managers with their decisions on stakeholder management and help external stakeholders with understanding the decisions a project manager makes. An overview of the different concepts and their utility to respectively project managers and external stakeholders is in table 1.

Social Network Analysis technique	**Utility for Project Managers**	**Utility for external stakeholders**
Centrality	Grants insight in the key stakeholders within the network.	Grants insight in their own relative position compared to other stakeholders. Also, makes them better understand their position and the choices project managers make.

Prestige	Grants insight in the authoritative stakeholders within the network.	Grants insight in their authority compared to other stakeholders.
Cliques	Grants insight in the stakeholders who gain power by being a group.	Empowers stakeholders as they can reach more with a group than as an individual. Ability to choose a representative inside the boundaries of the clique.
Insight in missing ties	Grants a quick overview of the relations between stakeholders, so the project manager can evaluate who is represented in the engagement process.	Grants a quick overview of the relations they should initiate to become more central or to become part of a clique, giving them a strategical advantage.

Table 1: *Summary of the utilty of social network analysis*

RESEARCH METHOD

To provide empirical evidence and explore if social network analysis is useful in managerial practice, we conducted a case-study on a public-private partnership project of the city of Almelo in the Netherlands. The projects goal is to establish a building that accommodates a hotel, several catering companies, and other peripheral retail organizations. The project got the name Almelo Nouveau and had to be an attractive building, both inside and outside. For several years, the municipality of Almelo and the private party they cooperated with, a project developer, worked on the plans for Almelo Nouveau.

Figure 3: *Artist impression of Almelo Nouveau (Tubantia, 2010)*

However, the municipality has designated more sites in Almelo for peripheral retail. This means that the municipality is going to realize a lot of extra commercial space in the upcoming years. It is questionable whether the municipality can fill all of this space with private commercial parties, as the designated functions of the new locations are all similar. Additionally, the previous responsible politicians (from other political parties than the current responsible politicians) have initiated the revitalization and restructuring of the town centre, which will be under construction for the upcoming years. This has led to enormous opposition by entrepreneurs throughout the city against the realization of Almelo Nouveau. Eventually, the City Council decided to put a hold on the project.

The project managers of the municipality and the project developer wanted to know how this stakeholder obstruction could occur, as they thought they were working on plans that were good for the city. But, during the years of preparation, making the plans for Almelo Nouveau, the project managers of the municipality and the project developer hadn't paid much attention to stakeholder management. At the end, this led to the opposition of several stakeholders, delaying the project. So they wanted to know how to proceed *with* these stakeholders involved and how to engage the opposing stakeholders better in the planning phase. Hence, this project was an ideal opportunity to test our hypothesis on the utility of social network analysis in stakeholder management on a real life project and in close collaboration with practitioners. Figure 4 illustrates our overall research effort.

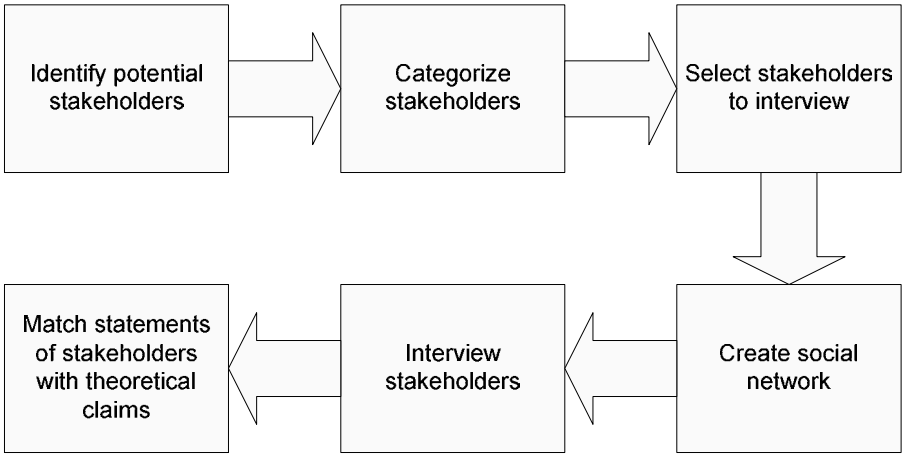

Figure 4: *Overview of research methodology*

When we started on the project, we first identified the potential stakeholders of the project. So, we conducted a brainstorming session with to members of the project team of the municipality; two employees of the Department of Economical Affairs. This resulted in a vast list of (potential) stakeholders.

From this list we selected seven stakeholders to interview. Overall, we selected some internal stakeholders from the community of Almelo (Alderman, project manager) and some external stakeholders. To allow for a meaningful collection of interview data, we selected only stakeholders which had already come in contact with the functional interpretation of Almelo Nouveau.

We also tried to select interviewees from a broad range of stakeholder groups to enable us to draft a complete image of the problem perceptions on the project. Table 2 lists the seven interviewees and why we selected them.

Stakeholder	**Selected because**
Alderman	He played an important role during his time in the opposition (till march 2010) and in the time he has been Alderman. He was part of the opposition in the City Council that has set a hold to the plans. As Alderman he still objects to with the initial plans for the project.

Project manager municipality	The project manager is responsible for the management of the project and the additional processes, including stakeholder management.
Chamber of Commerce	The objecting parties asked the Chamber of Commerce for advise about Almelo Nouveau. The Chamber of Commerce was also part of the group of speakers who convinced the City Council to bring the project to a halt. The main role of the Chamber of Commerce is giving objective advise to the municipality and entrepreneurs.
SOBA (Foundation Entrepreneurs Town Centre Almelo)	The SOBA is one of the objecting parties, but also the representation of most entrepreneurs in the town centre. With the revitalization plans for the town centre, the SOBA has a clear opinion about other projects.
Owners residential boulevard	The residential boulevard is another commercial part of town that struggles with the financial crisis and fears competition from Almelo Nouveau and other projects.
MKB Almelo (Small to Medium-sized Entreprises Almelo)	MKB Almelo is the organization that represents most of the objecting parties. MKB Almelo was also part of the group that spoke to the City Council to convince them that the current plans would harm the economical balance in the city.
Project manager project developer	The project developer is the partner in the Public Private Partnership with the municipality of Almelo.

Table 2: *Reasons for selection of interviewees*

In advance of the interviews, we created an example of the social network of this project. We created this network with the information we retrieved from our conversations with the project manager of the municipality and the information we got from the project team members during the brainstorm session. During the interviews, we presented a more detailed graphical representation of the network (Figure 5).

In Figure 5, the thickness of the arrows represents the frequency of contact between stakeholders. The arrows between stakeholders within the municipality the thickest arrows, as there is frequent contact between them. The arrows between the stakeholders of the municipality and the external stakeholders are thinner, as there is less contact between these stakeholders. They only communicate with each other when there are new developments to mention. The same is valid for the group of external stakeholders at the right side of the chart. They only communicate in relation to the project Almelo Nouveau when there is news to discuss.
After showing them the social network and the chart below, we asked the interviewees two questions regarding the social network analysis: (1) what they thought of their own position and that of other stakeholders and (2) what they thought of the value of such a visualization to them. After conducting the interviews we then analyzed the statements of the stakeholders.

During this analysis, we tried to link the interview statements with the claims we made in table 1 for the utility of the social network concepts centrality/prestige, cliques, and missing ties. In the next section, we will describe these analysis outcomes for each of the concepts.

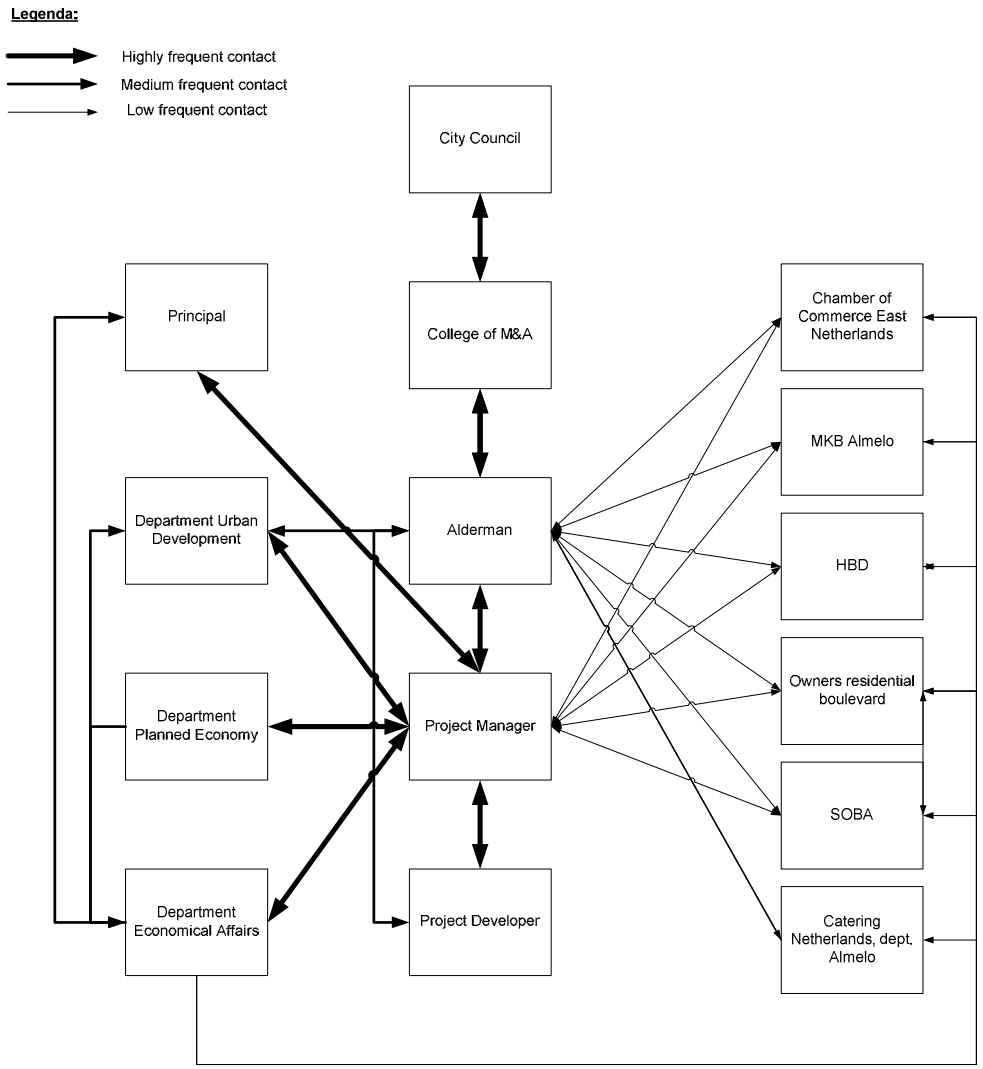

Figure 5: *Chart of relations between stakeholders, shown to interviewees*

RESULTS OF DATA ANALYSIS

Centrality & Prestige

Utility to external stakeholders: Grants insight in their own relative position and authority compared to other stakeholders.

In general, the external stakeholders saw a practical value in the visualization of the social network for determining their own relative position compared to other stakeholders. They could decide whether they felt they were on the right place or not. The representative of MKB Almelo said the following about his central position in the network and his resulting role as key stakeholder: “It’s our responsibility to represent entrepreneurs”. As a central

stakeholder in the network, MKB Almelo can act as a representative for the external stakeholders they are in contact with. The representative of the Chamber of Commerce is more a prestigious stakeholder, as he receives many ties that are initiated by external stakeholders. He tries "to group these a little bit and let them function better." As an authoritative stakeholder, he is asked for advice by the external stakeholders.
Utility to project managers: Grants insight in the key stakeholders within the network.
The first remark of the project manager of the municipality was the importance of the correct filling in of the network. If the right names are not on the right place and the information on ties and the direction of relations is not correct, the network looses its analytical value. If the prerequisite of correctness is fulfilled, the visualization of the social network clarifies the stakeholder environment to the project manager. This clarification of the social network is established through the insight in the relative prominence of the stakeholders, reflecting their importance to the project manager.
For the project manager of the project developer centrality also played a role. Especially their own centrality in the network. "We are not in the right place here. We have to be much more in the middle", was his first comment after seeing the visualization of the social network. He would like to be more central, to be visible to external stakeholders and proclaim the positive message of their building aspirations. He also saw in the visualization that the municipality has a central position in between the project developer and the other external stakeholders. This gives him the information to consider a strategy with the municipality as middle person: "All of the other stakeholders can bring their questions to us via the municipality". Furthermore, as "the importance of stakeholders is tested by the municipality and their project manager, and us", the visualization of the social network grants them insight in the importance of stakeholders based on the relations these stakeholder have.

Cliques
Utility to external stakeholders: Grants insight in the cliques they can join or leave, giving them a strategical advantage.
The visualization also gives the project managers and the external stakeholders insight in the existing cliques. As the representative of the Chamber of Commerce mentioned, the visual representation of the social network gives him an idea of which stakeholders he can group together to make them better organized in protecting their interests. The stakeholders we spoke to who where in the clique, where content with their position, as they had a strong position with the other stakeholders as a clique opposing the plans.

Grants insight in the stakeholders who gain power by being a group.
The experience of the project manager of the municipality is that "making an overview of the relationships between stakeholders is very enlightening". This is because of the insight in the cliques stakeholders form and the consequences of those alliances to their power to influence project outcomes.

Insight in missing ties
Utility to external stakeholders: Let's them better understand why they are in a certain position.
The final utility of the visualization of the social network is the insight in missing ties. The visualization helped the interviewees to determine which relations they should initiate for certain goals. External stakeholders could for example see why they were not in direct contact with the municipality: they were already represented by a prominent stakeholder in their clique, the MKB. As the Alderman said, "this also makes the structure clear". The

visualization makes clear to project managers and external stakeholders which relations are apparent and non-apparent between other stakeholders as well.
As we stated earlier, the visualization showed the project manager of the project developer that he was de-central in the network, despite his company having invested a lot of money in the project. The visualization gave him insight in the missing ties: there was no direct contact with the external stakeholders, whereas initiating these relations could enlarge his visibility within the network. Furthermore, the insight in the missing ties also emphasized the ties he did have: he had a direct tie to the Alderman and the project manager of the municipality. This led to the earlier mentioned strategy to give the centrally positioned representatives of the municipality a role as intermediate between the project developer and the external stakeholders.
Utility to project managers: Gives a quick overview of the stakeholder environment and the relations between stakeholders.
The visualization also showed the project manager of the municipality that he was a central figure within the project team and the municipality, but to the outside world, the external stakeholders, the Alderman held a more central position. “On the new project I have too little influence,” was the remark of the project manager. The visualization of the social network showed him why: the greater part of the communication with external stakeholders went through the Alderman. External stakeholders also mentioned during the interviews the minimal contact they had with the municipalities project manager. The Alderman is their ‘reference point’ for decisions.
Overall, the above shows that the visualization of a social network can indeed help project managers with stakeholder management, and external stakeholders with the determination of their position and strategies.

LIMITATIONS & SUGGESTIONS FOR FUTURE RESEARCH

Generalization comes with numbers. When executing a case-study, these numbers come in the number of cases that are studied in one research. A researcher does this to discover a pattern in the form of similarities between comparable cases. Due to a limited period of time to execute the research, we could only perform a study on one case. This makes the results possibly sensitive to deviations in comparison to similar cases. Nevertheless, the case studied in this research, Almelo Nouveau, is suitable for generalization because this sort of construction project is likely to be found elsewhere. A Public Private Partnership, where a municipality, or other governmental organization, cooperates with a private party on the realization of a commercial building. The public party facilitates, while the private party bears the risks. Furthermore, commercial activity is everywhere. The chance to find similar kind of construction projects elsewhere is quite high. At last, the kind of stakeholders identified in this research where quite general ones in relation to the realization of the construction of a commercial building (entrepreneurs from elsewhere within the city, umbrella organizations for these entrepreneurs, public party, private party). Nevertheless, we suggest that future research efforts start to evaluate the utility of social network visualizations on other projects as well to improve the generality of the here presented work.
Because the conclusions of the research are mainly based on the interview data collected during the twelve weeks of research and on a specific case, the data have possibly been influenced by the opinion of the interviewees or their emotional involvement with the project. Besides, the amount of interviewees has been very limited in comparison to the total amount of identified stakeholders. This has (partly) led to assumptions about the non-interviewed stakeholders.
Another limitation of this research is the relative simplicity of the used network graph. The more variety and interdependencies among stakeholders, the more complex and less

transparent the social network will be. That makes it harder for the project manager to oversee the network using a visual graph presentation (de Bruijn & ten Heuvelhof, 2008). For example, if a social network consists of more stakeholders, it will be harder for project managers to identify the central stakeholders or find out where the cliques are. However, mathematical methods exist that can allow for the calculation of centrality values and cliques within social networks (Knoke & Yang, 2008). We suggest that future research also evaluates the utility of these methods to support stakeholder management activities.

Another downside of this research is that we did not look at the process itself wherein project managers will use the social network analysis. In general, project managers should identify stakeholders at the start, during the initiative phase of a project. They should do this to build support among the stakeholders and give them the possibility to add their own ideas. In our research, we applied the social network analysis only late in the project planning efforts. In the initiative phase, the goals and implications of a construction project are still ambiguous. It is likely that boundary conditions (e.g. political environment, legal regulations) will change during the decision-making process, changing the stakeholders and their relationships which again will make it harder to understand a graphical network presentation. Additionally, the social network on projects will change over time. Researchers should evaluate how to best integrate social network analysis in the planning process and how once established social network graphs can be updated throughout a project.

Overall, we claim that social network analysis visualizations should make the work of project managers easier, because the external stakeholders better understand their own relative position. However, stakeholders will choose their own strategy to reach their individual goals and serve their interests which might be quite different from the ones of the project manager. Hence, there is a real chance that the application of social network tools in the stakeholder management process will increase the overall complexity of the planning process.

CONCLUSION

Social network analysis is a tool that can both help project managers and external stakeholders. The project managers get a quick overview of all the cliques, key players, and overall position of stakeholders. Through the interdependencies between these stakeholders, project managers can determine pathways of communication. This means, which stakeholders they can reach through other stakeholders they already have ties with. The visualization and analysis also helps in determining which cliques are apparent and which stakeholders are part of these cliques. If project managers take in account the expectations and opinions about the project of the stakeholders within the clique, threats or opportunities can be mapped.

The visualization and analysis of the social network gives external stakeholders insight in their own relative position, compared to other stakeholders. It can help them to determine whether they are central or at the side of a network and which ties to make or strengthen to gain more influence within a project by becoming a more prominent stakeholder themselves or forging cliques with equally minded stakeholders. This grants them better understanding of their possibilities to cooperate with other stakeholders. It also gives them better understanding of the choices made by a project manager about the stakeholders that project manager engage. They can also determine whether they are part of a clique and if they can choose someone in their midst to act as a representative on their behalf.

Our case-study shows that social network analysis is a useful tool in complementing the ‘tool box’ of project managers. It helps to determine positioning, cliques and key players within the complete setting of stakeholders. Not only the project manager(s) benefit, also the other stakeholders, in being able to gain a visual insight in their own positions and that of others, giving them information on the strategies they can follow.

A PHASED CITY ENERGY PLATFORM FOR NETWORKED PRECINCT BUILDINGS IN THE CONTEXT OF MANAGEMENT INFORMATION SYSTEMS AND SMART GRIDS

PROFESSOR TOM BARKER
University of Technology Sydney, Australia
tom.designer@gmail.com

Abstract
This research investigates the context and advantages of energy sharing between networked precinct buildings in the context of pre-existing urban stock. The paper considers whether the sharing of patterns of use and knowledge of buildings' spatial, architectural and energy-related components can act as a phased prequel to energy sharing and provide a 'knowledge pool' to facilitate changes to the technological mix in a building, as well as modes of usage. In the context of energy use and conservation it is well understood that resource sharing can be advantageous across multiple buildings, but less is known about the potential benefits of energy knowledge sharing across buildings. The sharing of energy data across buildings with different owners/operators but offers the advantages of balancing demand across facilities, right-sizing technology components, intelligent planning and future usage pooling – particularly for smart buildings with energy storage and generation capacity. With a focus on the Australian context, this research investigation examines how an initial energy information platform phase could benefit a range of building stakeholders and be lead to a subsequent energy sharing phase. The author argues that there is value in a city energy information platform as a prequel to smart grids and subsequently as a complement to smart grids.

Keywords: building energy management; building information management; information aesthetics; green buildings; urban sustainability

INTRODUCTION

This research investigates the advantages of energy knowledge sharing between public, institutional and commercial buildings in the context of pre-existing urban stock. The purpose is to mitigate the energy-related environmental impact through the 3 primary areas noted in International Energy Agency Annex 31 (IEA, 2001) for Life Cycle Analysis (LCA), namely: energy and ventilation, and passive systems. There is significant demand: for example 75% of firms in the US consider that the driver for 'green building' is increased energy cost and view sustainability as consistent with their profit mission (McGraw-Hill, 2009).

The hypothesis of the research is that the sharing of patterns of use and knowledge of buildings' spatial, architectural and energy-related components could act as a phased prequel to energy sharing and provide a 'knowledge pool' to facilitate changes to the technological mix in a building, as well as modes of usage. The argument for phasing the energy platform in two stages is that a precinct of smart buildings can initially be established prior to a smart grid. When smart grids are available, the platform can then take advantage of the energy sharing options.

With a focus on the Australian context, this research investigation examines how an energy information platform tool could leverage real-time 'information aesthetics' techniques in visual interfaces for use by a range of building stakeholders.

Several contextual and developmental aspects are critical to the described energy phasing options for a precinct. These are: 1) the future direction of infrastructure, 2) smart buildings and energy efficiency, and 3) management information systems. Each of these is discussed in the paper. Following the consideration of an energy platform, the author concludes that there is value in a city energy information platform as a prequel to smart grids, and subsequently for the platform to become a core building feature.

Energy use in the Australian context

Australia has the highest per capita level of greenhouse gas emissions in the world (Turton, 2004). In the context of this situation, three objectives of this investigation were to explore unique ways of using city buildings to provide: (1) a better stakeholder understanding of energy use in a city and a sense of the scale of this energy use, (2) actionable advice to allow building stakeholders to reduce their energy use, and (3) a digital enterprise platform for Australian energy saving and alternative energy companies to get better reach.

There is a pressing need to achieve better energy management in Australia. Better energy management is a key component offered by the energy saving industry. Because of Australia's heavy reliance on coal-based energy which in 2001 contributed to 72% of CO_2 emissions (Saddler et al, 2004), the only short term approach to CO_2 reduction is to encourage conservation, which is typically driven by economic benefits and/or legislation – there may also be an element of corporate social responsibility and customer pressure. The researcher argues that making the energy reduction issue visible and actionable by stakeholders will get a much broader engagement across the city of Sydney. Building owners and operators will also see how their own energy use relates to other buildings, and finally there is evidence that social networking can encourage positive peer behaviour through example and information exchange.

Although there have been efforts to establish new sustainable cities globally, no such project has reached fruition. For example, the planned sustainable city Dongtan in China has been a notable failure that lacked an execution (Larson, 2009) despite a strong consulting team that included Arup. Sustainability work on new cities is important; however the vast majority of urban buildings is composed of existing historical stock. This puts the emphasis on ways of improving current cities.

In Australia, energy use per capita continues to increase. Between 1990-91 and 1998-99 Australia's total energy consumption increased by 23% (ABS, 2002). Over the same period, population increased by just under 10%. Recent figures show that an increase trend is still underway (DEWHA, 2004). This is not inevitable and good environmental policy and legislation can make a big difference: since 1974 California has held its energy use per capita constant, while the USA as a whole has leapt 50% (Mufson, 2007).

FUTURE OF INFRASTRUCTURE

The services infrastructure of a city comprises power and water distribution, gas, telecommunications and the internet, along with waste management. There are two main

challenges in the case of power management: firstly ensuring that the supply is closely matched to demand and secondly to make sure that the distribution supply allows power to be rerouted when parts of the network fail. In practice, to avoid power outages traditional power distribution requires power stations to generate excess electricity and this can rarely be stored. The inefficiencies of power distribution in the route from a power station via grid and substations to the customer due to losses are significant at 6.9% in the USA during 2008 (EIA, 2009). Traditionally, power management is based on analysing historical data to predict demand. The result is a supply-driven system. The concept of a smart grid is to create a demand-response system, effectively making the power supplied demand-driven. Through this approach, it is estimated that smart grid technologies in the USA can reduce peak demand by 5% in 2030 (EPRI, 2008). Additionally, smart meters allow other savings to be made by shifting customer usage with pricing patterns that are both responsive and clearly communicated.

The Economist Magazine's special report on smart systems (Economist, 2010) writes that:

'The physical and the virtual worlds are converging, thanks to the proliferation of sensors, ubiquitous wireless networks and clever analytics software. Increasingly there will be two interconnected worlds: the real one and the digital reflection.. and "Smart cities", in which more and more systems are connected, are multiplying.. the number of [smart] applications is vast. Yet the most promising field for now may be physical infrastructures.'

In terms of operation, smart grids use digital technology to achieve a two-way communication to control appliances at the user end of the distribution. The digital technology is an overlay to the existing power distribution that is interfaced into it with smart meters, also know as net meters, at the customer end. Smart grids allow consumers and other users to respond to changes in grid conditions in a way that has previously been the preserve of very large users or utilities. Smart grids also facilitate economically-intelligent generation and supply of power back into the grid from users that can create excess power from their own generating facilities such as renewables, cogen or trigen. Customers in 57 countries (Global Feed in Tariffs, 2010) are able to supply back into the grid – some for a number of years. This feed-in system predominantly pioneered by Germany in 1991 with the Electricity Feed Law (Federal Law Gazette, 1990). A more recent example is the UK's Renewable Obligation Certificates or ROC's, available since 2002 (Ofgem, 2011) for renewable customer generation of over 500kWh annually. This requires three devices: a generation meter to measure system output, an export meter to register the amount of electricity fed into the grid, and an inverter to synchronise voltage variations with the grid. With a smart grid and varying pricing schedules, these customers can benefit economically by fine-tuning when to use power, when to provide it to the grid and when to draw it from the grid. The ROC system incentivises providers to buy back renewable power from customers by setting a percentage of renewable power that the provider must source, currently 11.1% for 2010/11, with the penalty of paying proportionally into a fund when obligations are not met.

The dominant interest in smart grids is for power distribution, but they are also suited to water and gas supply. Although these utilities can get less value from a real-time demand-response because they don't suffer from supply-driven losses, they can benefit from demand-response control in the context of pricing and user control based on availability and demand. In advance of smart grids many governments have introduced legislation to incentivise renewables, along with retrofit programmes for insulation in buildings.

Smart grid development is gaining momentum. The American Recovery and Reinvestment Act provides $4.5 billion for smart grid demonstration projects (ARRA, 2009). In Australia, the government is providing $100M for a demonstration project called Smart Grid, Smart City (Smart Grid Australia, 2010). Based in the city of Newcastle, New South Wales, this will be the first commercial smart grid in Australia and covers power and water. The consortium comprises EnergyAustralia, IBM Australia, GE Energy Australia, AGL Energy, Sydney Water, Hunter Water Australia, and Newcastle City Council.

Better distribution and smart grids do not overcome legislative issues that can remove incentives for users to return power to a distribution system. Good energy tariffs in Germany have resulted in 200 time the solar production of Australia even though as a country it has half the amount of sunshine.

Australia does have a Renewable Energy Certificate or REC scheme that is not unlike the UK's ROC. However, the underlying feed-in tariff system is problematic. There is no national Australian feed-in tariff programme (Energy Matters, 2010) and although there are feed-in tariffs for a number of grid-connected renewable electricity generation sources, the rules vary between states and there are significant limits on the amount of power that will be bought back into the grid: at renewable premium tariff rates for photovoltaic solar only up to 5kW in Victoria, 10kW in New South Wales, and limited to solar panels in South Australia. Standard tariff rates are available for increased power feed-in in Victoria for up to 100kW from a range of renewables (State Government Victoria, 2010).

There is an issue for commercial building operators in Australia who wish to supply significant power back into the utility distribution system either to sell, for subsequent later use, or for use in another city precinct where a customer may have other buildings that can use the power at that time. This is because in many cases the energy utility company only has to buy a small amount of power at a premium tariff, some more at a standard tariff, but most power at wholesale prices. The utility provider is then able to sell it back to the customer at retail prices, representing a loss for the customer. Hence, there is a significant financial loss involved even if the power is moving only 100 metres between buildings.

It is worth noting that smart meters are required in Australia for feed-in of renewable power. Although these are installed on an ad hoc basis for domestic renewable suppliers, the aim is that the full roll out of smart meters will have been completed by the state of Victoria in 2012 and by New South Wales in 2017. The smart meters provide time based metering with 30 minutes update intervals.

Advanced power distribution and transmission

A promising area that relates to energy saving with smart grids is technologies for advanced power distribution and transmission. Power transmission from power stations to cities normally use three-phase alternating current (AC) at 110kV, but can run over long distances or underwater with high-voltage direct current (HVDC). The choice of system is based on keeping energy losses to a minimum. The original city-based power distribution used direct current (DC), and was set up by Thomas Edison in New York in the 1880's. AC replaced DC soon afterwards because it offered reduced energy losses. More recently, the development of high temperature superconductors may make DC distribution in cities viable once more for high load areas and can halve losses, even though the cables need cooling with liquid nitrogen or hydrogen. Hydra, a pilot project by Consolidated Edison and American Superconductor was recently launched in New York to connect two substations together

(New Scientist Tech & Reuters, 2007). Although this technology is not yet developed for low-load areas, the use of DC could result in 30% savings by eliminating losses that are caused by the mismatch between AC supply and electrical devices which are generally DC (EPRI, 2011).

SMART BUILDINGS AND ENERGY EFFICIENCY

The Lawrence Berkeley National Laboratory (LBNL, 2009) has created a smart building model for the US Government. In this, there are three strategies: enterprise operations, systems integration, and a high performance building core. The strategies give rise to enhanced operational effectiveness, enhanced productivity and improved tenant satisfaction, and energy efficiency.

Siemens is one of the world's leading integrated building services solutions providers of energy controls for buildings (Economist, 2010). The company bundles products and services together and offers guaranteed 'energy performance contracts' . Siemens defines smart buildings as:

'A safe, secure, reliable building, campus, manufacturing, or production facility that efficiently and productively consumes purchased or created onsite, electricity, natural gas, renewable, other fuels, and water, in a integrated, holistically planned and day-to-day executed, environmentally friendly strategy, from its initial green field design, through construction, migration, modernization, until retirement/demolition, that provides a acceptable return-on-investment.' (sugay, 2010).

How do these definitions of smart buildings compare with sustainable buildings? The International Energy Agency defines sustainable buildings as:

'*Those buildings that have minimum adverse impacts on the built and natural environment, in terms of the buildings themselves, their immediate surroundings and the broader regional and global setting.*' (IAE, 2001).

The definitions of a smart building and a sustainable building have significant overlap when it comes to energy efficiency. Furthermore, given that 40% of the world's energy is consumed by buildings (IEA, 2002), smart buildings have the capacity to contribute significantly to sustainability.

MANAGEMENT INFORMATION SYSTEMS

The collection of information technologies that the construction industry can now take advantage of for building design and operation come under the umbrella of Management Information Systems (MIS). Recently a top-level, human-collaborative component of MIS has been identified as Integrated Project Delivery (IPD). IPD can be used for new build but it can also be used for retrofitting and refurbishment projects. IPD is defined by the American Institute of Architects as:

'*A collaborative alliance of people, systems, business structures and practices into a process that harnesses the talents and insights of all participants to optimize project results, increase*

value to the owner, reduce waste, and maximize efficiency through all phases of design, fabrication, and construction.' (AIA, 2007).

IPD typically uses collaborative software and internet-based software on demand, avoiding firewall issues between users. The value of collaborative working through web methods for improved efficiency and innovative working is highlighted by Taspscott and Williams in MacroWikinomics (Taspscott & Williams, 2010), and they quote Google CEO Eric Schmidt:

'Organisations that learn how to participate in (networks) can access a greater diversity of thought and talent than they could ever hope to marshall internally. Collaborative innovation is now an essential skill, as important as budgeting, R&D, and planning.'

Building Information Modelling (BIM) can be used in conjunction with IPD to offer increased communication and team efficiencies. For an advanced smart building project execution, the 3D model and building component data held in a BIM system can be used in conjunction with a Building Management System (BMS) or a Building Energy Management system (BEM) to operate the building. These systems can in turn integrate with Distribution Management Systems (DMS) for greater running efficiencies at a precinct or citywide scale.

Information aesthetics

The information technologies that comprise MIS have numerous human-computer interfaces (HCI – also known as human-computer interaction). Information aesthetics is an important dimension of HCI and hence MIS. Information aesthetics relates to the visualization and communication of information numerically, visually or symbolically for a computer system or application user.

Tractinsky, N. (2004) sets out three reasons why information aesthetics is relevant to information technology: 1) for many users, it is the critical aspect of interaction; 2) our evaluations of the environment are primarily visual, and the environment becomes increasingly replete with information technology; 3) aesthetics satisfies basic human needs which are increasingly supplied by information technology. Tractinsky also describes five categories of variable that exist within an information aesthetic framework: design characteristics, aesthetic processes, aesthetic evaluations of IT, outcome variables, and moderating variables. These variables collectively define the impact that information aesthetics has on user behaviour.

The positive benefits on decision making through affect – which is an aesthetic response type – in complex situations has been demonstrated (Isen, 2001). There is also research that highlights the significance of graphics in managerial decision making (Jarvenpaa & Dickson, 1988), as well as the user's acceptance and intention to use information technology (Davis, 1989).

ENERGY PLATFORM FOR A NETWORKED PRECINCT

In the context of energy use and conservation it is well understood that resource sharing can be advantageous across multiple buildings, but less is known about the potential benefits of *energy knowledge sharing* across buildings. Such knowledge relates to patterns of energy use based on: core 24/7 activities, seasonal cycles, and irregular events, the physical characteristics of a given building, along with the mechanical, lighting and services systems,

and external environmental data such as location and orientation. Effective decision-making environmental tools should allow a user of such a system to evolve solutions as well as understanding the problems (Williamson, 2003), and users should be able to explore 'what if' scenarios to investigate the impact of changes, and where those changes offer the best return when compared with a range of metrics.

Under the umbrella of MIS, retrofittable Energy Management Control and Information Systems (EMCIS) running applications such as the Siemens InfoCentre Suite® effectively inform where efficiencies can be made (Yee, 2004). Consequent upgrade options for individual buildings can follow, for example in terms of financial and/or CO_2 cost-benefit analyses. Upgrades of existing buildings can take place in many ways. These include: insulation, more efficient HVAC, heat-recovery, natural ventilation, building-integrated renewable energy devices, architectural components, passive solar architecture and spatial design. Additionally, a building or group of buildings within a single organisation can be improved in a site-wide context by systems such as trigeneration combined cooling, heating and power generation. These approaches offer significant improvements in energy use; the question is whether knowledge sharing can extract further notable savings. The sharing of energy data across buildings with different owners/operators is atypical, but offers the advantages of balancing demand across facilities, right-sizing technology components, intelligent planning and device usage pooling – particularly for smart buildings with energy storage and generation capacity.

The first phase of a planned city energy information platform for networked precinct buildings for Sydney, Australia, would be a process tool to facilitate such efficiencies. The visualisation components of the tool will be user-centered, but could also include a real-time public viewing system for energy awareness that can be used in building lobbies and public places.

The choice of a precinct is to allow several buildings to be part of the investigation, thereby differentiating from a MIS for a single building. Furthermore, the precinct can then be upgraded to be part of a smart grid within the confines of the precinct, or as part of a city-wide smart grid. This again offers a phasing route, on the basis that fully functional citywide smart grids are a number of year away. The city infrastructure has been discussed and this has a critical impact on the extent to which precinct-wide energy management is possible, as well as integration into a city's energy management.

For the phases of the energy platform to be successful, the measurement of where energy losses occur within the precinct buildings is vital, as opposed to simply the energy use. This requires extensive use of sensors and monitoring at a very granular level. This is where the EMCIS technology comes into play. The energy platform MIS should also permit the iterative development of the best possible associated information aesthetics through a user-centred design method (ISO 13407: Human-centered design process).

Six important considerations relating to the energy platform development are:

Stakeholder engagement: the demand-side stakeholders in a proposed energy platform would be developers, operators, tenants, city-wide authorities. The supply-side stakeholders would be systems suppliers and integrators, consultants, energy companies.

System and service design: energy use, energy prediction, energy efficiency, environmental responsiveness to location, knowledge sharing, information aesthetics, public visualization, internet technology.

Understanding retrofit hierarchy (listed as easy to hard): awareness, training, retrofit, smart grid, urban rebuild, new build (the typical focus on new build makes the least contribution).

Facilitation: visualising and communicating to stakeholders, modeling, integrated energy technologies, knowledge bank, new power management methods.

Economic benefits: Australia's National Objectives, competitive advantage for industry partners, understanding of 3, 5, 10+ years on financing and environmental benefit.

Strategic questions: what components are missing or needed to achieve it? What are the benefits of products, systems, services? What is the sensitivity of the options - value and effort assessment? Where are the technology gaps, ie: where is there is demand? What are the barriers to demand?

Stakeholder participants need to supply data from themselves and their energy providers, to allow the platform to model and visualize existing energy flows and usage in their buildings at a macro scale and relate this data to environmental climatic change and time cycles. A user platform and information architecture must be established, running the system using live data with real time stakeholder control. Data visualization nodes would be established in buildings and possibly for a public smart phone 'app'. A prototype platform comprises hardware, network and software for user testing and revisions to interface and functionality with prototypes located in each participant's building. During the location of the device, as well as measuring energy use, it would record data such as on energy information download use, collaborative aspects, and frequency of use of the device.

CONCLUSION

Over the last 20 years, major efficiency improvements in manufacture and supply among businesses in developed countries has come from computerised supply chain management – accelerated by uptake of web-based processes and Systems, Applications and Products (SAP). These effectively relate to efficient and effective use of information to streamline and re-organise functional physical processes that are already in place. In other words, the improvements are knowledge-based.

Networking now provides an opportunity for building efficiency: much of the physical infrastructure of existing building stock has to remain for economic reasons, and the vast majority of Australia's major city buildings are more than 5 years old. However, the continuous use of usage information to extract efficiencies, coupled with retrofitting, can produce energy improvements for existing buildings along with new build.

By setting out the context and future developments in the built environment, the paper has shown that there is value in a city energy information platform for networked public and commercial buildings as a process tool to facilitate energy efficiencies. The paper has set out the scoping for a program that would include site experiments and prototype evaluation in Sydney, Australia, planned during 2012-14 in collaboration with [name] corporation. The energy information platform tool envisaged would utilise the latest real-time information

aesthetics techniques in visual interfaces for use by the range of building stakeholders, as well providing a web-based viewing system for energy awareness that can be used in building lobbies, public places, or on the web.

Smart cities can be constructed from scratch and these are now emerging. The most notable examples under construction listed by the Economist (Economist, 2010) are: Masdar in Abu Dhabi using Siemens technology for 40,000 people and built on a raised platform with all services below; Songdo City near Seoul for 65,000 people with fully wired building devices by Cisco; PlanIT Valley near Porto in Portugal for 150,000 people using prefabricated parts with built-in urban IT infrastructure. While these new smart cities may point the way to the future of construction, with the bulk of cities already built the emphasis for many generations will be on retrofitting or replacing existing infrastructure.

Ultimately, smart buildings are needed to provide all the data for effective use of a smart grid. But as a prequel to the smart grid, smart buildings can provide energy savings now and also share information to help owners, occupants and operators to improve energy efficiency. As such, there is value in developing such a phased energy platform. The long term goal would be to provide energy saving across the city, encouraging businesses and raising the 'digital hub' profile of Sydney. The project could be scaled to other cities in Australia with an end goal to help meet Australia's national CO_2 targets over time.

Abstract
Adaptive re-use can be a significant strategy for achieving sustainability as it ensures a continuous building life-cycle and prevents it from destruction. Adaptive re-use projects have their own unique environment and specific challenges to ensure success. There are complex designs and construction problems unique to adaptive re-use projects thus specific skills and expertise are required. As Australia's building stock ages, more and more attention are being turned to adaptive re-use projects and the critical factors towards its success. The literature review identified and regarded project management as a critical success factor for these projects. Given the extremely complex and conflicting construction challenges we contend that construction management is a critical success factor. The aim of this paper is to identify the unique problems in the adaptive re-use process of historical buildings. It is a highly specialized field with significant learning accumulated and significant levels of intellectual capital created within the project teams. Two case study projects with similar project teams are examined to explore the relevance of the concept of reflexivity. We propose an intellectual capital model for project success to understand how to capture, transform and accumulate intellectual capital within project stakeholder's communities who are dedicated to adaptive re-use projects. The model is a step towards the development of a practical construction management methodology grounded in theory and empirical observations.

Keywords: Adaptive re-use, critical success factors, knowledge management, intellectual capital, case study methodology

INTRODUCTION

In late 1970s to early 1980s, the Australian Council of National Trusts defined 'recycling' as the best method to protect and maintain the historical building with new uses (Latreille 1982). Approximately 106 adaptive re-use projects have been analysed within that time related to functions and the benefit of recycling. However, the data is no longer relevant to the present situation due to new era of construction industry.

Adaptive re-use project has the complexity of the design and construction aspects. As example, the complicated regulations and requirement, the complicated of the process and involve with multidiscipline with different background. This paper focused on the issues

occurred around the complexity of adaptive re-use projects. According to Ball (1999) and Kurul (2007), lack of professional expertise in the adaptive re-use project leads to project failure. The cause of the project failure is that there is no expertise to reduce or overcome the complexity during the transformation process. In addition, incomplete and inaccurate design information also contributes to the complexity of the process (Shipley, Utz and Parsons 2006; Karim 2007). The reason behind this complexity is dealing with historical elements that need to be treated with care and skill. The empirical observations discussion on unpredictable circumstances elements is not included in this paper and it will be explored further in the interview data collection and analysis (second stage) of the study. This study will attempt to make two contributions towards knowledge accumulation. Firstly, by defining a set of critical success factors in proposing an intellectual capital model of project stakeholders' in regards to overcome the complexity issues in adaptive re-use project. London and Chen (2004) defined intellectual capital as a collection of skills, experience, competences and knowledge in organizations. It generally explains that the accumulation of intellectual capital would involve human capital, organizational capital and social capital.

The case study analysis on knowledge accumulation of complexity issues and critical success factors is the second contribution in this study. This is considered as to show the critical link between the past, present and future adaptive re-use projects. The involvement of multiple disciplines of stakeholders is also a key element to this study. Their understanding of history and the method of collection, creation and transfer of knowledge will support the management of intellectual capital in adaptive re-use projects.

To overcome the issues of complexity, this study seeks to propose the model to managing intellectual capital of multidiscipline project team members through knowledge management initiative and critical success factors. This paper begins by discussing the literature related to the root of complexity in adaptive re-use and the critical success factors. Since this paper is an on-going PhD research study, this paper set a limitation where the experiences and views of multidiscipline stakeholders are not included.

LITERATURE REVIEW

Adaptive re-use

The terminology of adaptive re-use can be interpreted in many different ways; however, all of the definitions are inter-related. Adaptive re-use can be defined as building recycling (Latreille 1982) which involves unique and complex processes (Bullen 2007; Kurul 2007) without altering the building façade (Tatum 2003), changing the intent of structure, interior spaces and building functions (Gorgolewski 2008; Cys 2008) to meet modern user's needs (Clark 2008).

This paper defines adaptive re-use as a process of transformation of the functions, the structures and the fabric or building envelope of historical buildings to new and contemporary design and construction process. The process is complex and needs to be managed appropriately and skilfully as there are multiple project stakeholders that may involve directly or indirectly through a knowledge approach in relation to creation, transfer, learning and sharing of knowledge.

Complexity issues

Kurul (2007) argued that there are barriers in adaptive re-use because of limited project stakeholder's knowledge and understanding of adaptive re-use processes and thus led to

complexity. This means that the limited knowledge and understanding on the process can increase the degree of project complexity. It can also lead to other issues where there are lacks of skill of project stakeholders due to limited adaptive re-use of knowledge. Within the limited knowledge and expertise, the design and construction confrontations or problems are impossible to be well managed. According to Shipley, Utz and Parsons (2006), lack of expertise of the design team can lead to poor design and cause client dissatisfaction with the design. It is considered as serious issues and makes it vulnerable towards the entire adaptive re-use project.

Inaccurate and incomplete information about the history of the buildings and the related information on design could contribute to the complexity in adaptive re-use project. It can be exemplified as inconsistent specification of workmanship and material clauses and such internal risks can affect the project implementation and project performance. Typically, the complexity in adaptive re-use project is mostly related with design development. Pham (2006) stated that incomplete information during the design process is the source of complexity in adaptive re-use projects. The similar issues were stated by Gorgolewski (2008) that lacking clear information would provide a challenge to the architect in the early phases of design decisions and contribute complexity to the entire process. It is important to investigate and locate the original information, as it will reflect the design decision. Any delay would cause the architect to require more time in preparing the design and negatively affect the whole project schedule. This relates with issues on the project management processes such as insufficient time of completion and risk of losing a historical significance of the original fabric resulting from negligence (Karim et. al 2007).

Differences in practice and discipline of multidiscipline stakeholders contributed to the difficulty in obtaining collaboration in making decision, especially in solving the adaptive re-use problems. An example of adaptive re-use problems that could occur during design development process is the design changes. Any further design changes will challenge the architect as it involves design amendments and increases the number of unscheduled meetings. Thus, it will effect on the project performance, for example, the construction project time and project cost will be extended from the original time and cost estimated (Ali, Kamaruzzaman & Salleh 2009). It is ideal if the architect has specialized experience in capturing the client's requirements, as they are unique building types. It is also critical that the design team has specialized experience and knowledge in heritage conservation. However, it is also important to all multidiscipline stakeholders to nurture and have the responsibilities to collaborate at any decision stage to avoid complexity to the entire adaptive re-use process.

On the whole, the lack of expertise, inaccurate and incomplete information and multidiscipline collaborative difficulties can be linked with understanding the critical factors contributed to the project success. As Baccarini and Collins (2003) notes, the critical success factors are important influences that contribute to project success. It can also enhance the ability of project stakeholders to forecast future project, identify potential problems and prepare the resources to the entire process (Khang & Moe 2008).

Critical success factors

Success in re-using historical building can be achieved through good planning at the early stage, followed by systematic process and full concerns by the project leader and project team to the project completion (Latham 2000). The systematic process involve with preparation feasibility study and building assessment on historical buildings. The role of project leader

and project team towards achieving success is related with the level of workmanship (expertise) and the collaboration. Since this study is related with historical buildings, this study presumes that preserving the historical value of historic buildings into new design is also critical factor for project success.

Feasibility study

Planning is an important stage for adaptive re-use process and possible creates the route of success to the projects. This is considered as the critical practice in planning stage is the preparation of feasibility study for the adaptive re-use project. The benefit of feasibility study by Watson (2009a) noted that "planning stage is related to how, when and where the project is to be carried out". Hence, as a critical factor for success, the feasibility study must be simple, flexible and contain accurate information for project resources such as material, workmanship and equipment for running the projects. Latreille et al (1982) suggested that to develop good feasibility studies, it is required and important to analyse all development cost including construction cost, new services cost, fireproofing cost and the degree of finish required. In particular manner such as delay in completion can also push up the development cost and need to be aware by the quantity or cost surveyor. It is related to cost planning for adaptive re-use projects and it should consider the initial cost and it is carefully distributed for the future running cost within the client's budget or fund (Watson 2009b). On the other hand, Watson (2009a, b) stated that the key to a successful adaptive re-use project lies on having no problems on cost thus the complexity of future adaptive re-use project can be reduced or avoided.

Building assessment by qualified and expert teams

Clark (2008), a professional project manager in Baltimore, United States mentioned that the investigation and assessment of the building condition by qualified and expert teams is a step to project success. A good assessment can help to reduce the unpredictable circumstances and avoid costly problems.

Good workmanship

The actual work on site must be performed with a high level of expertise to avoid errors and poor workmanship. Most importantly though is that with existing buildings, a level of adaptability and creative problem solving skills are required from the construction teams because often unpredictable circumstances can arise as redevelopment unfolds. A responsive attitude to such a creative construction problem solving environment is critical to project success. Clark's experience with adaptive re-use project proposes steps to success, but it is not associated with knowledge approach to project success (Clark 2008).

Collaboration

According to Roecker (2008), a potential critical success factors in adaptive re-use are to have the project stakeholders' collaboration and the historical dynamic. The collaboration refers to multiple partners and users involvement to adapt to the architecture and history in sustainable revitalization as input in design decision. Later, Clark (2008) also defines that a high level of collaboration between professional experts including the client or project manager, architect, contractor, historic conservator and the local preservation office as critical for adaptive re-use success.

Preserve the historical value of historic buildings in the new design

The history focused on the architectural that embeds spatial relationships within the buildings, meaningful information in the inter-relationships between environmental,

economic and cultural/social categories. The heritage building's history is to be interpreted in the context of contemporary design and in particular of a formal, spatial, structural, material and program (Roecker 2008).

In summary, complexity issues and critical success factors elements that contributed to intellectual capital model in this paper are as follows:

1- Causes of complexity
- Lack of expertise and knowledge in adaptive re-use
- Inaccurate and incomplete historical information
- Stakeholders collaboration difficulties

2- Critical success factors
- Good feasibility studies
- Building assessment by qualified and expert teams
- Good Workmanship
- Collaboration

3- Preserve the historical value of historic buildings in the new design

The professionals involved in adaptive re-use projects should integrate the context of complexity and critical success factors together with the higher level of skills as accumulative intellectual capital. This paper proposes that the accumulative intellectual capital on tacit knowledge about project complexity and critical success factors through human-capital based could benefit to the project success. Thus, this paper will develop the framework of adaptive re-use process within the knowledge approach that consist of the creation and transfer process of intellectual capital. The knowledge creation from intra-project knowledge and knowledge transfer to inter-project knowledge is necessary and important to continue and enhance the success of future adaptive re-use projects in intellectual capital approach.

Intellectual Capital Model for Adaptive Re-use Success

This section proposes a model of project success that supports the development of intellectual capital through critical success factors and the complexity issues (Figure 1). The model shows the importance of understanding the input by project teams in producing complex issues to enhance the experience and expertise of project stakeholders. The important point here is what and how they learn and share their tacit knowledge (experience and expertise) gained from previous projects within similar project characteristic. Experience and knowledge will critically enhance adaptive re-use project to ensure a continuous success. This model is composed of complex issues and proposed success strategy (highlighted from critical success factors literature) as a collection of intellectual capital elements. The following six components will explain how the intellectual capital relates with complexity issues, critical success factors and the connection of historical and architectural significance; providing knowledge creation (inter-project) and transfer (intra-project) for future references to enhance the project performance and promised success.

The Project
Critical Success Factors Strategy
Complexity Issues
Sharing and Learning

Knowledge Creation and Knowledge Transfer
Intellectual Capital

The Project

The Project represents adaptive re-use project that includes design and construction activities in relation with preserve the historical value of historic buildings in the design decision for new functions. It consists of the challenges and critical success factors strategy to achieve project success and provide existing intellectual capital for an adaptive re-use project. It will then utilise the strategies of the stakeholders through the process of sharing and learning to undertake the complexity. All created knowledge shall then be transferred to the intellectual capital of the project and serve as valuable information for future reference. This is particularly important and beneficial for the stakeholders who may be working back together to enhance the future project performance. It will also benefit project stakeholders who may not be involved with similar project previously as added knowledge in managing the design and construction process and challenges for future projects.

Critical Success Factors Strategy

At this stage, expertise can be assessed in terms of multidiscipline's experience and qualifications in carrying out the projects. Expertise may increase the creativity in providing design, highly skilled in managing the construction and high quality of workmanship in relation to heritage factors. It is also extended expertise in identifying all the channels that could provide source of information on historical buildings in helping to provide the best result for the entire development process. Establishing collaboration among multidiscipline project stakeholders is considered critical to achieve a consensus on the result of good design and construction.

This study also contributes new knowledge in intellectual capital by proposing process-based factors in relation with feasibility studies and building assessment on the historical building condition. This is the unique characteristic of the model suggested by this study, as it is not applicable in common projects. It is very critical for multidiscipline stakeholders to have the excellent knowledge in preparing two important documents for adaptive re-use project. First, provides good feasibility studies in relation with controlling the cost from initiation stage to the occupation stage since this type of project is full of surprises and unpredictable circumstances (Clark 2008). As well as providing good building assessment on structure and fabric could give the benefit to the new functions in terms of safety. The argument is not every multidiscipline stakeholder could prepare good building assessment without specific expertise in this process.

Complexity Issues

The issues in this model that are synthesizes from literature review are lack of expertise and knowledge in adaptive re-use, inaccurate and incomplete historical information and stakeholder's collaboration difficulties.

Sharing and Learning

The group should develop an understanding on the key problems to solve and develop approaches to solving future problems through the development of a particular group culture. Knowledge sharing is critical factor in achieving organization's success (Cohen & Levinthal 1990 in Jasimuddin 2008). Knowledge is important in the historic environment because transforming historical buildings is full of richness in interpretation. Shared understanding about the importance of history in relation to the building, hence history of the area and

history of the building is significant and a shared understanding and respect for this amongst the stakeholders is critical.

Hence, it is important to identify that there is a history with some of the key stakeholders and project team members associated with adaptive re-use projects. The project stakeholders in many cases may have developed a shared learning capacity over time within the group. As often it is a specialized, small and unique market segment, a group may have previously collaborated and carry out all the activities and processes of adaptive re-use projects. This is an ideal situation whereby the teams can capture what they have learnt from past projects and share their knowledge to the current project.

Knowledge Creation and Knowledge Transfer

An important part of understanding the creation and transfer of knowledge within a shared professional collaborative environment often comes with a shared history. It is important to identify a working history with some of the key stakeholders associated with adaptive re-use projects. The group may have developed an intellectual capital which is then aided by past project completion. Past involvement in adaptive re-use processes particularly during design brief development makes it much more comfortable to confront the problems related to design creativity and flexibility, design information and stakeholders' collaboration for the current project in hand. As it is with a new and different project, new approach and solution are created and later transferred into the intellectual capital for future project undertakings (Senaratne & Sexton 2011).

Intellectual Capital

It is an accumulation of information, knowledge of issues and solutions. Identifiable approaches in handling a situation and many other valuable inputs that are generated by actual experiences. The intellectual capital would serve as the main reference for having a better outcome with a faster response time due to its prior occurrences in other similar projects.

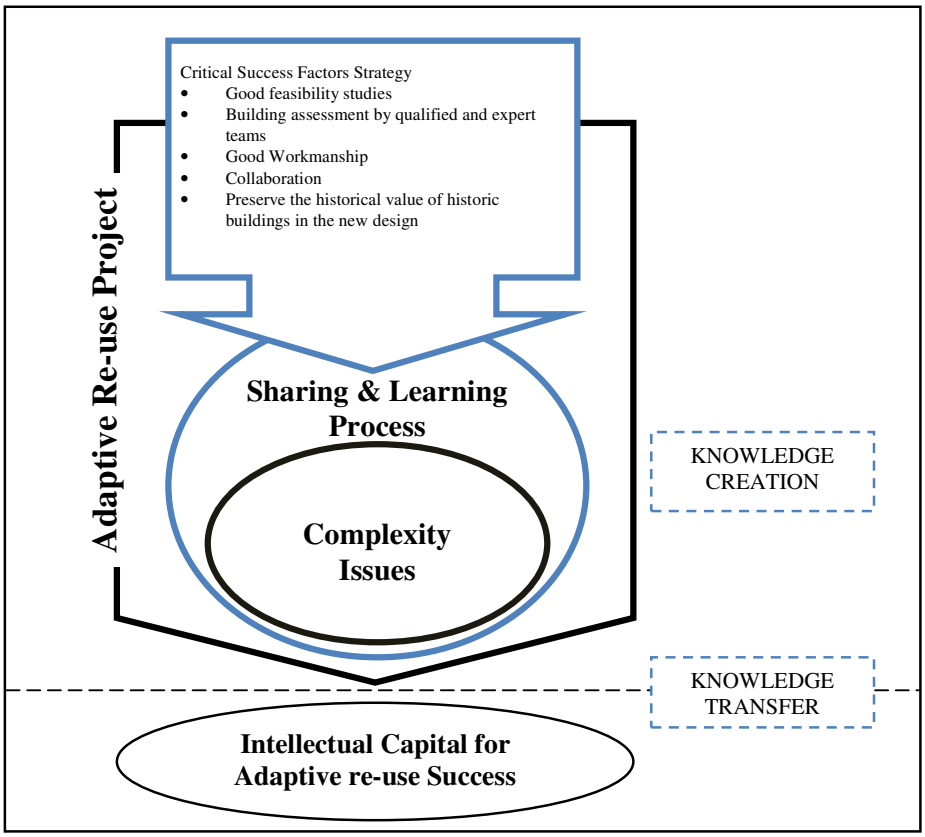

Figure 1: *Intellectual capital Model for adaptive re-use success*

The knowledge created and transferred reflects the different backgrounds of project stakeholders and impacts upon how they individually and collectively approach the current issues. Shared understanding about the importance of history in relation to the building and the area is significant and a shared understanding and respect amongst the stakeholders is critical.

Research questions generated from the above model based on the findings from project management and adaptive re-use literature and need to be tested in related case study are as given below.

1. To what extent does 'historical' knowledge contribute to the combined intellectual capital on adaptive re-use projects?

2. How do stakeholders experiences contribute to the intellectual capital required for adaptive re-use project success?

The research question one, to what extent does 'historical' knowledge contribute to the combined intellectual capital on adaptive re-use projects will be answered in case study document analysis.

RESEARCH METHODOLOGY: CASE STUDY DOCUMENT ANALYSIS

This study is using a case study methodology using a qualitative data collection and analysis method. The methodological design for this study is summarized in figure 2. This study presents the exploratory and preliminary results and describes the data collection and analysis from the two case studies. The first step towards developing an understanding on the unity and wholeness of the particular case begins with developing a deep understanding of the history of the original buildings and the relationship with the historical development analysis

for adaptive re-use. The second step is an empirical study involving interviews with the multi-disciplines teams. However, this paper only focuses on reporting the document analysis. The historical documents that were reviewed were conservation management plans, contract documents, drawings and other related project documents. Two completed adaptive re-use projects in Geelong were selected and used and the detail of the case studies is explained in the following sections.

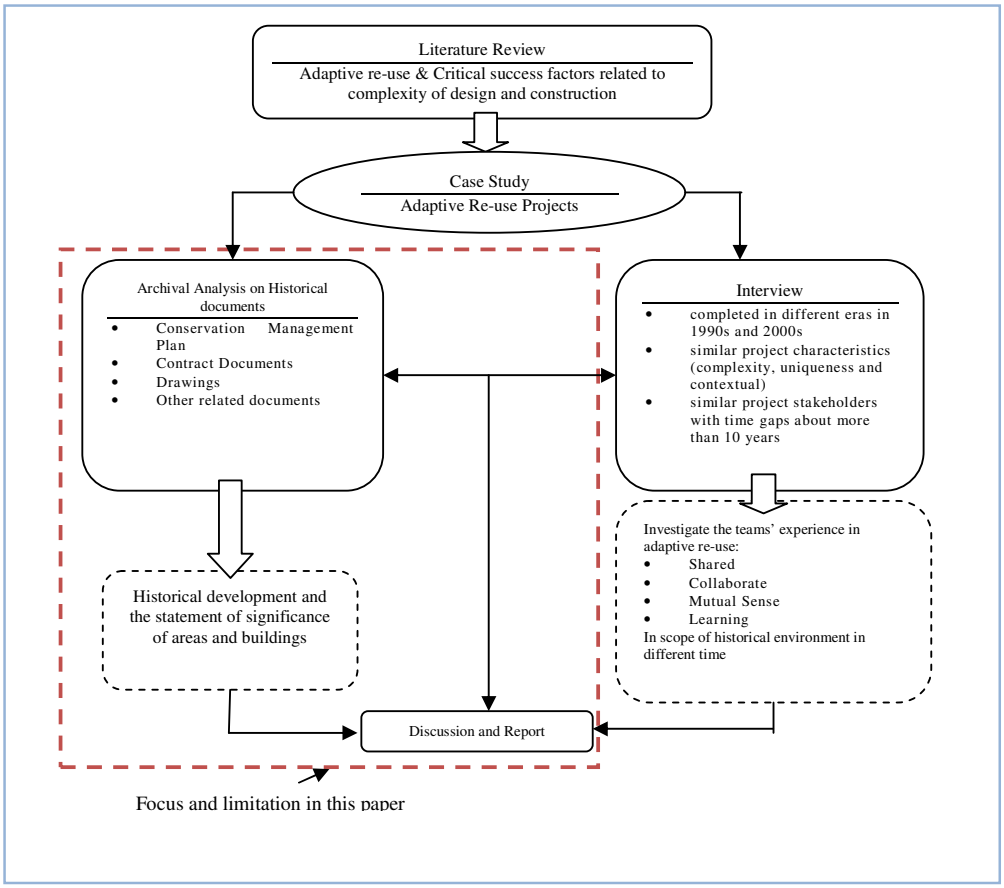

Figure 2: *The methodological design*

Case studies

A case study methodology was considered appropriate to explore the role of design management of intellectual capital as a mean to ensure project success. According to Kurul (2007), a case study approach enables us to develop a holistic and meaningful view of real-life events. It also facilitates "getting inside the project or the minds of individuals", to uncover explanations (Punter 1989, Larkham 1996 in Kurul 2007). According to O'Leary (2004), case study can produce a knowledge contribution in itself because a case study is unique and interesting with an intrinsic value. Through the analysis of case studies, we can begin to develop theory and exploratory case studies can bring new understanding. Most importantly, case studies can provide strong supportive evidence for a proposed conceptual model. The evidence from the 'real world' provides anecdotal evidence to support a theory. Besides that, the research provides concrete findings that will assist in generating a new theory in relation to project success for adaptive re-use projects. Once the development of the two buildings was completed, they were transformed from unused wool stores to a modern university. The redevelopment was undertaken in two different eras, 1990s and

2000s. The paper of course has limitations in relation to data collection and data analysis because the empirical study has not been completed yet.

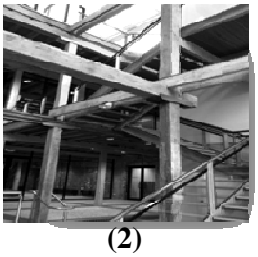
Archival analysis

To support the data analysis from the interviews, the documents for both case studies will be used towards understanding the completed projects. The documents analysis in this paper has been used for the development application for approval and along with the project life-cycles until completion and occupation stage. The analysis on related documents is important as documentary is evidence that reflects on the importance and significance to the history of the area (Geelong, Australia) and the buildings (the former Dalgetys Woolstores and former Dennys Lascelles Woolstores) for adaptive re-use application. The discussion on the documentation analysis understands the historical value in regards to manage the complexity of adaptive re-use process. It is also related to the experience on knowledge creation and knowledge transfer to future projects and developed intellectual capital particularly for adaptive re-use success.

CASE STUDY DISCUSSION: ADAPTIVE RE-USE PROJECT OF FORMER WOOLSTORES TO UNIVERSITY

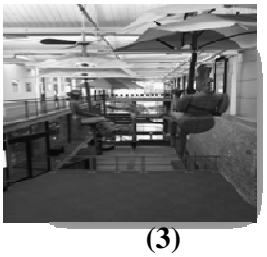
The importance of information or knowledge in the history of the original buildings in relation to develop a historical development for intellectual capital in adaptive re-use projects will be discussed in this section. The decision to develop Deakin University in the Dalgety Woolstores and Dennys Lascelles Woolstores is influenced by historical factor and the importance of protecting the historical heritage. According to the statement of significance in the Victorian Heritage Database states that "the architectural significance of this building relies on the retention of the remaining parts of the wool store complex". In this section, there are two significant relationships of Dalgetys Woolstores and Dennys Lascelles Woolstores are discussed.

Historical development of buildings: the adaptive re-use project background and the significant of former Dalgetys Woolstores



The Dalgetys Woolstores have been built through seven major stages. The building is four storeys and it was used and functioned as wool storage and business until the mid-1980s. In 1990s, the action to protect this woolstores was started with a national architectural competition to conversion of these buildings to appropriate functions. The design competition was held in May 1993 and the local firm McGlashan Everist won this competition with the function of a university. The refurbishment of the wool stores includes removal of the three floors of hardwood timber. The construction strategy that has been used by contractor is to maintain the structural conditions; the floor has been removed from the roof all the way down to foundation steps. The top floors have been used as scaffolding for roof refurbishment work. The architect for this project won the Royal Australian Institute of Architect's President Award for recycled buildings in 1997. The winning criterion was based on the following:

- The design and management skills of the architect and his team when dealing with client and contractor.
- The level of achievement of identification, maintenance and enhancement of the heritage value is quite high in this project. The merging of a existing and new components, provide comfortably and naturally into space and light quality for a different building function as been successfully achieved.



As evidence, there is collaboration and sharing attitude among the design team with other disciplines such as the contractor and at the same time oversee the interests of the client requirements and ensured a quality preserved historic value as stated in Conservation Plan prepared by Alan Willingham in 1994 based on building's condition assessment. The most important are the issues on design flexibility and information provide guidance, learning process and mutual sense in proposed the appropriate design decision for modern and smart university. As described in Authentic Heritage Services Pty Ltd Report for Local Government Planning Scheme, "the architect was reviewed based on their design and ensuring the retention of as much of the original building fabric as possible as part of their contemporary design" (Victoria, 2010). This is important of blended the knowledge about design and cultural significant related with historically and architecturally in the development of intellectual capital for future re-use projects.

(3)

Photo 1: *the front view (external) of former Dalgetys Woolstores; the signage, the parapet and the external wall were maintained*
Photo 2: *inside the building, the timber structure were maintained and merged well with new staircases*
Photo 3: *inside the building, view from the 4th floor*

Statement of cultural significance in Authentic Heritage Services Pty Ltd report was prepared by Dr. David Rowe, the heritage advisor for the City of Greater Geelong, stated that this building have architectural and historical significance at a LOCAL level. "The architectural significant attached with design qualities that associated with the late 19th and early 20th century of Dalgety and Company Limited Woolstores". The design qualities includes redbrick external wall and parapet wall, roof and the rainwater downpipe, lintel above openings, doors and windows and the signage of "Dalgety Company Limited" need to retain those remaining parts of the wool stores complex. The report also stated that "the historically significant building are associated with the development of the Dalgetys Woolstores from 1891, 1929 and 1940 and parts of the building also have associations with the Geelong architectural firm of Laird and Barlow, and later, Buchan Laird and Buchan" (Victoria 2010).

Historical development of buildings: the adaptive re-use project background and the significance of the former Dennys Lascelles Woolstores

One of the largest wool stores was erected in adjacent with the Dalgetys woolstores in 1934. The original plan of Dennys Lascelles Woolstores is to accommodate more than 25,000 bales of wool which cover over 3.5 acres of floor space. The Dennys Lascelles Wolstores was equipped with lifts and modern wool-handling appliances (Victoria 2010). The Dennys Lascelles building was constructed by C.J. Taylor and Sons in May 1934 based on a design by Buchan, Laird and Buchan.

In 2009, the six storeys of the Dennys Lascelles Woolstores have been redeveloped for new functions as the Alfred Deakin Research Institute, the Deakin Geelong Health Precinct and the Alfred Deakin Prime Minister's Library. This section of the wool stores complex was officially opened as Deakin University on 10 June 2009. The project cost to refurbish 1934 sections was approximately $37M AUD and was a joint project between Deakin University and the Victorian and federal governments. On the other hand, the collaboration, sharing and mutual sense existed at the beginning/early stage. This project was also funded by the Commonwealth and Victorian Government who provided approximately $15.6M each. The project started on October 2006 and was completed in 2009. The project manager was the Facilities Management Services Division at Deakin University. Again, the architect responsible for the design of former Dennys Lascelles is a local professional architect, McGlashan Everist. This study assumes that the project stakeholders (focused on architect, project manager and contractor) applied and developed the knowledge transfer and knowledge creation through the attitudes of learning, collaboration, sharing and mutual sense among multidiscipline in Dalgetys Woolstores project in 1993 until 1996. This refurbishment project has been constructed by Wycombe Constructions. Thus, future stage in this study is to explore the intellectual capital among multi-disciplines stakeholders in managing the adaptive re-use stages from both projects.

(4)

(5)

(6)

Photo 4: *the external view of the former Dennys Lascelles Woolstores, more creative and well merged between the existing external walls with wall cladding*
Photo 5: *the internal view, new staircases inside the existing brick wall and timber floor*
Photo 6: *the internal glass partition with the face of former Prime Minister Alfred Deakin (1903-1910) /after the building/ is for The Alfred Deakin Prime Ministerial Library of Deakin University*

According to Authentic Heritage Services Pty Ltd report, the heritage advisor for the City of Greater Geelong, the former of Dennys Lascelles Woolstores have cultural significance which is architecturally significant and historically significant at a LOCAL level. Architectural significant demonstrates some original interwar qualities on unpainted and redbrick external wall, windows, doors and the signage below the parapets wall that stated "Dennys Lascelles Ltd Woolbrokers". It also relies on the retention of the remaining parts of the wool stores complex. The report also mentioned that "historically significant is associated with the development of the Dennys Lascelles Ltd woolstores from 1934, and in more recent years as part of the Deakin University Waterfront Campus" (Victoria 2010).

As a summary in the case study discussion, the Dennys Lascelles woolstore has proposed to create an exciting multipurpose environment, providing light filled spaces of varying dimensions. The historical value of this building merges with technology, and environmental

sustainability as a critical part in design development for Dennys Lascelles that the stakeholders learned from Dalgetys woolstores. The location of this building at well-known corners and waterfront views also provide /the answer/ that understanding the history of the area (surrounding) and buildings itself is important and critical in the way to get the intellectual capital. The decision on designing Deakin University is under historical influences and its importance of protecting the architectural and historical significance. According to the statement of significance in Victorian Heritage Database stated that "the architectural significance of this building relies on the retention of the remaining parts of the wool store complex". This study provides assumptions that the knowledge creation in Dalgetys projects has been transferred as accumulative intellectual capital or knowledge to achieve project success.

CONCLUSIONS

This paper considered lack of expertise and knowledge about/on adaptive re-use, inaccurate and incomplete historical information and the difficulty of getting multidisciplinary stakeholders collaboration could cause difficulty to achieve adaptive re-use success. However, this study suggested critical success factors strategy which could provide intellectual capital for multidiscipline stakeholders as the best strategy to overcome the complexity and achieve success especially for the difficulty of transformation process. In relation with the case study preliminary analysis on the contribution of 'historical' knowledge, there were initial findings that critical success factor is in used in the beginning process. As for example, the architect used his expertise to define the sources of historical information for design purposes and to get development approval particularly, information on assessment of buildings significance. The critical success factors are identified in case study is collaborative problem solving according to the winning criteria "the design and management skills of the architect and his team when dealing with client and contractor". However, there is an assumption for this study that this project has prepared good feasibility studies, building assessment by qualified and expert teams and good workmanship for the construction process. There is little theoretical development and empirical research in relation to developing an intellectual capital influenced by critical success factors to overcome the project complexity. We began exploring the proposed Intellectual Capital Model for adaptive re-use projects success into two heritage listed buildings which were located in an Australian city adjacent to each other and had architectural and cultural heritage significance and were developed more than ten years apart largely by the same project team and client. The document analysis provides substantial background towards understanding the nature of the projects within a case study research methodology. The document analysis is ongoing. This paper has served to described the historical characteristics of the project in order to give an indicate the scope of knowledge, expertise, collaborative problem solution skills required in order to respond to the complex design and construction issues that may have arisen.

Further research

This study is a part of an on-going research for a PhD on the critical success factors and intellectual capital in the adaptive re-use projects. The chosen case study provides the guidance in establishing research aims and identifying research questions for knowledge creation and knowledge transfer from one project to another. In addition, it also gives attention to investigate what happened in the time period between project 1 and project 2 in terms of knowledge gained from experience and other external factors.

The contextual background of the two adaptive re-use projects provides a unique situation to explore the knowledge and skills gained from internal experiences (inter-project knowledge and intra-project knowledge) and external experiences (from external sources during the gap between completion time) that contribute to the development of intellectual capital within the project team members. We propose three situations that could contribute to the pool of intellectual capital of adaptive re-use projects (Figure 3).

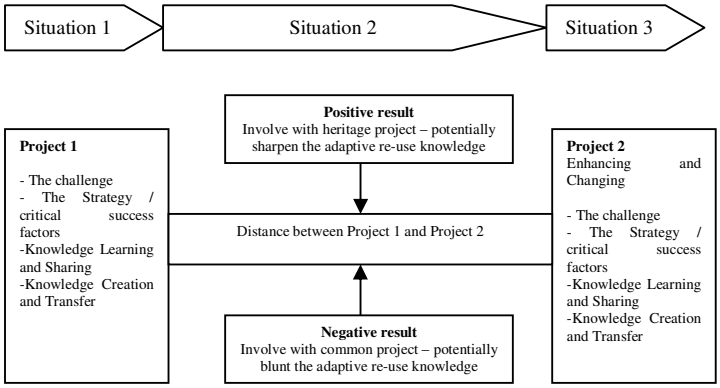

Figure 3: *Summary of on-going research framework*

Situation 1 is what and how knowledge creation in project 1 managed. How project stakeholders understands historical significance of the building and area towards integrating client requirements with existing structure. It also involve with design review approach in preparing the document for development approval on historical buildings. Other specific identification in project 1 is how the project stakeholders overcome adaptive re-use issues during the processes of changing the building functions, the steps taken to solve the problems and the approach taken in knowledge accumulation and management within human-based capital and historical dynamic capital. However, the potential critical success factors of adaptive re-use projects remained as intellectual capital mechanism in this study.

The distance or gap between project 1 and project 2 is the second situation in this study. The aim is to investigate the knowledge contribution from project 1 and the distance period. The positive assumption was a better knowledge on heritage when they were involved with related heritage projects. The negative assumption could be a blunt of their knowledge on heritage due to their involvement with many common projects within the year gap. It could influence the knowledge creation and knowledge transfer to project 2 when the similar stakeholders are working back together.

Situation 3 involves with project 2 that started more than 10 years after project 1 was completed. The investigation on knowledge impact from project 1 successful criteria and the knowledge change (positively and negatively) from the distance period is critical to understand the intellectual capital in human based capital and historical dynamic capital. The interconnection between situation 1, situation 2 and situation 3 results could be providing a dynamic managing approach in managing the intellectual capital uniquely for adaptive re-use project.

This study will further embark on the empirical phase and face–to-face interviews with project team members, the client, and document analysis on key project documents. To ensure the validity of the situations, the project manager, client, the architect and the

contractors chosen are of the same person for both projects. The empirical data analysis will seek to refine the conceptual model proposed and evaluate its effectiveness in relation to critical success factors for multi-disciplinary design management with different backgrounds, skills and knowledge for continued success of future adaptive re-use projects.

Abstract
The complexity inherent in construction project environments can lead to emergence of informality and vice versa. This paper suggests that studying informalities in projects could lead to identifying paradoxes. Informalities in construction could be conceptualised through an economic or social perspective. Informalities may be explicit and visible, or simply implicit and thus invisible; commonly encountered in projects or specific to a particular project's context; ethical/legal or unethical/illegal. These dimensions suggest a framework within which to describe the emergence of a project's organizational behaviour. Non-functionalists and subjectivists argue that the informal issues are best understood through subjectivist paradigms. This paper presents an approach to the design of research approach appropriate to such tasks. In doing so it accommodates various philosophical perspectives, and the blending of various methods, to construct rigorous analysis to deliver context specific outcomes. It is argued that conceiving informality through alternative methodologies such as hermeneutic-emancipation and critical realism-semiotics offers opportunities to study informality in a meaningful way. Moreover, a design that combines multiple research strategies, e.g. case studies-ethnography, case study- ethnomethodology, is most suitable for informality investigations. It is suggested that operational aspects, such as ethical protocols and participant's concerns, are taken into consideration in the design of a research methodology.

Keywords: informality, methodology, method, construction.

INTRODUCTION

The complexity perspective of projects (Bresnen, Goussevskaia, and Swan 2005; Marrewijk et al. 2008; Baccarini 1996; Remington, Zolin and Turner 2009) and paradigm shifts in qualitative research methodologies (Denizen and Lincoln 2005) has enabled alternative conceptualisations in the study of construction projects. It is argued that the connectivity and interdependencies between the multiple systems in projects, operating in uncertain, ambiguous and dynamic environment, pose the difficulty in understanding and predicting the projects overall behaviour (Geraldi 2008). The interdependencies occur between a number of sub-systems including, organisational, technical, social or social systems. Increasing recognition of the role of fussy socio-cultural-political environments in management of project, necessitate understanding projects as socially constructed realities (Cooke-Davis et al 2007; Small and Walker 2010). Moreover, studying complex connections between the systems can develop insights into project behaviour; including issues relating knowledge sharing; communication and relationships building etc. However, such studies can be challenging when the complexity underpinned by informal and shadow elements in the project organisations. Some of the informal issues that could create chaos in projects may not even be visible to warrant an inquiry or hinder at times hinder research studies (see Small and Walker 2010). Moreover, paradoxes emerge when irreconcilable contradictions exits between systems, including between elements of formality and informally (Bourne & Walker 2005; Alderman & Ivory 2007; Baresnen 2009). This suggests that studies into informality could assist in understanding project organisations as complex systems while providing an opportunity to identity paradoxes.

Recently the interest in 'informality' research in the construction management discipline has gained significant attention (Chan and Räisänen 2009). The need for such a research focus arises from the recognition of inadequacies in the current approach to studying construction organisations (Dainty 2008) and gaps in developing meaningful understanding or solutions to some of the complex issues (Berggern and Soderlund 2008; Moldoveanu 2004) facing construction. This trend can also be attributed to a movement that is seeking to understand projects as socially constructed realities. This provides much-needed subjective relevance while maintaining high levels of dependability, authenticity, transferability and auditability (O'Leary 2004).

The key element of 'informality' refers to the informal, casual or unofficial activities that occur in business firms, industries, societies and the economy as a whole. The conceptualisation of 'informality' is discipline specific, and in construction management informality is implicit in a number of research areas e.g. communication (Gorse and Emmitt 2007), safety practices (Lingard Rowlinson 2005), gender/ethnicity based research (Byrne, Clarke, and Meer 2005; Pink et al. 2010), procurement/recruitment practices (Bresnen et al. 1986), knowledge management etc (Senaratne and Sexton 2008; Bresnen 2003). These studies develop an understanding of key issues in projects, in the context of complex project environments with elements of informality.

However, explicit accounts of how to research informality in construction are limited (see Chan and Räisänen 2009, Rooke, Koskela and Kangioglou 2009). In this paper, 'informality' definitions from Economics, Urban Studies and Organisational Theory domains are reviewed to develop a conceptual understanding of informality. The conceptualisation is notably influenced by both economic and sociological perspectives, and subjected to alternative philosophical paradigms. As a consequence it seems likely that multiple worldviews of the

concept exist. While the conceptualisation presented in this paper is dominated by a sociological view, the economic view is briefly discussed.

The choice of an appropriate research paradigm in designing a strategy/method to study 'informality' is critical to produce meaningful outcomes. However it is equally important to accommodate the practicality of the research design. Aligning the conceptual research design to the operational research design is a frequent challenge faced by researchers (see Gorse and Emmitt 2007, 2009; Pink et al. 2010). In some instances practical execution of the most appropriate conceptual research design may prove impractical or impossible. The practical challenges can arise from the unwillingness of subjects to cooperate in the study (because of commercial sensitiveness, discomfort of participants of them been studied in-depth and profiled) and challenges posed by the national/institutional ethical protocols' (not allowing some pursuits based on privacy, risk, benevolence etc) (Australian Government 2007). This paper builds on the extensive intellectual debates that have taken place from time to time about the choice, relevance, understanding and adequacy of research methodologies when studying construction phenomena (see Rooke & Kagilogou 2007; Dainty 2008; Rooke, Koskela and Kagilogou 2009). Much of this debate is central to designing methodologies to study informality from a social perspective.

This paper explores three interrelated aspects critical for designing research approaches to study 'informality'. They are (a) a conceptual understanding of 'informality' in project organisations (b) the worldviews underpinning the ontological and epistemological positions relating to the concept of 'informality' and (c) the practical design of appropriate research methods to explore informality within various worldviews. These three aspects are reviewed in the context of selected studies that dealt with informalities in construction. It concludes by providing an overarching framework to identify appropriate research methods to study informality in construction. In doing so it consciously avoids prescribing the best approach to study different informality issues since the multiplicity of possible combinations of research approaches renders such recommendations as both naive and misleading.
To develop a meaningful understanding of the informality phenomenon a shift from the positivist paradigm is warranted. O'Leary (2010) suggests that "without an appreciation of how attributes, positions of power and privilege, and worldviews conspire to create subjectivities, researchers can easily fall into the trap of judging the reality of others in relation to their own reality" (p. 47). This could mean looking at the same issues with two different worldviews could lead to two different, but relevant and meaningful outcomes. The deeper the sociological perspective in the research approach, the greater the need for researchers to evaluate their philosophical predispositions when dealing with biases in constructing their research strategy, in order to improve the credibility of their research.

CONCEPT OF 'INFORMALITY': A REVIEW

'Informality' can be understood and defined from a variety of perspectives. By reviewing definitions and attributes of informality from other disciplines this paper develops a conceptual basis for informality for construction. The aim is neither to unearth the roots of 'informality' research nor to give an in-depth account of informality research in other disciplines. Rather it is to generate a broader perspective of 'informality' in order to to identify alternative paradigms/worldviews underpinning it. This provides an opportunity to develop research approaches that could unearth informalities that create paradoxes.
This informal sector was characterised by activities and people not being clearly identifiable. However, the essence of the informality discussions can be attributed to two perspectives-

economics and sociology. The migration of people (between countries or regions) caused situational changes to the society (attracting the interest of urban architects, sociologists etc) and often created informal sectors, which attracted the interest of economists (Alsayyad 2004).

The study of '*urban informality'* is about discovering the social actors and forms of social organization (Alsayyad 2004), and has similarities to organisational informality. Urban informality is 'a way of life [and] may be approached from three interrelated perspectives: the physical structure, comprising a population base; a system of social organization, involving a characteristic social structure and related patterns of social relationships; and a set of attitudes and ideas of individuals or groups engaged in or operating under forms of collective behaviour and/or social control' (Alsayyad 2004p.8). The research on urban informality focused on developing an understanding about the functions and structure of informal groups/enterprises. However, some studies looked into the nature of informalities. Alsayyad (2004) suggest that informality is theorised as a marginal activity that is (i) a temporary manifestation occurring as a transient feature within an organisation, or; (ii) closely connected to the formal structure and is an essential and permanent component of way of life. Here the research focus is more about understanding the meanings. Meyerson (1991) suggests that any ambiguity in meanings can create paradoxical situations that could lead to irreconcilable contractions.

Studies on *'economic informality'* focused on illegal economic activity (Parry et el. 2007) taking place "below the radar" of government. The illegal activities could take many forms including the activities of unregistered small firms, street labour and large registered firms employing workers without written formal contracts (Oviedo, Thomas, and Karakurum-Özdemir 2009). It is important to be precise as to what kind of economic informality is studied – e.g. unregistered firms, unprotected workers, or the self-employed- so that appropriate approaches can be devised to study the problem (See Lewis and Hosein 2006; Wells 2001, 2007). Inaccurate comprehension of the nature of the illegal economic activity could lead to suggesting inappropriate response strategies. Economic informality research has focused on: (i) Identifying and measuring informal economic activities; (ii) The impact of the informal sector on an industry and nation e.g. labour market, unemployment, productivity, GDP etc, and; (iii) Strategies for managing or controlling informal sectors e.g. regulation, legislation etc (Oviedo, Thomas, and Karakurum-Özdemir 2009; Parry et el. 2007). Here the focus is more on causal impacts of informality on economic outcomes and the effectives of regulation to deal with informality.

The conceptualisation of '*organisational informality'* is largely underpinned by a sociological perspective, while the economic domain is also acknowledged. Morand (1995) makes an interesting point about informality in organisational research, noting that the term is 'often used as conventional descriptors of social behaviour and social situations in organisation… [and] researchers generally have avoided rigorous attempts at construct definition and validation' (p833). He describes that the 'term, informal, and its accompanying noun informality, refer to social situations or gathering that are generally characterized by behavioural spontaneity, casualness, and interpersonal familiarly'. The distinction between informal and formal aspects of organisations translates into interpretation of artefacts such as dress codes, jokes, behaviour in meetings etc. However, his articulation of informality relates to interactional behaviours between actors in social construction and production; and the subsequent categorising of organisations (e.g. organic, inorganic, bureaucratic etc.) and their traits (e.g. innovative, agile etc).

The non-hierarchical, self-coordinated, new means of communication along with significant division of labour are all creating transient boundaries in the organisation and complex organisational setups. Informality emerging in this context is viewed as a contributor to creativity and innovation. It plays crucial role in developing links and trust among business partners operating in turbulent and uncertain business environments. Therefore, informalities can operate as a control mechanism offering flexible arrangements and fast solutions, where it is impossible to deal with all possible events formally. However, informality can also be seen as a threat to social justice (e.g. aiding discrimination) and hierarchical rules. Misztal (2000) suggested that creation of the Asian economic crisis could be attributed to the failure of 'informal connections' - such as nepotism, leading to a lack of accountability and transparency - as a way of doing business. He argues that informality is best understood when explicitly compared with formality and suggests that maintaining a delicate balance between formality and informality is critical for order and control in the new forms of organisations. The formality is described as structures, processes and protocols. This reinforces interactional nature of informality as proposed by Morand (1995).

Informality issues can be related to interpersonal relations, informal leadership, behavioural control and informal communication (Hodgetts & Hegar 2008). Activities associated with interpersonal relationships could include informal advice, trust, or communication. Informal leadership is associated with the development of power within non-formal structures: this may best be described as gate keeping or perimeter guarding. Behavioural control is a form of manipulation of members of an informal group using a variety of control strategies including establishing in-groups, coercion or persuasion.

INFORMALITY IN CONSTRUCTION: TAXONOMIES OF RESEARCH

Complexity, chaos and paradox in projects, at least in part, can be attributed to emergence of informality. The loosely coupled nature of project organisations (Dubois and Gadde, 2002) is a setup conducive for informalities to emerge. Informality in construction in the context of a firm, project or industry could be argued to be a blend of both economic and organisational elements. Chan and Raisanen (2009) have discussed the informality concept in the context of construction and identified a number of challenges facing researchers. In essence any of the informality issues examined within a construction organisation are related to its practices, structures/systems, or social groupings (e.g. "networks/clans of actors") in the context of a phenomena (e.g. knowledge generation, safety management, competitiveness, learning process etc). However, studies explicitly designed to study paradoxes or identifying paradoxes as part of research outcomes are limited in construction management.

It is synthesised that the informality research conceptualisation involves five aspects, and they influence the design of the research approach. However, subsequently it is argued that methodological paradigms also influence the conceptualisation of informality. This complex interactional process is disused later in this paper. This framework (ref. Figure 1), along with the methodological framework in the subsequent section (is Figure 2) is then used to review how the existing studies of informality are approached. This will assist to identity the research approaches practices in studying construction informality and possible alternatives.

Conceptual underpinnings

Using the above review potential directions for informality studies in construction can now be conceptualised. This conceptualisation is intended to serve as a guide in the choice of research strategies for informality studies. It suggests four related aspects underpin

taxonomies of informality research: Informality domain, Research issue, Legality/ethics of the issue and Informality visibility (refer Figure 1).

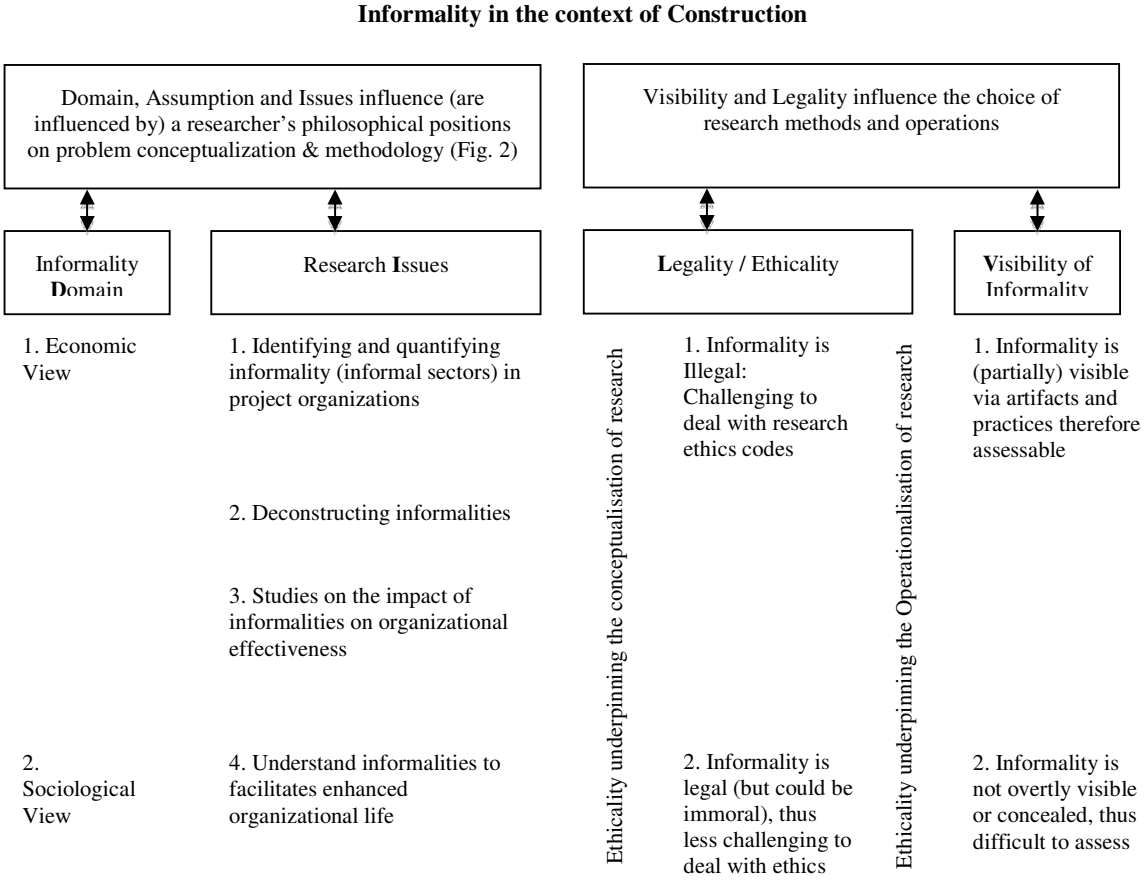

Figure 1: *A framework for conceptualising informality in construction.*

Informality Domain refers to the disciplinal - that is economics or sociology - attributes influencing the core conceptualisation of informality research. As the areas of research in construction management are diverse, treatment of topics can be influenced by different disciplinal assumptions and training (Rooke & Kagioglou 2007; Runeson 2007). In this context an economic view of informality is focused on identifying and quantifying illegal economic activities and devising regulation and strategies to mange them. The social view is focused on 'structural and interactional' issues of socially constructed realties (and some times with the real world). Ethical and moral aspects are central to both social and economic of informalities research conceptualisation and operationalisation (Denzion and Lincoln 2005).

Conceptualisation of *research issues* is influenced by the attributes of the *'research domain',* and *methodological predispositions* (as identified in Figure 2) of a researcher. In the context of this paper four general research issues are identified. Each informality aspects e.g. interpersonal relations, informal leadership, behavioural control and informal communication etc, could be researched via one or mix of the four-research issue. The research issues can be: (i) assessing actors' interpretations of informal interactional orders, (ii) Developing meanings of informality issues and their associated characteristics via observed behaviours (e.g. bodily postures, conversational interruptions, phonological slurring, etc), or deciphering

unobservable deep beliefs (values, assumptions tc) (iii) Assessing the impact of informality on organisational effectiveness and (iv) Understanding informality in terms of enhancing organisational life (not directly associated with improvements in organisational effectiveness). One could argue researchers' deep assumption about the nature of informality, whether it is a temporary or permanent phenomena, could influence research conceptualisation. Researchers, assuming informality as a permanent aspect, may not seek to identify strategies to eradicate informality. They rather conceptualise their research with an interpretative, hermeneutic- emancipatory tradition- that enables them to understand the meaning and/or transform the socially constructed realties by liberating the members from their traditionally held beliefs (Alvesson and Willmott 1992; Alvesson 2002). Assumptions of the temporary nature of informality could lead to technical and rational approach to eradicate informality [Refer Figure 2].

The level of *visibility of an informal* issue is dependent upon on how it is conceptualised. For example interpersonal relations in an organisation can be studied via more visible rituals depicted by artifacts (e.g. jokes, form of language), or via less visible trust and advice networks. The visibility of the issues has a significant influence on the method section. *Legality/illegality* of the aspect under study has significant influence on the operational design and choice of method. Almost all universities are bound by research ethics protocols that aim to minimise the risks associated to research design and upholding the welfare of the participants (see Australian Government 2007). Research projects studying illegal issues (even a possibility inadvertent identification) are imposed with additional statutory obligations. The minimal obligations attached to anonymous illegal studies could attract researchers to engage with methods that offer anonymity.

Although research on unethical and immoral informal actives (but not the explicitly illegal) are not subjected to additional statutory obligations, data collection and reporting of the findings should nevertheless be treated with sensitivity, and the findings should not exploited out of context. Ethics is not solely about 'procedural ethics' that seeks compliance with established protocols (see Guillemin and Gillam, 2004; Brydon_Miller 2008), being an intrinsic aspect of the research conceptualization, where researchers sublimate their power positions, privileges and prejudices (O'Leary 2010). The argument that all research is value-ridden (as opposed to value-free), makes it is essential that researchers understand the value system and its impact on their own research position (Corbin and Struss 2008; Christians 2005).

It is inaccurate to view the conceptualisation process of interaction between the above five aspects as linear. Conceptualisation of an informality research problem is a resultant of highly complex interactions among the numerous aspects under consideration- e.g. domain, assumptions, issues, methodological paradigms. The following section discusses the methodological issues associated to study of informality. Subsequently aspects discussed in this and following section will be used to review selected published informality studies to identify some of the current research approaches and propose any possible alternative strategies.

Research Approaches and Processes

Keeping pace with the rapidly emerging paradigm variations in the qualitative methodologies (the 'isms' revolution) is challenging (Denizen and Lincoln 2005). Most evolving paradigms are arguably variations to existing post-positivist paradigms, accommodating deviations in ideology or research process (Joesph, and Roberts 2004). The evolution of alternative paradigms can be observed as staying true to the cause of the fundamentals of post-

positivism: that is to acknowledging multiple worldviews (Denizin and Lincoln 2005). The evolution of paradigms constantly challenges the prevailing worldviews (constructed by the ontological and epistemological positions) that may stand in the way of developing a clear understanding of a problem (O'Leary 2010; Bryman 2008).

Process 1: Selecting a Methodology: Paradigms/ worldviews	**Process 2: Selecting a Methodology: Research Strategy**	**Process 3: Selecting a Research Method-Data collection**	**Process 4: Selecting a Research Method-Techniques**
Positivism Post-positivism Constructivism Interpretivism Critical Theory Hermeneutics-Emancipation Critical Realism Pragmatism (as proposed by Creswell and Clerk 2007)	Case study Ethnography Action research Grounded Theory Phenomenology Ethnomethodology Discourse analysis Semosis	Surveys (open ended-close ended; postal-email-online etc) Observation Interviews (face to face-telephone etc) Focus groups Diaries Artefacts, documents, and records Visual (video) methods	Descriptive statistics Inferential statistics: Paramedic and Non-Parametric statistical techniques Coding: (Open codes, Axial Codes, Selective codes, Memos, diagrams etc) Conversion analysis Thematic analysis Textual analysis

Figure 2: *A framework on the possible Research methodologies for informality research*
Synthesis based on Strauss and Corbin (1998); Scale (1999); Denzin & Linclon (2005); Clerk and Creswell (2007); Corbin and Strauss (2008); Bernard and Ryan (2010)

Two key terminologies, methodology and method, are used in Figure 2 to describe the methodological practices in informality research. Strauss and Corbin (1998) say that methodology is "[a] way of thinking about and studying social reality' and method is '[a] set of procedures and techniques for gathering and analysing data' (p3). Morse and Richards (2002) use the term 'research strategy' in lieu of methodology and describe research strategy as 'a way of approaching data with a combination of techniques that are ideally consistent with the method the researcher has chosen to use. … [T]he term method … refers to a more or less consistent and coherent way of thinking about and making [collecting] data, way of interpreting and analysing data, and way of judging the resulting theoretical outcome' (p 10). The term 'Technique' to refers to a way of attempting or completing research task (e.g. data coding). Although 'techniques' themselves do not indicate which method is employed in the research, the ways in which the techniques are applied could indicate the research method in application.

Figure 2 identifies four processes to the methodological design of research. The first two processes are related to the choice of a methodology, a worldview(s), and a research strategy(ies) that is accommodative of that worldview. The last two processes are related to choice of methods that focus on data collection and analysis techniques. Despite the numerous combinations of possible research practices, some combinations may not be

philosophically aligned. It is obvious that positivist, critical theory, close-ended survey and qualitative coding are one such combination. It is not the aim of this paper to give an in-depth review of methodological aspects, but rather to discuss the possible combination of methodologies and methods in studying informalities.

Selecting a methodology which aligns with the paradigm (Process 1) and strateg(ies) (Process 2) is interactional with the conceptualisation of an informality issues (i.e. the domain and issues). The worldview or paradigm affiliation of a researcher is intrinsic to the way a research issue is conceptualised (Morgan and Smircich 1980). As indicated earlier, this means conceptualisation of a research issues occurs in multiple interactional layers, constituting the worldviews (as described in Figure 2) and informality conceptualisation aspects (as identified in Figure 1). Varieties of post-positivist or constructivist philosophies "enable researchers to deal with complex layered and often unobservable strata of reality that impact upon our action and thinking" (Joseph and Roberts 2004, p1). One of the eight worldviews proposed in the Process 1 in Figure 1 could conceptually underpin informality research. The subtlety of the paradigm variations demands deep engagement with the literature to perceive the differences. Moreover, it is instructive to map the development of philosophical alternatives beyond the dominance of social constructivism and interpretivism. The tensions between emerging constructivist/ interpretivist/critical theorist philosophies is evident in literature (Joseph and Roberts, 2004). In essence, during the Process 2, researchers conceptualize their research issues with a worldview they uphold (if they are fundamentalists) or the worldview they want to adopt (if they are pragmatists). Researchers need to carefully evaluate and respond to critiques of the chosen worldview and why it will deliver meaningful outcomes.

Process 2 is about identifying a *research strategy* that complements the choice of worldviews. A research design to study informality could combine multiple strategies. As an example 'ethnography' is complementary to 'case studies' and 'grounded theory' (see Barrett and Sutrisna 2009). In the case of a construction project the nature of the project, and identification of the boundaries defining the social units of which it is comprised are best investigated using case studies. The case study is an overarching research strategy rather than simply a data collection method or a research design concept (Yin 1994). Stake (1995, p. 2) says. "The case study methodology/strategy allows any selected method to "study a case analytically or holistically, entirely by repeated measure [positivist] or hermeneutically, organically or culturally and by mixed methods…" (Stake 2005, p. 443). Therefore, the case study could be designed with combinations phenomenology, ethnomethodology, discourse analysis and semiosis.

The methodological position will influence the selection of the appropriate *methods to collect and analysis data (*or vice versa). In theory the choice of a data collection method should be predominantly underpinned by the methodology. However, in practice, numerous other considerations, such as ethical protocols or the cooperation of participants tend to act as constraints on the choice of data collection method. Although methods supporting positivist paradigm are reduced to surveys and published numerical data, a trend has developed for the use of quantitative methods to analyse the results arising from non-positivist methods such as Key Word in Context analysis (Bernard and Ryan 2010). Almost all non-positivist methodologies could use interviews and focus groups as data collection methods. Ethnographic studies in addition to the interviews and focus groups could use observations and any relevant artefacts/documents as data. Patterns of informal behaviour can also be studied with visual (video) methods and use of diaries. Nevertheless, Coding used in quantitative analysis techniques, is commonly understood as a qualitative analysis technique.

Strauss and Corbin (1998) have provided an extensive discussion on coding process (e.g. open codes, axial codes, selective codes, memos, diagrams etc. Conversion analysis technique is central to discourse analysis. Thematic analysis identifies themes emerging from data and is a technique that is conceivably applicable to most qualitative approaches (See Bernard and Ryan (2010) for guiding the operationalisation of these methods).

The researcher as the 'Research Instrument': The fundamental issue

Designing an appropriate non-positivist research approach is only a part contributor of good and meaningful research. The research design only establishes the ideology underpinning the research and the processes that are followed in the design and execution of the research. However, the fundamental concern is 'how this methodology will be executed by the researcher, who is the instrument, in arriving at a meaningful research outcome. In contrast to quantitative research, where researchers rely upon validated statistical instruments, qualitative research believes that researchers themselves are the instruments. Corbin and Strauss (2008) argue that good qualitative research emanates form the researchers who share the characteristics of having a humanistic bent, curiosity, creativity and imagination. The key characteristic that distinguishes the good qualitative researchers from the others is the ability of the researchers to deal with risk and to live with ambiguity. Moreover, researchers who develop trust and confidence in the self as the research instrument (as opposed to established tools and techniques) conduct good qualitative research. However, designing good quality research practices that maintain the adequacy and deliver meaningful outcomes is crucial (see Dainty, 2008 on the principles of methodological plurality)

A SELECTED REVIEW OF INFORMALITY RESEARCH

This section reviews methodologies used in studying informalities in construction, based on selected published work in the arena. This review includes papers in which informality is dealt implicitly and/or explicitly. It should be noted that the selected studies are not a representation of the informality studies in construction. However, this review can inform a range of research approaches that can be discussed in the context of Figure 1 & 2. This can assist in developing an understanding of taxonomies of methodologies that can be used for studying different informality issues.

Review of informality studies based on the economic perspective

A study by Lewis and Hosein (2006) focused on estimating of the size of the informal (hidden) construction labour force in the Trinidad and Tobago (T&T). That is identifying the nature of illegal labour and quantifying the extent of informal (illegal) labour employed in construction projects/sectors in a particular region. Lewis and Hosein (2006) rationalised the methodological approach using anecdotal evidences and citing the difficulty in obtaining reliable data on illegal sectors or activities within the construction industry. This study used published statistics from a number of sources to estimate the extent of informal construction labour in T&T. The human research ethical issues impacting their study are irrelevant, as the paper is based on published documents. However, in the context of current National ethics guidelines (at least in the context of Australia), the primary data collection related to identifying and quantifying the hidden sector will pose significant challenges.

The paper by Wells (2001) focused on unrevealing the informal sector in a region in the context of capital formation in less developed economies. In this paper the illegality aspect of the informal sector is not overtly discussed. Like the previous study the assumption about the temporary/permanent nature of the informally is difficult to gage. The paper is based on

observations and/or discussions with participants and published data. Mentioning of not to interpret the findings along the racial context highlights the ethical issues confronting the researchers beyond the study.

Oviedo, Thomas, and Karakurum-Özdemir (2009) identify a number of other methods that could be used to study economic informality. The approaches are classified as direct (micro) methods and indirect methods (macro) methods. The micro methods could employ (i) voluntary surveys (Nuget and Sukiassyn 2009), interviews and Tax audits (Oviedo, Thomas, and Karakurum-Özdemir 2009). Use of the survey method, specifically anonymous surveys, to collect primary data is relatively less challenging from an ethics clearance point of view. The unidentifiability of personalities associated to any illegal activity, minimises the risk to and responsibilities of the researchers and institutions conducting.

The interview method could pose significant challenges due to the identifiablility of the actors in the illegal informal sector. The protocols call for reporting such accounts to relevant authorities. With tax audits, the collection of private nature of the data could also prove challenging. Moreover, any identification of informality associated to tax evasion could be treated as criminal activity; researchers are required to notify this to appropriate authorities. Debating about doing the 'right thing' could spark difficult ethical dilemmas for researchers who assume both economic . However, tax-based analysis can be conducted suing secondary published data, if available. These methods include (i) studying the discrepancy between aggregate and income expenditure, discrepancy between total labour force and formal employment and physical input of resources (e.g. use of electricity or water consumption). In essence economic informality studies can be said to be dominated by positivist methods, although there is room for the use of post positivist methods.

Review of informality studies based on the sociology perspective

Baarts (2009) and Pink et al. (2010) studied safety practices in the construction sites using ethnography. Baarts studied the collective individualism as an informal emergent social process relating to construction site safety practises (fits into Research Issue 2 in Figure 1). Making meaning of partly visible emergent informalities was approached through an in-depth ethnographic study. Ethnography is commonly used as a means for exploring cultural aspects of human organisation (Geertz 1975; Morse & Richards 2002; Schein 2004). Ethnography can unearth hidden informal practices as part of the culture of an organisation. In this study researcher become part of the cultural group, conducing observations during the normal course of work. The ethnographer has questioned/evaluated the ethical concerns and personal prejudices in an explicit manner in the conceptualisation and operationalisation of the research study. The descriptions made during the site observations and data from semi-structured interviews were used to create meaning and develop an understanding of the informal social process.

Pink et al. (2010) discussed the opportunities offered by the new bread of ethnographic approaches in developing better understanding of social phenomena. This study through the ethnographic process developed an understanding of invisible routes of communication in construction sites employing migrant workers (research issue 4 in Figure 1). The use of photographic and video-based data in addition to conventional ethnographic data is also proposed. Pink et al. (2010) indicate the 'essential criteria [of their study] is that the researcher retains the reflexive awareness of how her or his work is informed by theory and a self-consciously considers how theory and practice remain in dialogue though the ethnographic process'. The focus on developing meaning of social practices to understand

organisational life fits will with the hermeneutic-emancipatory paradigm. The above two studies analysed both visible (using observations) and hidden aspects (using in-depth discussions) of informalities. However, they did not report any ethical practical challenges in executing the research design. Moreover,
Gores and Emmitt (2007, 2009) looked into the informal aspects of communication process during the construction progress meetings (research issue 1 in Figure 1). The analysis of the observable/visible physical behaviours and linguistic interactions during the site meeting (across 10 projects) was used to unearth the not so visible socio-emotional interactions influencing informal relationships among the team members. They used observation methods and Interaction Analysis Process approach (a qualitative approach to generate quantitative data) to analysis the communication process. The difficulties faced with executing the conceptual research design in practice are highlighted. A study by Styhre, Josephson and Knauseder (2004) implicitly dealt with informalities associated to learning capabilities in organisation networks (Research Issue 2 in Figure 1). They employed case study and action research strategies using individual interviews, group interviews and published documents as data to identify informal networks.

Bresnen (2009) employed inductive approach to study emergent practice of partnering through a practice-based approach. The study used interviews, documents and observations to grasp the emergent nature of partnering practice (research issue 2 in Figure 1). Furthermore, the paper discusses alternative methodologies and methods for generating knowledge, reinforcing need for multiple lenses to study informalities. Barrett and Sutrisna (2009) have advocated the use multiple approaches within the context of case study strategy for generating meaning for social phenomena (Research Issue 3 in Figure 1). However, caution in the abstraction process is urged to maintain the relevant meanings of events and not to delude the meanings by making it out of context. Their study on understanding process in construction projects was conceived within the critical realism paradigm, using case study and grounded theory strategies. The critical realism paradigm enables them to assume both objective and subjective realities of constructs associated to their study. They used condition consequence matrices and cognitive maps to show relationships between concepts and to identify some causal relationships.

DISCUSSION

The above review highlights that diverse, but effective methodologies and methods employed in studying informality and emergence in construction. The studies on economic informalities, due to difficulties in gathering reliable primary data, have used anecdotal evidences and existing published data in identifying and quantifying informalities. Studies on sociological perspective employed multiple strategies including case study, ethnography, action research, and grounded theory, using different types of data gathering techniques, including observations, interviews, published documents etc. It can be inferred that all the above studies, except Gorse and Emmitt (2001, 2009), used qualitative methodology conceived by the non-positivist tradition. Although not explicitly stated, expect Barrett and Sutrisna (2009) who assumed the critical realism paradigm, all the other sociological studies fall into one or blend of constructivism, interpretativism, and hermeneutic-emancipation paradigms.

Although not reviewed in this paper, limited use of discourse analysis (Kao, Green, and Larsen 2009) and ethnomethodology strategies (Hugill 2001, c.f. Gorse and Emmitt 2009; Rooke, Koskela, and Kagioglou, 2009) to study informality is evident in the literature.

Discourse analysis, phenomenology and ethnomethodology are focused on understanding realties based on the use of language in written or oral form. These strategies are closely aligned to the interpretativist paradigm. Discourse analysis can enlighten the different types of informal structures of the language used by different project team members (e.g. architect, contractor, engineering talks). The phenomenology and ethnomethodologies, focused on "micro-social interactions- that is interaction on a small scale, between individuals or within small groups" (Seale, 1999 p. 30) can also provide different lenses to study informality as a social construct.

The discourse analysis, phenomenology and ethnomethodology in the context of constructivism, interpretativism and hermeneutic emancipation paradigms can provide a sound base to develop an in-depth understanding of informalities through the use of language. This enables transformation of (or liberation from) the traditionally held beliefs and practices underpinning informality in construction (Alvesson and Willmott 1992).

The use of semiotics could deal with analysis of structures, generative mechanisms and practices beyond language. This can provide an alternative to critical theorists who reject the use of discourse strategies to explain causality, keeping in line with the hermeneutic emancipation tradition. Therefore, semiotic strategies, conceived within the critical realism paradigm could offer a better research approach to study informality enabling causal analysis while maintaining some the rich attributes of non-positivist paradigms (Fairclough, Jessop and Sayer, 2004).

CONCLUSIONS

The complexity in project environments can lead to emergence of informality or vice versa-that could create paradoxes. This paper suggests that studying informalities can in part enable identifying paradoxes. This paper explored three interrelated aspects critical for designing research approaches to study 'informality'. Four key dimensions were identified in conceptualising 'informality' research: the disciple context (economics or sociology), nature of the research issues, ethical/legal dimensions and visibility of the informality. This is established Processes associated the conceptual and operational research designed is also discussed. The methodological process involves identifying a paradigm(s) within which the research is conceptualised. This will influence the way the strategies and research methods are used for colleting and analysing data. Practical (ethical and operational) considerations of conceptual research design are paramount for meaningful outcomes. A number of methodological taxonomies, in studying different informality research issues, are identified from existing literature. It is evident (within the limited observations) that the case study strategy, ethnography and action research, conceived in the tradition of interpretative/ constructivism/hermetical emancipation paradigm are used to study informality from a sociological perspective. Moreover, it is also evident the critical realism could prove to be worthwhile paradigm alternatives to study informality in construction. Furthermore, it is proposed that the alternative methodological lenses such as ethno-methodology, phenomenology and semiotics could add richness to the of informality studies. This paper shy's away from prescribing the best approach to study different informality issues. Numerous probable combinations of research taxonomies suggest that developing a prescriptive approach to constructing a research methodology to study informality (distinctively as a social phenomenon) is naive.

Abstract
Sustainable building technologies such as Photovoltaics (PV) have promising features for energy saving and greenhouse gas (GHG) emissions reduction in the building sector. Nevertheless, adopting these technologies generally requires substantial initial investments. Moreover, the market for these technologies is often very vibrant from the technological and economic standpoints. Therefore, investors typically find it more attractive to delay investment on the PV panels. Nevertheless, they can prepare "Solar Ready Buildings" that can easily adopt PV panels later in future at the optimal time; when their prices are lower, energy price are higher, or stricter environmental regulations are in place. The conventional valuation methods such as Net Present Value (NPV) are unable to identify the optimal timing for investing in the PV panels. Hence, in order to avoid over- and under-investment, the decision makers should be equipped with proper financial valuation models that help them identify the optimal investment timing. We apply Real Options Theory from finance/decision science to create an investment valuation framework for finding the optimal time for investing in PV technologies. Our proposed investment analysis model uses experience curve concept to model the changes in price and efficiency of the PV technologies over time. It also has an energy price modeling component that characterizes the uncertainty about future retail price of energy as a stochastic process. Finally, the model incorporates the information concerning specific policy and regulatory instruments that may affect the investment value.
Using our mode, investors' financial risk profiles of investment (i.e. Cumulative Distribution Function of the Investment Value) in the "fixed" Solar Building and "flexible" Solar Ready Buildings will be developed. This will determine the Financial Value (if any) of investing in the Solar ready building and identify the optimal time for installing the PV panels.

Keywords: Investment Valuation, Photovoltaics, Real Options

Introduction

Given the increasing scale of investments in sustainable building technologies such as the Photovoltaic (PV) panels, it is of crucial importance to offer the proper financial decision-making tools to the stakeholders and decision-makers. Without a proper methodology, the risk that funds are misappropriated is imminent, e.g., by choosing wrong technologies or by timing the investment incorrectly.

Proper allocation of resources to sustainable building projects (e.g. installing Solar Panels) requires an assessment of the cost and performance of proposed solutions to establish their profitability. Metrics such as Payback Period (PP), ROI and NPV have been traditionally applied to measure this profitability. Of all these measures, Net Present Value (NPV) is the widely prescribed metric, e.g., in ASTM E917–05 (2010) for conducting life cycle costs and benefits analysis for a building system. Despite the popularity of NPV, this method has serious limitations in financial assessment of an energy retrofit solution.

A NPV analysis approach assumes that all decisions related to an energy investment are made at once and are completely irrevocable. These assumptions are not consistent with real-world decision-making processes for investing in sustainability projects such as installing the PV panels. Many of the PV technologies are still in their early development stages. It is expected that their prices will go down and their efficiencies will improve in future due to the economies of scale and learning by doing effects. Therefore, it seems reasonable that building owners delay investing in these technologies but maintain the capacity to implement them in future when investors become more confident about technical and financial aspects of such investments. Thus, constructing Solar Buildings (with PV panels already installed in the building) may not be an economically attractive solution today. However, it could be a financially-wise choice to prepare Solar Ready Buildings that enable the easy installation of PV panels at the optimal time in the future; when the electricity retail price reaches a new high level or the price and efficiency of PV panels improve significantly. Nevertheless, the NPV method ignores the significant impact of timing on the financial value of investment in the PV technologies. It is inherently unable to address Investment Timing. Hence, if NPV is used, the financial performance of investing in the solar ready buildings is computed erroneously. This, in turn, may lower the overall effectiveness of the sustainable investments.

Any efforts towards advancing the valuation process will improve the quality of investment decision-making in energy interventions and, considering the multibillion dollar nature of the green building industry (McGraw-Hill Construction 2010; SBI Energy 2009), this can lead up to enormous savings through smart investment choices. To avoid under- and over-investment and ensure that scarce financial resources are efficiently allocated an appropriate valuation method is needed (Ellingham and Fawcett 2006). The Real Options Theory from finance/decision science could be utilized to evaluate the investment in the solar ready buildings and price the delayed investments for PV panel installation.

Real Options Analysis

Generally, the financial assessment of a delayed investment (e.g. installing PV panels in the case of solar ready buildings) is performed under the uncertainty about whether and when the investment should be implemented. Real Options Analysis properly meets this objective. The term “Real Options” refers to the application of financial option pricing techniques such as the Black and Scholes (1973) formula to assessment of non-financial or “Real” investments with strategic management flexibility features like delayed retrofit solutions (see Dixit and Pindyck

(1994) for a detailed overview of real options analysis). This field has gone through a significant transition from a topic of modest academic interest in 1990s to considerable, active academic and industry attention (Borison 2005). However, the applications of real options in building design and engineering have not been numerous. (Greden et al. 2006; Greden and Glicksman 2005; Ashuri 2010; Ashuri et al. 2010). To the best of authors' knowledge, real options analysis has not been applied to evaluate energy investments in buildings including the investments in PV technologies and solar ready buildings. Considering the expected increase in the level of investments in sustainable buildings, creating more appropriate investment valuation models in order to avoid under- and over-investments is crucial and the application of the real options theory from finance/decision science can result in significantly improvements in the investment valuation of energy retrofit solutions.

Investment Analysis Framework for Solar Ready Buildings

An Investment Valuation Model based on Real Options Theory is at the core of the framework proposed in this paper. It receives input from external modeling components, which generates the information that proper financial analysis of the investment in solar ready buildings requires. Specifically, the model receives input from an external Building Energy Simulation component, which is used to assess the energy performance of the solar ready building prior and after the installation of the PV panels. Thus, the module determines the potential energy savings resulted from the installation of the PV panels. An important component of our model is Retail Energy Price Modeling module, which shows future projected paths for the energy price. The financial benefit of installing the PV panels will be calculated based on these energy price models. The other component is Experience Curve Modeling, which is used to characterize how price and efficiency of the PV technologies evolve over time. This is critical in finding the optimal investment time for a proposed energy retrofit. The modeling process is described in the following sections

Building Energy Simulation: Characterize Energy Savings Performance

The Building Energy Simulation component explicitly addresses the determination of the energy savings performance of PV panels. The analysis first quantifies the performance of the solar ready building prior to the installation of the PV panels considering a variety of factors including the meteorological, urban and micro climate effects, related to the environmental conditions around the building. Next the simulation model quantifies the expected level of energy saving in the building following the installation of the Solar Panel. The detailed discussion about the implementation of Building Performance Simulation is out of the scope of this paper. Our financial analysis only uses the expected energy consumption of the solar ready buildings prior to the installation of the solar panels and after their potential installation as the essential inputs.

Retail Energy Price Modeling: Create a Stochastic Model for Energy Price

Retail Energy Price Modeling explicitly addresses uncertainty about energy price as major benefit driver of an energy retrofit investment. Financial benefits of energy savings depend on the price of energy in the utility retail market. Although average energy price rises over time, it is subject to considerable short-term variations (Figure 1). A Binomial Lattice model (See Hull (2008) for detailed descriptions) can be created to characterize the energy price uncertainty. A binomial lattice model is a simple, discrete random walk model, which has been used to describe evolving uncertainty about energy price (Liski and Murto 2010; Ellingham and Fawcett 2006).

The modeling choice of binomial lattice is also consistent with the general body of knowledge in real options (Hull 2008; Luenberger 1998). In economics and finance, binomial lattice is an appropriate model to capture uncertainty about a factor like energy price that grows over time plus random noise (Dixit and Pindyck 1994).

Binomial Lattice Model

To define a binomial lattice (Figure 2) for energy price (S), a basic short period with length Δt will be considered. Suppose the current energy price is S_0. Energy price in the next period is one of only two possible values: $u \times S_0$ or $d \times S_0$ where both u and d are positive rates with $u>1$ and $d<1$. The probabilities of upward and downward movements are p and 1-p, respectively. This variation pattern continues on for subsequent periods until the end of investment time horizon. Binomial lattice parameters can be determined using data on the expected annual growth rate of energy price (α) and the annual volatility of energy price (σ) as explained by Hull formulation (2008). This binomial lattice can be used as a basis to generate future random paths for energy price.

Figure 1: *Annual Average Residential Electricity Price (EIA 2010)*

Monte Carlo Simulation

Next, Monte Carlo simulation technique can be applied to generate several random paths for energy price S – from the start to the end of investment time horizon – based on the described binomial lattice. Considering the binomial lattice formulation, energy price in any period of the lattice is a random variable that follows a discrete binomial distribution; this is the basis of applying Monte Carlo simulation technique for generating a large number of random energy price paths along the investment time horizon (Figure 2). Random energy price paths are used to compute respective energy savings series. In addition to benefits, it should be specified how the initial cost of the PV panels changes over time to find when it is optimal to invest in. This is discussed in the following section.

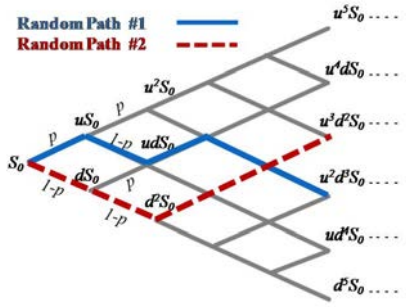

Figure 2: *Random Energy Price Paths along the Binomial Lattice*

Experience Curve Modeling: Create an Experience (Learning) Curve for the Proposed Emerging Technology

The concept of Experience Curve describes how the marginal costs decline with cumulative production over time (Hartley et. al 2010; Weiss et al. 2010). Typically, this relationship is characterized empirically by a "Power Law" of the form: $Pt=P_0X^{-\alpha}$ where P_0 is the initial price ($ cost of first Megawatt MW of sales), X is the cumulative production in MW up to year t, and $2^{-\alpha}$ is Progress Ratio (PR); for each doubling of the cumulative production (sales) the cost declines to PR% of its previous value. For instance, Figure 3 shows an experience curve created for PV modules. The apparent decline in costs may be due to several reasons, including process innovation, learning-by-doing, economies of scale, R&D expenditures, product innovation/redesign, input price declines, etc. (Hartley et. al 2010; Yu et al. 2010). Experience Curve Modeling characterizes price reduction and efficiency improvement trends of a proposed emerging technology. The parameter α in the experience curve – i.e., $P_t = P_0X^{-\alpha}$ or $\ln(Pt) = \ln(P0) - \alpha\ln(X)$ – is defined using historical data of marginal costs and cumulative productions of the emerging technology. α can be estimated by a standard Ordinary Least Square (OLS) method. Nevertheless, the development of experience curves is not without trouble mainly because the estimation of PR for each technology is subject to great uncertainty (van Sark et al. 2007); it is not easy to forecast whether this PR remains constant or change over time (Yeh et al. 2009). Research has been focused on development of models that incorporate such uncertainties (Yeh et al. 2009; Gritsevskyi and Nakicenovic 2000). The best engineering judgment for the future level of decline in price of a technology can be used in these circumstances to characterize the cost trend of the PV technologies.

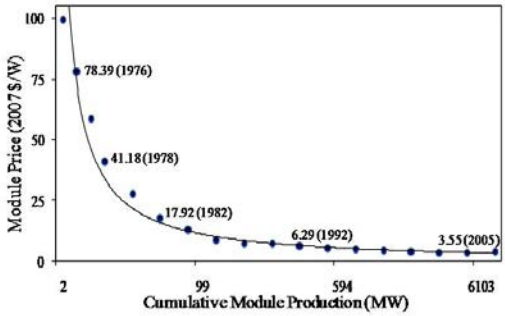

Figure 3: *Experience Curve of PV Modules 1968 to 2006*

Investment Valuation Modeling based on Real Options Analysis

With the input from above three steps, Investment Valuation Modeling will determine the optimal time to invest in the installation of the PV panels in a solar ready building. It also establishes the value of embedding flexibility in the building.

A probabilistic NPV analysis can be conducted to describe the financial risk profile of the immediate investment in the PV panels. This is carried out under the assumption that investors adopt the current PV technologies right away at the current price and efficiency rate. Randomly generated energy saving streams are used to characterize investors' NPV distribution (Figure 4). Investors' cost of capital or required rate of return can be used as the discount rate in NPV analysis.

In addition, using the risk-neutral valuation method – developed in mathematical finance for pricing options and derivatives –the correct market-based value of a delayed PV installation in the solar ready house can be determined. In this technique, the probabilities of upward and downward movements in the initial energy price binomial lattice are modified – as described by (Luenberger 1998; Hull 2008) – to conduct option valuation. Risk-neutral binomial lattice can then be used as Decision Tree to determine the optimal investment time. Hence, investors' NPV distribution is calculated considering this optimal PV installation time. The difference between

expected investors' value under immediate and delayed investment represents the expected value of optimal delayed investment (Figure 5).

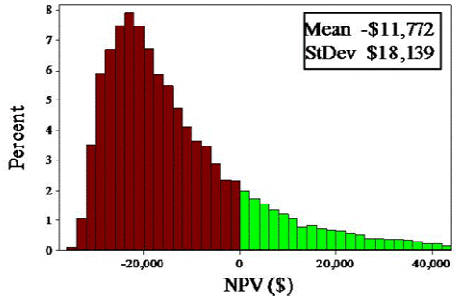

Figure 4: *Investor's NPV Distribution of Immediate PV Installation*

Impact of the Political and Regulatory Environments

Political and Regulatory Environments component encompass the impact of energy efficiency policies and incentive programs on investment valuation. Scenario analysis should be applied to specify possible energy targets and their likelihoods. Random upgrade scenarios, e.g., regulatory, political, technical, and/or market environments, in which an energy retrofit solution takes place should also be generated. Each scenario can be investigated with respect to its impact on future level of energy price, as well as its contribution to cost reductions of the proposed energy technology. Through what-if analyses, the impact of the regulatory conditions on the investment timing for an energy retrofit solution can be evaluated.

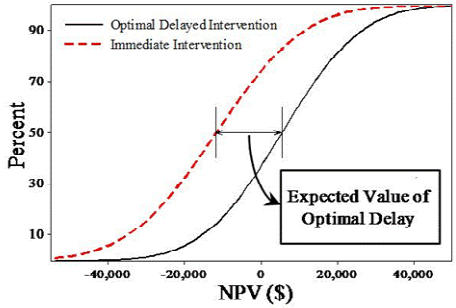

Figure 5: *Investment Value of Optimal Delayed Investment*

Illustrative Example

Approximately half of the installation cost of a solar power system on a building is spent on brackets, inventers, structural support (reinforcing the roof, repairing the roof, patching holes, etc.), and reconfiguration of the building electrical system. Rye (2008) summarizes several features, which can be included in the initial design, to proactively build a "Solar Ready Building": (a) Two additional slots on the electrical main panel; (b) A reserve location for an inverter; (c) Two conduits: one from the main panel location to the inverter location and one from the inverter location through the attic and onto the roof where the panels would be installed; (d) Reinforced roof rafter structure to support the weight of solar panels; and (e) Electrical jacks through the roofing material. The total cost of a Solar Ready Building with these additional features is approximately 3-5% higher than of the overall cost of a standard building. However, adding the same features to existing buildings could cost up to $15K in future solar upgrades. Based on the proposed investment analysis framework, the financial performance of the "flexible" Solar-Ready Building was compared with the financial performance of the "fixed" Solar Building. The initial cost of preparing electrical, structural, and roofing systems for PV panels was considered to be $10,000. This is the additional cost of embedding flexible features in

a solar-ready building. Also, it was supposed that the purchase price of PV panels with the service life of 40 years is currently $4/W and is anticipated to decrease every year due to experience curve effect (PR=0.46329). It was assumed that the solar panels for this building were will provide 6,300W power. The initial retail price of electricity was also assumed to be $0.1031/kWh; this unit price changes over time with the expected annual growth rate 4% and the volatility of 20%. These values were used to create a binomial lattice to model electricity price variations. Financial benefits of PV panels are in terms of energy savings, which must otherwise be purchased from the utility company. Federal and State tax benefits are $5,000 and the homeowner's discount rate is 7%/year. Under these circumstances, the real options analysis methodology was applied and the financial performance of solar building and solar-ready building under uncertainty about the electricity price were evaluated. It was also determined whether and when it is optimal to convert a solar-ready building to a solar building and how much embedded flexibility in a solar-ready building is worth investing.

Figure 6(a) shows the optimal electricity price, which triggers conversion from a solar-ready building to a solar building; the increasing boundary effect is due to the option expiration in 2030. Below the price threshold, an investor or homeowner should delay the installation of PV panels. When the electricity price rises to a substantially high level, the value of waiting becomes lower than the energy savings benefits of the immediate PV panels installation; therefore, the solar-ready building should be converted into the PV building. Figure 6(b) shows the likelihood profile of the optimal conversion year; this is the probability of the event that the random electricity price path reaches the optimal investment threshold specified in (a) for the first time in the current year. It can be seen that initially waiting is more valuable than immediate exercise; but, as the time passes, the opportunity cost of waiting becomes large enough that triggers investment. Figure 6(c) shows the NPV distribution of a solar-ready building under uncertainty about energy savings. Figure 6(d) shows the NPV Cumulative Distribution Functions (CDFs) of solar and solar-ready buildings. The expected NPV of the solar building is $-11,772 and the chance of investment loss, i.e., Probability (NPV<0), is approximately 75% , which make the solar building an unattractive retrofit solution. Delayed retrofit decision-making can enhance the value of solar upgrade. The two-phase development of the solar-ready building represents the hidden value of flexibility in the solar upgrade. It can be seen that the expected NPV of the solar-ready building is $5,480, which is much larger than the expected NPV of the solar building $-11,772. Therefore, the expected price of flexibility in the solar-ready building is $5,480-($-11,772) =$17,252. Also, due to the two-stage installation of PV systems, the chance of investment loss for the solar-ready building is approximately 35%, which is much lower than 75% for the solar building.

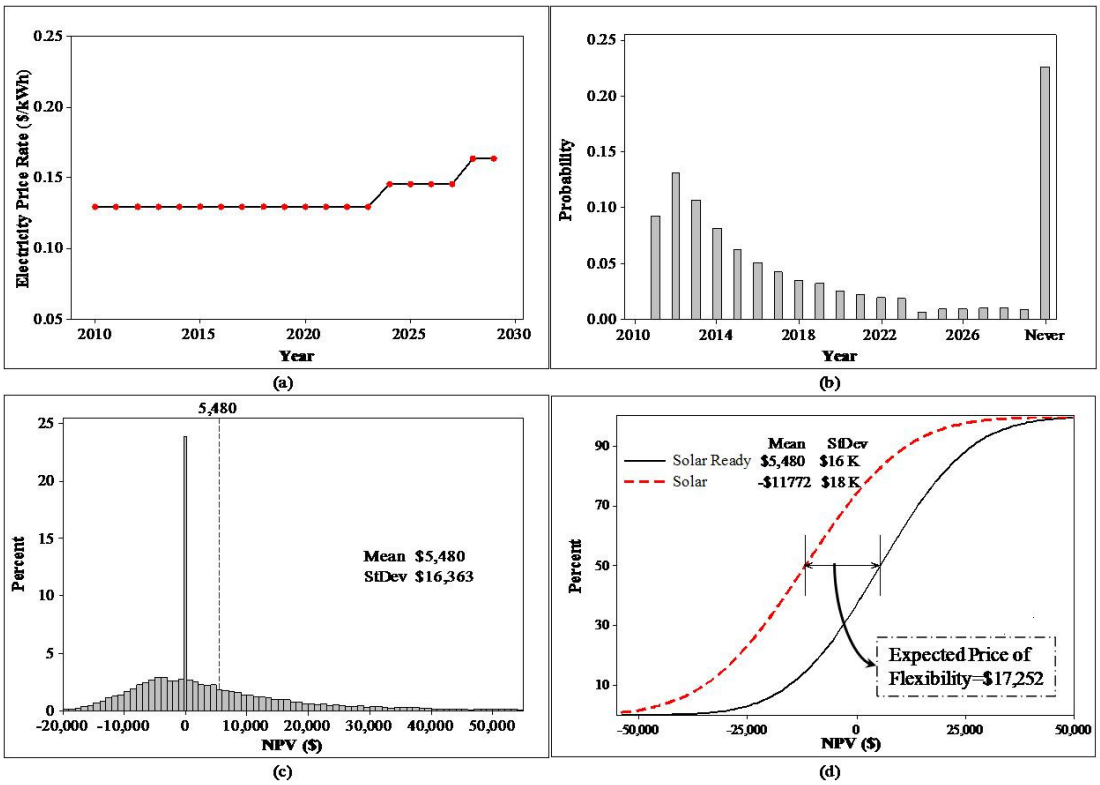

Figure 6: *(a) Optimal Retail Price of Electricity ($/kWh) Triggering the installation of Solar Panels; (b) Installation Likelihood of PV Panels Over the House Service Life; (c) NPV Distribution of Solar Ready Home; (d) NPV Cumulative Distribution Functions (CDFs) of the Solar House and Solar-Ready Building and Price of Flexibility*

Conclusion

Better investment decision models can facilitate achieving energy savings in the buildings through increasing the efficiency and effectiveness of investments in energy efficiency measures. The proposed investment analysis framework for evaluating investment in solar ready buildings will enlighten investors about the economic inefficiencies that conventional fixed energy investment strategies produce and facilitates the valuation of the flexible solutions that mitigate such inefficiencies. Explicit pricing of flexibility is significant for systematic decision-making beyond the current energy target; embedded options in delayed retrofit solutions reflect on the possibility to meet future stricter targets and prepare for future upgrades.

The proposed investment framework can be used as a decision making instrument, looking at different scenarios in technology and market developments, and deciding between immediate or delayed investment in PV technologies. Thus, it can also become an instrument in the selection of the right government incentives over time. As a corollary, the methodology will be used to single out the type of technologies that are ripe in the expected market of competing sustainable technologies.

Abstract
The purpose of this paper is to take up a call for more "identity" research in construction management by exploring the potential of position theory as a framework for examining the ongoing construction of self through discourse. Using some basic constructs: storyline, speech-act and position, we examine how tensions and contradictions unfold in high-stake conversations at the micro-level, and how these micro-level features may be linked to contradictory institutional practices. The data – consisting of audio-recordings and extensive field notes of body language, facial expressions and stance of the meeting participants – were collected during five strategy meetings focused on an organisation's new environmental strategy. We argue that a positioning theory lens enables the researcher to "get inside" the discourse and provides better understanding of how actors construct their identities in discursive practice with others.

Keywords: contradictions, discursive practice, positioning theory, self-concept, strategy.

INTRODUCTION
Managing organisational activities challenges actors' abilities to negotiate contradictions and paradoxes inherent in much human practice. To help deal with these challenges, organisational scholars have devised generic, cognitive models for dealing with paradoxes, e.g. engage, avoid or transcend (Poole and van der Ven, 1989), or manage paradoxes by embracing and balancing them (Smith and Tushman, 2005). Such models, albeit helpful for researchers at an abstract macro-level, do not address the dynamic, relational and elusive nature of contradictions as they emerge through organisational talk and action at the micro-level.

Based on a review of strategy literature in construction, Price and Newson (2003) argued that strategic-management success depends on strategists' ability to balance binary opposites, e.g. rational versus creative strategies, strategies versus organisational effectiveness. Their study is predicated on the claim that construction organisations lack "appropriate" knowledge and skills to develop formal strategic processes. To remedy this situation, the authors rather than offer a model, prescribe normative, textbook propositions, e.g. construction organisations must develop an effective strategic planning process; they need a guide to best practice and a framework to serve as a checklist; they need to supplement their short-term approaches with long-term approaches. Although these prescriptions may be sound on a general macro-level,

the authors ignore the empirical evidence emerging from the strategy-as-practice field, showing the situated messiness and contradictions that obtain at the micro-level of strategising (e.g. Whittington, 1996; Johnson et al, 1998; Hendry, 2000). The strategy-as-practice scholars argue that strategy is not a stable product that an organisation develops and then possesses; rather it is something that the people in an organisation continuously do through talk and action.

Beech et al (2004) criticised the notion of cognitive, unitary solutions to paradoxes, suggesting that if left open, paradoxes could rather serve as resources to stimulate creative and transformative actions. Using an action research approach and designing a "serious play" framework (focusing on emotions, creativity, meaning making and rule breaking), the authors explored how paradoxes may be dealt with in practice. They argued that attempts to solve paradoxes through the use of cognitive models and problem-solving approaches are likely to lead to inertia, while "living with paradox" and using it as a stimulus increases possibilities for creative action. Further research would need to be carried out to test this claim.

Still, much of the literature on organisational paradoxes remains theoretical. There is a need for empirical studies of how paradoxes and contradictions arise and are negotiated in situated practice. Influenced by the "practice turn" in the social sciences (e.g. Schatzki et al, 2001), organisation and management studies have increasingly been taking a practice-based approach to the study of organisational activities (e.g. Nicolini et al, 2003; Hendry, 2000). Simultaneously, if not consequently, more and more attention is being paid to the role of discourse and discursive practices in the construction of organisational identity, culture, knowledge and routines. This "linguistic turn" (Alvesson and Kärreman, 2000) has resulted in an upsurge of qualitative and interpretative studies of organisational and managerial discourses (e.g. Holman and Thorpe, 2003; Räisänen and Linde, (2004); Westwood, 2001).

Shotter & Cunliffe (2003:18-20), drawing on Bahktin's (1986) view of dialogue, show the advantages of studying the "moment-by-moment unfolding of relationally responsive events occurring in the 'interactive moment.'" They suggest that managers in their management of interactions can be "practical authors" of the textual outcome of the organisational conversations they have since they "create meaning in relationally responsive ways … [and] might be seen as someone able to restore a flow of action, giving shape and direction to the actions of other participants in the organisation when they are either disoriented or stuck." This view seems to be an idealized view of managers' reach, pertaining mainly to their authority embedded in predetermined transactional behaviours primarily aimed at solving problems, achieving goals and generally getting things done. It tends to see "manager" as an organisational role, underscoring the formal, static and ritualistic functions of "manager".

Yet, the job of managers spans a continuum of activities, in which transactional objectives are intricately intertwined with relationally oriented actions and idiosyncratic behaviours. Affordances and constraints for the deployment of these behaviours exist not only in the contexts in which they are deployed – the institutionalised structures and local situations – but also the perception of self that an individual enacts in a particular situation. Individuals' beliefs and representations of themselves are neither consistent nor always coherent; they may even be contradictory. In one and the same conversation, the way individuals think of themselves may shift depending on the context, situation and unfolding of the actual conversation at hand. By extension, this same conversation may have unpredicted implications and consequences for some future conversation. To understand the complexity of social interaction, position theory offers an analytical tool that enables us to examine the

ways in which individuals position themselves in conversation with others. Moreover, understanding how contradictions arise and unfold in situated discursive action will raise interlocutors' sensibilities to the relational aspects of social interactions and mitigate face-threatening acts (Brown and Levinson, 1987).

The purpose of this paper is to take up the call for more "identity" research in construction management advocated by Brown and Phua (2011) by exploring the potential of position theory as a framework for examining the ongoing construction of self in a discursive practice. We use some basic constructs of positioning theory to examine how tensions and contradictions unfold, get resolved or get locked in high-stake conversations at the micro-level, and how these micro-level discursive activities may be linked to broader institutional practices. The data is drawn from strategy-audit meetings focusing on an organisation's new environmental strategy. The issues under scrutiny in the audits were: Top-management's intention with the audit; the interpretation of the strategy downstream; and the actions generated by the strategy downstream.

POSITIONING THEORY

The constructivist view sees individuals as continuously constituted and reconstituted through the multiple discursive practices and activities in which they participate. As such, individuals are active agents in the development of their identities; who one is at a specific moment in time will depend on the positions that are made available in conversations with others as well as with oneself (Langenhove and Harré, 1999). Individuals use fluid positioning to cope with the situations that they find themselves in. Positioning theory as defined by Moghaddam et al (2003: 140) is "concerned with the process by which short-term and small-scale moral orders are established and maintained, and with the way the actions of participants are constrained to flow in accordance with sharply delimited schemata or conventions."

The root of the theory is that the self or personhood of an individual is "ongoingly" produced and is relational to the ongoing production of others' selves in discursive practices (Harré and Moghaddam, 2003). Positioning theory thus offers a framework for analysing the dynamics of micro-social relationships as these are being negotiated in conversations, in contrast to role-theory in which an individual's personhood is separated from his/her formal and pre-determined set of behaviours.

Discursive action takes place within a specific local moral order of speaking and acting. The force (or impact) of an individual's speech-act or utterance within this context is relative to the rights, duties and obligations that obtain within the moral order in which the conversation unfolds. In other words, in a conversation the interlocutors locate themselves and others according to personal stories, *storyline,* which render their actions intelligible to themselves as social acts. A speaker positions him/herself within his/her story as well as opens a position for the interlocutor to take up. The moral and personal attributes of the speaker, *moral order,* and the force of the speaker's utterance, *speech-act,* determine his/her success of legitimising the particular position that allows the speaker to be both effective and powerful. Hence, conversations have a tri-polar structure consisting of a storyline (culturally influenced and conventional description of events and cast of characters) enacted through speech-act (linguistic acts defined by the intention, belief and attitude of the speaker (illocutionary force) and a position (the implicit or explicit actors' adoption of a set of rights, duties and obligations that avail them in the ongoing storyline). This position may or may not be changed during the conversation. In this paper we focus on four types of positioning (Langenhove and Harré, 1999):

- Deliberate self-positioning: strategic positioning with a specific goal
- Forced self-positioning: position established by the institutional structure
- Deliberate positioning of others: positioning another to enable an objective to be attained.
- Forced positioning of others: positioning to bring people into order by using institutional power.

THE SETTING AND DATA

As part of the current greening wave, contractors are keen to demonstrate that they are harnessing their resources to mitigate negative impact on the environment. In accordance with this trend, the contractor in this study focused on greening in its 2008-2010 strategy revision, highlighting one specific strategy: "to be a sustainable builder of society". This strategy, according to the environmental top-manager, should distinguish the contractor from its competitors in the eyes of the clients. Therefore, this strategy was to be prioritized and compliance evaluated by means of an audit throughout the levels of the organisation.

In 2008, data were collected from one initial top-management meeting with audit consultants and from four audit-meetings carried out by one of the consultants in one geographical region sorting under a regional manager. The four audit-meetings, lasting approx. 15 hours in all, were audio-recorded and transcribed in part. The initial top-management meeting was not audio-recorded, but extensive field notes were made. The meetings took place at different venues in the contractor regional offices. In all, 11 actors from the constructor were involved in the audit meetings, some attending two or more. These represented all the management levels in the organisation as well as HR, executive development staff, and environmental management. Since the focus of this study was micro-level interpersonal interaction, detailed notes were taken on the speakers' body language, facial expressions and gestures. 'Water cooler' conversations between the meetings and during short breaks were also documented.

We listened to the audio recordings several times, first separately and then together, resulting in a rough analysis of the meetings in terms of speech-acts and storylines. We then transcribed one meeting in full and mapped the ongoing construction of the interlocutors' selves through identifying the positions they took up and made available during the conversation. We compared our detailed analysis with our rough ones and with our field notes. For this paper we discuss three short speech-acts from the initial meeting and one short exchange from one of the audits at district level.

CONVERSATIONS AT CROSS PURPOSES

In the following section we present the interlocutors followed by the examples and our analysis of the conversations. In the examples, the left-hand column identifies the speaker, followed by the speech-act in the middle column, and in the right-hand column is our interpretation of storyline and of position taken up or made available by the speaker.

Interlocutors

Environmental Consultant (CON): Female in her 50s; soft-spoken and conciliating; older woman with expert knowledge and genuine interest in environmental issues; she carried out the auditing at all the levels of the region.

Corporate Environmental Manager (CEM): Male in his 40s; executive; very busy; only time to attend part of the initial meeting; used hortatory discourse.

Corporate Development Staff (CDS): Male in his 30s; close to top management; actively involved in the process of strategy formulation and communication; no decision-making mandate, familiar to most managers in the organisation.
District Manager (DM): Male in his 40s; non-compliant with the audit; lacked familiarity with corporate management systems; had not prepared for the audit; dominant and charismatic.

Most of the representatives from the constructor were men in some kind of position of power. The few women in this study, apart from the consultant, had advisory roles with no decision-making mandates and very little power.

Example 1. *Initial meeting at corporate level: Corporate Environmental Manager, Corporate Development Staff representative and 6 Auditing Consultants.*

[1] **CDS**	Our environmental strategy: to be a sustainable builder of society, has to be funnelled downstream in the organisation.	Instruction storyline Forced self-positioning
[2] **CEM**	Sustainable builder of society is an overarching principle…it is this strategy that shall distinguish us from other constructors. The environmental bit is now being strongly pushed in the company.	Instruction storyline Deliberate self-positioning
[3] **CDS**	It is ok though to clear "hygiene level".	Clarification storyline Forced positioning of consultants

Note: The speech-acts in this example are not consecutive utterances.

The venue for the initial meeting was a conference room at the constructor headquarters and included three organisational strategists, the environmental top-manager and six audit consultants. These consultants were from an environmental-auditing and accreditation firm with long-standing professional experience. The purpose of this meeting was to inform the auditing consultants of top-management's intention with the strategy and audit as well as to identify the areas upon which the audit should focus. The consultants' jobs were to assess the degree of compliance with the strategy out in the organisation, the level of competency concerning environmental issues, and how the environmental measures and indicators were being handled.

An "instruction" storyline was consistent throughout the initial meeting. The consultants were gathered to receive information and instructions for their upcoming audits. The corporate development staff representative opened the meeting. He was used to this kind of situation and took up the forced self-position that his role ascribed him, i.e. as proxy for top-management. This position allowed him a cluster of rights, duties and obligations: the right to instruct people that were senior, older and more knowledgeable than he; the duty to behave in a manner conforming to the values of the organisation; and the obligation to provide the consultants with the information that would enable them to carry out their commission effectively. It should be noted here that when he positioned himself, he automatically positioned his interlocutors, the consultants. They willingly took up the deliberate positioning made available to them by the executive, namely that of "being instructed," and typically responded by back-channelling, posing questions, asking for clarifications and repeating information. The Corporate Environmental Manager arrived in the middle of the meeting and only stayed long enough to reinforce the instructions using hortatory statements, see example 1. He maintained the "instruction" storyline and deliberately positioned himself as an authority. He did not add any information to what had already been conveyed, but his presence bestowed weight and corporate legitimacy to the younger executive's speech-acts.

The third speech-act in the example had a different force from that of the CDS's earlier speech-acts. Rather than "instruction," the storyline now seemed to be "clarification," in the form of a proviso. As we interpret it, the CDS is implicitly force positioning the consultants to carry out the audits according to informal norms rather than the "objective" audit procedures of the consultancy. This speech-act contradicted much of the hortatory discourse that had preceded it, and may have contributed to the locked positions shown in example 2. The phrase "hygiene level" appeared to be commonplace in the organisation, meaning to fulfil the base qualifications of greening. However, "hygiene level" and the notion of "sustainable builder of society" are somewhat paradoxical, which the participants of the initial meeting chose to ignore.

Example 2: *Audit District B: Consultant, District Manager, Environmental Rep, Environmental Project Rep*

CON	Your SCI is 80%. Is that an objective for this year or have you always had 80%? Do you work with continuous improvements?	Audit storyline Deliberate positioning of DM
DM	Well, I think we have had index at 70 as well as 100. But I don't know the average value.	Competent manager storyline Deliberate self-positioning
CON	I mean do you set goals that are a little bit higher each year in order to sharpen your efforts further?	Audit storyline Forced positioning of DM
DM	No, we have had 80 for a long period of time. Sometimes we reach our goal, and sometimes we do not.	Competent manager storyline Deliberate self-positioning
CON	But isn't it interesting to try to perform better and better for each year?	Audit storyline Forced positioning of DM
DM	It depends on your reasoning. Sometimes it is fun to exceed the expectations. […]	Game storyline Deliberate positioning of CON
CON	But I do not agree with you	Refuses storyline and position
DM	Well, then we have different opinions.	Competent manager storyline Deliberate self-positioning
CON	From the quality perspective, it is all about trying to improve…	Reverts to audit storyline Tries to re-establish her position
DM	But there is nothing that prevents improvement. The main thing is that you know what to do, and that the group is behind it.	Competent manager storyline Deliberate self-positioning
CON	That's true, but isn't the result supposed to be a little bit better than last year?	Audit storyline Deliberate positioning of DM
DM	But how do you get that result, then?	Competent manager storyline Deliberate positioning of CON
CON	By taking exactly the measures that you have.	Competent manager storyline Takes up the position made available
DM	Yes….	Competent manager storyline Reinforces his position

Note: This example is part of a longer dialogue between the consultant and the district manager.

The audit at district level, of which example 2 is an extract, took place in a conference room in one of the regional offices. Present are the consultant, the district manager, a district environmental official and a project support official. The latter two audit participants took minor parts in the conversation, but played important roles in the interaction. When needed they were either mobilised by the district manager to support his storyline of competent and caring manager thereby strengthening his position, or they themselves volunteered with expert commentaries and digressions. Either way, they supported the manager's resistance to the audit.

In order to make this extract intelligible, more details are necessary. As for all audits, this one started with a round of self-introductions of the participants, which was set in motion by the consultant. She responded to each introduction with small talk thus evoking a storyline of

"friendly conversation" and positioning herself as competent consultant. However, the tense atmosphere in the room created by the body language of the district manager, whose facial muscles were taught and arms were crossed, contradicted her storyline. Without saying a word, he had positioned himself as antagonist. When it was the consultant's turn to introduce herself, she signalled a shift in her storyline to "environmental audit" by code shifting to formal discourse and deliberately positioning herself as competent environmental expert. She ended her presentation of herself by saying: "So I have seen the problematic side of construction." No sooner had she completed the utterance than the district manager interposed: "Yes, yes, yes, exactly, may I ask a question? Do you live in Sweville?" Through this speech-act he refuted the position of auditee that the consultant made available for him, reverting back to the earlier story line of "friendly conversation," but with a rather aggressive undertone. He enacted the rights, duties and obligation his institutional role bestowed on him, shifting the prerogative of controlling the conversation to himself. He then maintained the storyline of "friendly conversation" over several exchanges, subtly making available the position of "guest" for the consultant. Since she did not want to confront the manager, her only option was to play along and accept the position he offered. The DM frequently used these kind of interruptions and non-sequiturs during the conversation to resist the audit and destabilise the consultant.

The extract in example 2 took place in the latter half of the audit and was part of a longer exchange concerning the district's Satisfied Customer Index. The CON tried to maintain the "audit" storyline and fulfil her task of evaluating the environmental compliance to the corporate strategy in terms of goals and actions. In her three first speech-acts she tried to force position the DM, but he refuses to take up the position and counters by deliberate self-positioning. The DM resists her attempts by refusing to align with her storyline. Instead he maintains his own storyline of competent and caring manager. He challenges her right to question his authority, his control or his routines, justifying his decisions as being the outcome of co-worker consensus. What we see in the excerpt, which epitomises the audit, are two parallel storylines and incompatible positions. The DM either purposefully refused to answer the CON's questions, or he did not understand them. She wanted concrete measurable figures in answer to her questions concerning goal setting and actions, which she could then report back to top-management. The DM gave her equivocal answers. The CON was not able to break the locked positions nor was she able to fulfil her audit satisfactorily. The DM evoked the patriarchal values of a good leader and the importance of engaging and motivating co-workers. His district was performing well, and this, according to him, should be sufficient information for the CON. The audit ended in a deadlock.

DISCUSSION AND CONCLUSION

The brief analyses presented here suggest that individuals seek to demonstrate distinct social identities or self-concepts that position them as knowledgeable and responsible members of a social group. As such, through the storylines they create and the speech-acts they use to enact the storyline, they reveal not only the value, but also the emotional significance that they attach to their membership (Tajfel and Turner, 1979). In the case of the audit meeting, the DM's attitude and affect toward the audit is patently reflected in his speech acts, his behaviour and his actions. He almost takes pride in showing ignorance of index figures: "Well, I think we have had index at 70 as well as 100. But I don't know the average value." Earlier on in the audit, he shows his lack of familiarity with the organisation's performance-assessment system and his total lack of preparation for the audit. At one point in the meeting, he even has to go to his office to get his laptop.

In a study of organisational change, Moghaddam (1997) found that informal aspects of organising sustained normalcy in spite of formal rules and directives. In the case of the audit, it is interesting to observe how the DM subverts the institutional and formalised audit discursive practice that the consultant tries to achieve by imposing an informal meeting discourse that he is probably more comfortable with. For example, he answers her questions with questions, he questions her knowledge of the organisation, and he refuses to provide the information she seeks in the form she wants it. These micro-level features are revealed using a positioning theory lens, which allows the researcher to "get inside" the discourse. It also enables a deeper understanding of how actors construct their identities in discursive practice with different others, e.g. superiors, blue-collar workers, inspectors.

In example 2, we showed how the storylines of the consultant and the DM are "self-sealed" (Beech et al, 2009) with no attempt at engagement. The storylines militate against dialogue, which we can predict will have negative effects on the strategic environmental change that top-management is advocating. Beech et al (2009) in their study of three contesting change stories in a financial service company found that the stories, in spite of their proximity, did not, or could not, engage with each other. Each story had its own logic, constructing problem and solution according to its storytellers' world-view and work-view. The positioning of each story did not open up for dialogue across the self-created group boundaries. The consequence for senior management of these three change story processes according to Beech et al (2009) was that the change initiative remained at the strategic level. Senior management created a platform for the change, but failed to translate the rationale for the change in a discourse that the various groups could make sense of.

The focus of positioning theory is to understand how psychological phenomena are produced in discourse. However, conversations take place in a context, and between interlocutors that have some kind of association with each other. It is therefore important for the researcher to have knowledge of contextual and relational factors. For example, a conversation always has a fore-life and an after-life (Pearce, 2007). Example 1 serves to illustrate the importance of taking account of these dimensions of a conversation in one's analysis. From the consultant's point of view, the initial meeting is an important part of the fore-life of the audit, and could help explain some of her behaviour during the audit. At the initial meeting, the consultants are sent off to do their job with the somewhat paradoxical proviso "it is ok to clear hygiene level." This proviso contrasted to the hyperbolic discourse of the corporate environmental manager earlier on in the meeting could have given rise to uncertainty even in an experienced consultant: on the one hand she has institutionalised rules and routines for the audit, but on the other she has to relate to the somewhat vague proviso. This could explain her seeming reluctance to wield the rights, duties and obligations that the moral order of the audit avail her, e.g. to confront the district manager's refusal to cooperate and, more importantly, to forego her duty to report the environmental-management flaws that were so obvious. The latter puts in question the purpose of the audit, and, we can speculate, will have an effect on future conversations. For the district manager, the outcome of this conversation underpins his storyline of competent and caring leader who knows what is best for his district and co-workers.

As Shotter & Cunliffe (2003) suggest, the DM in this case could be viewed as the practical author of the textual outcome of the audit, rather than the consultant as would be expected. The likely after-life of the audit conversation, in the same way as the change stories discussed earlier, is an entrenchment of the current (informal) environmental practices and solutions already authored by the DM. Rather than lacking "appropriate" knowledge and skills to

develop formal strategic processes as suggested by Price and Newson (2010), organisations and their members seem to lack awareness of the psycho-social mechanisms and dynamics that underpin or undermine organisational structure and processes. No matter how effective the strategic plans, process diagrams and checklists are to strategists, if the operational levels cannot make sense of them they will not appropriate them. The consequences will inevitably be lip-service compliance or overt non-compliance.

This study has introduced positioning theory and illustrated the value of micro-level analysis to raise researchers' and practitioners' awareness of the inextricable link between talk and action. If we are to understand how construction managers think and function, and why they behave the way they do, or what drives them, we need, as Brown and Phua (2011) promote, "a sophisticated appreciation of how they conceive their selves." We would like to suggest position theory as a strong candidate for achieving such an appreciation.

THE AREA-BASED PLANNING PROCESS OF DUTCH HOUSING ASSOCIATIONS

Abstract
Dutch housing associations are important actors in the field of urban planning. They are independent social enterprises, which take their own decisions on this stock. Many housing associations work with asset management plans to secure that their portfolio meets company goals and market demand. However, in practice decisions of housing associations are often not a direct result of these plans, but of incidents at the neighbourhood level, or of emerged opportunities. Next to that, housing associations nowadays do not only focus on the quality of their own housing stock, but also on the physical, economical and social quality of the whole neighbourhood, which implies cooperation with a wide variety of local actors. As a result housing associations in the Netherlands are increasingly employing an area-based approach towards asset management. In order to analyse the different ways housing associations implement this area-based approach, the concept of planning is used. Five planning types are identified (rational, incremental, collaborative, political and advocacy planning) and transformed into propositions that are tested in a survey among housing managers. From this survey a diffuse picture arises. Housing associations use different elements from different planning types. However, emphasis is on the elements of the rational and collaborative types.

Keywords: Housing, planning, the Netherlands, asset management

INTRODUCTION

Housing associations in The Netherlands are important actors in the field of urban planning. They own and manage nearly one third of the total Dutch housing stock and account for 49% (2009) of all newly developed housing (Centraal Fonds Volkshuisvesting, 2010). Next to that, as a consequence of the concentration of their stock in, often less affluent, areas, they play an important role in the upgrading of deprived neighbourhoods. This upgrading can take shape in numerous forms. It can consist of merely physical activities in the form of maintenance, renovation, demolition, new construction of dwellings and other real estate. It can also encompass socio-economic measures like improving schools, care and welfare arrangements.
Traditionally housing associations were focussed on building and managing dwellings for low-income households. Nowadays they have taken up a wider role.
Since the 1990s housing associations developed into independent social enterprises that take their own decisions, with their stock as their main asset. How to manage these assets, how to take decisions on the stock, is an important issue within housing associations. Because decisions affect the people living in and around the stock, these decisions are also important for external actors.

There are two notions that make it relevant to look at these decisions on area level. First of all, this level is seen as the suitable level for the process to come to decisions. Secondly, more

related to the content side of planning, on this level a combination of physical, social and economical factors determine the quality of a neighbourhood.

In this paper the area-based planning process of Dutch housing associations will be elaborated using concepts of planning, of the social enterprise, and of urban renewal. Normative propositions are constructed which are used in a survey to provide an overview of the way Dutch housing associations in urban renewal areas make decisions on their asset management activities. First I will introduce the Dutch housing association sector, including the development into social enterprises and the urban renewal agenda. Next, the concepts of asset management and planning will be discussed. Finally, the results of a survey will be shown.

THE DUTCH HOUSING ASSOCIATION SECTOR

418 Housing associations own 32 percent (2.4 million dwellings) of the total Dutch housing stock, resulting in the largest market share of social housing in Europe (Centraal Fonds Volkshuisvesting, 2010). Since the introduction of the *Besluit Beheer Sociale-huursector* (decree on management of social rented sector) in 1993 and the abolition of structural government subsidies for new construction and renovation in 1995, housing associations operate relatively independently. Since then, they had to decide for themselves what to invest where and how to finance their investments. In practice, the sale of existing social housing is the main source of income which is used to finance urban renewal.

Housing associations operate in a system in which they are supervised on the basis of general 'fields of performance': accommodation of target groups; preservation of the quality of dwellings and their environment; consultation of tenants; securing financial continuity; and providing housing and care arrangements (Ministerie van VROM, 2005). To contribute to these 'fields of performance' the main asset of housing associations is their housing stock.

Housing associations are nowadays often regarded as social enterprises (e.g. Boelhouwer, 1999, van Dijk et al., 2002, Marshall and Lovatt, 2004, Gruis, 2005, Pawson, 2006) and less as task-oriented agents of government. Social enterprises are private organisations operating on the market, pursuing social goals which are related to the general interest, producing goods and services and of which the financial surplus is (re)invested in the social goal (Toonen et al., 2003).
Although social enterprises have a hybrid position between the state, market and society, Dees (2001) has identified in his definition some shared characteristics. He states that:

> "Social entrepreneurs play the role of change agents in the social sector, by:
> • Adopting a mission to create and sustain social value (not just private value),
> • Recognizing and relentlessly pursuing new opportunities to serve that mission,
> • Engaging in a process of continuous innovation, adaptation, and learning,
> • Acting boldly without being limited by resources currently in hand, and
> • Exhibiting heightened accountability to the constituencies served and for the outcomes created."

Next to the increased autonomy and independence which led to the development of housing associations towards social enterprises, the increased focus on the neighbourhood is a major development among Dutch housing associations. In 1997, 'liveability' of the neighbourhood

was added as a field of performance to the BBSH. Since then, housing associations are also accountable for their activities to secure or improve the liveability of the neighbourhoods where their dwellings are located. This enabled as well as stimulated housing associations to develop activities that benefit the living conditions in the neighbourhood, to develop non-residential real estate and to maintain and improve the environment of their estates (Ministerie van VROM, 2005).

Area-based planning of housing associations should contribute to 'better' neighbourhoods. What constitutes a good neighbourhood depends on the specific characteristics and context of that neighbourhood. However, goals that are shared in most urban renewal neighbourhoods can be distinguished. For that purpose I use the main policy document of the national government on urban renewal: *Nota Stedelijke Vernieuwing* (Memorandum on Urban Renewal) (VROM, 1997).

According to this memorandum urban renewal encompasses 'policy that is centred on the attractiveness of areas as places to reside, to work, to run a business and to sojourn'. Goal is to create vigorous cities, being differentiated, varied, but not divided. One of the measures is *urban restructuring:* building new housing, selling rental housing and adapting existing housing to increase the quality of housing conditions. Goals are to stop spatial segregation, to ameliorate liveability and to retain and attract the well-to-do residents and businesses (VROM, 1997).

The memorandum states that the process of urban restructuring requires the joined effort of all stakeholders. The local authorities have the lead. Housing associations are seen as partners that act out of their social mission and out of financial self-interest (to prevent voids, poor lettability, and vandalism). Housing associations are expected to contribute to restructuring by the adaptation of their stock. They sign performance agreements with and are accountable to the local authorities. Urban renewal is focused on neighbourhoods. Different forms of policy come together in the neighbourhood, keeping the wider relationship with the city in mind (VROM, 1997).

This neighbourhood focus was strengthened by the 'action program urban restructuring'. 56 Neighbourhoods were assigned by the Housing Minister in 2003 that were in need of specific attention and extra investments and financial support. This was part of a more general government policy to stimulate urban regeneration. One of the main objectives of this policy was also to achieve a more comprehensive approach towards urban regeneration, including not only renewal of the housing stock, but including physical, social and economic measures in a balanced way. In practice, however, the emphasis remained on physical measures (e.g. Gruis et al., 2006).

Partly in reaction to this, in recent years several reports were issued on Dutch housing policy of which the most prominent are the advice reports of the Dutch Scientific Council for Government Policy "Vertrouwen in de buurt" [Confidence in the neighbourhood] (Wetenschappelijke Raad voor het Regeringsbeleid, 2005) and the Council for the Ministry of Housing, Spatial Planning and the Environment "Stad en Stijging" [City and Upward Mobility] (VROM-raad, 2006). In both reports the neighbourhood is seen as the place where the social and political confidence of residents can be regained. The reports plead for more attention for social regeneration of deprived areas, including measures for empowerment of socially disadvantaged people and to keep the upwardly mobile people attracted to their

neighbourhood as to retain them for the city. Both councils recognize a key role for housing associations.

In the end of 2007, the former Housing Minister Vogelaar has designated 40 neighbourhoods where extra funds have come available. Furthermore, policy is focussed explicitly on increasing socio-economic measures, in addition to physical renewal. Many housing associations have taken up a much broader task and have taken on new roles. They remain primarily responsible for the physical renewal of their housing stock, but also have begun to facilitate, finance and develop activities to stimulate safety, care, welfare, education and employment (e.g. Brandsen et al., 2006). Many of these activities are developed at neighbourhood level, in cooperation with the local government and other societal organisations, thus increasing the neighbourhood focus in housing associations' management.

THE DECISION-MAKING PROCESS OF SOCIAL LANDLORDS REGARDING THEIR HOUSING STOCK

Housing associations have to fulfil their objectives with their stock as their main asset. Many housing associations in The Netherlands work with asset management plans to secure that their portfolio meets company goals and market demand. However, in practice decisions of housing associations are often not a direct result of their strategic plans, but of incidents at the neighbourhood level, or of emerged opportunities.

Due to the reduction of government control and the abolishment of financial support housing associations have developed their own asset management strategies to fill in the gap in the housing associations' policies and to cope with financial risks (see e.g. Gruis and Nieboer, 2004a, Gruis and Nieboer, 2004b). Asset management is meant to secure that the housing portfolio meets the organisation's goals and market demand. It can be seen as 'the decisionmaking process of social landlords regarding their housing stock' (Gruis, 2005). This process results in (proposals for) physical and non-physical activities regarding the housing stock. Physical activities can for instance be maintenance, renovation, demolition and new building. Non-physical activities can for instance be adjusting the rent, changing the target group and hiring a caretaker. Physical activities (like the building of community centres) and non-physical activities (like organizing social events) that are not directly focused on the housing stock can influence asset management strategy, but is not considered as a part it.

Several models for determining asset management strategies have been developed since the 1990s (van Vliet, 1993, van den Broeke, 1998, Gruis and Nieboer, 2004b, Eskinasi, 2006, van Os, 2007). In general, these models have been derived from theories on and models for strategic business planning in which strategies for individual estates are derived from general portfolio objectives in a systematic, rationalized manner. According to Nieboer and Gruis (2004) all models have the same general outline of analysis, formulating provisional policy options, testing (ex ante evaluating) these options (option appraisal), and formulating definitive options. Many models follow a top-down approach, in which general strategies for the development of the portfolio are linked to investment strategies for the individual estates. The existing models can be seen as part of the rational-analytical paradigm of strategy formulation within organisations (Nieboer, 2007).

These models, however, have various drawbacks, some of which are linked to the fundamental drawbacks of strategic business planning and others to the specific context of social landlords. Nieboer (2009) states that investments of housing associations do only

partly result from systematic decision-making. He explains this by the difference in the level of abstraction between the portfolio policies and the investment choices and by the assumptions behind the process models (investment decisions follow from central policy, the housing association is one undivided actor, the housing association decides on its own) that are not applicable to housing associations.

In practice decisions of housing associations are often not a direct result of their plans, but of incidents at the neighbourhood level or of emerged opportunities (e.g. Nieboer, 2007). According to Straub (2002) a clear link between the strategic stock and the planned maintenance is lacking as well. The existing models for asset management can be seen as normative models. The models describe how strategic planning could be done, but not how strategic planning is actually done. The models put great emphasis on analysis and translation into policy. The strategic relationship between the asset management plans and the actual investments is, however, weak. Formal documented strategies do not reflect the actual strategies followed in practice (Nieboer, 2007). Gruis (2006) also notes that on paper many housing associations already transformed to dynamic enterprises that are customer- and society-driven, but that there is a discrepancy between policy formulation and policy implementation. Mintzberg et al. (1999) refer to this difference as the difference between the 'intended strategy' and the 'realized strategy'. The realized strategy is a combination of intended and emergent strategy.

There are specific circumstances that make it difficult for housing associations to incorporate effective top-down planning mechanisms. Gruis (2006) lists four properties of the housing association that make it difficult to plan top-down: the rigidity of the product (the house); the complexity of the environment; the functional organizational structure; and the vague border between supplier and buyer of the housing service.

Housing associations nowadays do not only focus on the quality of their own housing stock, but also on the physical, economical and social quality of the whole neighbourhood, which implies cooperation with a wide variety of local actors. As a result housing associations in the Netherlands are increasingly employing an area-based approach towards asset management, which takes into account the characteristics of areas and the other actors present in the area. Several authors have suggested that a neighbourhood-based asset management fits better with the practice and context of housing associations. Gruis (2006) and Van Os (2007) mention the following reasons for a neighbourhood-based approach:

- The neighbourhood is important for the living experience of people. It is the level on which residents identify themselves and on which outsiders form an image;
- The neighbourhood level is concrete enough to debate on and to plan on in cooperation with external parties;
- It is often the level on which partnerships with stakeholders and urban restructuring plans are made;
- The neighbourhood level is a suitable level for balancing costs and revenues and for planning in stages;
- Planning at neighbourhood level can contribute to internal cooperation. Representatives from the 'functional' departments within the organisation (such as the maintenance department, the real estate development department, treasury and the front-office) can work together on neighbourhood plans.
- Thinking about the portfolio, the quality of public and commercial services and social structures coincide on this level.

Next to these reasons, location is of great importance for housing associations as real estate owners. The quality of the surroundings of a property is an important determinant for the value and popularity of a dwelling. Secondly, the dwellings of housing associations are often concentrated in certain neighbourhoods, which give them a specific interest in the development of the neighbourhood quality.
In Dutch practice, there are already several housing associations where management decisions are not based on portfolio considerations, but on considerations on neighbourhood level. Activities originate from negotiations with different parties and are based on social problems, technical quality and future market position of estates in a specific neighbourhood (Nieboer, 2007).

PLANNING BY HOUSING ASSOCIATIONS

In order to analyse the different area-based approaches the concept of planning is used. Planning is concerned with 'shaping futures in which better conditions for human life and planetary survival can be achieved' (Hillier and Healy, 2008: xxiii). Planning is thus aimed at future improvement of the environment. This fits well with most asset management strategies of housing associations, which aim to improve the quality of the housing stock, and with the wider role they have taken in not only improving the housing stock itself but also contributing to the improvement of social and economic quality of neighbourhoods. In the past planning was primarily the task of the government, but nowadays also other actors engage in planning.

Planning has both a process side and a content side. As Healy (2006) notes: "The planning tradition […] represents a continual effort to interrelate conceptions of the qualities and social dynamics of places with notions of the social processes of 'shaping places' through the articulation and implementation of policies" (Healey, 2006: 7). Planning can also be described as 'an activity centrally concerned with the linkage between knowledge and organized action' (Friedmann and Hudson, 1974: 2). Since the action is organized, we can see the organisation as another component of planning. An organisation can be seen as 'a goal-directed entity that serves an explicit purpose' (Anheier, 2005: 142). So planning can be deconstructed into the following general elements which I will use in describing the practice of housing associations: actors, activities, knowledge and purpose.

Next to these descriptive criteria, I will use evaluative criteria formulated by Hudson et al. (1979). They developed criteria "for comparison of different traditions' strengths and weakness, along with their varying intentions and accomplishments". They are "basic criteria that one might use for assessing the scope, character, and adequacy of the various planning traditions" (see Table 1).

Criteria	Characteristics and applications
Public interest	Explicit *theory of the public interest*, along with methods to articulate significant social problems, and pluralist interests in outcomes. May include principles of distributive justice, and procedures for dealing with conflict.
Human dimension	Attention to the *personal and spiritual domains* of policy imp acts, including intangible outcomes beyond functional-instrumental objectives -for example, psycho-social development, enhancement of dignity, and capacity for self-help.

Feasibility	*Ease of learning and applying* the theory. Implies the theory is practical to translate into policy implications, and adaptable to varying types of problems, scales of action and social settings.
Action potential	Provision for carrying ideas into practice, building on experience underway and identifying new lines of effective solutions to problems.
Substantive theory	*Descriptive and normative theory* of social problems and processes of social change. Predictive capacity based on informal judgments, not just trend extrapolation; ability to trace long range and indirect policy consequences; historical perspectives on opportunities and constraints on action.
Self-reflective	Capacity for laying analytical assumptions open to criticism and counter -proposals; provision for learning from those being planned for; capacity for depicting concrete experience in everyday language, as well as conceptual models using aggregate data.

Table 1*. Criteria for evaluating planning traditions (Hudson et al., 1979)*

PLANNING STYLES

Planning can be done in different ways, with various interpretations of the above criteria. Many authors have tried to classify these ways. The classification in this paper is based on classifications of Healey (2003), Hudson et al.(1979) and Innes et al. (2005) and encompasses the rational, incremental, collaborative, political and social movement style.

Rational planning

Within the rational planning approach (also called rational–technical, synoptic, rational comprehensive or technical-bureaucratic planning) planners try to formulate policy in a scientific way. “Planning is the application of scientific method –however crude- to policy-making” (Faludi, 1973). Important characteristic of rational planning is the distinction between ends and means. According to Davidoff and Reiner (1962) the formulation of values (ends) is the first step in the planning process. These values are delivered by the client and are the result of a political process. Second step is the identification of possible means to reach the ends. This is the rational-technical process, which includes the selection of the best means to reach the end. Last step is the effectuation of the goals through the application of the selected means. This approach offers ”flexibility to address the particularity of decision circumstances while constraining corruption by clear accountability of actions to policy criteria” (Healey, 2006: 23).

Incremental planning

Incremental planning (also called successive limited comparisons) is planning where a plan is based on a limited number of alternatives. These alternatives originate out of the planner’s experience and consist of little steps to accomplish a part of the goal. By successive repetition of this process and adjustment to changing circumstances eventually the ends can be reached (Lindblom, 1959). This approach is characterised by Lindblom (1959):

- “Selection of value goals and empirical analysis of the needed action are not distinct from one another but are closely intertwined.
- Since means and ends are not distinct, means-end analysis is often inappropriate or limited.
- The test of a "good" policy is typically that various analysts find themselves directly agreeing on a policy (without their agreeing that it is the most appropriate means to an agreed objective).

- Analysis is drastically limited: Important possible outcomes, alternative potential policies and affected values are neglected.
- A succession of comparisons greatly reduces or eliminates reliance on theory."

Collaborative planning

The concept of collaborative planning (also called communicative planning) assumes a pluralistic society where local conflicts arise between people from different cultural communities. These conflicts can be dealt with through collaboration by recognizing 'the potential cultural dimensions of differences' and by creating 'an additional "layer" of cultural formation' (Healey, 2006: 64).

Collaborative planning can be characterized with the following concepts:

- integrative place making: interrelation of economic, social, and environmental relationships;
- collaboration in policymaking: emphasis on collaboration in strategy development, and a mingling of formal politics with pressure groups, citizens groups, business lobbies, and environmental groups.
- inclusive stakeholder involvement: to generate both mutual learning and even consensus building before people come to 'fix' their positions.
- use of 'local' knowledge; the mixture of knowledge built up through practical experience and the frames of reference people use to filter and give meaning to that experience.
- building 'relational' resources: a rich social infrastructure of positive relationships between governance, citizens, and companies (Healey, 1998).

Political planning

Within the political planning approach (also called 'manipulative politics', 'political influence') a leader works on a one-on-one basis with people which he offers benefits in exchange of support for his agenda. This approach depends on personal loyalty, reciprocity, behind-the-scene deals, promises and rewards (Innes and Gruber, 2005). It refers to relations of power in everyday life as well as to 'deliberate efforts to gain influence and exercise power in the public realm […] beyond the household and the firm' (Healey, 2006).

Social Movement

Planning based on the social movement (also called advocacy planning) is characterized by defending the interests of the weak against the strong (Hudson et al., 1979). It originates from groups of people who feel excluded and/or unrepresented. Typical instruments of the social movement are demonstrations, media-attention and instigating legal action (Innes and Gruber, 2005). A social movement planner develops an alternative vision (compare the alternatives in the rational style) that support the interests of the excluded groups. He uses arguments that serve their interests and that cast doubt on the contested plans (Davidoff, 1965). The goal is 'to convert people to support this vision and to make their collective voice powerful enough to force a response' (Innes and Gruber, 2005).

In table 2 the different planning styles are summarized using the general elements of planning.

	Actors	Activities	Knowledge	Purpose
Rational	Specialists (and client)	Analysing	Scientific/objective	Optimal solution
Incremental	Experienced planner	Adapting/adjusting	Experience	Satisfying/agreed upon solution
Collaborative	Stakeholders	Deliberating	Local	reach a consensus

Political	Leader (and constituency)	Negotiating	Strategic/selective	have support of all powerful players by serving their interests.
Social Movement	Unrepresented (and 'lawyer')	Demonstrating, opposing	Legal/logical Arguments	'to convert people to support their vision and to make their collective voice powerful enough to force a response'

Table 2. *Summary of planning styles*

SURVEY

These planning types and their elements are transformed into propositions that are tested in a survey among housing managers working in priority neighbourhoods (see Appendix for the propositions) in order to get a general picture of how housing associations plan their area-based asset management in practice. The survey was restricted to these neighbourhoods because in these areas we expect to find the most complex problems resulting in an area-based process. 34 Surveys out of a potential 51 (in some neighbourhoods more than one housing association is active) were returned of which one was not useful because it was evident that it was not filled out seriously.

The survey was divided into three parts. In the first part, respondents were asked if they completely agreed, agreed more than disagreed, disagreed more than agreed or disagreed with propositions concerning the general process resulting in (proposed) activities concerning the housing stock. In the second part respondents were asked to indicate if the proposition was (almost) never, sometimes, often or (almost) always applicable to the (proposed) activities in their area in the last four years. In the third part respondents had to place elements relating the planning styles in order of importance.

Expectations

Although no housing association is the same, housing associations working in priority neighbourhoods do have some shared characteristics. They all have the same legal status and function in the same regulatory framework. They can all be considered social enterprises, working on the renewal of problematic areas. Out of these shared characteristics expectations regarding their planning style were derived.

If we relate the concept of the social enterprise to the elements of the planning styles, we expect that the planning style of a social enterprise has elements of the rational style. First of all, ends and means within a social enterprise are separated. The ends relate to the mission to create and sustain social value. The opportunities to serve that mission can be seen as the means. Secondly, the relentless pursuit of these opportunities can be seen as the rational emphasis on analysis (think of the O in the SWOT analysis). Thirdly, the process of innovation fits well with the rational style. The continuous adaptation and learning fits with the incremental style and the heightened sense of accountability fits well with the collaborative style. Political and social movement styles are expected to occur less frequent.
When we look at the general urban renewal agenda, a combination of collaborative and rational planning elements are expected. The joined effort, the agreements with and the accountability to the local authority, and the connection with wider urban and national policy fit with the collaborative style. The housing market analysis and the denomination of explicit goals fit with the rational style.

Results

The survey shows that housing associations use different elements from different planning styles. However, emphasis is (as expected) on the elements of the rational and collaborative styles. Activities often result from planning based on elements of these styles. Elements of the social movement style and the political style are reported to be used least. In between are elements of the incremental style.

When we take a look at the different elements of the planning process, it seems that the actors that are most involved in the planning process are the stakeholders (including the housing association) and the policy advisors. Often the process consists of activities such as the balancing of alternative means to reach the formulated goals and the adaptation to changing circumstances. Proposed activities regarding the housing stock are often based on objective, local and/or personal knowledge. Often consensus on the (proposed) activities is reached and often the (proposed) activities take the wishes and interests of all stakeholders into account. Often there is a clear relationship between de (proposed) activities and the goals that are formulated for the area.

When asked to place different elements in order of importance, collaborative elements are considered as most important, incremental elements (except for staff carrying out the work) are ranked second most important. Remarkably, the rational elements on average are ranked second lowest (except for the (policy) advisor) (see table 3). So it seems that in practice rational elements are often used to formulate (proposed) activities, but that they are not recognized as being of top importance.

	Actors	**Knowledge**	**Activities**	**Concepts**
1	Stakeholders (C)	Local knowledge (C)	Consulting / collaborating (C)	Consensus (C)
2	Management (P)	Personal experience/ common sense (I)	Piecemeal adjusting activities/plans to changing circumstances (I)	Experience (I)
3	(Policy) advisors (R)	Strategic/selective information (P)	Exchanging means/interests/positions and deal making (negotiating) (P)	(collective) Action (S)
4	Special interest groups (S)	Scientific/objective (R)	Analysing/Researching (R)	Ratio (R)
5	Staff carrying out the work (I)	Logic/legal arguments (S)	Agitating against other plans / developing alternative plans (S)	Power(P)

Table 3. *Elements of planning in order of importance*

A possible explanation is that the rational style is seen as a 'basic' style, which is taught at school and is omnipresent. The other styles can be seen as departing from or reacting on this basic style (see also Hudson et al., 1979). In many planning processes rational elements are used; for instance explicit goals are set, alternatives means are compared, or a thorough quantitative analysis is made. However, these rational elements are combined with other elements that are distinguishing the process and are more visible. These elements are defining the perception of the planning process, and not the 'basic' rational elements.

Most housing associations in this study often act as a social enterprise. Four out of five of the characteristics of the social enterprise are subscribed by most of the respondents. On the proposition that activities are innovative or based on innovations, most respondents indicate that this is only sometimes true. An explanation might be that the nature of innovation requires a small share of activities (if all activities were innovative, how innovative are these activities?).

In general, activities of most housing associations in the survey contribute to the urban renewal goals of the government. The goals to attract businesses and to serve the business interest of the housing association are an exception; activities contribute less frequent to these goals. This can be explained by the core mission of the housing association, which is to provide affordable housing on a non-profit basis. Also in urban renewal areas emphasis is on housing and not on attracting businesses to neighbourhoods. Because of the non-profit status of housing associations the contribution of activities to the business interest is not necessary.
Most respondents agree on the propositions derived from the evaluative criteria of the planning process, except for the feasibility criterion. Most respondents do not think the process is easy. This shows the need for a better understanding of the process.

DISCUSSION

The survey's focus is on the actual and proposed activities of the last four years. However, because the respondents are employees of the housing associations, results are possibly biased. Responses reflect the perceived reality of the respondent. Especially with the propositions concerning the criteria to assess the planning process, this bias can be expected. With the other propositions we tried to avoid bias by not asking their opinion on an abstract proposition but by relating these propositions to the actual situation in the actual neighbourhoods the respondent works in. In this way respondents were forced to look back at real situations.

Also, the propositions and expectations are based on normative concepts on how planning should be done. In reality the picture might be quite different. Political elements are for instance often not that overt and may not be written down as a formal, designed planning style. The social movement style can be seen as a style that is employed in reaction to the failure of other styles to acknowledge the interests of all stakeholders and as a consequence is not likely to be formally promoted as the preferred style. The incremental style can be seen as a reaction to the flaws of the rational style. Moreover, the urban renewal agenda reflects the politically desirable situation, and can be different from the societal and scientifically desirable situation. This agenda is based on assumptions that can be contested (e.g. Kleinhans, 2005). It is possible that this normative preference for certain styles has influenced the answers of the respondents.

Furthermore, the survey gives a general overview of the use of planning styles. It does not describe the specific local context in which the different planning styles are used. For instance the different characteristics of the dwellings, of the stakeholders, and of the organisation are not taken into account.

Therefore, these findings will be further explored in a multiple case study. In this case study the planning practice of housing associations for a neighbourhood will be studied more in-

depth, taking into account the local context and the type of activity. Document research and interviews with internal and external people involved in the planning process will provide a better understanding of the process and of the strengths and weaknesses of the elements of planning applied in different situations.

CONCLUSION

Housing associations, being private actors with public tasks, have become more important in the production of places, especially in urban renewal areas where they own a large share of the housing stock. They have taken up a wider role in theses areas, which made their asset management strategies become more complex. With this growing complexity a pure rational approach does not seem to be sufficient. From literature it was expected that, next to rational elements, elements from other planning styles, especially from collaborative planning, play a role.

The survey confirms this expectation. It shows that, in general, rational elements of planning still play an important role in decision-making on activities regarding the housing stock in regeneration areas, but that these rational elements are combined with elements from other styles, of which the most important is the collaborative one.

Raising awareness within housing associations on the different ways to plan their activities regarding the housing stock can help them to improve their performance in urban renewal. Next to raising awareness a better understanding of the pros and cons of the styles and of when and how to apply the different styles is necessary.

Abstract
In this paper, we focus on the influence of occupant behaviour on the energy performance of dwellings, before and after renovation process. In this context, 'ventilation control pattern', 'maintenance', and 'heating energy demand' are selected as the key parameters of the study. The aim is to reveal the sensitivity of energy performance of a dwelling to occupant behaviour, considering the pre and post-renovation process. Sensitivity of dwelling energy performance to occupant behaviour is analysed using Monte Carlo method. This method is one of the most commonly used methods to analyse the approximate distribution of possible results on the basis of probabilistic inputs. The inputs are selected as: window and grid operation, and mechanical ventilation set for ventilation control. The data used about occupant behaviour is gathered from OTB Survey [2008]. The Dutch reference building is used as a generic building to test the behavioural patterns. The result shows that a renovated [maintenance] dwelling is more robust to ventilation behaviour of the occupant.

Keywords: occupant behaviour, ventilation, renovation, energy performance, sensitivity analysis.

INTRODUCTION

It has long been known that energy efficiency improvements in the building stock cannot be furthered, unless strategies for renovation of existing dwellings are developed. Moreover, occupant behaviour has been a growing research interest, since the expected energy performance levels have not been achieved with low energy design, and occupant behaviour could be a reason [GuerraSantin and Itard, 2010]. This study focuses on the behavioural aspects of energy performance in renovation of dwellings. The aim is to reveal the sensitivity of occupant behaviour to the energy performance of a dwelling, considering the pre and post-renovation process. Main research question is: Is there an occupant behaviour threshold that defines a significant difference on the energy performance, considering renovation process?

Following, this paper's approach towards the domains of 'renovation' and 'behaviour' are explained:

Kohler defines 'simple renovation' such as insulating walls or replacing single glazing with double glazing, and states that this is only possible if the quality of the existing dwelling is sufficient to fulfil current needs [Kohler, 2006; Itard and Klunder, 2007] redefines simple renovation as 'maintenance'; and furthermore, provide the terms 'consolidation' and 'housing transformation' as steps between simple renovation, demolition and new construction [redevelopment]. In their paper, consolidation is explained as improvements of the building shell [such as insulation, without any change in the floor plan of the house or housing block]. Transformations are improvements or interventions in a housing block or complex that go beyond an individual house. Examples of this are joining houses together horizontally or vertically. Housing transformation requires that at least the loadbearing structure will be preserved when the remaining components are renewed. The scope of this study includes 'maintenance', namely the improvements in the building shell.

In this paper, occupant behaviour is considered as: presence patterns in a space, together with the actual heating [thermostat setting and radiator control] and ventilation patterns [operation of windows, grids, and mechanical systems], and the use of lighting and appliances.

METHODOLOGY

Method

The research methodology is based on sensitivity analysis, which is the study of how the variation in the output of a model can be apportioned, qualitatively or quantitatively, to different sources of variation. In sensitivity analysis, a mathematical model is defined by a series of equations, input factors, parameters, and variables aimed to characterize the process being investigated. Input is subject to many sources of uncertainty including errors of measurement, absence of information and poor or partial understanding of the driving forces and mechanisms. This uncertainty imposes a limit on the confidence in the output of the model [Hamby et al, 1994; Helton et al, 2006; Saltelli et al, 2006]

There are several possible procedures to perform sensitivity analysis. The most common sensitivity analysis practice works based on sampling. Several sampling strategies are available, including random sampling, importance sampling, and Latin hypercube sampling. In general, a sampling-based sensitivity analysis is one in which the model is executed repeatedly for combinations of values sampled from the distribution [assumed known] of the input factors. There are several examples of the application of sensitivity analysis in building thermal modelling [Spitler et al, 1989; Corson, 1992; Lam, 1996; Fulbringer and Roulet, 1999; McDonald, 2004; Westphal and Lamberts, 2005; Harputlugil et al, 2009]. For sensitivity of energy simulation models, a set of input parameters and their values are defined and applied to a building model. The simulated energy consumption of the model is used as a base for comparison to determine how much the output [here measured in terms of energy use per year] changes due to particular increments of input values [Corson, 1992]. Consequently the results show which parameters can be classified as "sensitive" or "robust". Sensitive parameters are the parameters that by a change in their value cause effective changes on outputs [in this case heating energy demand]. Contrarily, change of robust parameters causes negligible changes on outputs.

The sensitivity of occupant behaviour; which is considered here as factors influencing energy use by behaviour; are analysed using Monte Carlo method. The Monte Carlo method is one of the most commonly used methods to analyse the approximate distribution of possible results on the basis of probabilistic inputs [Lomas and Eppel, 2007; Hopfe et al, 2007]. In this research, the inputs [parameters] include use of ventilation system, and resulting air change rates. The steps of the analysis are as follows [Figure-1]:

- Pre-processing survey data [see next section] within statistical analysis program [the mean and standard deviations [SD] of the input parameters are determined]
- Gathering Latin-Hypercube samples from SimLab [SimLab] pre-processor
- Simulating each sample by a dynamic simulation program to collect output data. The simulations are made with 'one at a time' approach. Each input is perturbed in turn while keeping all other inputs constant at their nominal value.
- Combination of inputs and outputs in post-processor of SimLab to get Monte-Carlo
- Interpretation of the results

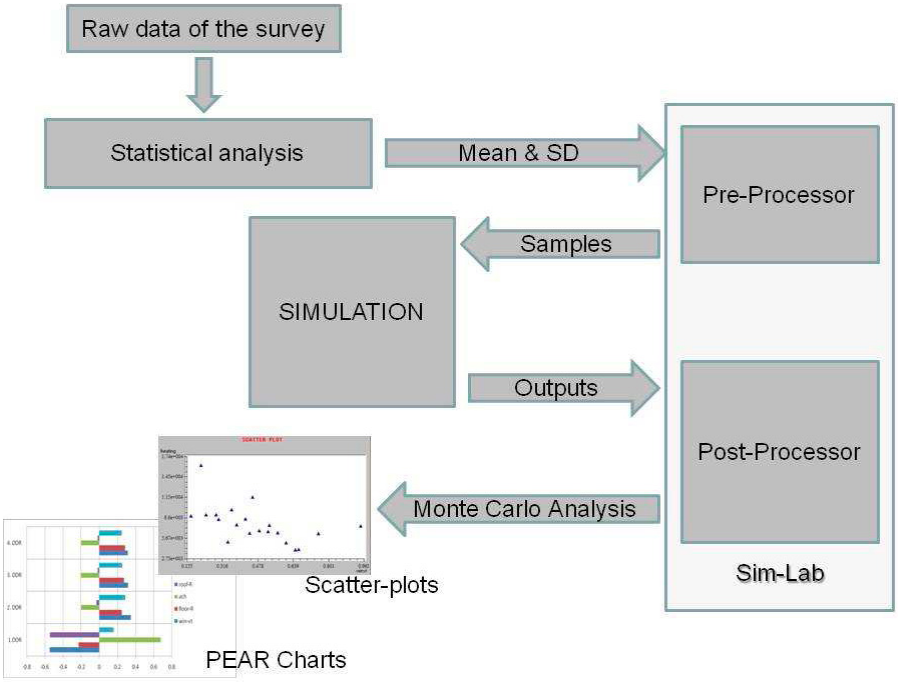

Figure 1. *Experiment/Computation/Observation*

Data

Dutch reference row house [Referentie woning, 2010] is modelled using the simulation software. The characteristics of the dwelling is explained below.

Figure 2. *Plans and sections of the reference row house*

Envelope properties of the non-renovated case [common row house of 1946 [Itard, 2006]] and the renovated case [contemporary row house [NEN 5128]] are displayed in Table 1.

Table 1. *Envelope characteristics and Energy use of sample dwellings*

Characteristics		Row house [contemporary] [renovated]	Row house [1946] [non renovated]
Dimension	Width [m]	5,1	
	Depth [m]	8,9	
	Height [m]	2,6	
	Floor area [m^2]	45,4	
	Volume [m^3]	118,0	
Envelope properties	Rc façade [m^2K/W]	3,0	0,58
	Rc roof [m^2K/W]	4,0	0,42
	Rc ground floor slab [m^2K/W]	3,0	0,38
	U window [W/m^2K]	1,8	5,1
	U front door [W/m^2K]	2,0	3,5
Energy use	EPC value [NEN 5128]	0,78	-
	Yearly energy use	359 MJ/m^2 [NEN 5128]	596 MJ/m^2 [Itard, 2006]

For calculating the *total ventilation rates*, Dutch standard for ventilation: NEN 1087 values are assumed [Table 2].

Table 2. *Dutch standards for ventilation*

	Living room	Bedroom	Kitchen	Bathroom +WC	WC only
Netherlands [NEN 1087]	1,0 $dm^3/s/m^2$ floor area	1,0 $dm^3/s/m^2$ floor area	21 dm^3/s	14 dm^3/s	7 dm^3/s

The following formula and the physical descriptions of the dwelling model provide the air change values for each room, listed below.

Supply Air Rate [AC/h] = Volume Flow Rate [m^3/h] / Room Volume [m^3]

Living room: 1,25 ach	Bathroom: 1,26 ach
Attic: 1,47 ach	Bedroom 1: 1,26 ach
Bedroom 2: 1,26 ach	Bedroom 3: 1,15 ach
Entrance: 1,26 ach	Circulation: 1,26 ach

Data about *ventilation behaviour* is collected in two neighbourhoods, that began to develop in 1996, in the Netherlands. The survey was conducted in Winter 2008, in 319 dwellings. Number of row houses in the sample is 117 [37%]. The data collected through the survey is about dwelling characteristics, household characteristics, energy consumption figures, actual behaviour about heating and ventilation behavioural patterns and use of lighting and equipments. In the scope of this research, data used about behaviour from the survey include: hourly ventilation behaviour changes: use of windows, and grids in each room, and hourly set point adjustment of mechanical ventilation.

In the survey, respondents were asked to fill in tables, mentioning if they open/don't open windows and grids in each room, each hour; and if they turn on/off mechanical ventilation each hour, during the week and the weekend. These tables are converted to values for further mathematical calculations [1: open window/grid, mechanical ventilation on, 0: closed window/grid, mechanical ventilation off]. Then, these values are used to calculate the air change per hour values [ach] of each room, when there is/not natural and/or mechanical ventilation present.

All 117 dwellings from the survey database have open kitchens. Therefore, reported data on ventilation behaviour in living room and in kitchen is combined. In addition, entrance, bathroom and circulation zones' natural ventilation patterns reported in the survey database are not simulated, because the reference dwelling model did not propose natural ventilation through windows, in these rooms.

Using the ach value assumptions calculated from the NEN standard and the reference row house, and the converted/quantitative ventilation behaviour data [from the survey database], air change rates of each room during the day are calculated. Afterwards, descriptive statistical analysis is applied to be able to obtain the mean and the standard deviations of ventilation patterns. These values [Table 4] are processed in SimLab pre-processor for gathering the generic 50 samples of ventilation patterns [see Pre-processing survey data step, in previous section]. As this study only focuses on ventilation behaviour, the remaining behavioural patterns are kept constant and taken from the NEN 5128 [Table 3].

To calculate average internal heat-gain from lighting, assumption for 1 m^2: 6,0 W For this study, 50 samples of ventilation rates are generated with SimLab.

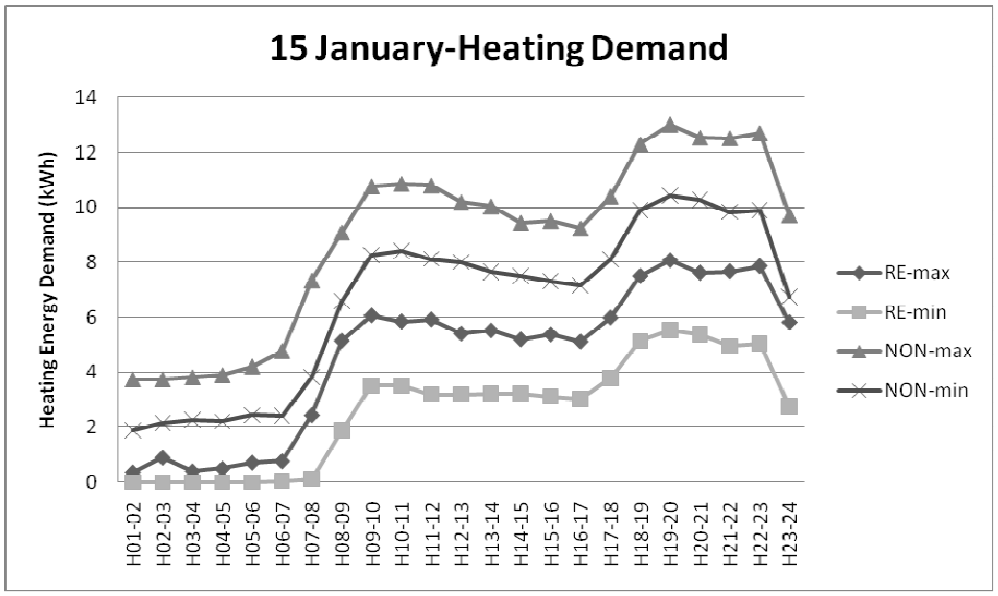
Based on the 50 samples generated from pre-processor of SimLab, heating energy demand for each sample during the Dutch heating season [assumed as 01.October-01.April] is calculated with 'one at a time' approach [see previous section], using a dynamic building simulation program. Both renovated and non-renovated reference building models are simulated with the 50 samples of ventilation behaviour, and the analysis of the results is conducted using the Monte Carlo statistical analysis method, in the post-processor of SimLab. Results are discussed in the next section.

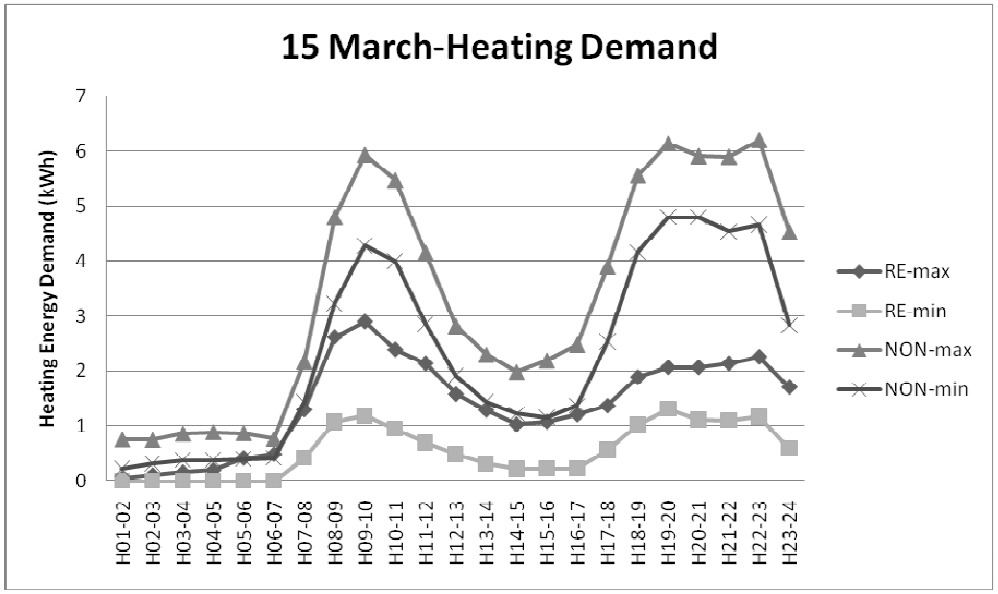
RESULTS AND DISCUSSION



Considering the great amount of hourly input and output data produced, representative days within the heating season are selected to facilitate interpretation of the results: 15.October, 15.January and 15.March. Discussion of the results, focusing on the comparison of the renovated and the non-renovated, is covered through: [1] comparison of the influence of the variations in daily ventilation behaviour on daily heating energy demand, and [2] on seasonal heating energy demand.

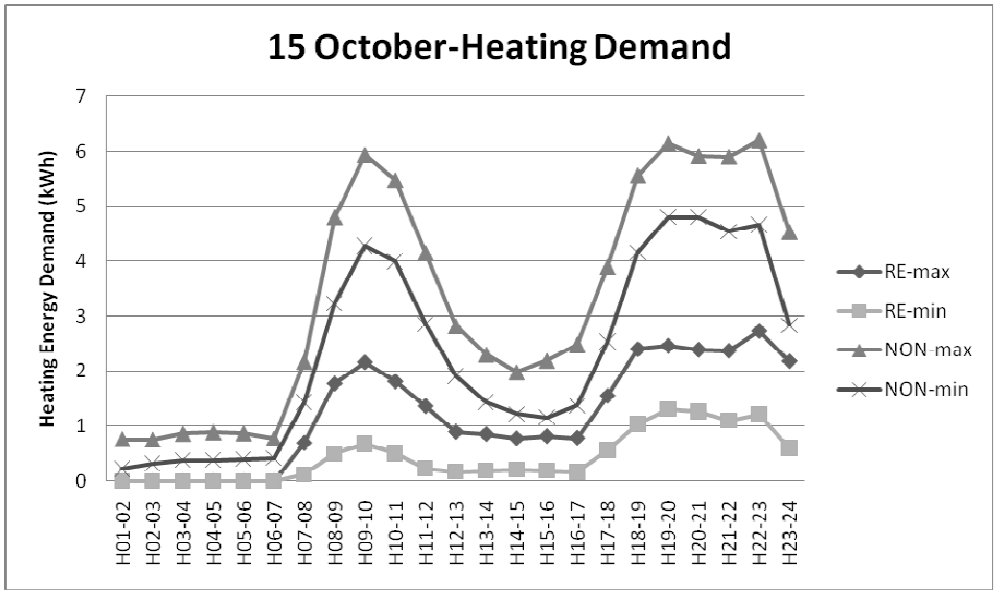
Daily heating energy demand of both renovated and non-renovated cases, regarding hourly ventilation behaviour of the occupants in each room showed that: On 15.January [Figure 3] heating energy demand of the non-renovated case is much higher than the renovated one. However, the changes in ventilation patterns seem not to be directly related with the resulting heating energy demand, occurring each hour. Similar non-relation could be seen on 15.March [Figure 4] and 15.October [Figure 5].

Heating energy demand of the renovated case displays the inference of heat conservation during early hours of the day, when occupants are present. However, this should not be interpreted as heating energy demand would be less during occupancy, than non-occupancy,



because during evening hours presence results in increasing heating energy demand. For further evaluation, Monte Carlo analysis was conducted over the outputs of 50 samples. The results of Monte Carlo showed that:

Based on the ventilation behaviour of 24 hours in living room, the hours that have the biggest impact on heating energy demand on 15th January, 15th March and 15th October differ in renovated and non-renovated cases. In non-renovated cases the biggest impact period is between 8 and 9 am. However, in renovated cases, the biggest impact periods are 11 and 12 am for 15 January, 8 and 9 am for 15 March, and 9 and 10 am for 15 October [Figure 3,4,5-Table 5].



[Re-: Renovated case, NON-:Non-renovated case]

[Re-: Renovated case, NON-:Non-renovated case]

Figure 5. *15.October daily heating energy demand change*

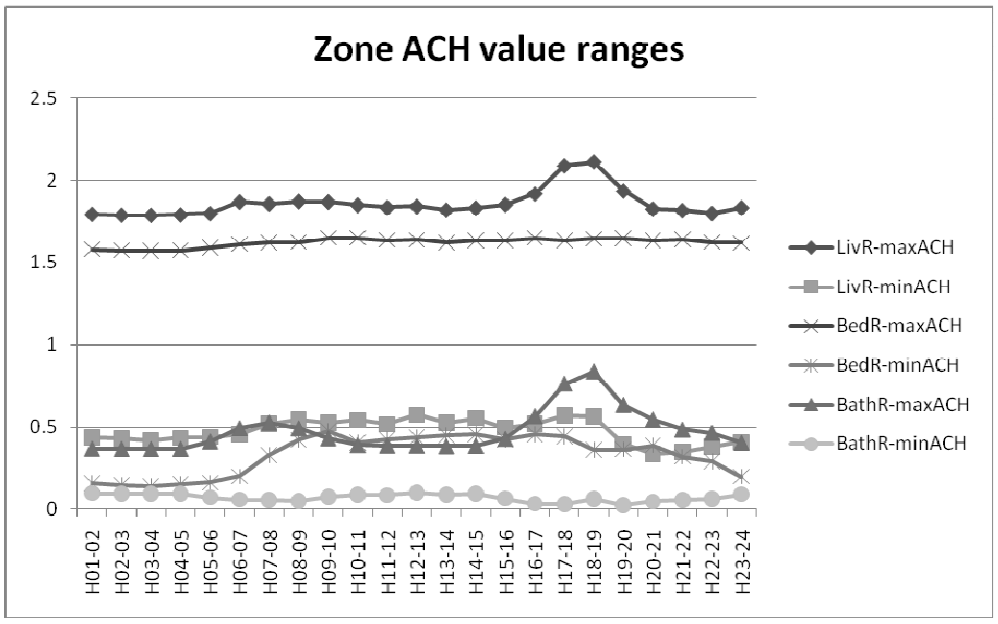

Figure 6. *Room ach values, minimum and maximum*

The seasonal heating energy demand analysis has been executed as well [Figure 7-8, Table 5]. The hours, that the ventilation behaviour influences the heating energy demand most are the same with the non-renovated case daily values, namely 8:00AM and 9:00AM. On the other hand, the values of correlation coefficients [PEAR] are closer to each other in the renovated cases than the non-renovated cases. This shows that, non-renovated dwellings are more sensitive to ventilation behaviour, considering the heating energy demand.

CONCLUSION

In this paper, we focused on exploring the sensitivity of energy performance of a dwelling to occupant ventilation behaviour, considering the pre and post-renovation process. Results of this preliminary study showed that there is a correlation between occupant behaviour and heating energy demand of dwellings, and the more energy conservative the dwelling gets, the less it is sensitive to occupant behaviour.

However, this conclusion covers only ventilation behaviour, and it is necessary to include presence, and heating behaviour in further analysis. Energy performance simulations are conducted with one-at-a-time approach. In this case, only ventilation behaviour for each hour of the heating season was changed, while the rest of the behavioural variables left constant. This conclusion also directs us for further investigation.

In order to reveal the interrelations among different behavioural patterns, and their influence on the heating energy demand of dwellings, a further analysis is still under progress with 250 samples and three behavioural variables as presence, ventilation, and thermostat settings.

Abstract
It is aimed to design a study that facilitates a fair comparison of construction speed performance for residential and office developments in UK and Germany. The definitions of the populations are restricted hence there is a necessity to construct a common basis for two different data sets. Subsequent to data base filtering, random sampling was performed via computer algorithm and 200 observations from each location were retained in the samples. Available quantitative variables were utilized to create factors and the response variable. 2 sample t-test was designed to test the group differences between two samples resulted in no substantial variation exists between population means. Limitations applied to 2 sample t-test forms a motivation for further investigation and in this context a factorial study is designed. This enables to observe the effect of not only the location factor but also the hypothesized factors that may influence the mean response. The analysis yielded that project location causes a significant variation in the mean response when factors regarding facility, standard and height are taken into account. Consistent with the complexities involve in construction projects, it is concluded that neglecting the effect of construction speed related factors and only taking project location into account would not be an appropriate approach for a post ex facto research where observations can not be controlled.

Keywords: Construction speed performance; 2 sample t-test; factorial design; international benchmark.

INTRODUCTION

As of January 1993, the Single European Market, which enables the end of trade barriers, a relaxation of customs regulations and free movement within the European Union (EU), was introduced (Proverbs *et al.*, 1998). Consequently, competition of the counterpart sectors in EU roses. In a time of globalisation and an increasingly competitive environment, measuring performance has become critical to business success, spread to many industries including construction (Bassioni *et al.*, 2004). Current statistics presents EU construction investments has reached to 1,173 billion C which corresponds to 9.9% of GDP in EU (FIEC, 2009). The figure demonstrates that the industry is too important to be allowed to stagnate (Egan, 1998).
The construction industry is project oriented where each project is referred to be as unique (Ofori, 1990). Although similar production methods and sequences are employed in every project, each project is considered as a prototype (Wegelius-Lehtonen, 2001). Therefore, performance measurements mostly focus on factors associated with project levels rather than organisational ones (Love & Holt, 2000; Kagioglou *et al.*, 2001). In today's fast paced construction environment, the clients stipulate for fast track construction in order to enhance

their competitive positions by entering the market first and capitalise high profitability until other rivals penetrate the market (Kog *et al.*, 1999). To contractors increased construction speed enhances the profitability and provides competitive advantage, too (Walker, 1995). In addition, ability of constructing faster and completing projects on time objectively reflects the capacity to organise and control site operations, to optimally allocate resources and to manage the information flow between design team and among subcontractors (Murray, 2003).

In this context, it would be a valuable contribution to evaluate and benchmark one of the key performance indicators, construction speed, between Germany and UK based on projects executed during the last three decades. Although international alterations involve in construction industry such as economical, cultural, and environmental as well as industry specific ambiguities make comparisons arduous, conducting a comparison is not impossible (Xiao & Proverbs, 2002). An intervention study was designed aims at determining group differences between two locations. In addition, it is aimed to assess the variations in construction speed influenced by not only the location but also the other factors that were established by theory and intuition.

THEORETICAL BACKGROUND

Construction speed was utilized as a response variable by Love *et al*. (2005); Stoy *et al*. (2007). While Stoy *et al*. (2007) defines the term as executed gross floor area per month, Love *et al*. (2005) describes it as the time necessary to execute a unit gross floor area. This study adopts the definition provided by Stoy *et al*. (2007). The review of the literature reported many studies intended to determine the factors affecting construction time performance and/or to provide predictive models (e.g.(Bromilow, 1974; Ireland, 1985; Walker, 1995; Kumaraswamy & Chan, 1995; Love *et al*., 2005; Stoy *et al*., 2007)). The findings of relevant studies indicated numerous factors including project level macro factors such as construction cost and gross floor area (Chan & Kumaraswamy, 1995), number of storeys (Ireland, 1985; Love *et al*., 2005), project location (Nkado, 1995; Dursun & Stoy, 2011), building height (Chan & Kumaraswamy, 1999), type of facility (Ng *et al*., 2001); and organisational level factors like managerial control (Sidwell, 1982), client objectives and communication (Walker, 1995). Moreover, Chan & Kumaraswamy (1999) analyzed the influence of special factors within the construction process (micro factors), such as construction site productivity, external wall surface, and frame type. Limited number of studies (Proverbs *et al*., 1998; Xiao & Proverbs, 2002) made an attempt to compare construction time performance in international context. Proverbs *et al*. (1998) perform a comparison between UK, French and German building construction sectors on the basis of a hypothetical project. The respondents from 3 locations were asked to estimate the construction duration of the property designed by research team and the results were compared via ANOVA test. The results demonstrate that substantial variations occur in average construction duration. It was concluded that French companies are superior to German counterparts while UK companies remains the slowest (Proverbs *et al*., 1998). Proverbs *et al*. (1998) also investigated the factors reported in early studies that may influence the duration such as labour utilisation, reinforcement fabrication, formwork solutions and scaffolding systems. Another relevant study was conducted by Xiao & Proverbs (2002) and it utilized a hypothetical project (a six-storey concrete frame speculative office building) to collect data from USA, UK and Japan contractors. The results revealed that average anticipated duration to execute the project is the shortest for Japanese firms followed by UK and USA, respectively.

THE SAMPLE

The *ex post facto* research which is designed to perform an international benchmark incorporates several problems when two historical data sets from the distinct locations are employed. The problem arises hence the standardisation in data collection, the structure of the data sets and definitions of available variables do not present a perfect match. Particularly for cost information, UK data base employs definitions in accordance with British Cost Information Service (BCIS) standards, while German data set classifies them according to DIN norms. Consequently, descriptions of the cost related variables must be examined attentively to figure those that correspond to each other. European Council of Construction Economists (CEEC) published Code of Measurement for Cost Planning (Wright *et al*., 2008) that emerges to determine cost group descriptions and presents a comparison basis between Germany and UK, exhaustively (table 1). Accordingly, the term "construction cost" or "cost" corresponds to the equation given below in this study.

UK (substructure + superstructure + internal finishes + fittings) = DE (300 – 327 – 390)

Another aspect of cost information involves in time value of money. Hence sampled projects executed in a wide span of time, all cost information are rebased to 2005 market prices via construction price index provided by BKI in Germany, and BCIS in UK. Last issue regarding cost related variables is the problem of different currencies. Subsequent to index the cost information to 2005, all German cost information was converted to British Pounds with the average exchange rate in 2005.

This study enjoys working with large number of observations when compared to relative studies in the literature cited in the previous section. UK data set comprises more than 15,000 observations where German one consists of approximately 2000 objects. The intervention study is designed to assess the affect of an explanatory categorical variable - in this case: location of the project. To form a common base between two data sets filtering shall be performed. Filtering observations to determine those that will retain in the sample involves in several steps. First, it is crucial to set the boundary years. In this regard, the sample is limited to the projects which were commenced after 1980 and completed before 2004. Also, it is expected to have large variations between different type of construction works. Therefore, the second limitation is applied for the type of construction works and only new construction jobs are included in the sample. There exists no common foundation for the descriptions of type of facilities in two distinct data sets. In addition, while one data set consists of some type of facilities the other does not. Thus, a decision regarding the type of facility to be included in the sample was made and only residential and office building projects were retained. The last

Table 1: CEEC cost planning cost codes and their corresponding definitions in UK and German standards

CEEC code	UK cost group (BCIS)	German cost group (DIN 276)
Substructure	Substructure	311, 312, 313, 319, 321, 322, 323, 324, 326, 329
External superstructure	Roof, external walls, windows and external doors	331, 332, 333, 334, 335, 337, 338, 339, 361, 362, 363, 369
Internal superstructure	Frame, upper floors, stairs, internal walls and partitions, internal doors	341, 342, 343, 344, 346, 349, 351, 359
Internal finishings	Wall finishes, floor finishes, ceiling finishes	325, 336, 345, 352, 353, 364

Table 2: Quantitative variables retained and derived

Variable description	Abbreviation	Unit
Number of storeys	NoS	nominal numbers
constrution duration	Dur	months
gross floor area	GFA	m^2
construction cost	cost	£
construction speed	speed	m^2/month
standard of the building	standard	£/ m^2

restriction applies to the scope of a project. According to Bromilow (1974) construction cost does not only indicate the project size but also reflected the work's complexity and quality. Therefore, the projects that has construction costs below 200k £ and above 20 million £ are excluded from the data set. Subsequent to filtering process the numbers of observations that were retained in the German and UK data set are 347 and 901, respectively. The last step is the random selection of properties to be included in the sample. 200 random observations from each country were selected via a computer algorithm that generates the list of projects to be included from given data sets. This avoids any judgemental selection that may manipulate the results of the analysis in favour of the hypotheses.

The final sample consists of 4 quantitative variables which are number of storeys (nominal scale), construction duration in months (nominal scale), gross floor area (ratio scale) in square meters, construction cost in £ (ratio scale) (table 2); and 2 factors each with 2 levels that are associated with the location of the project and the type of the facility (table 3). Via employing those variables 2 more quantitative variables are derived: construction speed (ratio scale) defined as the average amount of constructed gross floor area per construction duration unit and standard of the building (ratio scale) that is measured by construction cost per gross floor area unit (table 2). Finally this leads obtaining 2 more factors identified as height and standard of the building. Creation of factors associated with height and standard was performed based on investigation of descriptive statistics for the corresponding quantitative variables. Principally, the threshold values of levels were obtained from minimum, first quartile, median, third quartile and maximum values of the variables associated. Please see table 3 for exhaustive information of factors retained and derived.

METHODOLOGY

Bi variate and multivariate statistical analysis are employed to draw and verify conclusions. Two sample t-test is a bi variate statistical procedure suggested to compare means of two distinct population sample. It determines if the difference in two sample means (if any) is

Table 3: Factors retained and/or derived

Factor name	Levels	Abbreviation	Description
building location	2	f_loc	1=Germany, 2=UK
building height	4	f_hei	Based on number of storeys: 1=low (0-2), 2=medium (3-5), 3=med-tall (6-8), 4=tall (9-12)
building standard	4	f_std	Based on standard: 1=low (250-451), 2=medium (451.01-649.86), 3=med-high (649.87-997.26), 4=high (997.27-3500)
type of facility	2	f_tf	1=office, 2=residential

caused by the random chance or not, under given circumstances (Tabachnick *et al.*, 2001). Certain assumptions must be fulfilled prior to conducting the test. The first one involves in sampling procedure that the analysis shall be based on data from two independent, random samples. The sampling procedure was presented in detail at previous section and therefore the assumption related to randomisation of sampling was considered to be fulfilled. Hence, the observations located in different countries there is no reason that why dependencies between observations would occur. Since t-test is a parametric one, the second restriction of the test assumes that both samples are normally distributed. Parametric tests assume that the distribution is known, or that the sample is large, so that a normal distribution may be assumed (Fellows and Liu, 2008). The test statistics is given as follows

$$t = \frac{\overline{x_1} - \overline{x_2}}{standard\ error\ of\ the\ difference\ in\ means}$$

where $\overline{x_1}$ is the mean of sample from Germany and $\overline{x_2}$ is the mean of sample from UK. The significance of the results will be evaluated according to *p* value of the test that is derived from *t* distribution. The null hypothesis will be rejected in case *p* value is less than 5% ($p(t) \leq 0.05$). This indicates the level of risk one is willing to accept of making the opposite of above conclusions (null hypotheses) when it is not true.

It is crucial to report a shortcoming of the test that also stands for the main motivation to construct a factorial design for further investigations. 2 sample t-test assumes that utilized samples are identical to each other and only receive different treatments (in this case: project location). Then it is powerful instrument to draw a conclusion regarding the effect of treatment under given circumstances, where control and treatment group only differs in intervention. Observational studies of single groups are rarely useful for evaluation because the characteristics of the populations to be compared may differ in ways that affect the outcomes being measured-characteristics other than the interventions being compared (Grimshaw *et al.*, 2000). Every construction project (each observation in the sample) is referred to be as unique and therefore, construction related researches can not be evaluated such as controlled experiments performed in laboratory conditions.

Commonly the term "factorial design" is utilized to describe situations where two or more factors are assumed to have effect on dependent variable. A factor is a categorical variable with two or more nominal values referred to as levels (recall table 3). Factorial design is a powerful multivariate instrument to field scientists as a preliminary study, allowing them to judge whether there is a link between variables, whilst reducing the possibility of experimental error and confounding variables. For instance, intuitively one can argue that the standard of a building may vary within different locations also effects the construction speed alongside. In this context, the study constructs 2×2×4×4 factorial design that addresses two aims. The first one is to verify the result obtained by two sample t-test and the second one is to monitor the main effects and interactions of hypothesized factors on the construction speed. Each multiplier element of the study design is derived from the number of levels by the factors created. The method can be assumed as an extended version of ANOVA (analysis of variance); evaluating the effect and interactions of more than one factor simultaneously on mean response from various samples. The underlying principle applies to many cases in construction related researches hence various factors are interdependent to each other. For instance, intuitively one can argue that the standard of a building may vary within different locations for a given type of facility, also affects the construction speed alongside. The test routine incorporates calculation of *F* statistics which corresponds to the ratio of estimated

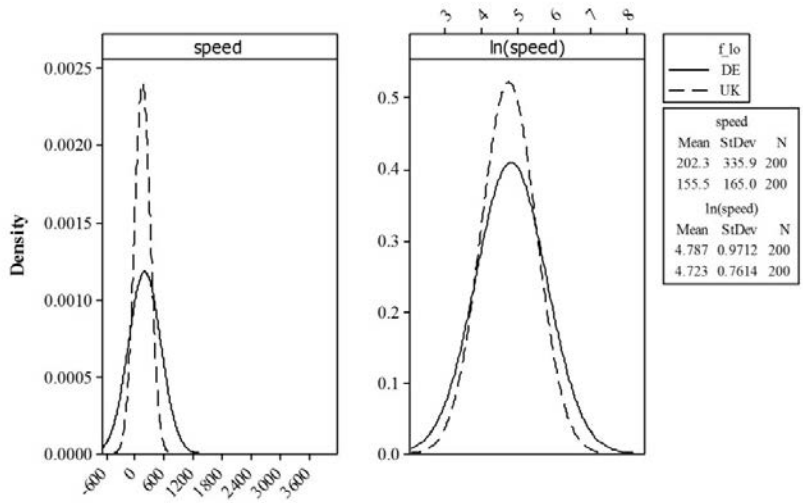

Figure 1: Distribution function of the response variable with respect to project location

variance between groups to estimated variance within groups. Accordingly, the null hypothesis is rejected if probability of the statistic computed is less than 5%.

ANALYSIS AND DISCUSSION

Exploratory Data Analysis

Prior to the commencement of analysis careful investigation of the data shall be performed due to verification of the assumptions outlined in the last section. In addition, to demonstrate the properties of the data shall ease the readers' ability to interpret the results. Hence the analysis involves in parametric tests the distribution function of the response variable plays a vital role. The histogram of the response variable presents that the distribution function is positively skewed (figure 1). Natural logarithm transformation is applied to the response which results in inducing symmetry and reducing skewness (figure 1). Subsequent to variable transformation, one outlier in each sample was detected visually by investigating the box plot of the *ln(speed)* with respect to project location (figure 2). Those observations were excluded from samples and therefore will not be retained for the analysis.

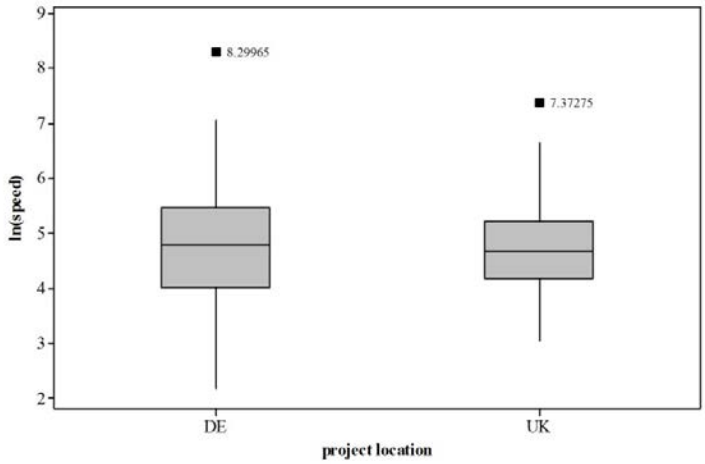

Figure 2: Box plot of *ln(speed)* with respect to project location

Table 4: Descriptive statistics of quantitative variables by means of project location

Variable	Location	N	Mean	SE Mean	St Dev	Median
NoS	DE	199	4.005	0.111	1.565	4
	UK	199	2.899	0.105	1.477	3
dur	DE	199	14.729	0.541	7.633	13
	UK	199	12.417	0.286	4.034	12
GFA	DE	199	2551	206	2912	1564
	UK	199	1915	136	1913	1282
cost	DE	199	1264951	121892	1719495	672240
	UK	199	2056515	190600	2688738	1154075

Table 4 presents descriptive statistics of the quantitative variables: number of storeys, construction duration, gross floor area and construction cost. One can see that, average height of German buildings - function of number of storeys - is greater than UK ones. It is also observed that mean duration to complete construction works of residential and office properties in Germany is slightly greater than those in UK. While average gross floor area of the sample is greater in Germany, construction cost shows a strong opposite trend. The figure might be caused by different factors such as national standards; cost of labour, material and machine; market conditions; site conditions; and so on. It should also be noted that, the argument is also supported by Construction Statistics Annual Report published by Department of Trade and Industry (DTI) in 2006. According to DTI (2006), although the average labour cost is more expensive in Germany, to construct a square meter of residential and office buildings in UK is significantly more expensive than in Germany.

Table 5 acknowledges location as the main factor and presents descriptive statistics of the other factors created. In both locations mean response of construction speed in office buildings are greater than in residential buildings. One can see in table 5 that the spread in

		tall	0	*	*	*	*

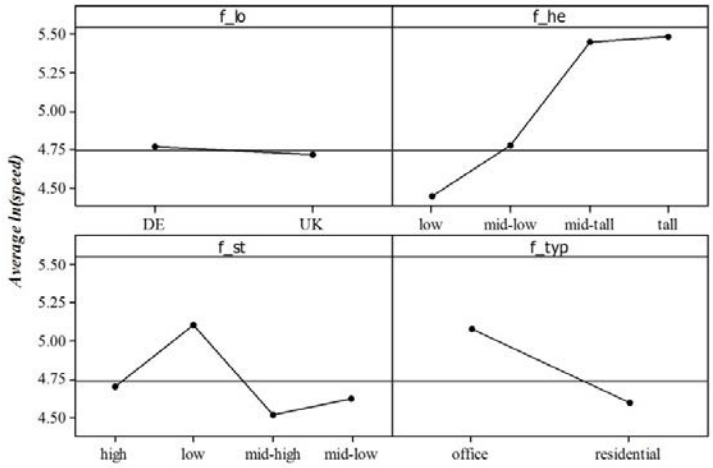

Figure 3: Main effects plot for *ln(speed)* by means of factor defined

number of observations for defined standards shows an opposite pattern. While low and mid-low levels of projects are dominating the German sample, UK sample is dominated by mostly mid-high and high levels of projects. The motivation stands for this figure is no different than the motivation for "cost" variable and has already been outlined in paragraph above. In addition, both in Germany and UK low standard buildings leads the construction speed. Lastly, one can observe in table 5 that the average speed roses as the height of the building increase. Main effects plot presents the changes in average response with respect to the factors defined (figure 3). This in turn may illustrate the behaviour of the *ln(speed)* by means of single factors.

Inferential Statistics

The first test to be conducted aims to assess the significance of group differences in mean response assuming that both samples have identical properties except the intervention: project location. Minitab 16 statistical software was employed to perform 2 sample t-test. 3 assumed conditions will be tested through the analysis (null hypotheses):

- $H_{1,N}$ = the mean response of German sample is not significantly different than UK
- $H_{2,N}$ = the mean response of German sample is not significantly less than UK
- $H_{3,N}$ = the mean response of German sample is not significantly greater than UK

The statistics of the hypotheses tests are given in table 6. CI stands for confidence intervals and it quantifies the uncertainty associated with estimating the difference from sample data. It indicates one can be confident 95% that the true difference of sample means lies between -0.10769 and 0.22594. *p* values can be observed in table 6 and consequently none of the null hypotheses can be rejected. Therefore, based on the 2 sample t test results there is not enough evidence to conclude that the means differ at 5% level of significance. Besides, it is concluded that construction speed of German residential and office buildings neither fast, nor slower when compared to UK counterparts. The test diagnostics are investigated carefully mainly focusing on determining possible outliers that may influence the results dramatically. No violations or outliers are detected.

Second stage of the inferential analysis involve in validating the results provided by 2 sample t-test as well as evaluating the influence of other factors created on the construction speed

Table 6: Two sample t-test and confidence intervals for $ln(speed)_{DE}$ and $ln(speed)_{UK}$

Hypothesis	Statistics	$ln(speed)_{DE}$	$ln(speed)_{UK}$
	Sample Size	199	199
	Mean	4.769	4.7099
	95% CI	(4.63 , 4.90)	(4.61 , 4.81)
	St Dev	0.941	0.7396
	difference between means	0.059122	
$H_{1,N}$	95% CI	(-0.10769 , 0.22594)	
	$p_{1,N}$	0.486	
$H_{2,N}$	90% CI	(-0.080768 , 0.19901)	
	$p_{2,N}$	0.757	
$H_{3,N}$	90% CI	(-0.080768 , 0.19901)	
	$p_{3,N}$	0.243	

Table 7: Analysis of variance for *ln(speed)*

Source	*d.f*	Seq SS	Adj SS	Adj MS	*F*	*p*(*F*)
f_loc	1	0.3478	7.387	7.387	13.85	≤ 0.000
f_tf	1	20.8714	22.8817	22.8817	42.91	≤ 0.000
f_std	3	31.6204	30.5766	10.1922	19.11	≤ 0.000
f_hei	3	23.6181	23.6181	7.8727	14.76	≤ 0.000
Error	389	207.479	207.479	0.5334		
Total	397	283.937				

along with project location. The task will be performed via 2×2×4×4 factorial study as indicated in the methodology section. It is aimed to test the following null hypotheses:

- $H_{4,N}$ = Project location affects no significant difference in mean *ln(speed)*
- $H_{5,N}$ = Type of facility influences no significant difference in average *ln(speed)*
- $H_{6,N}$ = Level of building standard cause no significant difference in mean *ln(speed)*
- $H_{7,N}$ = Level of building height affect no significant changes in average *ln(speed)*

The computation of the analysis is performed with the general linear model routine. The results are outlined in table 7. One can observe that all *F* values are statistically significant. Therefore, the null hypotheses, $H_{4,N}$ $H_{5,N}$ $H_{6,N}$ $H_{7,N}$ were rejected. The result of the general linear model concludes that there is a significant difference in construction speed by project location, type of facility, standard and height of the building.

Discussion

On top, the study shall address to discuss the reasons that the analyses present contradictory results. Although identical samples were employed; 2 sample t-test argued German and UK construction speed performance is not significantly differ from each other on the basis of test statistics that were shown in detail, while general linear model presented project location as a significant factor and it causes substantial variations in the mean that can not be explained by chance. The reason of this disparity lies in the design of the research and the methodologies employed to test the hypotheses. While 2 sample t test assumes that random observations in samples are identical except the intervention (project location) and therefore neglects the effect of any factor that may influence the construction speed; general linear model takes

other factors (derived from theory, intuition, common sense and field experience) into account that may cause variation in the response mean. Consistently, the effect of location

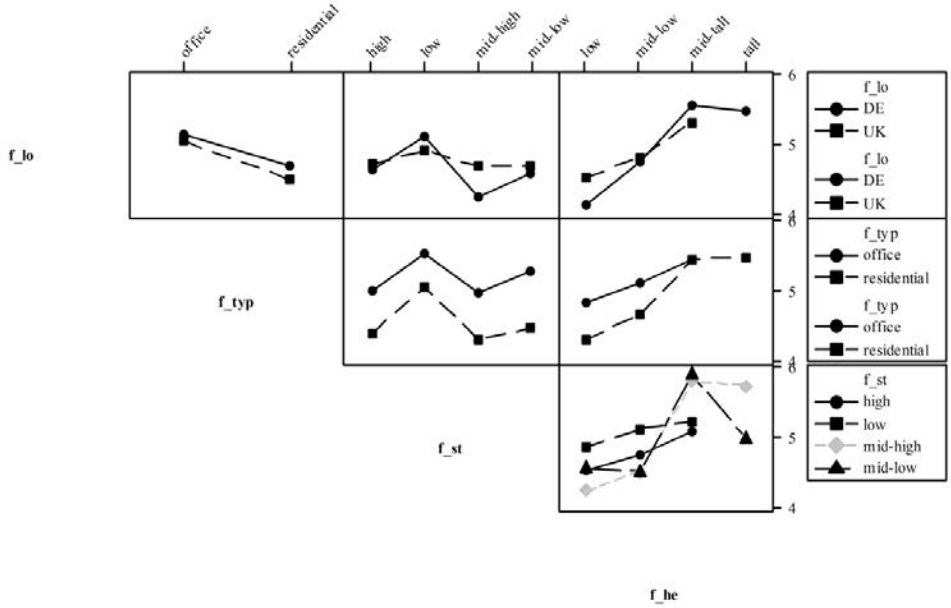

Figure 4: Interaction plot for *ln(speed)*

factor on construction speed becomes insignificant similar to 2 sample t test when general linear model applies to only one factor: project location.

On the other hand, interactions between defined factors may influence the results. The interaction plot of the factors (figure 4) illustrate the pair wise factors and corresponding mean of *ln(speed).* It is observed that in both locations for the given type of facility*, ln(speed)* shows an identical trend: speed of office buildings is superior to residential ones. This indicates there is no interaction between project location and type of facility. However, for the given location and standard ln(speed) presents different properties resulted in two lines intersecting each other (figure 4). It can also be observed that ln(speed) presents more sensitivity for a change in standard in UK when compared to Germany. This indicates a strong pattern of interaction between factor of location and standard. One can also see at the top right corner of the figure 4, given factor of height and location the mean response present two intersecting lines. Thus, it can be concluded that interaction is also present between factors of location and height. Similarly, another interaction can also be monitored between the standard and height of the building according to figure 4. However, one must bear in mind that visual inspections do not provide sufficient evidences regarding significance of interactions.

It is vital to note that perception of a researcher regarding the construction project environment plays a major role to interpret the results of the analysis and draw conclusions out of them. Therefore, consistent with the reasons outlined above, the results from general linear model are accepted and the results from 2 sample t test are declined. It is concluded that 2 sample t test is not an appropriate instrument to execute a post ex facto research because of the construction project specific complications. It is argued that multi variate design of a research that enables to take more than one factor at the same time into account is superior to bi variate design when utilized sample consists of uncontrolled observations. According to the results derived by factorial design it is concluded that factor of project location, type of facility, standard of the building and building height causes significant difference in construction speed.

The findings of this study supports the arguments postulated by Ireland (1985); Nkado (1995); Kumaraswamy and Chan (1995); Chan and Kumaraswamy (1999); Ng *et al*. (2001); Love *et al*. (2005); Dursun and Stoy (2011) and others that project location, standard as an indicator not only for project cost and size but also for the complexity involves in the project, type of facility, and building height as a function of number of stories are significant factors of construction time performance. However, it fails to evaluate the effect of organisational level factors such as communication and management, due to availability of data. Hence compared samples and methodologies employed do not match each other, the results are not sufficient to remark a discussion regarding the study conducted by Proverbs *et al*. (1998). Yet, one can observe at the left top corner of figure 4 that the average construction speed of German office developments are slightly greater than those in UK.

CONCLUSION

The study is designed to enable a fair comparison for construction speed performance of residential and office developments in UK and Germany. The definitions of the populations are restricted hence there is a necessity to construct a common basis for two different data sets. In this context, the populations are limited to projects that are executed between 1980 and 2004. Another restriction is applied to the scope of construction works measured as construction cost. In this regard, only projects between 200 k and 20 million pounds (indexed to 2005 prices) were included in the data sets. Subsequent to data base filtering, random sampling was performed via computer algorithm and 200 observations from each location were retained in the samples. Available quantitative variables were utilized to create factors and the response variable. 2 sample t-test was designed to test the group differences between two samples resulted in no substantial variation exists between population means. Limitations applied to 2 sample t-test forms a motivation for further investigation and in this context a factorial study is designed. This enables to observe the effect of not only the location factor but also the hypothesized factors that may influence the mean response. The analysis yielded that project location causes a significant variation in the mean response when factors of facility, standard and height are taken into account. Consistent with the complicated issues involve in construction projects, it is concluded that neglecting the effect of construction speed related factors and only taking project location into account would not be an appropriate approach for a post ex facto research where observations are not controlled. Therefore, the conclusions of factorial design are considered to provide superior results and accepted as the outcomes of the study. To sum up, it is concluded that project location along with type of facility, standard of a building defined as construction cost per square meters, and height of the building - a function of number of storeys - cause substantial variations in construction speed. It has to be noted that the conclusions are strictly limited to populations described.

This research also demonstrates how the design of a study may play a crucial role to reach the realistic responses to the research questions. Particularly, a research involves in an international investigation may face to various problems regarding availability of the data. Moreover, when the data is available, one has to deal with compatibility of the variables caused by different methods and definitions of storing the data. The research community shall consider developing international standards to create mass data bases. The authorities such as government representatives, parliament members, politics and etc. shall be informed regarding the benefits that can be earned in case such developments are supported by laws. Only then, the developed standards can be dictated to the industry practitioners. Further research shall focus on setting international standards for collecting the data. On the other

hand, setting international construction performance indicators and determining the standard methodologies to be employed is crucial to generate objective results.

ORGANIZING COLLABORATION IN CONSTRUCTION PROJECTS – FORMAL MODELS MEETING PRACTITIONER PERSPECTIVES

ANNA KADEFORS

anna.kadefors@chalmers.se

Abstract
There is a call for new project management approaches that are able to deal with increased flexibility and put people aspects more in focus. In construction projects, formal models for relationship management are increasingly being used. Based on a case study of a Swedish hospital partnering project, this paper discusses how project managers approach this new challenge of integrating systems for relationship management with core project processes, and if the partnering systems are effective in supporting collaboration and knowledge integration in a multiparty partnering environment. The findings indicate that partnering processes influence project processes in a favourable way, but that project managers also rely strongly on their personal experience in managing collaborative processes. The practices they introduce are often successful, but also tend to be patchy and related to collaboration problems in traditional contracts. The formal partnering processes, on the other hand, seem to be important in providing a basic structure for collaboration and to communicate collaborative intents, but are too general and infrequent to address more specific and pressing problems of process design and organization. Bringing in professional behavioural knowledge may be needed to achieve a more consistent and adequate relationship management that makes use of both formal partnering processes and core project processes.

Keywords: Partering, collaboration, knowledge integration,

INTRODUCTION

In many countries, the construction industry is criticized for being adversarial and inefficient (Latham, 1994; Egan, 1998; Byggkommissionen, 2002; PSIB, 2003). Resulting from dissatisfaction with the cost increases, delays and conflicts associated with the traditional methods, there is an international trend to develop contracting and management models which both make better use of project competences and allow for a greater flexibility in decision-making. Removing barriers of distrust that hinder collaborative problem-solving is believed to create opportunities for knowledge integration, learning and improvement. A key goal in these models is therefore to develop more collaborative relationships between the numerous specialist firms that participate in a construction project.

In the discipline of project management, there is and has been a strong emphasis on skills and techniques related to project planning and control. However, there is growing concern that when uncertainty is high, traditional techniques-based project management may not be sufficient and, if too rigorously applied, can impede the fulfillment of fundamental project goals. Thus, there is a call for more knowledge and new strategies for managing uncertainty and flexibility in cases when this is desired or necessary (Williams, 1999; Dvir and Lechler, 2004; Olsson, 2006; Pollack, 2007). That project managers focus more on establishing an environment that facilitates collaboration and knowledge exchange between highly skilled

individuals is seen as a key element (Fernie et al., 2003; Sense, 2008). A recent survey of management practices and procurement methods in 15 major European infrastructure projects (Hertogh et al., 2008) found that the "hard" aspects of project management (risk analysis, cost control, contracts) were generally more professionally managed than the relationships with both external and internal stakeholders.

Some project managers learn through practice how to create good working relationships and motivate project participants. Thus, also within a traditional regime, many projects are successful with few conflicts and trust-based relations between the principal parties. Partnering relationships differ from such informal collaboration by the emphasis on structure and formalization of relationship management and interaction. Typical key components are workshops for teambuilding and training of collaboration techniques, joint risk management and value management sessions, systems for periodic assessments of relational performance as well as conflict resolution, and a new role of partnering facilitator (see e.g Anvuur and Kumaraswamy, 2007). Consequently, project managers in partnering projects need to more consciously incorporate relational considerations and behavioural knowledge in their planning and execution of project activities and processes. This is especially so in more complex projects, where more parties are involved and the goals are more ambitious regarding knowledge integration and joint learning. Further, the integration of disciplines is likely to call for changes in established ways of working, such as roles, task sequencing and decision processes.

Against this background, this research project examines more in depth how new goals of collaboration and formal partnering mechanisms influence and interact with the more traditional and technically focused project management roles and routines. How do project managers and other actors approach these new ideas of formal relationship management and knowledge integration? How do project processes and aspects tend to be affected by partnering arrangements? Which are the implications for project management and future developments in partnering? These questions are addressed by an interview-based case study of a large Swedish partnering project in the hospital sector.

DEVELOPMENT OF COLLABORATIVE PRACTICE IN SWEDEN

In Sweden, it is only the in the last five years or so years that explicit and formal partnering has become more widespread. Although partnering has not been supported or explicitly encouraged by any official policy initiatives or industry change programs as has been the case in the UK, Denmark and the Netherlands, there has been a growing use of partnering arrangements. The Swedish construction contractor NCC has brought their partnering model from their Danish subsidiary, and the Swedish Construction Clients' Federation has organized courses in partnering for all actors, often using consultants from the UK. However, there are still few partnering guidelines in Swedish and few experienced partnering consultants. A survey of the practices and experiences of 39 partnering clients (Andersson and Johansson, 2008) showed that nearly all of them had used workshops with teambuilding practices and continuous evaluations of participants' views of the working relationships. Systems for conflict resolution, partnering facilitators and target cost contracts were also very common. Another recent survey of NCC partnering projects (Appelgren and Hellsing, 2009), indicated that when clients use partnering for the first time, the collaboration primarily involves the client and the building contractor. In their second project, however, clients tend to include also consultants and sub-contractors in a more formal way. In the survey by

Andersson and Johansson (2008), consultants and subcontractors were formal partners in around 50% of the projects. However, it was still unusual that other parties except the building contractor were involved in a gainshare-painshare arrangement. Thus, formalization is increasing, but experiences of organizing collaboration and knowledge integration in a larger group of actors are still scarce.

KNOWLEDGE INTEGRATION AND RELATIONSHIP MANAGEMENT

In contingency theory (Thompson, 1967; Galbraith, 1973), the need for communication and coordination is seen as the main determinant of organizational design. Available means of coordination are managerial hierarchy, plans, standardization (of routines, outputs or roles) and mutual adjustment. Different coordinating mechanisms are more or less costly, but they may not be used interchangeably in all contexts. Thus, standardization of rules and outputs is cheap, but sequentially interdependent tasks require planning. Hierarchy may handle many unique and exceptional situations, but is inefficient when the knowledge needed is held by subordinate experts only. Then, mutual adjustment between individuals, which is the most resource-demanding coordination mechanism, is needed.

One reason why mutual adjustment is resource-demanding is that different specialists belong to distinct communities of practice (Wenger, 1998), each with their own culture and terminology. Knowledge integration is not trivial even in the absence of goal conflict (Dougherty, 1992) and integrating tacit knowledge of different individuals requires direct personal interaction (Grant,1996). The more complex tasks, the more important are personal and communication-intensive forms of integration. Social processes, as opposed to routines and systems, are seen as particularly important in project settings with temporary relationships (Bresnen et al., 2003; Sense, 2008).

So how does coordination differ between traditional construction and partnering projects? Construction projects are temporary and unique organizations, consisting of a large number of specialized firms. The coordination needs are immense, but are (apart from the usual project planning and control systems) to a great extent resolved by a high and partly formalized industry level institutionalization of processes and technical components (Kadefors, 1995). A limited number of procurement routes are defined in standard contracts, further acting to standardize roles, responsibilities and risks of different parties. Companies are designed to fit into specific “slots” in the project organizations and building process, and individuals and firms to a considerable extent perform similar tasks in all projects (Koch and Bendixen, 2005). The same types of meetings with similar agendas are held in most projects, both during design and construction. In this way, the need for mutual adjustment in the form of project level communication and negotiation between parties is reduced, and new participants who join a project are expected to quickly start to produce at their full capacity.

In a partnering project, these existing roles, interaction patterns and communication arenas will have to be partly modified, and new practices added. This transition to more collaborative relationships implies that more resources are assigned to coordination by mutual adjustment, potentially enabling a higher level of knowledge integration. Ideally, then, all participants with key knowledge should be able to collaborate and exchange all necessary information face-to-face. However, efficient groups cannot comprise too many members, and needs for knowledge integration can therefore be hard to meet in practice. In effect, total group performance is achieved in interplay between the work done by individuals

on their own, according to their own routines, and group activities such as formalized project meetings and ad hoc problem-solving (Enberg et al., 2006). Thus, achieving an adequate balance between individual and group activity, as well as a balance between width and depth in partner involvement, should be core issues in partnering project management.

Other aspects to consider are trust and control, for example in the form of detailed contracts and formalized control systems. Depending on the circumstances, such control may counteract or complement trust (Klein Woolthuis et al., 2005). In construction, traditional contracts are generally perceived as sources of distrust, entailing conflicts and close supervision (Kadefors, 2004), but in partnering projects the pricing system is often shifted from fixed price to cost-plus or target cost schemes. However, formal contracts and systems also reinforce trust by their influence on communication and learning (Poppo and Zenger, 2002; Mahama, 2006; Vlaar et al., 2006, 2007). By forcing parties to scrutinize potential problems and formulate responses, contracting processes, just as other forms of knowledge codification, can support mutual understanding (Vlaar et al., 2006, 2007; Zollo and Winter, 2002). Organizational systems that are primarily designed for other purposes also interact with trust production (Madhok, 2006). Thus, performance measurement can bring about new arenas for communication and provide input to discussion, and a meeting that is organized to solve problems and enable coordination will inevitably lead to the development of personal relationships between participants. Thus, relationship quality is – in a positive or negative way – influenced by all communication and interaction in a project, not only by specific partnering activities.

Finally, there are some general social norms that are associated with positive relationships, trust and collaboration. Important in all types of exchange relationships is the norm of reciprocity (Gouldner, 1960; Berg et al., 1995). This norm is reflected in perceptions of fairness, in a preference for equal shares, fair processes and respectful treatment (Folger and Cropanzano, 1998).

METHODOLOGY

The study reported in this paper is a part of a larger research project focusing on collaborative contracting as an emerging practice. The project involves several case studies and the criteria for selection are that consultants and sub-contractors should be involved in the collaboration and that there are ambitions for closer collaboration between a wider range of participants. Most cases that meet these criteria have a contract sum of more than 10MEUR and a complex technology or social setting.

The project wss a new hospital building. Interviews were carried out during late stages of construction and shortly after the completion of the project with the client project manager, the user representative, the design manager, the building contractor, three architects, the mechanical engineer, one subcontractor and the partnering facilitator. Interviews lasted between one and three hours. Detailed notes were taken and transcribed within a day or two and the transcription was subsequently sent to the respondents for checking. The interviews were semi-structured and the interview guideline comprised questions about project history and development, partnering experience of the company and individual, project processes and organization, perceived differences to general practice, and personal views and experiences relating to collaboration and knowledge integration. With the client and the building contractor follow-up interviews were made, and with several other respondents comments to

transcriptions were clarified by phone conversations. The case study focused primarily on the design stage, where complexity and novelty of processes are highest.

THE HOSPITAL PROJECT

Background and choice of partnering

The new hospital building comprises with wards for various specialties, surgery and some additional functions. The building is 20.000 m2 with a total cost of around 45 MEUR. The client, a public county council, had the goal to achieve low total operating costs over the lifecycle of the building (life-cycle costs, or LCC). This included construction costs, costs for technical operation and maintenance of the building (LCC Building) and costs for hospital core business operations (LCC Hospital). The client project manager was convinced that by increasing costs for pre-design and design and improving the quality and flexibility of the building, both LCC Building and LCC Hospital would decrease significantly, thus saving very much money for the county council in a longer perspective.

To address LCC Hospital, a conceptual design contest for architects was organized. The chosen design envisaged single rooms operated by small care teams. Larger care units are less costly if construction and direct operating costs are considered, but were turned down because of higher risk for infections that delay patient recovery. In the next step, technical consultants were procured based on their competence, also with a special focus on LCC, and the design team developed design to achieve the lowest total operating costs. This way, low costs for heating, lighting, ventilation and cooling were not achieved by reducing window area, since patients recover more quickly in rooms with a view, but by better windows and by using daylight to reduce needs for lighting. Possible future changes in hospital operations were also analysed in order to arrive at an optimal level of flexibility and generality.

Another important project goal was that when the building would be completed, it should have up to date technology and be suited to the user requirement at the time of moving in. The process from start to completion for this type of building takes at the very least five years and often much longer. Using traditional project delivery models, requirements guiding design are formulated early in the process. Then, design is carried out and drawings and specifications form the basis of a procurement contest, resulting in a fixed price contract. Change orders after the contract is signed are expensive. In medical care, however, technological development is rapid and affects facilities in many ways. Political decisions may also change requirements from one day to another.

In this project, the client chose a partnering approach for the construction phase for two reasons: to include construction and cost estimation competence in the LCC analysis, and to introduce more flexibility and enable decisions to be taken later in the process.

Partner selection and contracts

Before commencing the detailed design, contractors were procured, also in quality-based selection. The group of companies involved in the project comprised a mixture of small and large actors. The architect, structural engineer and mechanical engineer were leading consultancy firms. The building contractor was one of the largest in Sweden, while several (nominated) sub-contractors were local firms. Very few of the individuals involved had participated in partnering projects before, although the larger companies had previous

experience of this kind of projects. The building contractor, however, had partnering competence in house, as well as a system for managing partnering projects.

Each consultant had a cost-reimbursable contract with a guaranteed maximum price for their work during the detailed design and construction phases. For the contractors, a target cost arrangement with a gainshare/painshare mechanism was set up, and the consultants would also receive a bonus if the construction cost ended up below the target cost. On top of this, there was a bonus system based on the client's evaluation of the collaboration (partners evaluated as a group) and their performance in reaching quality goals and doing LCC analyses (partners evaluated individually).

Works contracts were used for the contractors. This was very important to the client, who was convinced that the contractor would get a too strong influence in a design-build environment, and that it then would be difficult to prioritize long term performance and quality before construction costs.

Partnering model and processes

After the contractors had been procured, a start-up partnering workshop was held. About 30 people representing the partners participated: the client, the architect, the structural engineer, the electrical engineer, the mechanical engineer, the building contractor, the ventilation contractor, the piping and plumbing contractor and the electrical contractor. A partnering facilitator from the building contractor led the workshop. Joint goals were formulated in a partnering declaration and an action plan for how to reach each goal was developed.

Every 6 months, there were follow-up partnering workshops. Before each one of these, a questionnaire was sent out to all participants, asking them how they perceived the working climate. The results from the questionnaires were discussed at the workshops. 4-5 times during the project, consultants and contractors were evaluated by the client as a basis for judging compliance with the soft bonus criteria. These evaluations led to discussions about problems and needs and possibilities for improvement.

The design process

There was no joint project office at the hospital and the consultants worked at their respective offices. The project was not considered large enough to require the continuous presence of many consultants, and much of the design was done before the contractors were procured.

The client appointed an external consultant to manage the detailed design process. He had no previous experience from partnering projects, but had managed projects with high integration between design and construction in industrial settings. When deciding the structure of meetings and participants, he used a model from one of these. Although the explicit partnering system was supplied and administered by the building contractor, their partnering facilitator was not involved in planning such other project activities. Design meetings involved both consultants and contractors, and there was a whole day meeting every fourth meetings were organized to enable both week. The meetings combined large and small group to enable both overview and specialized discussions. The first two hours there was a design meeting where the whole group, about 20 people, was present. Then, the participants split up in three technical subgroups: building, mechanical (heating, ventilation, sanitation) and electricity. These included the consultant, the contractor and one client "quality leader", who also led the meetings. At the end of the day, the whole group assembled again. The technical

subgroups, the contractor group and the consultant group also met separately in between, on other Tuesdays.

The design manager was concerned that all meetings should be meaningful for all parties. Also, contractors are not used to contribute to design and he considered "bringing the contractors' knowledge to the drawing table" to be one of the most important challenges in the project. Splitting up the group, then, was a way both to reduce the time spent passively listening to other parties' problems and to create an environment where also sub-contractors would feel compelled to actively contribute to decision-making. Also important for meeting style was that the client project manager expressed a strong belief that decisions should be reached in consensus in order to increase initiative and commitment among participants. This implied that he very seldom intervened to make explicit decisions.

At the beginning of each design meeting, half an hour was spent on discussing two of the 17 partnering goals defined in partnering declaration and further developed in the action plan. Some of the goals concerned attitudes and behaviour (for example: putting the project first, sharing competence, joint responsibility for problem-solving) and others were more technical (work with LCC analyses, low energy consumption, a good environment for the patients, high flexibility, etc). Before each meeting, all participants had been instructed to prepare and think about the implications and meanings of a specific goal, and at the start of the meeting two of them were randomly selected to present their thoughts. According to interviewees, many participants initially considered these general discussions as being a waste of time, but successively discovered that they were of great help in preventing disagreements. The parties could refer to the mutual goals when they felt that somebody was acting too much in their own self-interest. Especially patient-related goals were influential.

Apart from the new structure and action plan discussions, the meeting agenda was rather traditional. Thus, building issues were always discussed before issues related to the building services systems. The design manager and client quality leaders had also decided the agenda of the technical group meetings beforehand. As a consequence, other participants had only a limited influence on which aspects should be brought up. One reason for controlling the meeting agenda was that the design manager saw a risk that some participants (mainly consultants) became to dominant while others (sub-contractors) would remain passive. The design manager stressed that the parties had to be equally strong to achieve a good collaboration, and it was therefore necessary to encourage some and hold back others.

Experiences and relational aspects

The project was perceived as successful by all participants, and especially the client and the architect were pleased. All parties expressed that the relational climate had been much better than in a traditional project and that the partnering relationship in combination with the cost transparency has allowed for more informed decisions. Quality, investment costs and maintenance cost have all been considered and more alternative solutions investigated. Due to the advanced LCC assessments, the estimated energy consumption is among the lowest in Sweden for this type of building. Several examples of over-design, where consultants play safe and choose excessively high quality and expensive design, have been eliminated. Many changes improving the usability of the building have been made during the construction process, some of them only months before completion. The quality of details is perceived as significantly higher than normal for hospital facilities. The target cost has only been adjusted marginally, and there was a gain to share since the costs were about 5% below the target cost.

However, despite that the participants generally saw the partnering model as preferable to traditional contracting there were also criticism and disappointment with certain aspects. The most problematic part, then, was the early phase with the joint design process. The design team had been working closely during the design process, and had made joint study visits to other hospitals. After the contract had been signed, the contractors had to be introduced to the project and relationships between the new partners established. The client representatives and design consultants thought that the building contractor behaved in a rather traditional way in the beginning, but already during the start-up workshop they saw a change in attitude. The role of the contractors in the design process was to identify and propose more cost-efficient solutions. However, the focus was on lifecycle costs and not construction costs. This was a new perspective for most contractors which also required some mathematical skills to understand. In the beginning, the building contractor often suggested cheaper alternatives of lower quality. However, as the proposals repeatedly met resistance from others, often with reference to the partnering goals and action plan, the contractor managers began to change focus. At the end of the project, the other participants perceived the contractor as a committed to delivering value for money for the hospital and the contractor employees were highly enthusiastic about this role.

Thus, attitude problems relating to costs and quality were not so important and did not take long time to overcome. However, the building contractors were strongly focused on the construction phase, and early in the project they suggested that it would be better to start construction earlier than the client had initially planned. Thereby, said the contractors, there would be more time in the important and usually messy later stages, an argument that the client accepted. This decision, however, had significant impact on the design process, since the design team had to start with the foundation details instead of systematically reviewing the design together with the contractors. As a result, the design process became disorganized and significantly delayed.

There was also some confusion regarding the relative influence of various partners in the design process. Due to the high energy requirements, the mechanical engineer had a more central role than normal. He was in charge of the LCC calculations for the heating, ventilation, lighting and AC systems, giving him a strong position also in traditional contractor domains of cost estimation. However, he found the participative but still hierarchical design process frustrating, since there was seldom time to resolve the issues that he perceived as most pressing. Also, he did not intervene with other parties' work as much as he would have from a purely technical point of view, since he thought that it would have threatened relationships.

The client's belief in consensus engendered mixed views in the partner group. This strategy was appreciated, but it also led to confusion as to when a decision was actually made. As the client did not make explicit decisions and the meeting minutes just said that questions were discussed, not decided, the same question tended to come up again and again. Despite that one of the partnering goals was to establish a clear decision process, this problem persisted more or less during the whole project.

An important purpose of the partnering questionnaires and follow-up workshops was to assess performance, especially in terms of working climate, to improve and fine-tune processes. However, these measures were only partially successful in this respect. Workshop participants were too many and questions too general to efficiently address more specific issues. Also, follow-up workshops were not held often enough to address problems when

they arose. The client found the bonus discussions to be more useful, much because they felt that is was easier to bring up problems in partner performance when there was a formal system. Still, the system was one-sided, since there was no similar opportunity for the others to bring up problems in the client organization.

DISCUSSION AND CONCLUSIONS

The focus of this paper is how partnering processes interact with other project processes in partnering projects, and how project managers approach this new challenge. The partnering model chosen in the hospital project with workshops, questionnaires for assessing performance, target cost contracts and quality bonuses was quite typical for recent ambitious Swedish partnering projects described by Andersson and Johansson (2008). The ambitions regarding knowledge integration were however higher due to a focus on life-cycle costs. The project was considered to be very successful by most all participants.

So which were the effects of the formal partnering system? The workshops, especially the start-up workshop, were seen as being of considerable importance for building relations and commitment in early stages. Further, that the action plan for reaching partnering goals was discussed in the beginning of every design meeting contributed to the establishment of shared interpretations of joint project goals and to the parties understanding of each other's situation (Mahama, 2006). The bonus system had secondary effects in providing a context for discussing improvement needs which were probably more important than the direct financial incentives.

However, explicit partnering processes only accounted for a smaller part of the total project communication, and the influence of the toolbox and partnering facilitator on core project processes was small. In deciding the organization of design meetings the client management team used their own personal experiences and beliefs regarding which prerequisites are essential for successful collaboration. A primary concern, then, was to ensure active participation and commitment from all parties by smaller groups, active support and consensus decisions. Thus, norms of equality and reciprocity gained strong influence on decisions about relationship design. To a great extent, project management succeeded in motivating participants to collaborate towards shared project goals. When it came to organizing knowledge integration experiences were more mixed. This aspect seemed to be less in focus; for example the decision to start construction activities earlier than previewed was made without considering the likely impact on design collaboration and on the schedule for design document delivery. There was some ambiguity in this, since the client wanted to give the design team a stronger position than it would have had in a design-build contract but still tended to prioritize contractor involvement and unreflectively accept contractor propositions. One way of understanding this is that the relationships to the design team were already established, while the contractors were new to the project and their commitment needed to be ensured. Further, following rules of reciprocity, this entitled the client to turn down some other, clearly unwanted proposals from the contractor. In effect, that the contractor's attitude changed over time might be partly attributed to this early client concession, although it may also be interpreted as a preoccupation with traditional problems at the expense of solving new ones.

Although committed project managers and members are essential to successful collaboration, so is an ability to make tradeoffs between relational and operational goals and challenge

expectations that may arise when a partnering label is put on a project. Especially in planning early phases of a project, before relationships are established, it is important to consider how relationship development can be reconciled with both knowledge integration and disagreement. Formal partnering tools and processes are too general to be truly helpful in this respect, and have to be adapted and complemented to a specific context. Professional behavioural knowledge may be needed to achieve a more consistent and adequate relationship management, combining formal partnering processes and core project processes.

Abstract
Dutch municipalities are faced with an ageing private housing stock, of which parts show a diversity of quality backlogs, including their energy quality. Dutch municipalities are in the process of developing a combination of communicative and economic policy instruments to seduce private homeowners to invest in their dwellings' quality. Homeowners' willingness and capability to invest, and their level of organization play key roles here. This paper investigates, if the applied policy instruments to improve the quality of private housing stock in three Dutch municipalities are effective as well as cost-effective for both municipal governments and private homeowners. First results indicate that municipalities are marketing quality improvements to private homeowners by organizations that support and communicate with homeowners, but yet it seems without the hoped-for large-scale improvements. A multi-level policy approach seems to be needed for private dwelling improvement to become successful. This implies an improved playing field shaped by the national government, in which municipalities can make use of their local long-term oriented economic policy instruments more efficiently, such as property taxes and rebates on such taxes for (e.g. energy) quality improvements.

Keywords: Dutch municipal policy instruments; quality improvement of private housing stock.

INTRODUCTION

In 2008, the Dutch housing stock consisted of around 7 million dwellings (CBS, 2011). More than two-thirds (68%) of the Dutch housing stock is privately owned, and almost one-third is owned by housing associations (ABF Research - SysWov, 2010): the owner-occupied share is 57,2%, whereas the private rental share is 10,8%. The social rental share is even diminishing due social rented property, which is sold-off by housing associations. The percentage of owner-occupied housing in the Netherlands and other European countries is growing, as a result of European policies stimulating homeownership.

The private Dutch housing stock is aging and problem parts can be found in the pre-war owner-occupied single family houses, in pre-war private-rented single family houses and in pre-war and early post-war private rented and owner occupied multiple-family dwellings (Meijer and Thomsen, 2006). In addition, there is a large energy saving potential in private housing stock, especially in dwellings built before 1985, where this potential is the largest (Menkveld et al., 2005). Apart from many other factors, such as the spatial quality of a location, housing quality seems to be dependent on the kind of tenure (cf. Visscher and Meijer, 2008; Meijer and Thomsen, 2006).

The national 'Qualitative Housing Survey' KWR (Kwalitatieve Woning Registratie) was a large-scale periodical survey on the 'overall' quality (including its building-, energy- and housing-technical quality) of the Dutch housing stock and its living environments. A diversity of KWR measurements indicated, the quality of this stock has strongly improved since 1990, especially in the pre-war part of the housing stock and in particular in private (and social) rental dwellings (cf. Companen, 2007). The KWR survey was succeeded by the national WoON (WoonOnderzoek Nederland), which until so far, and in terms of quality, has mainly measured the energy performance levels of dwellings in WoON Energie 2006 and WoON Energie 2009.

In the Netherlands, 'More with less' (Meer met minder), the national energy saving plan (2007) and covenant (2008) for the existing building stock were introduced. The plan aims to build up a 'structural market for energy saving' by removing investment- and other barriers for owner-occupiers, private landlords, and others (cf. Tambach et al., 2010). Lessons learned from pilots, workshops, experience and key- and expert-interviews have resulted in a More with less report on approaches, likely to be successful for building-related energy saving in the existing housing stock (Boerbooms et al., 2010). Hypotheses are founded on findings in literature on behavioural economics, focusing on people and their decisions being sensitive to irrational influences of their direct environment, their emotions and short-sightedness (ibid., p.16).

The Dutch municipal government as problem owner

Enforcement possibilities and sanctions (fines) as integrative part of Dutch energy certification regulation are still missing, the current Dutch Building Decree (2003) does not contain a minimum energy performance standard for existing dwellings, and Dutch dwellings are mostly no municipal property (cf. Tambach et al., 2010; Tambach, 2009). This playing field makes it difficult for municipal authorities to improve the energy performance of housing stock, also with regard to international agreements, such as the Kyoto Protocol (1997), entering into force on 16 February 2005, setting binding targets for 37 industrialized countries and the European community for reducing greenhouse gas (GHG) emissions. In addition, municipalities are faced with a decline in the social and economical value and the liveability of neighbourhoods, where maintenance backlogs of private homes become visible.

Despite the fact that a rising number of municipalities is formulating high-ambitions local climate policies (Tambach, 2009), the improvement of private housing stock is seldom to be found on the municipal political agenda due to missing insight into this stock's quality (Goudriaan and Ten Napel, 2004).

In this research, and with regard to the above playing field, the Dutch municipal government, is regarded as 'problem owner', trying to realize quality improvements in an aging private housing stock. In-depth insight of Dutch municipalities in the local housing stock's overall

condition is diminishing and is limited to ad-hoc quality registrations in (long-term) maintenance reports, and in reports, giving tailored advice on energy saving measures for a certain property ('Maatwerkadviezen Energiebesparing'). An Energy Performance Certificate (EPC) is also included in such a tailored energy-saving retrofit report (abbreviated as tailored retrofit report or advice, hereafter). An EPC is related to Directive 2002/91/EC, also known as the Energy Performance of Buildings Directive (EPBD, 2003), which intends to promote the improvement of the energy performance of buildings within the European Community.

The signatory parties of the Climate Agreement, the VNG (the Association of Dutch Municipalities) and several ministries (VNG et al., 2007), promote that the national government and municipalities realise considerable energy saving in the built environment. One of the ambitions is a reduction of dwelling's and building's energy consumption with more than 50% by 2020 (paragraph 6, article 10/1.). Signatory parties also agreed to promote, in dialogue with More with less programme parties, that municipalities actively contribute to the execution of the programme by the organization of 'target-group-oriented' (cf. Gladwell, 2002; Godin, 2002 and Ariely, 2009) communication and information campaigns, and other local stimulus to organize 'to let private owners and companies take energy saving measures for their property'.

Homeowners' barriers to dwelling improvement

Homeowners are responsible for the maintenance of their dwellings and Dutch owner-occupiers generally make more investments in the maintenance of their dwellings than any other owner category. Despite this fact, there remain financial, organizational and other constraints to work away maintenance backlogs, also encountered in private rental and owner-occupied, pre-war and early post-war apartments, mainly situated in (greater) urban areas, combined with mostly individually sold off flats (Meijer and Thomsen; 2006).

Case study research

This case study research makes part of a PhD project, focusing on municipal policy instruments for quality improvement of private housing stock, conducted in the framework of the research project 'Quality impulse for private housing stock' (see acknowledgements). The research question of this paper is:

Have the municipal policy instruments that were applied in three different urban areas (cases) been effective and cost-effective for both the municipal government and homeowners to improve the quality of private housing stock?

This case study research included literature and documentary studies, and interviews with municipal officials, aldermen, management board members of homeowners' associations (HOAs), owner-occupiers and private landlords. The cases were selected according to the severeness of quality backlogs of private dwellings in three urban areas (neighbourhoods or districts) and case studies were conducted and analysed by making use of literature on policy instruments, behavioural economics and marketing.

First, the role, policy and instruments of the Dutch municipal government are described. Second, municipal policy approaches and instruments in three of seven conducted case studies will be elaborated in this paper as well as the effectiveness and cost-effectiveness of the instruments. Third, the findings will be discussed. Fourth, brief conclusions will be drawn from this case study research.

THE DUTCH MUNICIPAL GOVERNMENT

The Dutch national Housing Act (1901), revised in 1991 and 2007, refers to the national Building Decree (2003) which contains technical building regulations for both new and existing buildings and for various building functions. It also includes minimum requirements in the areas of safety, health, usability, energy efficiency and the environment. Based upon the Housing Act, Dutch municipal authorities have to inspect the quality of the housing stock, which must not decrease below the minimum level according to quality requirements for existing dwellings of the Building Decree.

In the first Dutch National Environmental Policy Plan (NEPP, 1989) and first white paper on energy saving (1990), municipalities were given a role as co-executor of energy policy, linked to sustainable development. Dutch municipal authorities are the tier of government, which stands closest to the citizen. They possess an important informative role to point out the EPC to citizens (Agentschap NL, 2010). They can advise house-buyers to ask for an EPC to gain insight in a dwelling's energy quality or advise homeowners to think about energy efficiency measures at the moment of dwelling improvement and guide them to a diversity of subsidy options, for example the national subsidy for a tailored retrofit advice ('Subsidie Maatwerkadvies Energiebesparing'), which ran from 1 July 2009 till the budget stopped at the end of 2010.

Local authorities in the Netherlands have relatively limited own tax revenues and depend largely on the national government for their resources: about half of this national funding takes the form of a specific transfer, or ear-marked funding - the rest is in the form of a Municipal Fund (an open-budget system with a budget ceiling, with its distribution depending on criteria like the number of inhabitants) (Coenen and Menkveld, 2002). But compared to other European countries like Sweden, Belgium and the United Kingdom, the Netherlands has the lowest revenues from own local taxes (cf. Koopmans et al., 2005). For Dutch municipalities, OZB ('onroerendezaakbelasting') property taxes are an important revenue source, and they gain more than 90% of their fiscal revenues from OZB taxes (ibid.).

Municipal policies and instruments

Municipal authorities can force, seduce and/or persuade homeowners to improve the quality of their dwelling by sticks, carrots and/or sermons (Thomsen and Van der Flier, 2008; Bemelmans-Videc et al., 2003). This research distinguishes three types of policy instruments, municipal authorities can make use of, based on a distinction by Itard and Meijer (2008), Ürge-Vorsatz et al., (2007), and Derksen and Schaap (2007), which are: (1) Regulatory instruments, (2) Economic instruments, and (3) Communicative instruments.

For private dwelling improvement, local authorities often combine 'carrots', such as subsidies and preferential loans with 'sermons' by communication bodies, functioning as a medium and 'extension' (cf McLuhan, 1997) of the municipality towards homeowners. Force is applied to enforce the law or protect public interest, common good, civil right or basic private concern (Thomsen and Van der Flier, 2008). Regarding property rights, owners cannot easily be forced to serve public interests or suit governmental policies (ibid.). Thomsen and Van der Flier (2008) state that in today's western democracies, a shift from public force to civil responsibility can be noticed, and force (the stick) only to be applied if other measures fail (ibid.). Therefore, this research focuses on economic and communicative policy instruments, which are also applied in the cases.

Economic instruments

Seduction (the carrot) is an important but often expensive measure (Thomsen and Van der Flier, 2008; Bemelmans-Videc et al., 2003). Examples are subsidies, low-interest loans, fiscal instruments, market-based instruments such as energy performance contracting, typically by an ESCO etc. (Ürge-Vorsatz et al., 2007).

Economic instruments providing incentives for energy efficiency improvements are needed to promote energy efficiency through market-led measures and price signals: subsidies or preferential loans could be combined with EPCs (Klinkenberg and Sunikka, 2006). The improvement by one or two certificate levels could be a prerequisite for a financial incentive (ibid.). To be effective, the municipal government binds obligatory requirements for homeowners to carrots, such as organisational and/or managerial criteria to homeowners' associations (HOAs) etc. (cf. Tambach, 2009).

Subsidies and low-interest loans

Subsidies are applied to trigger investments in private dwelling improvement. In the past years, municipal governments applied subsidies for dwelling improvement, but without a long-term effect on the prolonging of dwellings' life span in terms of maintaining and safeguarding dwellings' quality (cf. Tambach, 2009).

For urban regeneration projects, local authorities can work together with SVn (stichting Stimuleringsfonds Volkshuisvesting Nederlandse Gemeenten), a corporation, functioning as incentive fund for municipalities. As low interest loans are seen as subsidy in Dutch jurisdiction, local authorities have to formulate 'low-interest-loan-regulation'.

Local authorities pay an amount of money in a revolving fund, which is managed by SVn. From this fund, they are able to provide low-interest (also called 'preferential') loans to support homeowners in financing home-improvements. Homeowners can spread repayment costs over a period of around 20 years (loan term) to have a relatively low increase in housing costs.

SVn controls homeowners on their ability to pay the improvements on credit, and advises municipalities upon this matter. In addition, some municipalities actively conduct first checks. By lending money for interest rates, (in average four percentage points) lower than market rates, municipalities lose interest and by issuing loans, they participate as a kind of societal entrepreneur emphatic in risk bearing investments (see also KEI, 2007).

Fiscal incentives

The use of subsidies grew fast in the sixties and seventies of the last century but was cut back in the last decades because of rising costs and political changes (Thomsen and Van der Flier, 2008). Over the last years, fiscal incentives are gaining attention as being less expensive and more effective (ibid.; Sunikka 2006).

The Organisation for Economic Co-Operation and Development (OECD, 2006) concluded that environmental taxes contribute effectively to environmental policy. The CPB Netherlands Bureau for Economic Policy Analysis and Ecofys also concluded that the energy tax contributes effectively to environmental policy, and without these taxes, the energy use would have been twice as large in Europe. The Netherlands is a leading European country with regard to the share of green taxes in the total amount of national tax revenues: revenues from green taxes increased from van € 6 milliard in 1990 to € 20 milliard in 2008, and make up 14% of the total share of the Dutch tax incomes since 1995 (Ter Haar, 2009). Calculations by CE, an independent research and consultancy organization, specialised in the development of innovative solutions to environmental problems, show that tax-increases on petrol, diesel and LPG are effective instruments to lower CO_2-emissies in traffic (ibid.).

Fiscal rewards or tax rebates for energy efficiency investments, combined with fiscal penalties for maintaining unsustainable situations could be an essential instrument to influence dwelling owners. Not only on national scale, but also on local scale as OZB tax relief for homeowners applying energy efficiency measures (Tambach and Meijer, 2009). Municipalities can levy OZB tax from owners and tenants of real estate (but not from tenants that rent a house). The basis for levying is the value in the economic market, which is determined by surveyors on the basis of the 'Wet Waardering Onroerende Zaken' (WOZ) - the 'Immovable Property Tax Act'- and every municipality determines OZB tax heights themselves. The Dutch national government (for the notional rental value for owners-occupiers and the income tax) and the district water boards ('waterschappen') make use of the WOZ value to determine their taxes, too (Koopmans et al., 2005).

Households and other minor consumers, pay much more per ton CO_2 than consumers in any other sector (major consumers make part of the emission-trading-system) (cf. Ter Haar, 2009). In addition, the current OZB-system does not reward owner-occupiers for their investments in energy efficiency measures – on the contrary: the more they invest in such measures, the higher the OZB-tax. This is in conflict with the many local climate policy aims to lower housing costs for citizens by the promotion of energy saving measures. So why not reward owner-occupiers for investments in energy efficiency measures for their homes?

Apart from this, and according to Ariely (2009), the incentive of offering s.th. 'for free' (e.g. a tailored retrofit advice) is a source of emotional and irrational excitement. Starting an action by offering s.th. for free seems to be effective (Clean Energy Group and Smart Power, 2009) and more effective than with a rebate (Boerbooms et al., 2010).

Communicative instruments

Communicative instruments play an important instrument for knowledge transfer by local authorities. For example municipalities need to communicate information on a dwelling's quality well to home-buyers, and communicate economic instruments well to homeowners. Other examples are (environmental) education, support, organization and voluntary action etc. (cf. Ürge-Vorsatz et al., 2007).

Where other policy instruments fail, persuasion - the sermon - (Bemelmans-Videc et al., 2003) can be an indispensible instrument for municipalities to influence civil behaviour, particularly with regard to sustainability. Examples in this sense can be appealing for sense of responsibility and/or self-interest, like owners' responsibility for the environment and climate change and the sustainability of interventions (cf. Thomsen and Van der Flier, 2008).

The EPC does not seem to be of decisive economical value in especially the private housing market yet (Tambach et al., 2010). In this respect, persuasion by the local and/or national government can be supportive in persuading homeowners, –buyers and brokers to understand the value of an EPC - and of energy saving measures that follow from it - for their home, translated most commonly not only in a lower energy bill but also in more comfort.

According to Godin (2002), the old marketing rules such as advertisements don't work so well anymore, because people aren't likely to have easily solved problems, consumers are hard to reach, and satisfied consumers are less likely to tell their friends. In addition, he stresses to differentiate customers, to find the group that's most profitable and the group that's most likely to sneeze, and to ignore the rest.

CASESTUDIES IN THREE MUNICIPALITIES

The Hague: case in Rustenburg-Oostbroek (district)

Policy approach and instruments

Rustenburg-Oostbroek is a district of The Hague with a weak position in the housing market, and dwellings with energy efficiency deficits. With this pilot, the municipality intends to develop a marketing strategy to market energy efficiency measures via a tailored retrofit advice for homeowners. A service organisation, named 'Serviceorganisatie Rustenburg-Oostbroek' supports homeowners with all aspects, entailing dwelling improvement. It developed three instruments in cooperation with the municipality, which are:

- A free tailored retrofit advice and/or extra subsidy upon investment costs, after application of all other available subsidies applied for seven staircase entrance flats, selected out of thirteen due to subsidy limits. EPCs show one E-, 5F- and 3G-labels with an average energy performance, indicated by an Energie-Index (EI) of 2.67 (F-label).
- A free tailored retrofit advice at the moment of designing a roof superstructure was applied for six selected owner-occupiers.
- A free 'Groen-MOP' (long-range maintenance plan including energy-saving measures) for large (and combined) HOAs. The service organisation selected one large HOA, combined by six smaller HOAs for experimenting with a Groen MOP.

A personal approach of and communication with owner-occupiers by the advisor at the moment of conducting a tailored advice at people's home, and of the project leader is applied. The steps, followed to seduce owner-occupiers to finance in and take energy efficiency measures are depicted in Figure 1.

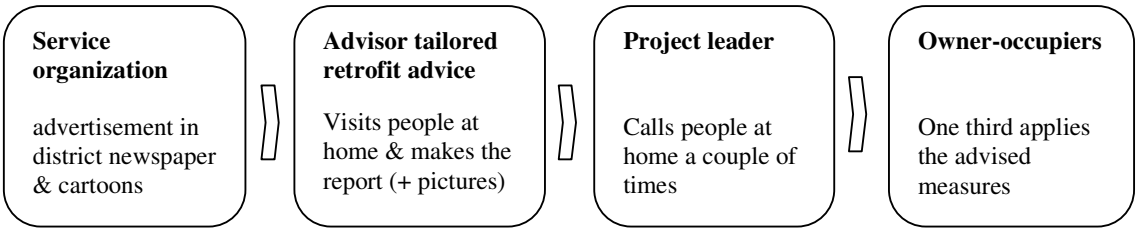

Figure 1: *Marketing strategy followed by the service organisation and the advisor.*

Effectiveness and cost-effectiveness

Thirteen owner-occupiers reacted on the advertisement in the district-newspaper to obtain a free tailored retrofit advice and extra subsidy for energy efficiency investments. Three of in total nine owner-occupiers finally applied the energy efficiency measures, advised by the tailored retrofit report. Half of six selected owner-occupiers, engaged in drawing up a design for a superstructure, integrated double glazing in the tender for the (isolated) superstructure (Serviceorganisatie, 2010).

The service organisation's subsidy did not make part of the tailored reports, the reaction and application time for subsidy was short and taking at least two measures in one time may have been too high a barrier for the owners. The application of renewable energy technologies using solar energy was stimulated neither by the subsidy nor explicitly by the reports: only two of nine reports promoted a solar boiler, respectively solar panels. The municipal government had no costs for both the pilot project and subsidy, granted by the service organisation. The costs of € 47.860 for the pilot project were covered by a national IPSV

('Innovatie Programma Stedelijke Vernieuwing') grant for innovative urban regeneration projects (Municipality of The Hague, 2010). The highest costs consist of personnel, project costs and the organization of the service organisation, followed by direct subsidies: intensive support of homeowners is both labour-intensive and expensive to make subsidy-regulation become successful.

Dordrecht: case in the Dichterskwartier (neighbourhood)

Policy approach and instruments

The Dichterskwartier is a neighbourhood with a weak housing market position, with dwellings suffering from maintenance and foundation backlogs, and energy efficiency deficits. The municipality started with gaining a social basis for neighbourhood regeneration plans by formulating a common approach with the residents. The approach entails three steps (Municipality of Dordrecht, 2010a):

1. Making homeowners aware of their own responsibility for their dwelling's quality,
2. Strengthening their organizational capacity, and
3. Realizing their investment capacity.

To support homeowners with dwelling improvement, the municipality has contracted 'Bouwadviesbureau De Groene Werf (dGW)', which has developed three 'improvement packages' with homeowners, taking a central place in the approach as they are seen as principals by the municipality. The lengthening of the dwelling's lifespan by 25 years by regular maintenance, made part of the municipal contracting criteria. Packages can be combined, but the intention is that the package for improving the energy quality must be combined with the package for working away construction backlogs and for major maintenance (Municipality of Dordrecht, 2010b). In addition a free report on necessary home-maintenance is provided to homeowners, and the municipality will offer a 2% interest loan (height and term package-dependent) (Municipality of Dordrecht, 2011).

Effectiveness and cost-effectiveness

The municipality expects, 75% of 141 property owners will be willing and considered for a subsidy and preferential loan. 40 to 50 homeowners, who are supported by dGW have indicated they are willing to think about dwelling improvement. Owner-occupiers are interested in a free maintenance report, and a few have started to ask for offers of contractors. However, barriers can be found in the time the municipality needs to prepare and decide on a (temporary) subsidy- and preferential-loan-regulation, intended to run till 2015 or till the subsidy ceiling is reached. A bottleneck to the project is the ending of the national subsidy for a tailored retrofit advice, and an uptake of measures on the level of an entire housing complex.

The breakdown of municipal costs for dwelling improvement (€ 2.4 million in total) (Municipality of Dordrecht, 2010a) is as follows:

- Payment SVn for preferential loan 44,6%
- Subsidies for improvement packages 30,6%
- Process costs 21,0%
- Municipal assessment of subsidy and loan requests 3,8%

Municipal costs are covered by € 1,5 million of so-called municipal strategic investments, € 0,9 million by an impulse regulation based upon the 'Besluit Impulsbudget Stedelijke Vernieuwing 2008-2009' (ibid.). But there also seem to be certain riscs, for example a worsening of the foundation condition of the dwellings.

Schiedam: case in the Newtonbuurt (neighbourhood)

Policy approach and instruments

The Newtonbuurt is a neighbourhood with a weak housing market position, with dwellings having mainly maintenance backlogs, energy efficiency deficits and some houses with foundation problems. The policy approach is based on total control of the execution of stimulated improvement measures to work away maintenance backlogs and by oral communication with homeowners. The improvement by taking energy efficiency measures is now explicitly integrated in this approach.

An interview with a civil servant, working on private dwelling improvement, delivered the following municipal approach: First, agreements on execution times with homeowners are written down in notes and letters. Second, owners are controlled by home-visits, oral communication and making new agreements - if necessary. Third, and if the first two steps haven't been effective, owners receive letters, home-visits and oral communication. The fourth step, which needs to be avoided, is enforcement, but also here, oral communication and a personal approach is intensively applied.

Other instruments applied are a free technical report of the dwellings for homeowners, a free tailored retrofit report, and free advice and support by the 'Servicepunt Woningverbetering'. In addition, homeowners can request one preferential loan (with an interest rebate of 5% and a minimum interest rate of 1,5%, but with different loan heights and terms) for financing the working away of maintenance backlogs, to improve the dwelling's foundation and energy efficiency. The municipality cooperates with the national government and with local brokers to finance the free tailored advice.

Effectiveness and cost-effectiveness

The effects if this case cannot be measured yet, but they can be compared to the approach, which will also be followed for the Newtonbuurt: Since the start of the municipal private dwelling improvement project in 2005, 1.400 low-interest loans stemming from a revolving fund have been honoured by the municipality. In 2.800 first-phase-dwellings, maintenance backlogs have been worked away, and one on three to four dwellings have been improved with a low-interest loan, with an average investment of € 17.000.

Despite high municipal investment in preferential loans by 2014 (the end of the dwelling improvement project), municipal costs seem to be limited to the interest lost and management costs for the revolving fund at SVn. The municipality obtained national grants to solve 'bottlenecks' in urban regeneration projects (from the 'Knelpuntenpot ISV'): one grant for excessive foundation problems and another grant for higher-than-normal maintenance backlogs stadsvernieuwing, including costs for supporting homeowners.

DISCUSSION

The level of participation in the subsidy schemes by owner-occupiers, as the case studies demonstrate is low. It requires an intensive communication by service organisations to become successful. This is labour-intensive and costly. A low cost-effectiveness of capital subsidies was also reported by Ürge-Vorsatz et al. (2007) in relation to CO_2 reduction. In comparison to preferential loans stemming from revolving funds, the investment level by owner-occupiers by a subsidy is relatively low.

The case study in The Hague indicates that by applying a personal approach and by oral communication by the advisor, who spent two up to three hours at people's homes (and by the project leader that calls them hereafter) seems more effective than the written communication via the district newspaper, a more distanced and 'cold medium' (McLuhan, 1997). This is illustrated by the thirteen reactions on the newspaper-advertisement, which also show, the old marketing rules don't work so well anymore (cf. Godin, 2002). The case also indicates that applying a personal approach at the moment of designing a roof superstructure seems more effective than at a random moment by advertisement.

However, for financing the stimulation of private dwelling improvement, the municipality is largely dependent on the national government. Offering a 'free' tailored retrofit advice for homeowners was made possible in the cases in The Hague and Schiedam on the basis of the temporary national subsidy regulation, which has now stopped. Municipal subsidy regulations or agreements with brokers, building upon this national subsidy tool, are now in danger to abruptly break down – and with it the local market for energy-saving measures.

In Germany, investors in energy efficient renovations and -measures for owner-occupied or rented housing stock are supported by the 'Energieeffizient Sanieren' incentive programme of the KfW Bankengruppe, a promotional bank under the ownership of the Federal Republic and the 'Länder' (federal estates) by preferential loans and investment subsidies. This and earlier programmes can be seen as successful in terms of CO_2 reduction, job-creation and continuity (cf. Clausnitzer et al., 2010). Whereas such loans could be regarded as a hidden subsidy with a risk for free-riders, in the KfW programme owners and buyers have to prove, subsidies are only spent for the purpose of energy efficient renovation or -measures, and that such renovations, meeting EnEV-standards, are executed by specialists (Tambach et al, 2010).

By an OZB-exemption or WOZ-tax rebate (or tariff differentiation), energy efficiency investments in dwellings could be stimulated (cf. Schillemans and Blom, 2006). The current Municipal Act ('Gemeentewet') neither offers possibilities for municipalities to differentiate OZB tariffs on the basis of a dwelling's energy consumption, nor does it include an OZB tax rebate on the basis of a dwelling's energy performance as lawful exemption (ibid.). It seems that to improve these possibilities, an adjustment of the WOZ Act or Municipal Act would be necessary.

CONCLUSIONS

First results indicate, municipalities are investing in costly support-and-communication-trajectories, in marketing quality improvements and providing financial support to homeowners, but yet it seems without the hoped-for large-scale improvements. Local authorities could act more effectively, if the national (and European) policy framework conditions were set properly (cf. Collier, 1997).

Notwithstanding, organizations that support and communicate with owners may have a positive effect on investment decisions on quality improvements of private homeowners. A personal approach and oral communication seems to come to the benefit of the effectiveness of policy measures like a tailored retrofit report and to urging homeowners to execute improvement measures. As oral and written cultures alternate, we can conclude to be living in a 'new oral culture' (McLuhan, 1997). The case studies indicate, good and clear oral

communication, but also control on the application of improvement measures is a prerequisite to the success of a subsidy or preferential loan regulation.

In conclusion, it seems that marketing strategies and financial support cannot be regarded as a panacea to overcome legislative hiatuses, described in the introduction. Nevertheless, chances for municipal governments to improve the quality assurance of blocks of flats lie for example in the attachment of legally binding quality criteria to division permits for such property into apartment rights, and to the sale of such rights.

More long-term oriented financing instruments are needed to support private dwelling improvement and build up a structural local market for dwelling improvement (cf. Tambach et al., 2010), for example by property (WOZ-) tax rebates. It may also be more effective, if the national government could set up a national revolving fund to support municipalities in providing low-interest loans for home-improvement on a more permanent base, and also to spread risks.

ACKNOWLEDGEMENTS

This research was conducted in the framework of 'Quality impulse for private housing stock', a research project funded by OTB Research Institute for the Built Environment, Nicis Institute, seven participating municipalities (The Hague, Dordrecht, Enschede, Lelystad, Leeuwarden, Schiedam and Zaanstad) and the 'stichting Stimuleringsfonds Volkshuisvesting Nederlandse Gemeenten' (SVn). We would like to express our gratitude to the interviewees for their insights they provided us and which were valuable for this research.

Abstract
In the life cycle of constructions we often cope with the problem if it is economic justificated to renovate certain construction. On the market we meet growing problem of older constructions which are more and more neglected and unkept. This is the consequence of high number of new apartments and other constructions. General crisis has also an influence on negligence and has forced owners of constructions to economize and consequently at negligence of older constructions what brings to diladaptation. This will also happen to new constructions because owners act too less responsible or economic, therefore the reason of diladaptation is the lack of knowledge of owners. They do not know how to take care of constructions and how to maintain them regularly and when to sanitate them. By originating the damages are often connected high cost which means that the issue of preventing diladaptation is important not only from the view of security and aesthetic but also from the view of national economies and sustainable development.

Keywords: Renovation, sanitation of buildings, maintenance of buildings, physical deterioration, functional obsolescence, economic obsolescence.

INTRODUCTION

Around the world the awareness of regular maintaining and renovation objects as the right and only way for preserving the value of buildings has been expanded more and more. However there is still not enough large emphasis at the field of planning basis and modernization of building in accordance with technical development and requirements of modern user, which would ensure not only preservation but also decrease of fixed property's value. Only with maintaining we ensure following exploitational ability of buildings, where we have to execute renovations on the basis of previous assessment of the reason for damage's origin and condition of damaged objects. For each object separately the costs, risks and advantages of renovation or substitutional building have to be deliberated. Built constructions as fixed property represent an important issue of national wealth of society or country. The aim of each country is that fixed properties keep their functional ability as long

as possible, which is possible to achieve only with appropriate relationship to fixed property and good managing with them. We have more and more neglected buildings all around the world which are at the edge of destruction and on the edge of suitability of pillar construction. At that kind of buildings the owners still do not know how to decide right or is it worth to renovate that building or to build the substitutional building. Thus it will be indirectly able for the owners by the help of this model how to decide in this case. The model does not include only economic decision but also includes all the others criteria which influent on this decision. Thus we are developing multicriteria decisive model of economic justification of renovation or substitutional building. By the help of that model it will be possible to decide about economic justification of renovation or substitutional building on the basis of criteria of physical deterioration, functional obsolescence and economic obsolescence and profitability. We consider profitability at buildings of business activities while we do not consider profitability at public buildings, because profitability of that kind of buildings is indirect. Pšunder and Torkar (2006) define mentioned criteria as.

- Physical deterioration: we understand it as reducing of value, caused because of condition deterioration as consequence of use.
- Functional obsolescence: it means reducing of buildings value because of bad construction, structure or materials, which can cause reduced usefulness of fixed property.
- Economic obsolescence is reducing of fixed property's value because of factors which origin from environment. These can e changes in standardization, legislation, infrastructure or environment town plan.

Model does not deal with objects which are written in register of cultural inheritance, which means that certain architectural changes are allowed only on the basis of very well-founded reasons and on the basis of essential studies by which existing possibilities have to be checked. Basic guidance at regular maintaining and investing maintaining work on the building of cultural inheritance is keeping of genuineness – authenticy. Thus we have to renovate that kind of buildings not regarding on costs which origin during renovation.

Thus we will enter mentioned criteria: physical deterioration, functional obsolescence and economic obsolescence and profitability into real problem by the help of methods of multicriteria deciding of economic justification of economic justification or substitutional building. Real examples of saluting with multicriteria deciding have been practically different form case to case, after which the deciding methods have been developed and then launched as methods for individual categorization of deciding problem.

Thus we are developing multicriteria decisive model by which we will be able to estimate economic efficiency of renovation or substitutional building. It is the definition of time term in the buildings' life time until when it is still justificated to renovate or sanitate considering higher profitability or benefit which will be brought by substitutional building with its activity.

THEORETICAL BASIS

Many scientific fields and disciplines like philosophy, psychology, economy, mathematics and even more specified fields as decisive theory and decisive analyze have been occupied with problems of deciding (Bohanec and Rajkovič, 1995). Especially important question is how to help to the one who is taking decision to take qualitative

decision on the easiest and the most systematically organized way. Decisive situations where we estimate variants only by one characteristic are very rare. Usually we take decisions on the basis of different views on variants, and then we speak about multicriteria deciding (Bohanec and Rajkovič, 1988).

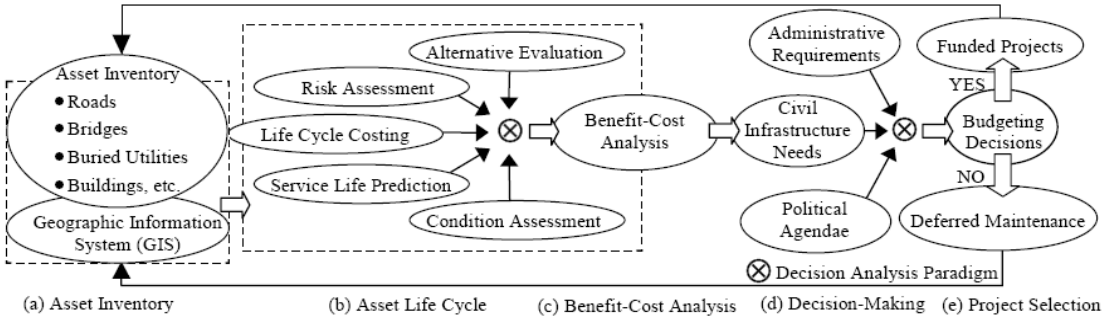
Multicriteria deciding is acknowledged and widely used method which supports decisive paradigm and is used on different fields of study (Bell et al, 2003). The origins of multicriteria deciding go back in the middle of the 20. century, when Koomans represented concept of non-dominant vector in 1951 and when Kuhn and Tucker represented optimal conditions for existence of non-dominant solutions (Pomerol and Babrba-Romero, 2000). Decisive moment for development of multicriteria deciding was in 1972 when the first international conference on multicriteria deciding was organized at Columbian university in South Carolina. Multicriteria deciding was there defined as independent scientific field (Pomerol and Babrba-Romero, 2000). Since then many scientific subscriptions have been published.

At multicriteria deciding we cope with more or less difficult decisions of choice among different variants where we are not able to create final decision of choosing the best variant without use of methodological accession.

Requirements at choice of the best product are for example the lowest price, the longest time of use, the strongest materials, the least influence on environment, the easiest use etc. We know out of practice and experiences that we can not fulfill all the requirements because usually these are opposite to each other. It is necessary to make compromise and choose one variant among many of them that suits to requirement or criteria the most. (Omladič, 2002). It is necessary to use methodology which makes possible the interactive optimization on the basis of many criteria.

Methodology of multicriteria deciding is based on the fact that there are many factor which influent on the choice of solutions, for achievement of final aim are not all the same important. Decisive problem is divided on smaller sub-problems on the first level, these can be further divided on even smaller sub-sub-problems-that means sub-problem on the first level and so on until the satisfaction of wideness and deepness of decisive scheme (Bohanec and Zupan, 2004). Thus we get decisive scheme. Wideness and deepness of decisive scheme are dependent of extensiveness and pretentiousness of problem with which we cope.

The essence of the multicriteria deciding method is that we divide the decisive problem on smaller sub-problems and treat them separately (Koprivšek and Oblak, 1997). At that method we divide decisive problem on levels (we make hierarchy) namely that on the highest level is the main aim or decisive problem and under it are criteria or sub-problems which can be set and divided on optional number of levels, hierarchically the lowest are alternative decisions or variants (Zadnik, 2000).



The basic question which appears at multicriteria deciding is how to find the appropriate profitability's function. Neuman (1953) and Chankong and Haimer (1983) cited by Rajkovič and Bohanec (1988) quote that is has to be ensured the existence and monotony of that function in accordance with measure theory. Rajkovič and Bohanec further ascertain that appropriate sentences ensure sufficiency for existence and monotony of profitability function. We call these conditions of sufficiency axioms.

Defining the profitability function by the help of axioms' checking is named axiomatic accession. Rajkovič and Bohanec (1988) quote that most of theorists acknowledge axiomatic access as the only right access at taking decisions. Practical men reproach difficulties to this access at checking of axioms and in certain situation not being practical. Therefore we often meet in praxis the direct access where person taking decision defines the function of profitability by his own judgments on the basis of his experiences and beliefs. It is possible that are direct and axiomatic access combined, which can be seen in practice. Here

we have direct identification of decisive knowledge which can be axiomatic grounded if it is possible (Rajkovič and Bohanec, 1988).

There exist many methods for support of multicriteria deciding. Individual methods are appropriate for simple decisive methods with small number of criteria and alternatives, again other are designed for the most difficult problems.

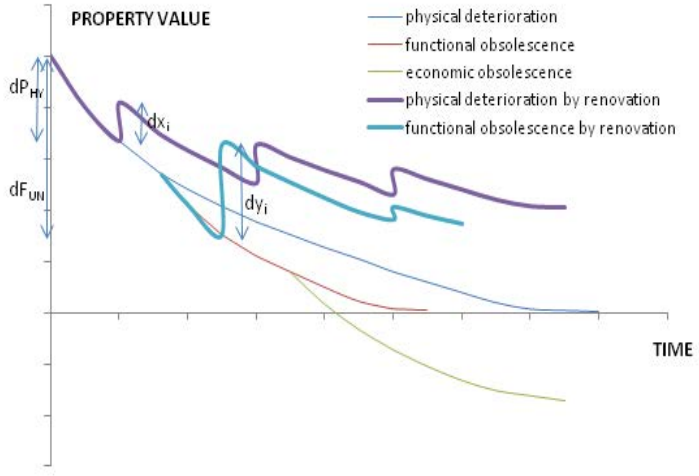
At developing of multicriteria model we resulted from model which was developed by Vaniers and co-authors (2006), which is decisive model for managing with fond of buildings.

Picture 1: Proposed framework for decision making. (Vanier and Lounis 2006)

It is the framework which was firstly designed for definition of building which needs certain interventions the most. Model is based on the relation of invested sources and profit which is got because of them and what can be defined by the help of analyze of costs and profit. In the complex of that analyze we consider momentary condition of buildings, their remaining life time, complete life costs and all potential risks connected with individual building. We have to analyze all the alternatives or variants which are available.

CONCEPT OF PROBLEM

Value of the building decreases because of deterioration's and obsolescence's kind which were listed above. As a rule first appears physical deterioration, then with time appear also functional and economic obsolescence. Thus we have formulated mathematically the value of building or fixed property after the certain time as (Kovačec, Pšunder, Soršak, 2010):



$$V(t) = V_i - dP_{HY} - dF_{UN} - dE \quad (1)$$

Where is:

V(t) – value of fixed property after the certain time;
V_i – initial value of fixed property;
dP_{HY} – extent of physical deterioration for which the value of fixed property is reduced;
dF_{UN} – extent of functional obsolescence for which the value of fixed property is reduced;
dE – extend of economic obsolescence for which the value of fixed property is reduced.

On the Picture 2 it is the chart where is represented that in the cases when we cure physical deterioration or functional obsolescence we can exceed initial value of the building or fixed property by enough high input. Regarding to cost of curing, the economic obsolescence (Pšunder, Torkar, 2007) is incurable. Here is necessary to ask a question how high can be the

inputs at the physical deterioration and functional obsolescence that it is not economic to build the substitutional building. Thus we are looking for time limit in the buildings' life time until it is justificated to renovate or sanitate buildings regarding to higher profitability which will be brought by new building and its activity.

Picture 2: Value of the building at "the recovering" of deterioration and obsolescence.

Thus we have formulated "Eq. (1)" as:

$$V(t) = V_T - \sum_{i=1}^{n}(dP_{HVi} - dx_i) - \sum_{i=1}^{n}(dF_{UNi} - dy_i) \quad (2)$$

Where is:
dxi – extend of inputs in the "recuperation" of physical deterioration;
dyi – extend of inputs in the "recuperation" of functional obsolescence.

On the basis of above equations 1 and 2 we have dervated following equation, which will be the basis for multicriteria decisive model for building's renovation described in the following chapter.

The condition of economic justification of renovation of non-economic buildings, these are public buildings, is formulated as:

$$V(t_{after\ renovation}) \geq V(t_{OS}) + C_{renovation}$$
(3)

Value of building before and after the renovation can be defined with method of comparable sales. Conditions of economic justification of business buildings' renovation, these are buildings which bring benefits, are formulated as:

$$V(t_{after\ renovation}) \geq V(t_{OS}) + C_{renovation} + benefits$$
(4)

MULTICRITERIA DECISIVE MODEL

Suggested multicriteria decisive model is based on represented theoretical points of departures in previous chapters and with combination of individual methods. It involves single criterion techniques, as well as multiple criteria techniques including, weighted mean.

At chosen multicriteria decisive model we treat one building. In the first stage we choose a building and try to study throughout the condition of it as it is represented on the Picture 3. Then we define possibilities of building's renovation in variants. After that we define renovation's costs of individual variants. Then we estimate the value of existing building and profitability of it in case of business building. We also define values of sub-criteria of existing building which are basis for further estimation. We choose the team of professionals and fixed property's estimators from build profession and who estimate and value fixed property after value international standards – MSOV (2007). Estimators and professionals estimate values of fixed property after purchase-value way which is based on the principle of Whitmer (Encyclopedia of Investments, 1990) that deliberate investigator for estimated fixed property is not prepared to pay more than costs of building equal fixed property amount, which has to be considered in our multicriteria decisive model because we are looking for economic justification of renovation or substitutional building. After defining the value of the building we start with multicriteria deciding. Here we use the team of professionals and fixed properties' estimators from construction profession, which estimate criteria represented in able 3 after preference measure scale with interval 0-10. Lower limit suits to expressive bad or undesired value of parameter, the upper one the most ideal and desired. Thus 10 mean ideal, the best, the most desired value, 0 the worst, undesired value. Thus the most important criterion gets weight 10 while are weights of remaining criteria defined relatively in the relation to the most important criteria. When the team of professionals finishes with the estimation with Delphi method we define estimations' unity of different professionals and we use achieved estimations for continuation of deciding.

After definition of estimation we start working on profitability's function. We define it after method of value's defining. The advantage of this method is that it is simple because we need to define only smaller number of preference in general. Thus we take as the example the sub-criteria of remaining life-time, where we make:

Class	To less	little	satisfying	appropriate
Interval of largeness (years)	0-25	25-50	50-75	75-100
profitability	0	0,50	0,75	1,00

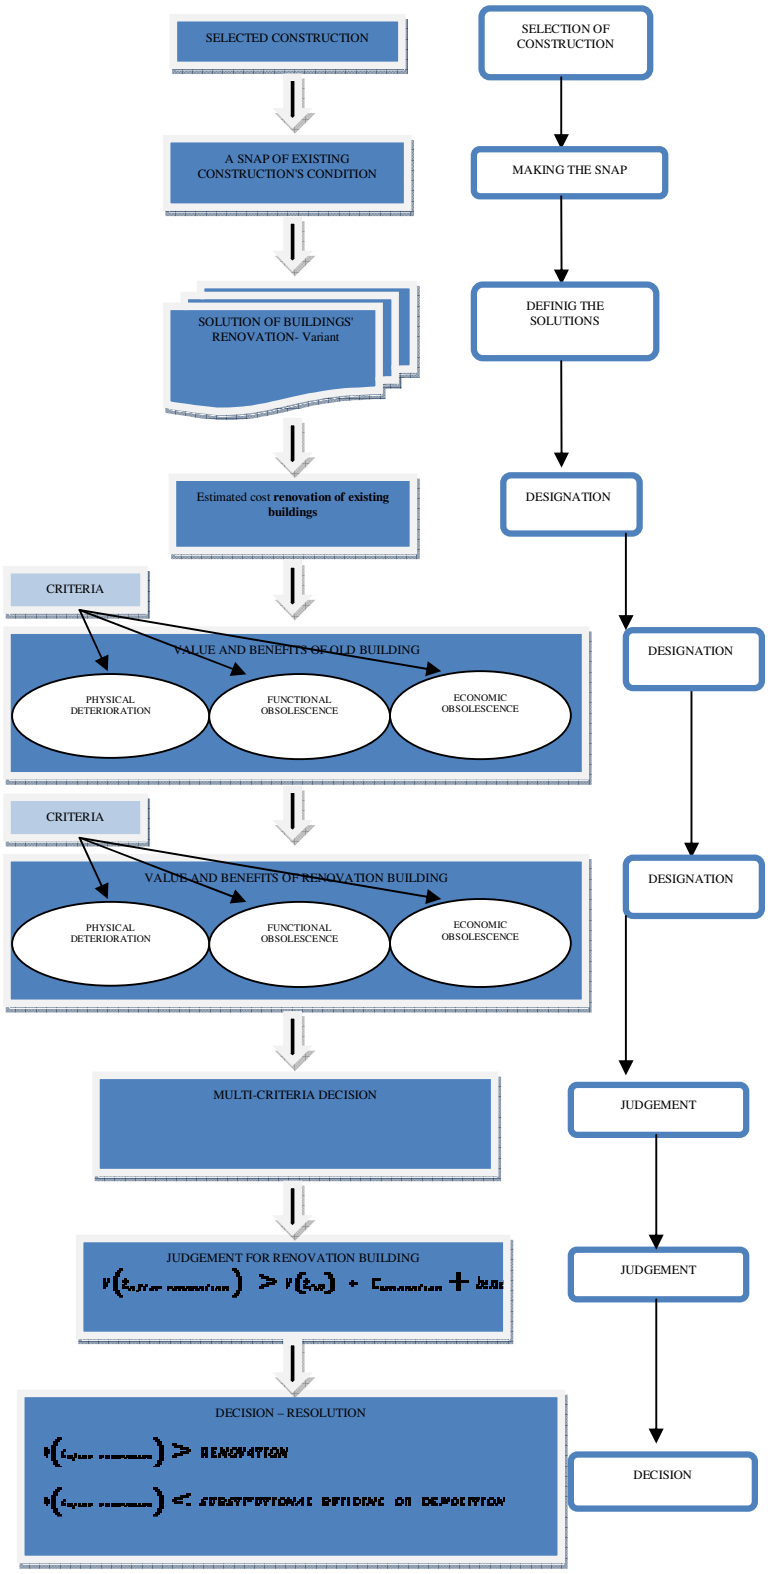
Table 1: Defining of profitability

We define profitability also for others sub-criteria on the same way.

After defining the estimation we start with count of profitability which is made after following equation:

$$Profitability = \frac{\text{Estimation}}{\text{Common estimation}}$$

(5)

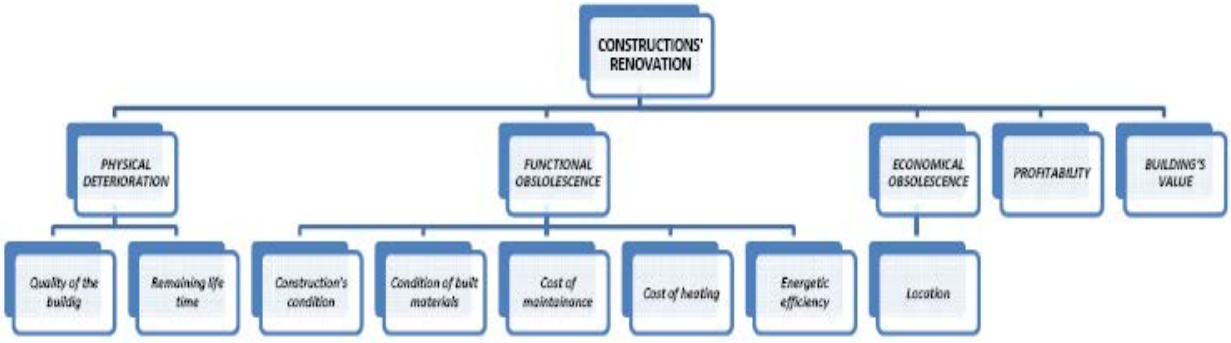


For estimation we take the estimation of individual main criterion (Table1), while we take common estimation of individual main criterion for common estimation. After definition we make scheme of criteria, Picture 4, where we divide main criteria by percentage in the way to add together estimations of sub-criteria and then we multiply this estimation with the sum of all estimations, thus:

$$k = \frac{\sum \text{estimation of sub} - \text{criterion}}{\sum \text{estimation of criteria}} * 100\%$$

(6)

Where is:
k – Main criterion



The same division expressed by percentage we make also for sub-criteria.

Picture 3: Multicriteria decisive model of economic justification of the building.

CRITERIA		Renovation of the building Variant 1			...	Renovation of the building Varianta n		
Main criteria (k)	**Sub-criteria (k_p)**	**Estimation (o_{p1})**	**Estimation together**	**Benefit (k_{r1})**		**Estimation (o_{pi})**	**Estimation together**	**Benefit (k_{ri})**
PHYSICAL DETERIORATION (X_1)	*Quality of the buildig (y_1)*							
	Remaining life time (y_2)							
FUNCTIONAL OBSLOLESCENCE (X_2)	*Construction's condition (y_3)*							
	Condition of built materials (y_4)							
	Cost of maintainance (y_5)							
	Energetic efficiency (y_6)							
	Cost of heating (y_7)							
ECONOMICAL OBSOLESCENCE (X_3)	*Location (y_8)*							
PROFITABILITY (X_4)	*Profit (y_9)*							
BUILDING'S VALUE (X_5)	*Value of the buildig after market method (y_{10})*							
VALUE								

Table 2: Multicriteria deciding

Picture 4: Scheme of criteria for evaluation.

After division expressed by percentage we count profitability of main criteria after equation:

$$k_1rX1 = (k_1(p(y1)) * k_1(r1(y1)) + k_1(p(y2)) * k_1(r1(y2)))/100 \quad (7)$$

$$k_1rX2 = (k_1p(y3) * k_1r1(y3) + k_1p(y4) * k_1r1(y4) + k_1p(y5) * k_1r1(y5) + k_1p(y6) * k_1r1(y6) + k_1(p(y7)))/100 \quad (8)$$

$$k_1rX3 = (k_1p(y8) * k_1r1(y8))/100 \quad (9)$$

$$k_1rX4 = (k_1p(y9) * k_1r1(y9))/100 \quad (10)$$

$$k_1rX5 = (k_1p(y10) * k_1r1(y10))/100 \quad (11)$$

After that we count final profitability of variant of building's renovation 1 after equation:

$$k_1r1 = (k_1X1 * k_1rX1 + k_1X2 * k_1rX2 + k_1X3 * k_1rX3 + k_{X4} * k_{rX4} + k_{X5} * k_{rX5})/100 \quad (12)$$

Equation is valid for each variant of building's renovation. After definition of profitability for individual variant we choose variant with higher value of profitability. After that we check chosen variant of building's renovation after equation 3 or 4, it depends if the building is business or non-business. On so far as we get higher value of renovation after equations 3 or 4 then the decision about renovation is right, in case that it is lower then the decision about renovation is not appropriate, however we can decide for substitutional building or demolition and selling the land.

EXAMPLE

Represented model has been tried in company Gradbeno podjetje Ptuj d.o.o. on many cases and we have got successful results and confirmation of use the chosen model. The test of the model will be show on one of the examples.
Quoted equations have been tested on the real building Color Medvode in Slovenia. Building is abandoned factory which was bought by Slovenian company. This company rents this factor which is old and necessary of renovation or substitutional building. Thus the company could enlarge its rental and use of building with renovation. In this way we will make comparison between two variants of renovation of mentioned buildings, which have been prepared by architecture biro.

Picture 4: Factory Color Medvode.

CRITERIA		***Renovation of the building Variant 1***			***Renovation of the building Varianta 2***		
Main criteria (k)	***Sub-criteria (k_p)***	***Estimation (o_{p1})***	***Estimation together***	***Benefit (k_{r1})***	***Estimation (o_{p2})***	***Estimation together***	***Benefit (k_{r2})***

Table 3: The example of Color Medvode.

Variant 1:

$k_1rX1 = (45 * 0{,}50 + 55 * 0{,}50)/100 = 0{,}500$

$k_1rX2 = (18 * 0{,}75 + 18 * 0{,}75 - 18 * 0{,}50 + 21 * 0{,}50 + 0{,}25 * 0{,}50)/100 = 0{,}466$

$k_1rX3 = (100 * 1)/100 = 1$
$k_{rX4} = (100 * 0{,}75)/100 = 0{,}75$
$k_{rX4} = (100 * 1)/100 = 0{,}90$

$k_1r1 = (17{,}46 * 0{,}500 + 44{,}44 * 0{,}466 + 7{,}93 * 1 + 14{,}28 * 0{,}75 + 15{,}87 * 0{,}90)/100 = 0{,}623$

Variant 2:
$k_1rX1 = (50 * 0{,}60 + 50 * 0{,}75)/100 = 0{,}675$
$k_1rX2 = (15 * 0{,}75 + 15 * 0{,}75 + 22 * 0{,}50 + 22 * 0{,}75 + 25 * 0{,}50)/100 = 0{,}625$
$k_1rX3 = (100 * 1)/100 = 1$
$k_{rX4} = (100 * 1)/100 = 1$
$k_{rX4} - (100 * 0{,}8)/100 = 0{,}8$

$k_1r1 = (17{,}64 * 0{,}675 + 47{,}05 * 0{,}625 + 7{,}35 * 1 + 14{,}70 * 1 + 13{,}23 * 0{,}8)/100 = 0{,}739$

The results show that variant 2 is better than variant 1. That's why we check variant 2 after equations 3 and 4, so it depends if the building is business or non-business. Because in this case we have business building we check with equation 4, where the building has also fulfilled the condition.

CONCLUDING REMARKS

By help of multi-criteria decisive model it is possible to decide in which time limit of building's lifetime is it reasonable and economic justified to take a decision not to maintain or to improve sanitary conditions, but to demolish and construct new building or substitutional building regarding the criteria, therefore physical deterioration, functional and economic obsolescence in connection with the value of the object and profitability or benefit. Discussed model was tested in company Gradbeno podjetje Ptuj d.o.o. which deals with construction of all kinds of buildings. In the paper are represented only short abstracts of model. We will develop this model in the future that will regard business and non-business buildings in details and at the same time define the possibility of economic judgments of renovation and substitutional construction of buildings.

Abstract
In the Architecture, Construction and Engineering (AEC) industry office activities link the information flows from project teams and the production processes on the field. Despite their importance to the overall project, office activities have been overlooked and several authors point out that they are often mismanaged, lack planning, or are buffered to account for the great amount of variability within processes developed at the office level, eventually resulting on site inefficiencies and cost overruns. This paper presents a study of the submittal process through the use of Lean Thinking. Submittals are documents exchanged between the general contractors, subcontractors, the project architect and its team of designers and consultants. Submittals carry information about products and processes used to deliver a project, and are submitted from the parties constructing the project, or supplying materials to it, to the designers so that the submitted information can be checked for conformance to project specifications. The study shows that for the project investigated the submittal process lacked transparency, had low workflow predictability, and showed low levels of reliability. The study concludes that the submittal process can be streamlined by enhancing communication and information sharing amongst stakeholders, through the understanding of the causes of variation in lead times and the understanding of participants' needs.

Keywords: lean construction, lean office, submittal process

INTRODUCTION

In the United States like in many other countries in the world the construction industry plays an important role in the country's economy. In the United States, in 2009 alone, the Construction Industry contributed with 4.1% of the US Gross Domestic Product (BEA 2010), and accounted for more than 7.3 million of paid employees (US-Census-Bureau 2010). However, the inefficiencies of the construction industry are well known and include: low productivity rates, poor quality of work (Koskela 1996), cost overruns, delays, constant changes, rework and claims (Gould and Joyce 2009).

Project management in construction is largely based on the traditional (conversion) model that considers that "the conversion processes can be divided into subprocesses, which also are conversion processes" (Koskela 1992, p. 12). For example, cost estimates are based on data gathered from previous projects and follow a work breakdown structure (WBS), i.e., a

hierarchical division of work in smaller parts, in which the unit cost of each major process (e.g., structure) is the sum of the cost of each subprocess (e.g., formwork, reinforcing steel, placing concrete). In these estimates, the flow aspects of the process (moving materials, inspections, waiting times) are not explicitly considered and accounted for and only the transformation tasks are tracked. As a consequence the focus of construction project management, based on the traditional model, lays in assuring that each subprocess performs as productively as possible, which does not necessarily translate in the best performance for the entire project. The sum of the local optimums in each subprocess does not equal the optimum of the entire process.

The use of Lean Production concepts, principles, and tools applied to construction production processes (e.g., activities developed on site) has proven to be possible and result in notable improvements in the performance of construction project (e.g., Kemmer et al. 2010; Schramm et al. 2009; Matt 2008; Howell and Ballard 1996). In spite of considerable success of the referenced studies, not much has been done regarding administrative processes of office-related activities in construction (Kemmer et al. 2009), notwithstanding the importance of these processes in any construction project.

Lean Thinking applied to nonproductive processes is termed Lean Office. In the office environment two main types of demand can be defined within an administrative system: value demand and failure demand. Value demand is the demand for the service that the system is set to provide, or in other words, what the client wants. Failure demand is the demand that results from "the failure to do something or to do something right to the client" in the first pass (Seddon 2008, p.32).

Office related activities support the work of construction teams working on site and without office activities production processes cannot occur because people have to be hired, paperwork has to processed, bills have to be paid, and information has to be made available. Besides their importance to support the overall performance of the project, some office related activities are often performed by highly trained and skilled workers, such as Professional Engineers, representing a significant part of the overhead cost of the projects and therefore of the overall cost of each project (Kim and Ballard 2002).

Some of the administrative processes in construction projects are related to the constant exchange of information between the intervening teams in the project (Atkins and Simpson 2008). These teams are responsible for two major processes in construction projects identified by Koskela as the design process and the construction process (Koskela 1992). The purpose of this exchange of information is to first ensure that the designers' intentions and requirements are implemented and second to record decisions of what happens on site in order to allow post-construction investigation (Mays and Novitski 1997).

Amongst the office activities, the submittal process deserves attention as it is one of the processes used to exchange information between the design team and the construction team. The submittals are documents that are prepared by the construction team and contain detailed dimensions, types of materials and equipment, and illustrate application conditions, allowing a determination of how interfaces with other products and systems should be dealt with during the construction phase (Atkins and Simpson 2008).

THE SUBMITTAL PROCESS

During the construction phase, the general contractor (GC) and the subcontractors (Subs) work with suppliers to define and detail the products that will be used to satisfy the specifications set forth by the Architects and Engineers (A/E) of the design team. These documents containing product information (e.g., shop drawings, samples, and product data discussed later in this paper) are then sent to the architect and project consultants for review and approval. Each group of documents related to a specific item of the project (e.g., specifications for the concrete mix, product samples related to the flooring) sent by the GC is called a submittal. The process of preparing, submitting and all the intermediate steps until the approval of the submittal is called the submittal process.

The submittals may include different types of documents such as shop drawings, product data, samples, reports, manuals, and warranties. Even though some of these documents are sent to the design team only to be part of the project's record, the majority of these documents, particularly shop drawings, samples, and product data, need to be approved by the design team before installed or built in the project (Atkins and Simpson 2008; Gould and Joyce 2009). Shop drawings are the working documents, detailed and precise, that represent every component of the project, method of assembly, and materials to be used. Product data presents information about products and may be required either as supplements to shop drawings or to ensure that the products meet the required standards. Product data may include illustrations of the product, brochures, and information about the product's performance. Samples show the characteristics of a specific material and are often required to show colors and finishes (Gould and Joyce 2009; AIA 2007; EJCDC 2007).

RESEARCH METHOD

This paper presents the results of a pilot case study that was part of a broader research project. The research work was carried out in two construction companies, based in San Diego/CA, and identified as Company A and Company B. Both companies independently pointed out to the submittal process when inquired about which process should be investigated as part of a study on office activities.

Case studies were used as a strategy to collect and analyze the empirical data. This research approach, as suggested by Yin (1994), concerns the study of contemporaneous events that cannot be manipulated in their environment.

According to Yin, case studies have the advantage of covering contextual conditions, relying on several types of evidence such as documents, interviews, observation, physical artifacts, and archival records (Yin 1994). The study started with two preliminary studies i.e., pilot case study 1 and pilot case study 2, followed by a case study and consequent conclusions and recommendations. This paper only addresses pilot case study 1 carried out at Company A with a brief cross-case analysis for the findings of both studies, due to space limitations.

Company A aimed at improving and standardizing its submittal processes based on the performance of one of its best teams assigned to a starting construction project. In Company A the submittal process was managed on site by the construction team, and according to a top manager of the company (information obtained during a meeting) the aforementioned team ran the process smoothly without major problems, but lacked a streamlined and standardized

procedure to develop the submittal process. Thus it was the company's goal to understand what was being done by this team, improve what could be improved on a new project, and standardize this process to implement it companywide.

This pilot case study was conducted on a 12-story building (cast in place concrete, post-tensional slabs, and structural steel roof). This 220,000 sq.ft mixed-use project with 136 apartment units, retail spaces and subterranean parking will support the charity work (feeding the hunger, and provinding housing, healthcare, and education to those in need) of a non-profit organization in San Diego, CA. The project had already been delivered to the Owner when the Pilot Case Study started. That said, all the information obtained was related to past events.

A mixed approach (Yin 1994) was used in this research project to simultaneously collect qualitative and quantitative data throughout the research. For the pilot case study cross-sectional quantitative data was provided by the company, which had kept archival records of the submittal process in the form of spreadsheets that were used as a submittal schedule (a.k.a. submittal log). The submittal log contained the record of the process to help manage and control the submittal process. The qualitative data was collected through semi-structured interviews that were performed on a weekly basis with Company A.

Sources of evidence

The data collected was categorized herein as: time data (actual and planned), quality data, nominal data, and procedural data. These categories are defined below. Based on the information provided by the company, Figure 1 was drawn to represent the major milestones of the submittal process from the date the submittal was received to the time it was finally distributed to those doing the field work.

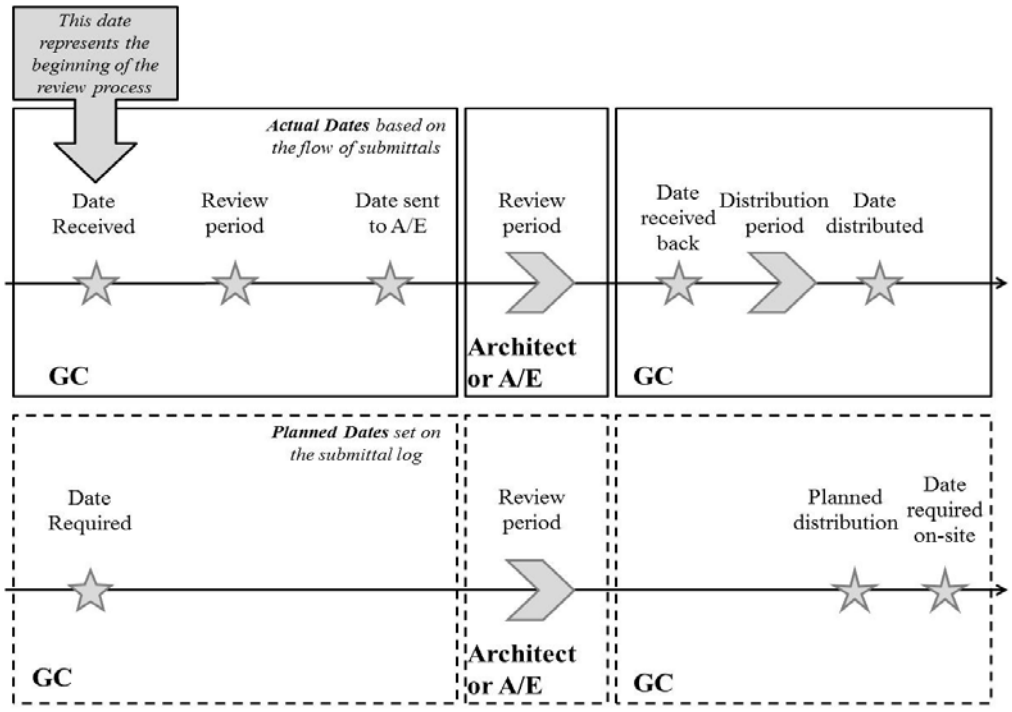

Figure 1: *Data collected.*

Time data
Time data includes actual data and planned data. Actual data reflects when an event actually took place (e.g., when a submittal was delivered by a Sub to the GC; when the GC sends a submittal to the A/E). Planned data are dates that were introduced into the submittal log at the beginning of the project (e.g., when a subcontractor was required to deliver a submittal to the GC; when the submittal was planned to be distributed approved to the subcontractor) which reflect the dates when the event happened, and the planned dates that were set in the log at the beginning of the project.

Quality data
The quality data reflected the approval status, i.e., Approved (A), Approved as Noted (AAN), Revise & Resubmit (RR), Rejected (R), and For Record (FR) that was determined in two different phases of the submittal process:

1) The GC's review period – during this phase a submittal marked as A, AAN or FR had no or minor notes and was released to the Architect for approval. A submittal marked as RR had major problems and could not be sent to the Architect before revised and resubmitted for the GC's review. A submittal marked as R was no longer needed to be submitted. A submittal marked as FR, was sent to the Architect to add to their files.

2) The Architect or the A/E's team review period - during this phase the Architect or the A/E marked "Approved", or AAN, or FR may had minor notes, but was returned to the GC and then to the subcontractor and was good to go. A submittal marked RR had major problems and had to be revised. In these cases the submittal was sent back to the GC and then to the subcontractor to RR, and all review cycle started again until the submittal was "Approved" or AAN. A submittal marked R was no longer needed to be submitted.

Table 1 summarizes the possible status for a submittal and the corresponding meaning for each one.

Table 1: *Status of the submittals*

Status	Meaning
A	The submittal is good to go
AAN	The submittal is approved with minor changes and does not need to go through a new cycle of review
RR	The submittal is not ready to go. It is returned to the party who submitted it for a new cycle of review. Once the party revises the submittal and addresses the comments on the submittal, a new round of review is started again. This loop may continue until all comments are addressed
R	The submittal is no longer required (as a result of a change order, for example)
FR	The submittal does not need approval, but will make part of the construction documents.

Nominal data
The nominal data reflected the type of submittal delivered for approval (e.g., shop drawings, samples, or product data).

Procedural data
The procedural data reflected the party responsible for the approval of the submittal, (e.g., Architect, Structural Engineer).

Data analysis
The data analysis was focused on review cycle times i.e., how often a part or a product actually is completed by a process, as timed by observation (LEI 2008), approval status, and variability within those indicators. In an attempt to identify patterns, and following the indication of the Project Manager (PM) of the construction team assigned to the project, the data was first analyzed for the entire process and then analyzed separately by variables within each category: quality, nominal, and procedural.

The findings of the pilot case study were presented to the GC's construction team who provided some comments which were later addressed in the analysis of the pilot study.

RESULTS

According to the information provided by Company A's informants, the submittal process for this pilot case study started when the GC prepared the submittal schedule (or submittal log), where the specification sections, due dates, and responsible parties were represented. For this project, as in many others where there is no contractual relationship between the subcontractors (and suppliers and fabricators) and the owner, the subcontractors submitted the submittals to the GC for approval. Then, ideally, the GC reviewed each submittal, approved it, and sent it to: a) the Architect who also reviewed it, approved it, and sent it back to the GC; or b) to the A/E, then the architect received the submittal, sent it to the respective consultant for review, the consultant approved it, and sent it back to the Architect, who then reviewed it once again, approved it, and sent it back to the GC. Once the A/E reviews were completed and the submittals approved, the GC would send the submittal back to the respective contractor. Figure 2 illustrates a desirable timeline for the submittal process as described. The shaded stars correspond to the due dates that were set by the PE on the submittal log (SL) at the beginning of the construction phase.

For this case, the SL was built on an excel spreadsheet and contained different types of information. The SL listed all the submittals required that were indicated in the specification book for the project, and key information such as: Architect or A/E allowed review time; the estimated delivery lead time (estimated time to deliver a product or service once the subcontractor received the approved submittal), the due date each submittal was required to be submitted, and the date the submittal was required on site.

The submittal review process would start once a subcontractor sent a submittal to the GC for review. In an interview, the PE stated that during this period (ideally 3 to 5 days) the GC's construction team assigned to the project verified that what was submitted matched the plans and specifications. This verification was done to ensure that no time was wasted by sending an incorrect or incomplete submittal to the Architect.

During the review process, the GC's construction team would define a category for each submittal. The possible categories for this project were: 1) A; 2) AAN; 3) RR; 4) R; and 5) FR (see Table 1).

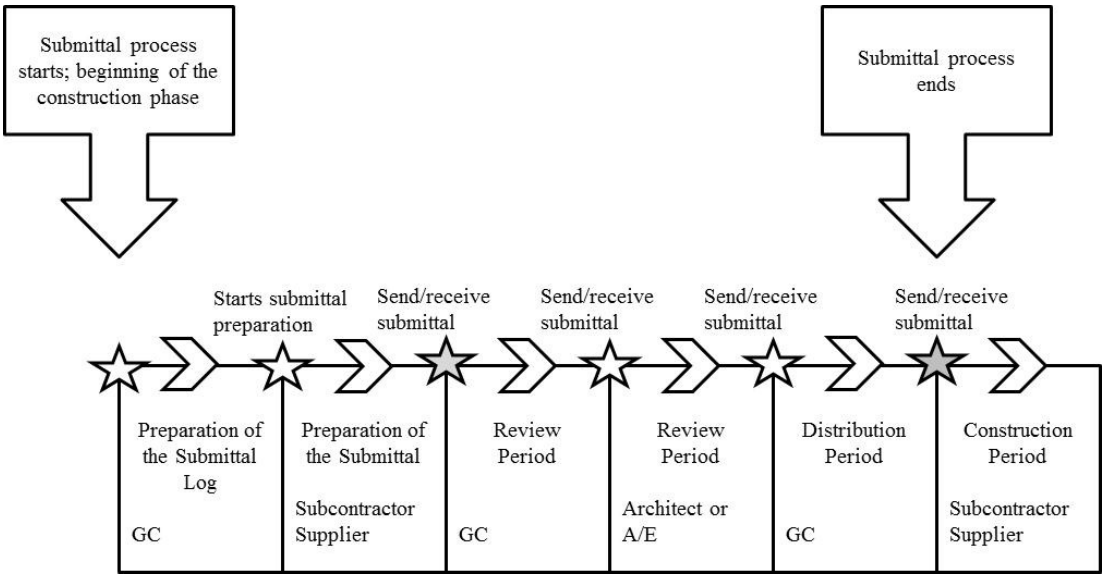

Figure 2: *Desirable Submittal Process Timeline.*

Once the submittal was sent to the Architect, a new review loop started. The review was done either exclusively by the Architect or with the help of consultants. Ideally, the Architect and/or the A/E had 14 days to review the submittal (in some cases depending on its complexity, different times were set for this review). Once the Architect or the A/E review was complete, the submittal was sent back to the GC, who in turn distributed it to the subcontractors. Ideally the GC released the submittal within 3 days.

Provided that the A/E stamped the submittal A or AAN, the subcontractors were not required to resubmit the submittal. In some odd cases even though the submittal was categorized as AAN the submittal had so many notes and corrections that the subcontractor was asked to submit a clean copy FR. In an interview, the PM's team informed the research team that the project for which the data was analyzed pertained to a project that had a smooth submittal process with no major problems. Ultimately, the submittals were delivered on site in a timely fashion, which is what the team considered important.

Data analysis

The indicators for this pilot case study were categorized into two groups: 1) time indicators, which include cycle times, and lead times, i.e., the time it takes one piece to move all the way through a process, from start to finish (LEI 2008); and 2) quality indicators, which include the relative percentage of submittals set as A, AAN, RR, R, and FR. Table 2 lists and defines those indicators.

The analysis of the data presented herein followed the indications of the PM's team. In an interview, the PM informed the research team of the estimated lead times including a breakdown of the estimated lead time (ELT) by participant of the project and estimated cycle time. This information is listed in Table 3. This information includes the cycle times (CT) for the GC and A/E reviews, the GC distribution time during the review process, and lead time (LT) for the submittal process as described by the PM's team. The values listed in Table 3 were obtained solely based on the PM's team expert judgment.

Table 2: *Indicators*

CATEGORY	INDICATOR	MEANING
Time	GC_CT - GC's Review Cycle Time	Represents the average time a submittal spent at the GC for approval
	A/E_CT - A/E's Review Cycle Time	Represents the average time a submittal spent at the A or A/E for approval
	GCD_CT - GC's Distribution Cycle Time	Represents the average time a submittal spent at the GC to be delivered to the subcontractors
	LT - Lead Time	Represents the average time a submittal spent at the GC and at the A/E for approval and delivery (LT= GC's CT + A/E_CT + GC_DT)
	PLT - Planned Lead Time	Represents the planned total time a submittal spent at the GC and at the A/E for approval and delivery (as set at the beginning of the project on the SL)
	ELT - Estimated Lead Time	Represents the estimated time a submittal spent at the GC and at the A/E for approval and delivery (as described by the PM's team)
Quality	Approval Percentage	Represents the percentage of submittals that were A, AAN, RR, R and FR.

Table 3: *PM's expert judgment estimates for the cycle times and lead time of the submittal process*

	GC	**A/E**	**GC**
CT	Review 3 to 5 days	Review 14 days	Distribution 3 days
LT	20 to 22 days		

The PM's team gave the research team access to the actual SL for the pilot case project. Indicators for all submittals were organized by the research team into different types of variables. To begin with, time indicators were analyzed considering the entire project and by each type of variable: quality, nominal, and procedural. After that, the quality indicators (A, AAN and RR) were calculated. Table 4 presents a summary of the results obtained for the time indicators. This analysis was only performed for the variables that were representative of processes that had a PLT of 11 days (93% of the data).

The shaded cells presented in Table 4 are discussed in more detail as they represent data that differs from what was expected by the project team. First of all, the LT (33.1 days) is about 1.5 times higher than the ELT (22 days) and more than three times the PLT (11 days). Next, the submittals spend, on average, more time to be distributed by the GC than to be reviewed by the GC (GCR-CT>GCD-CT). The GC-DT for product data (13.8 days) is about two times the GCT-CT for shop drawings (7.2 days). The submittals AAN took on average six days longer to be returned to the subcontractor than submittals A. Lastly, the LT of submittals sent to the A/E is lower than the LT of submittals sent to the Architect.

Table 4: *Submittal process: actual cycle times and lead times*

SUBMITTALS		GCR-CT (1) (DAYS)	A/ER-CT (2) (DAYS)	GCD-CT (3) (DAYS)	LT (1)+(2)+(3) (DAYS)	PLT (DAYS)	ELT (DAYS)
Project	Average	7.6	14.8	10.7	33.1	11	22
	Median	2	7	6	31	11	--
Quality							
A	Average	4.8	13.6	11.1	29.4	11	--
	Median	0	8	6	25	11	--
AAN	Average	9.5	15.8	10.7	36	11	--
	Median	3	11.5	6	34.5	11	--
Nominal							
Shop Drawing	Average	6.8	15.3	7.2	27.5	11	--
	Median	2	9	6	20	11	--
Product Data	Average	7.6	15.3	13.8	36.7	11	--
	Median	1	13	6	36	11	--
Procedural							
Submitted to the Architect	Average	10.5	14.8	16.9	42.2	11	--
	Median	1	9	8	36	11	--
Submitted to the A/E	Average	6.6	14.9	8.4	29.9	11	--
	Median	2	10	5.5	26	11	--

Figures 3 to 6 present charts with histograms for the LT, GCR-CT, A/ER-CT, and GCD-CT, respectively. On the same charts empirical cumulative distribution lines overlay the histograms on a secondary axis. Note that all submittals shown in Figures 3 to 6 had a PLT of 11 days as defined in the SL, corresponding to 139 observations. From the observation of Figure 3, it is clear that there is a great amount of variability in the actual lead time, and the LT numbers are very different from the PLT or even the ELT. The median value of the observed LTs is 31 days (see Table 4), which is quite different than the ELT of 20 to 22 days and only met on 38% of the cases (see Table 3).

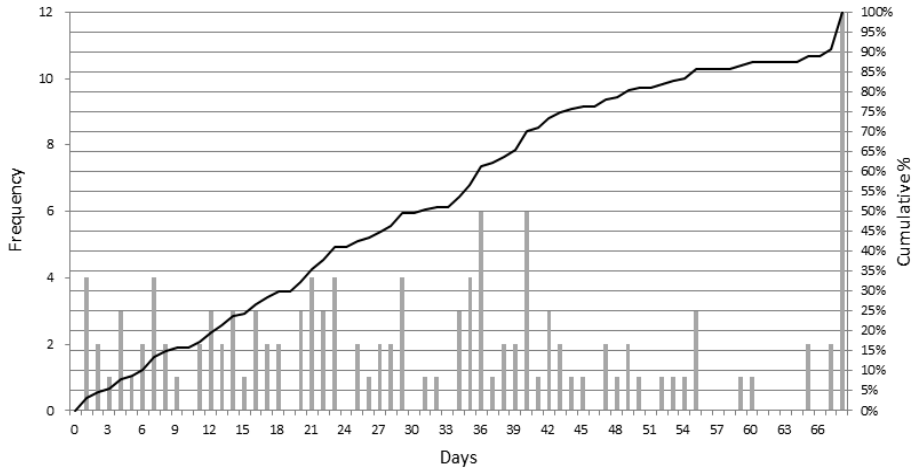

Figure 3: *Submittal process actual lead time.*

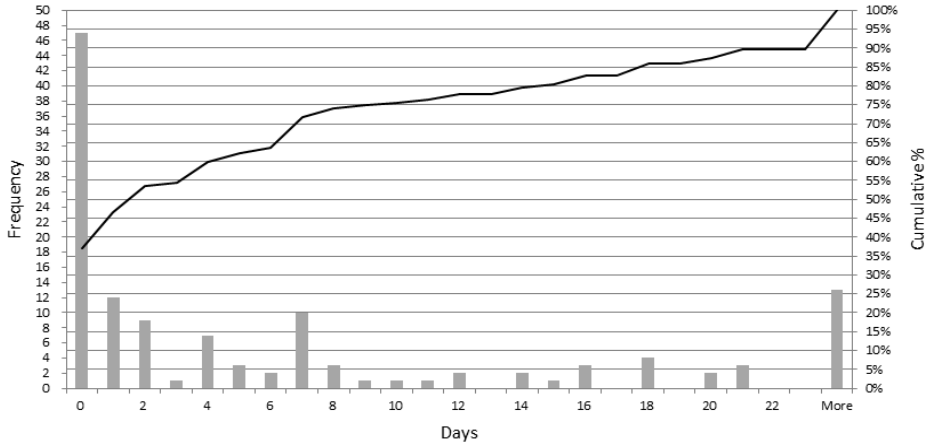

Figure 4: *General Contractor's actual review cycle time.*

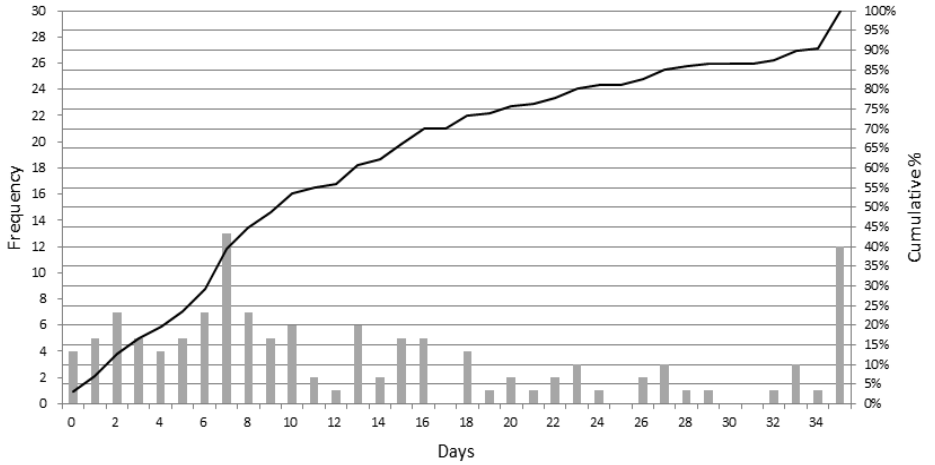

Figure 5: *A/E actual review cycle time.*

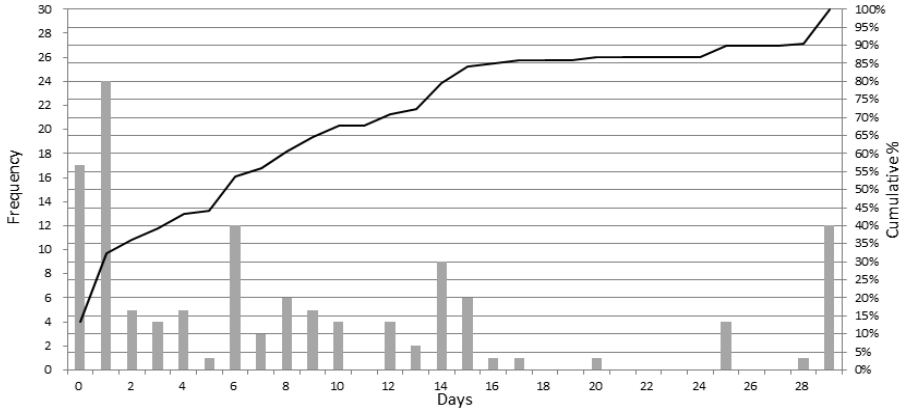

Figure 6: *General Contractor's actual distribution cycle time.*

Figure 4, which reports the GC review time, also shows great variability. However, the median value of about 1.5 days that may be observed from this figure is actually less than the estimated values of the 3 to 5 days reported in Table 4.

Figure 5 shows the A/E review cycle time. From this figure it may be observed that about 62% of the time, the A/E actually meets the estimated deadline of 14 days defined by the PM's team. Naturally, it is worth studying the reasons that lead to having the A/E team exceed the crucial value of 14 days in 38% of the submittals. Figure 6 shows the GC distribution time and it is worth analyzing the facts that lead to 62% of the submittals having a distribution time greater than the estimated distribution time (expected GCD-CT of 3 days).

Figure 7 presents a summary of the previous figures and allows a comparison between: planned cycle times and lead times as defined in the submittal log; estimated cycle and lead times, as described by the PM's team; and the actual average of cycle and lead times that were registered on the submittal log.

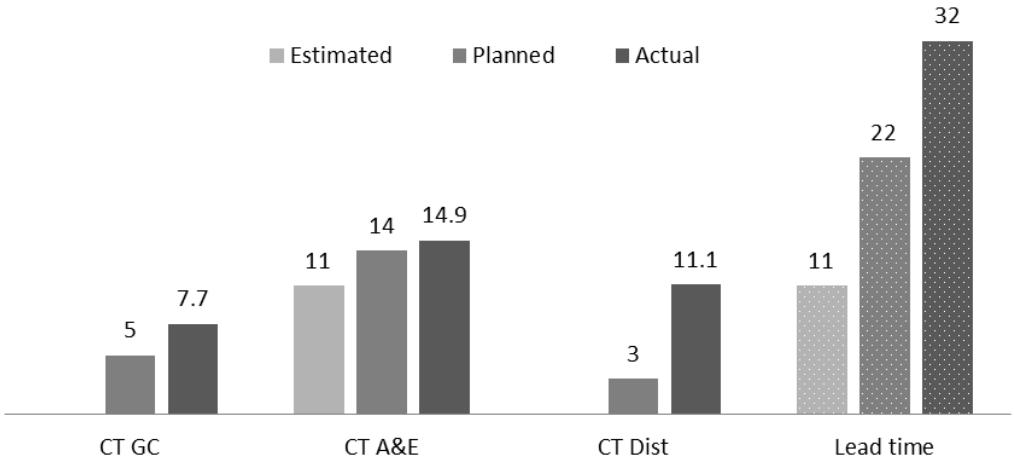

Figure 7: *Estimated, planned, and actual average cycle times and lead times.*

Figure 7 shows that the submittal activities took longer than planned and even longer than estimated. Also it is worth noting that the GC actually took longer to distribute the submittals than to review them. The reasons behind these findings should be analyzed. More importantly, the differences between planned and actual times should be accounted for in the future pre-construction preparation of submittal logs. A possible explanation for the deviations noted are that even though the PM's team acknowledged that they should consider their own review time, as indicated in Table 4, in the SL they did not in fact consider their own review and distribution times in the initial scheduling phase.

Figure 8 presents a chart which shows that in 57% of the time, the subcontractor delivered the submittal earlier than required to the GC, sometimes even much earlier than the due date that was scheduled by the GC. Although this number may not sound alarming, the complement is that 41% of the time the subcontractor delivered the submittals late to the GC as shown in Figure 8.

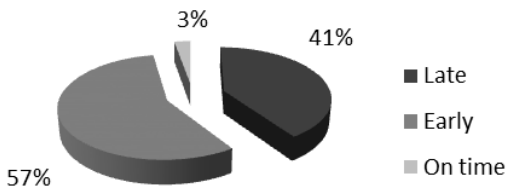

Figure 8: *Relative portion of submittals submitted by the Subcontractors to the General Contractor on time, earlier, and later than planned in the schedule.*

Another important finding was that in 49% of the cases the submittals were distributed late to the subcontractors, as shown in Figure 9.

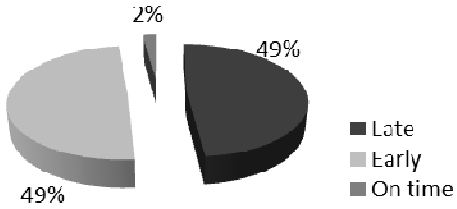

Figure 9: *Relative portion of submittals distributed to the Subcontractors on time, earlier, and later than planned in the schedule.*

Figure 10 presents a summary of the results obtained for the quality indicator. In this case one can see that the vast majority of submittals after the A/E review were AAN (58%) followed by the submittals A (35%) and the submittals RR & R (7%). The data did not have submittals FR.

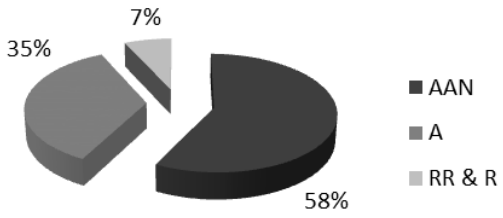

Figure 10: *Relative proportion of submittals status.*

Analysis

In contrast to the PM team's statements that the submittal process was smooth, the results presented in the previous section seem to indicate otherwise. The submittals were often delivered later than required on site and the lead times for the submittal process seem to be almost unpredictable. For 75% of the submittals the lead time for each submittal approval

took any time between 0 to about 45 days (see Figure 3) to be approved by the GC and the A/E.

The planned lead time did not reflect the estimated lead time, or the actual lead time, for that matter. In fact, the planned lead time was about half of the estimated lead time, and a third of the average lead time of the project. Additionally, the subcontractors pushed the submittals for approval regardless of the real needs of the project. This practice is well documented as impeding the flow of work/information and has been identified as a cause for rework and work in progress, a clear indication of wasteful practices.

The submittal process had different CT and LT for different variables within each type of variables studied. For example, submittals AAN took on average 6 more days to be returned to the subcontractors than submittals A. The submittal log did not account for those differences.

Three unexpected results were obtained. First, despite the PM's indication, the lead time for product data was, on average, 7 days longer than the corresponding lead time for shop drawings. The PM's team of the GC in Company A had indicated that shop drawings were expected to have a longer lead time than product data since they are much more complex and may detail dimensions with low tolerances.

Next, the cycle time for the Architect's review was longer than the cycle time for the A/E review, even though the review by both the A/E adds two more handoffs and a new approval loop to the process. According to the GC, when the submittal has to be sent to the consultants the Architect works on it immediately, suggesting that the Architect is more attentive to monitoring the work of the consultants than his own.

Finally, the cycle time for the GC's distribution was higher than the cycle time for the GC's review. According to the GC this should not occur. Nevertheless, the PM considered that it could be related to the fact that in some cases the Architect use submittals as a way to finish the design, leading to submittals where many notes have to be considered, and eventually leading to change orders.

The analysis of the meaning of the status for the submittals allows categorizing the each status in terms value. Only A and FR represent value added as they deliver value to GC and the Architect and ultimately to the Owner. AAN represents contributory activities as by adding notes to the submittal the GC and the A/E enable the submittals to add value to the process. RR, and R represent represents the failure to prepare the submittal right the first time in terms of what the Architect wants and it is waste. Table 5 summarizes the analyses of the submittal process for this pilot case study in terms of demand and value. The data shows that in 58% of the submittals there was value enabling demand and contributory activities, in 7% waste and failure demand were generated due to the need to rework.

Table 5: *Submittal process: actual cycle times and lead times*

STATUS	MEANING	DEMAND	VALUE
A	The submittal is good to go	Value	Value Added
AAN	The submittal is approved with minor changes and does not need to go through a new cycle of review	Value Enabling	Value Added/ Contributory
RR	The submittal is not ready to go. It is returned to the party who submitted it for a new cycle of review. Once the party revises the submittal and addresses the comments on the submittal, a new round of review is started again. This loop may continue until all comments are addressed	Failure	Waste
R	The submittal is no longer required (as a result of a change order, for example)	Failure	Waste
FR	The submittal does not need approval, but will make part of the construction documents.	Value	Value Added

Cross Case Analysis

The two pilot case studies were quite different from each another. The first difference is that Company A's projects are new building construction and building renovations, while Company B's projects are water and waste water infrastructures and treatment facilities. At Company A the submittal process was managed on site by the PM's team assigned to the project. In contrast, Company B managed the submittal process at the main office by an administrative department with different teams assigned to review different Divisions.

Despite the differences in the processes of the two companies, the results were similar: the unpredictability of the cycle time of the Owner introduces great variability to the process, and this variability reduces the reliability of the submittal process. In addition, failure demand is present in both submittal processes and is represented by the high number of submittals that needed to be RR or were R.

CONCLUSIONS

The first conclusion that was drawn from the study is that the submittal log set at the beginning of the construction phase to manage and control the submittal process is in fact a data base used to monitor the performance of the submittal process. This log does not help to manage or plan the process. In fact, because the indicators used to build the log do not reflect the reality, the plan is completely disconnected from what really happens. Additionally, because the log does not allow a visual reading of the real indicators of the process, the submittal log does not help control the submittal process either. The log does not show the flow of information and one cannot manage what is not measured.

In addition, the unpredictability of the cycle times of participants in the process introduce great variability to the process and this variability reduces considerably the reliability of the submittal process.

Finally, through this study, two main types of waste were identified in the submittal process:

- Time waste is reflected as the time spent by the PM's team to set up an inadequate submittal log.

- Rework and failure demand is reflected by the percentage of submittals that were R or RR

As final remarks it is worth noting that:

- The project was delivered via the design-bid-build method
- The project had already been completed when the research team had access to the data
- A limited number of events were observed which do not allow for statistical generalization. Instead, the study can be generalized through the application of a similar research method to similar populations to allow for analytical generalization.

ACKNOWLEDGEMENTS

Thanks are due to San Diego State University (UGP/GIA grant ref# 242331), and the J.R. Filanc Construction Engineering and Management Program for the financial support during the research period. Thanks are also due to Companies A and B and their team members who provided the data for the study. Any findings and conclusions presented herein reflect the authors' opinions and not of the participant organizations.

Abstract
There are significant problems in the supply of housing in Australia yet very little attention has been paid to the housing construction supply chain. To date the housing supply debate has been largely focussed on housing demand, affordability and land supply. It is contended that one of the key causal factors of poor housing supply is the poor coordination between supply chain actors. The development of integrated supply delivery solutions have not been extensively recognised in the Australian residential sector. Ad hoc examples and applications by some major building companies has seen some limited success, however, this has not been diffused throughout the sector with little real impact on overall sector performance and individual company competitiveness. Whole-scale industry improvement requires a concerted effort to undertake a stepwise change. A key to the solution is to investigate successful examples of integrated supply chains which have resulted in productivity and/or innovation performance improvements. The aim of this research is to undertake a case study analysis of successful implementation of delivering an innovation to the Australian housing construction industry which required an integrated construction supply chain model. The paper describes the theoretical background to the study and the preliminary results of the case study.

Keywords: housing, supply chain innovation, case study

INTRODUCTION

The housing sector has always been seen as an important part of the economy and is considered a key indicator of the health of the Australian economy. The construction industry typically represents between 6-12% of the GDP of an economy. In Australia in 2009 the residential sector accounted for approximately $70b and from 2000-2009 the average was 47% of the total spend in the construction industry. With anticipated population growth the significance of housing infrastructure provision is expected to increase in the next two decades. The Australian National Housing Supply Council estimates that around 3.2 million additional dwellings will be required in the next 20 years to accommodate a population growth from 2008 to 2028 (ANHSC, 2010). Moreover, it also forecasts that the current demand-supply gap of 178,400 dwellings will increase to approximately 640,000 by 2028. According to the Australian Bureau of Statistics (ABS, 2010), the country currently needs to be building 17,400 homes every month. Housing supply, however, has oscillated between 10,000 to 16,000 dwellings per month since 1990. Based on th e average number of approvals over the first three months of 2010, the current supply is around 14,500 dwellings per month. The shortfall means we are faced with a crisis in our capacity to plan, design and construct to meet our nations needs unless we act immediately to improve our capacity for a more efficient, effective and innovative supply system. Discussions on land supply, planning and development approval processes have been ongoing discussion in the housing

affordability debate for decades in Australia (Holmes, London and Sheehan, 2008). The land development and housing supply pipeline is an important future challenge for the federal government of Australia and is being spearheaded through the Council's 2010-2011 agenda. It is contended that very little attention has been paid to the housing construction supply chain and that productivity and performance improvement of this sector has a role to play in improvements to the housing supply problem.

The problems of the housing sector have been described as; low profit margins for builders and subcontractors, high risk, fragmented supply, adversarial relationships between firms, wasted resources (time, cost and materials), low innovation, poor communication flows, low productivity and poor project management skills. The industry is highly resistant to change, participants tend to not have a holistic view of the industry and feel powerless to affect change. There are significant large national companies who are the market leaders in the residential sector who have some capacity to affect change, however in reality it is suspected that this group struggles to do so in a whole-scale concerted manner. The underlying structural and behavioural characteristics create an overwhelming inertia that resists change. The next tier of the housing sector, namely the trade subcontractor level is highly competitive and fragmented and typically involves numerous small to medium sized companies who generally operate in an uncoordinated and uncooperative environment. Then the third tier of the chain typically involves the major multinational materials and product suppliers. The industry participants similar to most sectors of the construction industry tend to be focused on short-term survival rather than overall industry improvements for the medium or long term.

The industry structure involves chains of firms that contribute to many different parts of planning, designing and constructing the final housing development. Because the industry is highly fragmented with numerous firms and many steps along the production chain it is assumed that an integration of the supply chains will lead to innovations. It is assumed that whole scale industry improvement requires a concerted effort to undertake a stepwise change towards integrated supply chain solutions to improve coordination and thus reduce cost, time delays and risk. A key to the solution is to investigate successful examples of integrated supply chain case studies which have resulted in productivity and/or innovation performance improvements. This paper seeks to explore performance improvement efficiency through the creation, development and implementation of innovations in the sector by providing a description of the successful implementation of the waffle footing system innovation in Australia by an "innovator group".

The overarching aim of the study is to undertake a case study analysis of successful implementation of delivering an innovation to the housing sector which required an integrated construction supply chain model. The objectives include:

- Identify the barriers and enablers to creation, development, adaptation and implementation of the innovation
- Examine the characteristics of the process of integration of the construction supply chain towards creation, development and implementation of an innovation by an innovator group
- Develop a methodological process pathway for innovation creation and diffusion for an integrated housing construction supply chain

The overall research question which this study seeks to address is, "What is the pathway for identification, creation, development and implementation of innovation within the innovation group?"

THEORETICAL BACKGROUND

There are two underlying premises to this study. First the assumption that an integrated construction supply chain is necessary to achieve significant productivity and innovation performance improvements in the housing sector. Second that there is a structured methodology which can be developed which describes a pathway for supply chain management that will enable diffusion of innovations, either incremental or monumental, product or process that will improve the performance of the industry. The theory that provides the framework for this study is a combination of diffusion theory and construction supply chain theory.

Construction supply chain theory

A central idea of supply chain theory is that holistic supply chain integration relies upon each firm at each tier in the supply chain knowing and aiming for a common objective (London, 2008). The common objective may be an innovation or it simply may be concerned with efficiency and effectiveness across the whole supply chain. One of the most significant problems is that once a supply chain becomes fragmented at each tier in the chain there is an outcome from a firm and that firm passes their product and/or service to the next firm at the next tier in the chain and a silo effect takes place. Each firm has unique objectives and 'pushes' on to the next tier the outcome they assume the next tier can 'bear'. The outcome is generally the most efficient for the firm but may not necessarily completely satisfy the next tier's objectives [i.e. the customer's objectives]. It is almost certain that the firm would not be considering the objective of the whole chain nor any other levels in the chain at all. This is central to the concept of supply chain management where the concept of 'pull' vs. 'push' explores a different way of thinking about holistic supply chain performance outcomes alongside the individual outcomes at each tier. The final 'customer's objectives and desired outcome effectively 'pulls' through the products and/or services provided by each tier in the chain. Although this fundamental principle is a long standing assumption within the supply chain theorists domain it is suspected that it is still one of the most basic problems in relation to developing integrated supply chains and creating holistic performance goals for supply chains.

The case study that is analysed is an example of an innovation or an outcome being established that is outside the normal practice of the supply chain participants and the usual outcome at each tier. This particular case study was a step wise change in the practices related to residential footing system design and construction in the Australian housing sector. There is theory already established in relation to diffusion of innovations and this theory provides a starting point to interpreting and exploring the particular innovation that shall be studied in this project.

Diffusion theory

Rogers' theory of innovation diffusion (1962; 1995; 2003) provides an initial framework through which examination of the diffusion of an innovation through construction supply chains can be examined. Rogers' defines the diffusion of innovations as the process by which knowledge of an innovation is transmitted through communication channels, over time, among the members of a social system. The theory of innovation diffusion has been used in many different sectors including health, information technology and construction. In particular London et al (2007) and Walker et al (2005) explored e-business and information technology adoption in the Australian construction sector using concepts from this theory. The four key elements comprising Rogers' diffusion theory are defined as;

- The innovation: an idea, practice or object that is perceived as new;

- Communication channel: can be mass media and/or interpersonal networks and is the means by which messages about the innovation gets from one individual to another;
- Time: comprising a) the innovation-decision process, b) relative time which an innovation is adopted by an individual or group – an innovation's rate of adoption
- The social system; a set of interrelated units that are engaged in joint problem solving to accomplish a goal.

Rogers (2003) also outlined the innovation process as consisting of a sequence of five stages including:

- Agenda-setting: the initiation stage when a broad organisational problem is identified which generates a need for an innovation. Within this stage there are two key processes; firstly an identification and prioritisation of problems and requirements and secondly a search within the organisation to find innovations to resolve or manage the identified problems. It is in this stage that the initial motivation is created which drives the later stages in the innovation process.
- Matching: the stage where the problem from the organisation's agenda is conceptually matched with the innovation to determine how well they align. The feasibility of the innovation in resolving the organisational problem is also considered at this stage. This stage is critical to determining if a new idea is sustained in an organisation over time as key decisions are made which may lead to the termination of the innovation process even before its implementation. If it is perceived that the organisation's agenda fits with the innovation then the match is planned and designed.
- Redefining/restructuring: the stage when the innovation is adapted based upon the organisation's needs and structure or vice versa. It is anticipated that a degree of change occurs in the innovation and the organisation during this stage. The ease within which organisations experience the innovation process is influenced by the origin of the innovation (ie whether the innovation comes from within or external to the organisation) as well as the degree of change the innovation creates (radical vs incremental).
- Clarifying: the stage where the innovation has been spread more widely in an organisation. A high degree of uncertainty surrounds its members as an innovation is implemented in an organisation. As a result, individuals go about seeking answers to reduce uncertainty at this stage and construct their meaning of the innovation over time. Innovation champions can play a critical role in the innovation process during this clarifying stage.
- Routinizing: the stage when an innovation has become synonymous with the regular activities of an organisation, which completes the innovation process.

The identification of the different stages in the innovation process has been particularly useful for understanding how to effectively introduce new ideas in organisations because through this we are able to gain insights into the main sequence of decisions, activities and events in the innovation process. However, one would anticipate that to develop and diffuse an innovation in a fragmented industry such as the housing sector would require a collaborative effort between firms along supply chains. It would also require a champion or group of champions who have enough resources and 'pull' to enable the development of the innovation. Beyond these propositions we do not know any more detail of the characteristics of the innovation process or methodology which would integrate the supply chain and achieve innovation diffusion.

Within this framework diffusion is largely measured through the degree of adoption within a system. Adopters are categorised by Rogers' as innovators, early adopters, early majority or laggards. London et al (2007) eventually challenged this simplistic binary approach to categorisation. However, according to this categorisation London et al (2007) explored late adopters and laggards of technology to develop an e-business technology adoption profile of the majority of the industry players, whilst Walker et al (2005) explored early adopters of technology. The work by London et al (2007) on e-business innovation diffusion in the construction industry was unique in that this piece of work identified pathways of adoption by the later majority adopters and laggards. That study challenged the basic premise to Rogers' work in that adoption was considered as a binary proposition, ie to adopt or not to adopt. This conceptualisation was tested. There were different rates of adoption and these were related to the way in which the players involved underwent transformations in their perceptions about the particular innovations. These patterns can be seen in three identifiable pathways which were termed: Perceptions Pathway, Compatibility Pathway and Communication Pathway.

The present research is more particularly focussed on the creation phase, ie the innovators and towards the development of a pathways conceptualisation and methodology for the innovator group. Therefore it would be worthwhile to explore the relevance of the five stages of the innovation process for describing and explaining the successful implementation of an innovation in the housing construction innovation in Australia by an "innovator group" and after that preliminary analysis to then further examine any unique characteristics in relation to pathways for innovation creation, development and implementation. The participants in the "innovator group" include those players who were actively engaged with the identification, creation, development and implementation of the waffle footing system innovation process. The innovator group is differentiated from the other adopter groups in that participants are actively engaged in the creation and development of the innovation and they are not simply adopting something which has already been designed, tested, evaluated and implemented. Manley and McFallan (2006; 2008) also conducted research on innovators in the construction industry and their particular contribution was an identification of the business strategies used by innovators for effective implementation. In particular through a survey with over 3000 key Australian construction firms Manley and McFallan (2008) identified the relative importance of five key types of business strategies was examined relating to employees, marketing, technology, knowledge and relationships. The strategies which had the greatest impact included investment in research and development, participating in partnering and alliances on projects, ensuring transferral of project learning into business processes, monitoring of international best practice and recruitment of new graduates. This piece of work however did not explicitly map the process pathway for innovation creation, development and adaptation by an innovator group.

METHODOLOGY

The study involves an in depth analysis of the creation and diffusion of an innovation in the housing construction industry in Australia. The innovation case study is the creation, design, development and implementation of the waffle pod footing system. The empirical study is organized in three phases:

- Phase 1 exploratory description of case study: description of the chronological history of the creation and development of the innovation including key players, events, drivers and decisions. This will also map the development and then the transition into more widespread diffusion.

- Phase 2 critique of process: detailed critique of the process including the factors affecting creation, development and implementation. It will involve the identification of the barriers and enablers for development and implementation of the innovation.
- Phase 3: development of integrated supply chain innovation methodology: description of the actual process and then the critique of barriers and enablers will allow the development of a structured methodology of 'best practice' for innovations requiring an integrated supply chain approach. However it is noted that this is only one exemplary case study and so as an exemplary case study it is significant in its own right but further studies would be required for improved validity and reliability for broader generalisation.

The study focuses on the organizational, communication, economic contextual factors as they relate to the technological innovation rather than the technical factors of the innovation. It is apparent that the technical innovation has been reasonably well documented already. The project is ongoing and we are now midway through Phase 1. This paper reports the preliminary results of Phase 1. The study is limited by the reporting of only one example of an innovation.

Phase 1

The first phase involves the conduct of detailed semi-structured face-to-face interviews with key players of the "innovator group" associated with the waffle footing innovation. This data collection and analysis will be supplemented with a document analysis on the documents that have been published or developed during the time of innovation development and initial diffusion. Six interviews with seven participants from five organisations have been conducted to date. It is anticipated that in total there will be eight interviews with ten participants from seven organisations which will be analysed for this study. Table 1 presents details relating to the interview participants. The duration of the interviews is between 60-120 minutes.

The interview participants were asked questions relating to four key areas:

- their role in their organisation at the time and their specific role in relation to the waffle pod footing innovation
- key events or milestones/critical moments in the innovation process
- barriers and enablers which hindered/drove the innovation
- key players in the innovation process

The narrative inquiry approach is employed to uncover stories which highlight the organisational, communication and economic factors impacting on the creation, development and adaptation of the innovation. The key actions and events which influenced decisions made are systematically studied to connect and see the consequences of those events over time mapped against the creation, development and adaptation of the innovation (Riessman, 1993). The specific technique of story analysis is used for data analysis as it offers a way of connecting different stories to understand the phenomenon and in particular changes that take place over time (Bell, 1993). The unit of analysis is the participant and these are now considered as unique cases. There are two key parts to the analysis which are within-case and cross-case analysis. The interviews are recorded, transcribed and subjected to two stages of analysis.

The first part of analysis involves a within-case analysis of the case studies to identify links between stories particular to each case. Stories are identified and coded into the five stages of the innovation process. The following steps are undertaken in this stage of analysis:

- Entire interviews are transcribed into "rough drafts" to develop narrative segments.
- The narrative segments are interpreted to identify the meaning of each individual story. In each story a particular feature is identified to demonstrate a certain element of a particular stage of the innovation process. Based on the participant's decisions, activities or events described within the stories, each story is then classified into categories according to the primary characteristics of the five stages of the innovation process.
- The next stage involves linking the different stories into chronological order. The stories coded into the five stages of the innovation process are then "pasted together" to form a "metastory" to demonstrate the participant's experiences related to the waffle pod footing innovation.

The second part of analysis involves a comparison across cases to identify common themes and irregularities.

Table 1: Interview participants

Case study	**Organisation type**	**Position in organisation**	**Role in relation to waffle footing innovation**	**Location**
C1	Large housing developer, CO1	State Manager (retired)	Supply of experimental/prototype sites Organisation of supply chain to create and implement system	Australia-wide
C2	Footing contractor, CO2	Managing director	Construction of footing system for experimental/prototype sites	South Australia
C3	Building materials supplier, CO3	Sales representative (retired)	Promotion, distribution and selling of the system nationally	Australia-wide
C4	Plastic spacer manufacturer, CO4	Managing director	Manufacturing of key component of system, ie plastic spacer	South Australia
C5	Engineering consultant firm, CO5	Managing director	Engineering design of the system Monitoring and testing of experimental/prototype sites Obtained approval/ accreditation for system	South Australia, Victoria
C6	Engineering consultant firm, CO5	Managing director (retired)	Engineering design of the system Monitoring and testing of experimental/prototype sites Obtained approval/ accreditation for system	South Australia, Victoria
C7	Polystyrene supplier, CO6	Sales representative	Distribution of the system in Victoria	Victoria
C8	Industry association, CO7	State Manager (retired)	Promotion of the system in Queensland	Queensland

RESULTS

Each participant was analysed as an independent unit and subjected to the two stages of analysis as outlined previously. Barriers and enablers to the creation, development and adaptation of the waffle footing system innovation were identified and a summary of this is provided in Table 3 (refer to appendix). It is not the intention of this paper to discuss this part of the results, however, the table summary serves to indicate the various key themes identified in relation to the barriers and enablers which participants in the innovator group experienced. Many of the barriers and enablers are consistent with those identified in the literature, however, there are a number of these which are particularly unique to the innovator group (bolded text). For example, one of the key issues discussed by the participants involved complications associated with protection and formalisation of intellectual property. This is perhaps something that is unique to the experiences of the innovator group since other adopter groups would not have issues concerning protection of intellectual property.

A number of similarities between the participants experiences related to the creation and development of the waffle footing system innovation were identified and the five stages of the innovation process can be mapped reasonably well as a result of the interview data analysis. The first stage of the analysis involved categorising the participants' stories into the five stages of the innovation process; namely, agenda-setting, matching, redefining, clarifying and routinising. The findings reported in this paper are a result of the second stage of analysis, which involved a comparison across six cases. Analysis of cases C7 and C8 is ongoing. Specifically, the manner in which participants within the innovator group each experienced the five stages of the innovation process will be discussed with key themes identified across the six cases. Table 2 provides a summary of the key themes arising from the cross-coding of the participants' stories into the five stages of the innovation process. A detailed discussion of the key themes identified within each stage is provided in this section. Before this, a brief summary of the waffle pod footing story is described to provide context for the discussion which follows.

Table 2. Cross-case comparison of key themes arising from the participants' stories coded into the five stages of the innovation process

Stages	C1	C2	C3	C4	C5	C6
Agenda setting	Opportunistic surveillance		Opportunistic surveillance		Opportunistic surveillance	
	Performance gap				Performance gap	Performance gap
Matching	Establish fit between problem and innovation	Establish fit between problem and innovation	Establish fit between problem and innovation	Establish fit between problem and innovation		
Redefining/ restructuring	Changes to organisation/ innovation	Changes to organisation/ innovation	Changes to organisation/ innovation	Changes to organisation/ innovation	Changes to organisation/ innovation	Changes to organisation/ innovation
		Collaborative efforts between participants	Collaborative efforts between participants	Collaborative efforts between participants	Collaborative efforts between participants	Collaborative efforts between participants

Clarifying	Role of champions	Role of champions	Role of champions		Role of champions	
	Reducing uncertainty	Reducing uncertainty	Reducing uncertainty		Reducing uncertainty	
Routinizing	Widespread diffusion	Widespread diffusion			Widespread diffusion	Widespread diffusion
		Reinventions	Reinventions	Reinventions	Reinventions	Reinventions

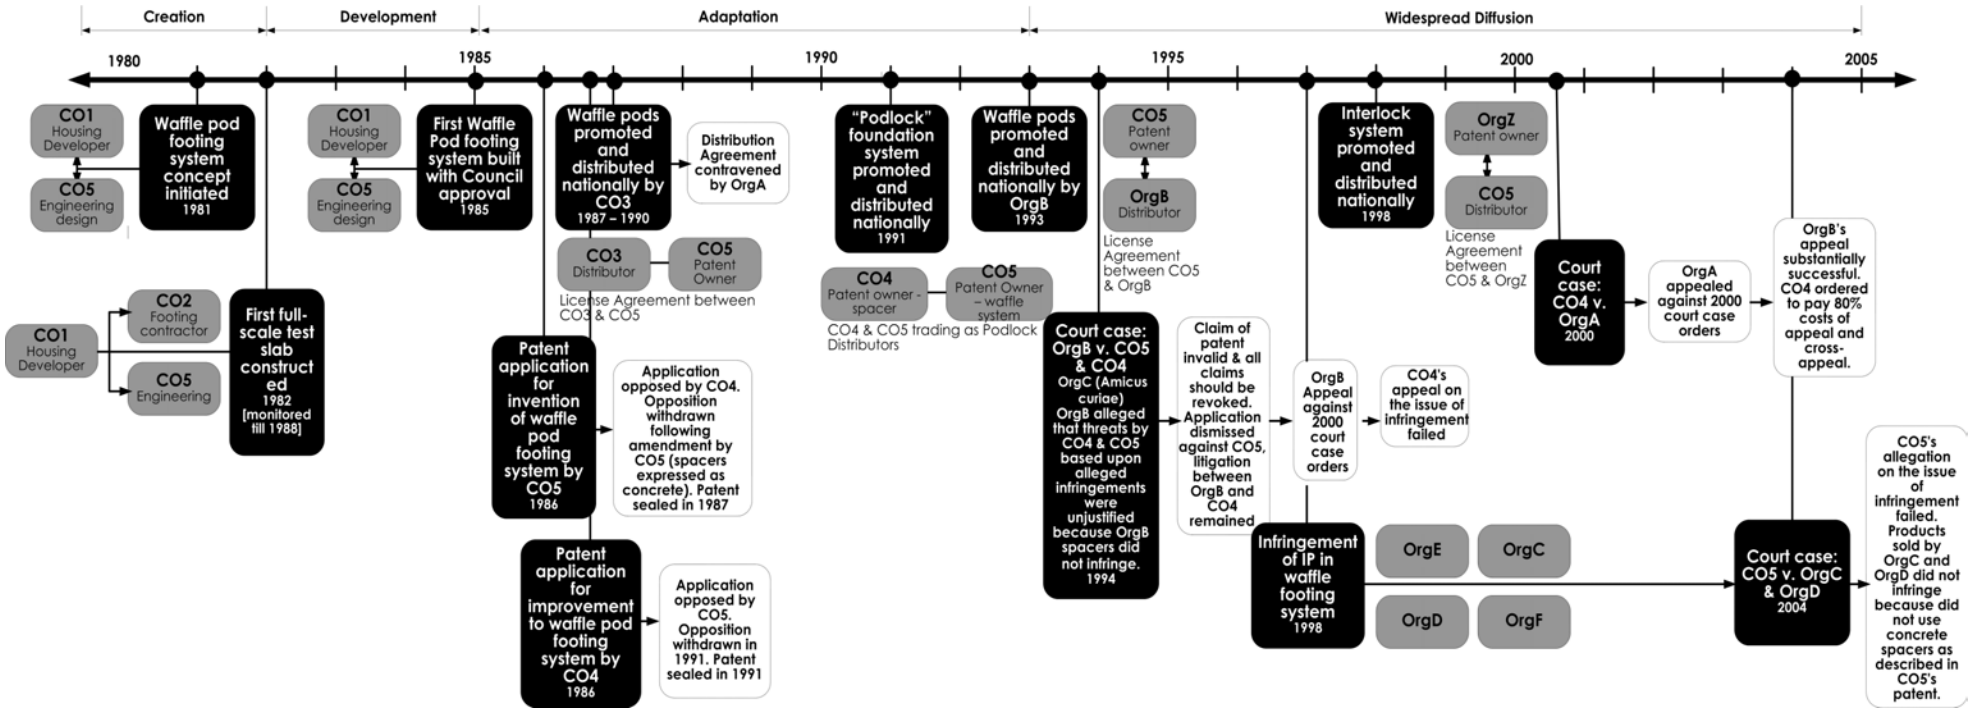

Figure 1. Summary of the chronology of events surrounding the waffle footing system innovation 1980-2005

A summary of the chronology of some of the key events and developments surrounding the waffle footing system is presented in Figure 1. The waffle pod footing system story begins in the early 1980s in Adelaide, South Australia. The state management of a large national housing developer (CO1) was looking for more efficient ways to increase revenues and the waffle footing system was seen as a strategy which offered an opportunity to achieve this. The initiative to create, develop and implement the waffle footing system innovation was championed by C1, who was the state manager of CO1 at the time. During that time, CO1 was trading with an engineering consulting firm, CO5, which had just embarked on a program of research and development in the footings area. The late 1970s and early 1980s saw major developments in Australian building codes in terms of how footings were specified and the waffle footing system was a part of the different streams of research CO5 were engaged with during that time, which was championed by C5. A number of other key players contributed to the creation, development and implementation of the waffle footing system (refer to Table 1).

The footing system although originated in South Australia some 18 months after the first installation had spread to the other states of Queensland, New South Wales and Victoria. There were interesting developments from 1986 onwards when CO5 sought protection to own the exclusive right to commercially exploit the waffle footing system by applying for a patent in 1986. The patent was entitled "Building Foundation Form Work Arrangement" which involved "levelling the ground on which the foundation is to be located, positioning a plurality of box-like hollow members in rows on the levelled ground, separating the hollow members by spacers, positioning lower reinforcing rods on the spacers and between the hollow members, positioning a reinforcing mesh over the hollow members and pouring concrete into channels between the hollow members and over the hollow members so as to envelope said reinforcing rods, mesh and hollow members and thereby form the foundation with a plurality of intersecting reinforced beams and an overlaying reinforced floor slab" (APO Patent Application 198667009, 2011). Not long after in 1987, CO4, sought to apply for a patent entitled "Improvements relating to building foundation form work". The invention CO4 was seeking to protect involved an improvement on the use of concrete blocks, which was proposed by CO5 as spacers. CO4's spacer is "in essence, a framework which holds in place pairs of vertical plates set at right angles to each other." (FCA-FCD, 2011). The plate fits over the corners of the hollow boxes and holds them in place relative to each other.

Both CO4 and CO5 opposed each other's patent applications. CO4's opposition to CO5's application was withdrawn following an application for amendment was made by CO5. The amendment involved specifying the specific use of spacers made out of concrete, which was different from CO4's plastic spacers. CO5's opposition to CO4's patent application was then withdrawn and both patents proceeded to sealing. Over the following years, the waffle footing system gained increasing popularity and there were various business ventures with alliances developed as 'spin offs' from the business in Adelaide. From the mid-1990s onwards CO4 and CO5 experienced a number of infringements on their patents which eventuated in a series of litigations and court cases (refer to Figure 1).

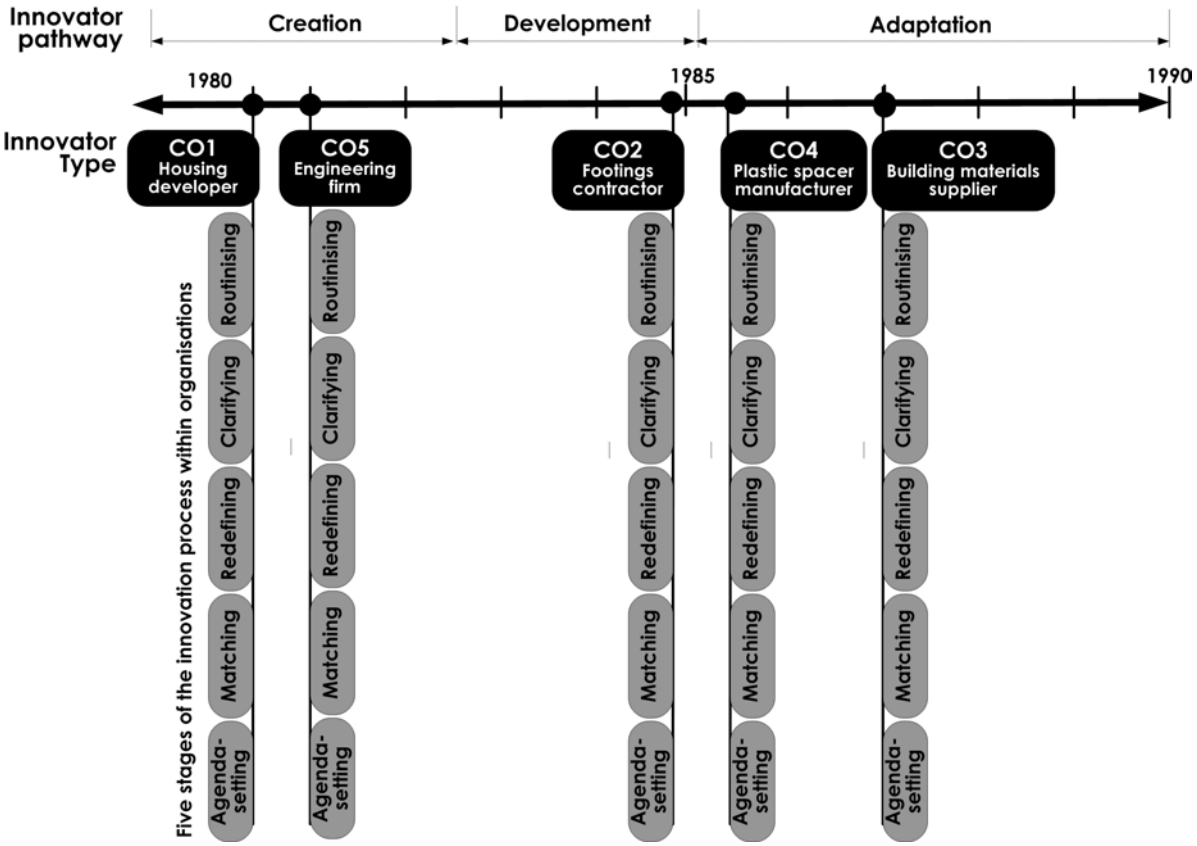

Figure 2. Innovator types and Pathway towards creation, development, adaptation and implementation of innovation

One of the key findings of this research to date is a more complex categorisation of participants within the innovator group. Whilst past research examined the innovation process within organisations (Rogers, 2003), this research explores the innovation process across organisations, ie, within an "innovator group" comprising a number of organisations located at different tiers of the supply chain. Given that the innovator group is made up of various organisations there was more than one clear "cycle" of the innovation process occurring whereby there were individual cycles within each organisation taking place concurrently alongside the overall innovator group pathway. The previously accepted broad classification of "innovators" does not capture the specific characteristics of those case study organisations observed in this research. The preliminary findings demonstrate that participants within the innovator had various roles to play at different stages of the innovation process in the successful implementation of the waffle footing system. Furthermore the analysis highlighted that there are different types of innovators which are:

- Innovator-creator: those who are responsible for initiating and creating the innovation
- Innovator-developer: those who contribute towards the design, planning and development of the innovation
- Innovator-adapter: those who enter at latter phases and contribute to the innovation by modifying/adapting the innovation

Agenda-setting

In diffusion theory (Rogers, 2003) the agenda-setting stage initiates the innovation process and is where an organisational problem is identified thus generating the need for an innovation. Analysis of the interviews with key players (C1, C5, C6) involved with the waffle

footing system innovation revealed that the agenda-setting stage was significant in that for many of the organisations it was during this stage that the initial motivation to resolve an identified problem was created which helped to drive the later stages of innovation. A total of eleven stories identified from the interviews were coded into the agenda-setting stage. Two main themes were identified as part of this stage including; performance gap and opportunistic surveillance.

The first theme of performance gap is about inconsistencies between how individuals within an organisation perceived its performance and how they expected to perform. C1, C5 and C6 indicated that a perceived performance gap was a trigger to search for an innovation.

> *"the traditional was a brick build-up…and what that meant was you had unknown rock excavation on the strip footings…when you hit rock, you called the customers up and said you're going to have to pay us some more money so straight away you're off-side… So my drivers were…so that we could actually fix the customer's price and charge no extras for them… I wanted to be able to control the actual costs… the other thing that hit me was in multi-storey car parks I'd seen where these waffle pods had been used…I just said, cant we do that same stuff here?" (C1)*

> *"the idea was to get a footing system that was as near as possible to a factory-produced…and above-ground…cause once you start digging you lose control of what you're building, you get over runs, your trenches collapse" (C5)*

> *"because we were involved with footing designs and having problems with movement. As a structural engineer I had designed waffle slabs for first floors…So I figured we got nowhere for support in soils or footings in soil and maybe a waffle will be a good concept"(C6)*

For these participants the need for an innovation was borne out of the inefficient manner in which traditional in-ground strip footing systems performed which involved excavated trenches with foundation walls built up to the required floor level from the footing. This method was considered labour intensive and not particularly cost-efficient. The problem also with the traditional footing system was unknown required footing depths due to differentials and variability in in-ground movement and consequently the difficulty of trying to accurately control the amount of concrete used. Both C1 and C5 highlighted the key disadvantage of the traditional system as its inability to control quantities and costs. The desire to develop an above the ground footing system which was *"as near as possible to a factory-produced product"* was thus seen as a way to achieve fixed or accurate cost predictions. The experiential problem solving method was employed in the creation of the innovation whereby the innovator-creators drew upon prior experiences in the attempt to create a more efficient product. For C6, the idea of the waffle footing innovation came from his earlier experiences of having designed waffle slabs for first floors as an engineer whereas C1 relied upon broader experiences gained from working overseas:

> *"…the margins in housing are quite low, they're terrible because of the inefficient way we did things but it reminded me of the landscapes around Durban where I'd been working over there. So in one of my thinking modes … I thought why cant we cut and fill and slab as we did over there. So I started exploring that"*

The second theme revolved around the participants being engaged in opportunistic surveillance (Rogers, 2003) by continuously being on the look out for new ideas which might be beneficial to the organisation. Past work into the innovation process has highlighted that organisations are often driven more by solutions as compared to problems (March, 1981). Given the high number of problems typically faced by organisations, the chances of identifying an appropriate innovation to deal with a specific problem is relatively low. The

possibility of matching an innovation to a problem faced by an organisation can, however, be higher if organisations begin with a wanted solution or innovation. As a result a large number of organisations tend to be involved in opportunistic surveillance to identify promising innovations which may be relevant for dealing with existing problems in the organisation. Indeed this was the case for three of the participants interviewed who each indicated that they were actively scanning the environment for new ideas and "thinking about things":

> *"So what we did was set up some internal R&D projects…so we had different streams to what we were doing" (C5)*

> *"had a break when I realised one day sitting in the office…I'm paid to think about things" (C1)*

> *"James Hardie is basically a building materials supplier…they were actually looking to diversify and try something else and have another product that they could promote Australia-wide" (C3)*

In the case of C4 in particular, knowledge of an innovation launched the innovation process in the organisation. The organisation took on an opportunistic approach whereby knowledge of the waffle footing system created a need for the innovation process. Prior to the organisation discovering the product there was no specific plans for its use except that the organisation was looking to diversify its product-line. Therefore even though the innovation process is often initiated by a perceived need to address a particular problem it can also be triggered by knowledge of an innovation, as in the case of this innovator-adapter (C03).

Matching

A total of thirteen stories were coded into the matching stage. A common theme that the participants experienced during the matching stage related to establishing the fit between problem and innovation. At this stage, participants determined how well the innovation aligned with the identified organisational problem:

> *"so in discussion with my marketing people that time, I said, "What do you really want, like if you could really put the price on the market fixed, no extras would that be a value proposition?" They went "oh boy, would that be!" They said, "go for it!"" (C1)*

> *"the first one I actually witnessed…it was an eye opener for me... Straight away I went into gear and said right, this is the easiest way to do it…if you dig a foundation right in the ground you really cant form it up…that'll cost money and time whereas just the simple process, form up the perimeter of your house foundation…lay some pods in there" (C2)*

> *"So we used to supply and fix. So he started the ball rolling on that and I would never have worked any other way because that's the way I liked to work so I was a good candidate" (C2)*

> *"cos basically everybody no matter what industry you're in especially in the building industry you're forever looking to save costs wherever you can. And this was a cost saving exercise" (C3)*

> *"I was a foundation contractor and when I heard about it I didn't like the way it was put together … and because I knew about patents … So I just wanted to improve it by making a better spacer to hold it together. So I came out with this" (C4)*

As highlighted by these quotes the matching stage was a particularly critical stage in the innovation process for these participants as it marked the decision to proceed with the design, development or implementation of the waffle footing system innovation within their

organisations. The specific benefits of the waffle footing system were anticipated in the form of fixed pricing (C1), ease of construction (C2), appropriate work method of supply-and-fix (C2) and cost savings (C3) and matched against organisational needs. The waffle footing innovation "found a home" in the respective organisations due to the high degree of fit between the innovation and organisational needs or problems. The matching stage can also be influenced by organisational capacity or specific expertise/experiences related to the innovation process as demonstrated by C4. For C4 the decision to adapt the waffle footing system innovation was largely a result of having prior understanding of dealing with an innovation in a different industry and in particular with patents. The waffle footing system innovation was established as one which fit with the organisation's specific expertise and capacity and thus a decision was made to be involved with the adaptation of the innovation.

Redefining/restructuring

Nine stories were coded into the stage of redefining/restructuring. The first theme of the redefining stage involves changes which occurred to the organisations or innovation during the redefining stage.

> *"We invested in a couple of staple guns and stapled them together. So it was so simple…and I self taught myself" (C2)*

> *"The only thing that I did was waffle pods…I was employed to drive that…They had people that were already promoting CO3 products and this was an add on for them to promote…And that's the other thing its changing the whole spectrum …they could then turn around and use it as an advertising thing and say CO3 can build a house for you" (C3)*

As highlighted above, the innovation process resulted in a degree of change for the participants in terms of work practices and organisational structure. For C2, the waffle footing system can be classified as an incremental innovation as it did not require a high degree of technical expertise to implement and therefore was implemented relatively easily as C2 indicated, "it was so simple…I self taught myself". For CO3 however, the innovation was a little more radical. Not only did the innovation lead to the creation of C3's role, which was specifically to promote the waffle footing system, it also affected the "whole spectrum" of the organisation's marketable products in that the organisation was then able to expand its market share by the ability to supply products for the construction of an entire house. According to Rogers (2003) the redefining/restructuring stage is when the innovation imported from outside an organisation loses its foreign character, that is, the innovation is adapted to suit the organisation's needs or structure and vice versa. Even though the innovation process did result in changes, there was a slight difference in the way the redefining stage was experienced by the innovator group analysed on this project in that given they were largely the ones creating and developing the innovation, they were provided the opportunity to shape the innovation to suit their organisational needs, rather than change the innovation to suit the organisation at a later stage, as highlighted by C1:

> *"I can remember…trying to find plastic tubs or bails or hay or something – but it didn't matter what we stuck in there and I was cost controlling" (C1)*

For C1, a primary objective of their organisation centred on an ability to control costs and therefore during this stage was found to be developing the waffle footing system to achieve that. Being involved at the start of the innovation process as an innovator-creator, the organisation was able to create the an innovation which was particularly aligned to the objectives of the organisation.

The second theme was the collaborative efforts between participants in the innovator group in the implementation of the waffle footing system innovation whereby various forms of agreements or arrangements were developed in order to successfully achieve diffusion of the innovation.

> *"I remember when we did the test slabs…I got all the materials and things from suppliers…I was communicating with our direct suppliers and I said you're going to be a part of this" (C1)*

> *""it was all up and down and I wasn't really enthused by them…So I suggested that we form it up with higher formwork. So out came my formwork cos I was a concretor over in Lincoln and I also had a concrete pump so I suggested we pump it in…to work in with the waffle system I think CO5 thought of it, CO1 took it, I produced it and it was just a happy meeting and we were all happy to work with each other. And CO1 always paid me on time so no major dramas" (C2)*

> *"CO1 gave us this block of land and that footings was built for free. All the suppliers and contractors contributed to it so people were happy to put in as an industry but to give us access to that block of land for that period of time was just something that they did. So there was quite a bit of visionary in doing that. A long commitment type of thing…we did that work very thoroughly very diligently and that provided base information that I think nobody had ever had to give credibility to the design methods we were using" (C5)*

> *"We did spend quite a bit of time so we did some researching…So once we got all that testing stuff we were doing engineering stuff for CO1 and they were quite keen to see the outcome of this because they could save money…. So they supported…they gave us a piece of land" (C6)*

> *"So CO3 were keen to be behind us and have the rights and we had some sort of a contract with them" (C6)*

Even after the decision was made to create the innovation, a considerable amount of time was spent in the design and development of the waffle footing system. This was particularly important because not only were the participants simply importing an innovation to be implemented within their organisations, they were also implementing an innovation in which required designing and planning. This is an added layer of complexity which the innovator group has to undergo, which many organisations adopting prior developed innovations do not have to encounter. Therefore the participants were committing themselves to a high degree of uncertainty in the decision to create, develop and/or adapt the innovation and as raised by C3, perhaps a "highly revolutionary" move. The quotes above clearly demonstrate the different roles each participant within the innovator group played in the successful implementation of the waffle footing system.

Clarifying

The clarifying stage occurs when an innovation has been implemented in a more widespread manner in an organisation (Rogers, 2003). Within the context of the waffle footing system innovation the clarifying stage involved the innovator group spreading and promoting the innovation to different tiers of players in the construction supply chain. Twenty-four stories were coded into the clarifying stage. Two key themes were identified in this clarifying stage of the innovation process including reducing uncertainty and the role of champions.

Given the newness of the waffle footing system, its implementation was surrounded by a high degree of uncertainty. The first theme revolved around the participants undertaking various activities and strategies aimed at reducing uncertainty of different players in the supply chain.

C5 highlighted a number of strategies which were used to diffuse the waffle footing system and reduce uncertainty amongst potential adopters including publishing and presenting at conferences to develop credibility and provide confidence to those who are considering adopting the innovation.

> *"I presented at a 1987 MBA conference in Queensland and out of that came a whole string of contacts. Then I presented…at a local government conference in Perth and out of that building surveyors who check and approve building applications all came to learn about it… The key thing was doing it at different levels" (C5)*

Despite this, the analysis is consistent with past work into the innovation process which has highlighted that the management of the clarifying stage is often challenging and complex because misunderstandings and side-effects may occur. Within the context of the waffle footing system innovation, professional jealousy and overcoming mindsets and perceptions were highlighted by participants as key problems in the promotion of the innovation.

> *"so the civil engineer wanted a raft footing system. So I said that's ridiculous why not we turn around and use a waffle pod system? The engineer wouldn't have it" (C2)*

> *"So it was professional jealousy … they [engineers] wouldn't use it for a long time" (C3)*

> *"The product might be terrific but sometimes it's very, very hard to change mindsets no matter what industry, no matter what you're doing. Because people are so used to their own practices, systems and whatever and it works" (C3)*

C3 in particular explained that he experienced a high degree of resistance and "head banging" in his efforts to promote the waffle footing system to engineers and footings/foundation contractors. According to him the resistance to adopt the waffle footing system was not related to technical issues but rather to do with "human nature". For the engineers, adopting the waffle footing system was seen to be something that would benefit another engineering company whom they were in competition with and therefore these engineers saw nothing to be gained out of being in favour of the innovation. On the other hand, the foundation contractors perceived that the newness of the waffle footing innovation would equate to a degree of difficulty in having to change their existing practices and systems. For these contractors, the waffle footing system was out of their comfort zone and seen as simply "too hard" adopt.

The second theme is about the role of champions in the innovation process during the clarifying stage. An innovation champion may be viewed as "a charismatic individual who throws his or her weight behind an innovation, thus overcoming indifference or resistance that the new idea may provoke an organisation" (Rogers, 2003, p. 414). The management of the clarifying stage during the innovation stage was characterised by a high level of uncertainty. C1 took on a central role in explaining to those players meant to construct the waffle footing system to reduce uncertainty by running seminars and providing demonstrations:

> *"I took the concrete gangs to CO5's offices … and ran seminars on how to put a box together…cos I was determined and you have to champion that so you've got to just push that through like most things in innovation" (C1)*

In the case of the waffle footing system innovation, uncertainty existed not only in the minds of those outside the innovator group but also within the innovator group. As highlighted previously, the collaborative efforts between participants in the innovator group was key to the successful implementation of the waffle footing innovation. This collaboration, however,

was enabled through the efforts of C1, who played a central role in "negotiating my [his] supply chain":

> *"Well I was negotiating my supply chain to move from timber decks on bearers to concrete which means that they were getting 13 metres of concrete of job ….So wouldn't you make sure that you looked after us... And they did believe in this as well…because I think we had a good… ethical trading. We always try to fulfil our part to pay you on time... I mean you've got to look after these people" (C1)*

As indicated, there seemed to be mutual understanding and respect between players in the innovator group in the effort to implement the waffle footing system. The champion in this case, C1, ensured that the anticipated benefits for the group were clearly spelt out so that they would be more willing and committed to participate and contribute to the creation and implementation of the innovation. The credibility and "ethical trading" practice of the organisation was also seen to help in creating a degree of assurance in the group within an uncertain environment. Furthermore, C1 took great care in "looking after" the players in the group by paying appropriately, which C2 indicated was seen as particularly important for his organisation.

Routinising

Twenty-six stories were identified from the interviews which were coded into the routinising stage. Two key themes were identified in this stage including drivers to widespread diffusion and re-inventions.

A number of key drivers led to the widespread adoption of the waffle footing system innovation. One of the primary drivers which C1 described as a "breakthrough" was approval gained from the relevant authority which deemed the waffle footing system as one which complied with the required codes and guidelines related to footing systems in Australia.

> *"So that was the actual first system built… so the significance of it was that it was approved by the authority that had to approve footing systems and it was a breakthrough…So from that point it became accepted and we were pricing our land and house packages with it or when people came to us we could definitely give a fixed price… and then it started to be picked up by other builders" (C1)*

Obtaining approval was significant in that it demonstrated to the industry and more importantly it provided the assurance for others to be confident in their use of the waffle footing system. Following this, it was the adoption by a group of early adopters consisting large builders which drove the innovation and "went like wild fire".

> *"…all the competitors were using it. They saw CO1 were doing it, got the ball rolling and they thought why not. I think it took a few years [for that wave to happen] before they were gutsy enough to come into it" (C2)*

> *"a couple of major builders thought it was a good idea and once they got on board it just went like wild fire" (C5)*

Sustainability is another concept closely related to routinising which has received considerable attention in recent years. It is defined as the degree to which the innovation continues to be used after initial adoption has occurred (Rogers, 2003). A number of factors have led to the sustainability of the waffle footing system innovation. C5 explained that specific events or characteristics of the industry at different times have helped to ensure the sustainability of the innovation. One example he provided is the ability of the polystyrene

component of the waffle footing system contribute towards achieving the current requirements for house energy ratings by the Building Code of Australia whereby:

> *"waffle pod footing system, because of polystyrene in it, it's worth 1-star out of six extra…So that at the moment is another thing that's pushing the system" (C5)*

The second theme is concerned with re-inventions which were done on the waffle footing system. Consistent with the literature related to the innovation process which indicates that innovations tend to undergo adaptations and are continuously re-invented to suit changing organisational and environmental needs, the waffle footing system experienced a number of iterations. Of significance was the introduction of polystyrene boxes for a component of the waffle footing system to replace an earlier cardboard box. As with many developments, the use of polystyrene was seen as beneficial in a number of instances when compared to the cardboard boxes however was also disadvantaged due to its bulky nature and the difficulties associated with transporting the product.

A key issue which was raised by all participants in relation to re-inventions concerned the protection of intellectual property. As the system begin to gain acceptance, the engineering firm, CO5, which developed the idea of the waffle footing system sought to protect their intellectual property by developing a patent on the system. The process which they eventually experienced was one fraught with difficulty and "a major stuff up" which was characterised by litigations and court cases. As C3 explained, a key player within the innovator group, CO4, which initially patented a plastic spacer which was a central component of the waffle footing system later attempted to patent the "improved waffle footing system" and claimed it as his own.

> *"And once the system started to move then all this other junk started to develop…the people that had the spacers were saying that the royalties should come to them from the waffle pods. And the people who had to waffle pods were saying that the royalties should come to them…it was a major stuff up" (C3)*

At the same time, as the waffle footing system was gaining increased widespread uptake in the industry, more and more companies started to re-invent the innovation to market as their own product. C4 and C5 explained how these companies were infringing on their patents which led to a series of litigations and court cases between various parties:

> *"well in Australia you can't defend a patent…without being very rich because you've got to be able to go through with the legal stuff to defend it against the people who're breaching it in small ways or even large ways" (C5)*

> *"we were having court cases and this is people infringing on our patent…everybody tried to get around our spacer" (C4)*

While the court cases and litigations did not hinder the successful implementation of the waffle footing system innovation it does raise another important issue in relation to the protection of intellectual property for those who were central to its creation as highlighted by C6:

> *"If anything Australia needs to do is change the system of patents because its not fair to someone like me who's started off something that's so popular that gets nothing out of it because of some crook" (C6)*

The lack of protection of intellectual property offered by the existing system of patents in Australia does not appear to be a conducive environment for innovative behaviour. There does not seem to be any incentive which rewards innovative behaviour. This is perhaps quite

a significant issue which needs to be considered particularly in an industry where the pace of innovation is low.

CONCLUDING REMARKS AND FURTHER RESEARCH

This paper presented the preliminary findings of a case study of successful implementation of delivering an innovation to the Australian housing construction industry. It specifically explored the relevance of Rogers' five stages of the innovation process for describing and explaining the successful implementation of an innovation in the housing construction innovation in Australia by an "innovator group". Analysis revealed that the experiences of each participant within the innovator group resembled the conditions of the five stages of the innovation process, namely; agenda-setting, matching, redefining, clarifying and routinising. However the findings also demonstrated that the previously accepted broad classification of "innovators" does not capture the specific characteristics of those case study participants in the innovator group observed in this research. Furthermore not only was the success of the implementation of the waffle footing system reliant upon one champion from one organisation, it was also driven by the collaborative efforts of various participants or champions from a number of organisations within the innovator group, each contributing at different stages of the creation, development and adaptation of the innovation. One of the most significant findings of this research has been an identification of different types of innovators which include; innovator-creator, innovator-developer and innovator-adapter. The next stage of the analysis will involve a detailed identification of the unique characteristics of the pathways for the innovator group for innovation creation, development and implementation.

Abstract
Building an inclusive society has been a goal with universal appeal. In respect of sustainable design and construction, due consideration in disability inclusion is necessary for it has social, economic, legal and environmental implications. It is not a new subject; however, there is still a long way for our built environment to be inclusive. In this paper, a practicable means to appraise the inclusiveness of built facilities quantitatively, the Building Inclusiveness Assessment Score (BIAS), is proposed. Literature, guides and standards of barrier-free access and universal design are reviewed so as to construct a hierarchy of relevant inclusion attributes. A multiple-criteria analysis technique, the Non-structural Fuzzy Decision Support System (NSFDSS), is then applied to analyse the weightings of attributes. On-site assessments are undertaken to collect data for grading individual inclusion attributes. The inclusiveness of built facilities in the University of Hong Kong is studied.

In BIAS, a hierarchy of inclusion attributes is appraised. The outcomes are integrated in form of a score. Notwithstanding the research project is still ongoing, preliminary findings from on-site assessments are presented. A novel insight is provided to sustainable design and construction which should not only regard environmental and economic sustainability but also social sustainability. Compare with earlier attempts to quantify the accessibility of buildings, BIAS further reduced the subjective elements. The framework of BIAS can also be modified to assess built facilities of other uses.

Keywords: Barrier-Free Access, Disability Inclusion, Non-structural Fuzzy Decision Support System, Performance Measurement, Universal Design

INTRODUCTION

Building a society for all has been a goal with universal appeal. A society as such is known as an inclusive society that rises above differences of race, gender, class, generation and geography to ensure equality of opportunity regardless of origin, and one that subordinates military and economic power to civil authority (Atkinson, 2010). In architecture, the persuasion of Richard Rogers, the architect of the world renowned Centre Pompidou in Paris, France, probably depicted the ideal of inclusion in broad sense (Cole and Rogers, 1985; pp11):

"It is my belief that exciting things happen when a variety of overlapping activities designed for all people – the old and the young, the blue and white collar, the local inhabitant and the visitor, different activities for different occasions – meet in a flexible environment, opening up the possibility of interaction outside the confines of institutional limits. When this takes place, deprived areas welcome dynamic places for those who live, work and visit; places where all can participate, rather than less or more beautiful ghettos."

Inclusion in architecture is, however, often synonymous to disability inclusion. Disability nowadays is considered as a social rather than a medical issue (Goldsmith, 1997; Holmes-Siedle, 1996), for it is seen as the outcome of interaction between persons with impairments and a non-inclusive society (United Nations, 2006). Under the United Nations Convention on the Rights of Persons with Disability, obstacles and barriers to accessibility in buildings and other physical environment shall be identified and eliminated. 147 countries and regions have already signed this convention since 2007. In the meantime, access for persons with disability to buildings has increasingly become a right under laws (e.g. the Americans with Disabilities Act in the US and the Disability Discrimination Act in the UK). Failure to observe these laws may result in legal proceedings. Universal design is a means to make inclusion in built facilities possible. It is the design of products, environments, programmes and services to be usable by all people to the greatest extent possible, without the need for adaption or specialised design, and it shall not exclude assistive devices for particular groups of persons with disabilities where this is need (Mace, Hardie and Plaice, 1991; United Nations, 2006). This idea is more specifically exemplified by 7 underlying principles (Table 1).

Though there has been gradual progress to promote disability inclusion in buildings, the subject is not free from challenges. A particular challenge is the assessment of accessibility for built facilities. This is done through access audit which is user oriented and access appraisal which is desktop survey dominated (Sawyer and Bright, 2004). The shortcomings of access audit and access appraisal are later highlighted in Wu, Lee, Tah and Aouad (2007). It is thought that the assessment processes are quire complex that involve a lengthy checklist. Meanwhile, they heavily depend on the experience of the assessor for a large number of subjective judgements are included.

The main purpose of this research is to review design guidelines and manuals for disability inclusion in built facilities, to develop a quantitative assessment scheme to appraise the inclusiveness of built facilities and to investigate the inclusiveness of built facilities of a higher education institution, the Hong Kong University. By conducting on-site assessments, both inclusive features and problems leading to exclusion are identified. The sample consists

of 28 buildings which are built between the 1910s and the 2000s. Since this research is still ongoing, only preliminary findings are reported at this stage.

The 7 Principles of Universal Design
Principle 1 Equitable Design The design is useful and marketable to people with diverse abilities
Principle 2 Flexibility in Use The design accommodates a wide range of individual preferences and abilities
Principle 3 Simple and Intuitive Use of the design is easy to understand, regardless of the user's experience, knowledge, language skills, or current concentration level
Principle 4 Perceptible Information The design communicates necessary information effectively to the user, regardless of ambient conditions or the user's sensory abilities
Principle 5 Tolerance for Error The design minimises hazards and the adverse consequences of accidental or unintended actions
Principle 6 Low Physical Effort The design can be used efficiently and comfortably and with a minimum of fatigue
Principle 7 Size and Space for Approach and Use Appropriate size and space is provided for approach, reach, manipulation, and use regardless of user's body size, posture, or mobility

Table 1: *The 7 principles of universal design (source: The Center for Universal Design, 2006)*

INCLUSION AND SUSTAINABLE DESIGN AND CONSTRUCTION

Very often sustainable design and construction is solely regarded as design and construction that is eco-friendly. Sustainability is, however, much more than merely environmental protection. It includes not only environmental sustainability but also social and economic sustainability. Social sustainability is seen as "the ability to maintain desired social values, traditions, institutions, cultures or other social characteristics" (Barbier, 1987), whilst the central idea of economic sustainability is "maintenance of capital or keeping capital intact" that follows Hick's well-known definition of income – "the amount one can consume during a period and still be as well off the end of the period" (Goodland, 2002). Sustainability in short centres on the maintenance of capital in environmental, social and economic aspects, and of course, the environmental facet is of particular concern. Further to the three aspects of sustainability, two paradigms of sustainability are developed. While capitals are assumed to be substitutable in weak sustainability, natural capitals are assumed to be non-substitutable to

other forms of capital in strong sustainability (Neumayer, 2010). To qualify as sustainable design and construction, social sustainability which is manifested in equity and accessibility should be represented, for everyone should have equal rights and freedoms. Whereas for economic sustainability, non-inclusion ends in loss of an enormous opportunity given the estimated rate of disability is 10-12% worldwide (The World Bank, 2009).

THE CASE OF THE HONG KONG UNIVERSITY

As the oldest tertiary institution in Hong Kong, the coming year marks the centenary of the University of Hong Kong (HKU) which was established in 1912. With 22,139 students and 6,010 academic staffs in 2009/2010, HKU comprises ten faculties which are mainly located in the Main Campus. The exceptionally hilly terrain of the Main Campus has been a great challenge to fostering disability inclusion despite the Universities' initiative to promote equal opportunities. The Universities' Equal Opportunity Committee (EOC) and then the Disability Action Sub-committee were set up to oversee and expedite disability inclusion affairs. The units are very dedicated in promoting equal opportunities for all and to make HKU a truly accessible campus is on the agenda (The University of Hong Kong, 2011; pp10). Upgrading of buildings to introduce more lifts and wheelchair ramps to ensure wheelchair access has been undergoing bit by bit and tactile guide paths are provided. Other than the endeavours to ameliorate the inclusiveness of built facilities, the Centre of Development and Resources for Students (CEDARS) offers supportive services to students with disability. They include assistance related to basic necessities, commuting and study, and coordination of buddies and volunteers to help the students (ibid; pp11). All in all, inclusion is seen as important cornerstone of a good employer and a good university in HKU: "…the socially inclusive environment, and the respect for individuals that we are promoting, are values that are of utmost importance in the holistic education of the University." (ibid; pp10)

RESEARCH METHODOLOGY

As the main purpose of this research is to develop a quantitative assessment scheme to appraise the inclusiveness of built facilities in higher education institutions, literature, guides and standards in connection with disability inclusion in built facilities are reviewed in the first instance. It plays a crucial role in the subsequent development of the assessment framework which is one of the cruxes in this research. Another crux is to determine the weighting of attributes towards disability inclusion in built facilities. In the following, the assessment framework, the weighting methods and data collection will be discussed separately.

THE ASSESSMENT FRAMEWORK

Designing for persons with disabilities is a movement emerged after the World War II, with the issue of American Standard A117.1 American Standard Specifications for Making Buildings and Facilities Accessible to, and Usable by, the Handicapped by Tim Nugent that earmarks such a move. This standard was later set as the model for corresponding code of practice in the British Standard issued in 1967 and subsequent legislations against exclusion of persons with disabilities in buildings (Goldsmith, 1997). Apart from guides and standards, there have been interests to evaluate whether a built facility is inclusive or not. It can be done qualitatively by access audit or access appraisal. Access audit was used to study the access provisions in public housing estates in Hong Kong in Chan, Lee and Chan (2009), however, it

involves a great deal of subjective judgments and the overall level of inclusiveness cannot be determined. On the contrary, rating scales for individual accessibility criteria are not explained in Wu et al. (2007) who seek to develop a quantitative building accessibility model using the Analytical Hierarchy Process (AHP) to prioritise the underlying accessibility criteria.

For the purpose of filling the research gap, a quantitative assessment scheme which is workable and practical is needed. In the course of developing the assessment framework, reference has been made to Design Manual: Barrier Free Access 2008 in Hong Kong and BS8300: Design of Buildings and Their Approaches to Meet the Needs of Disabled People to determine attributes or factors that contribute to the inclusiveness of built facilities (Buildings Department, 2008; British Standard Institute, 2009). Other guides and standards in Canada, Singapore, the US and the UK are also considered (BCA, 2007a; 2007b; International Code Council, 2009; NRC-IRC, 2010; Peloquin, 1994; Sawyer and Bright, 2007). As the problem is disability inclusion in built facilities in higher education institutions, it is decomposed into elements of different levels from the general to the more specific at the lower levels (Tam, Tong, Chiu and Fung, 2002). The decision hierarchy is then formed when the attributes have been grouped under corresponding criteria. The hierarchy developed for the time being is shown in Figure 1. During the making of this hierarchy a dilemma is posed. On the one hand, it has been underlined in literature that many criteria at multiple levels will make subsequent pair-wise comparison difficult (Tam and Tummala, 2001). On the other hand, items on the checklist should be assorted and incorporated into the hierarchy for pair-wise comparison accordingly. In such a case, the assessment scheme developed will be more objective and it fills the research gap in Wu et al. (2007). On account of disability inclusion which is concerned with physical, visual and speech disabilities, and hearing impairments, the current hierarchy may be amended by further decomposing into separate hierarchies. Example of an improved hierarchy is shown in Figure 2.

There are four levels in the decision hierarchy developed for the time being. Similar to Wu et al. (2007), the top level is the objective which is to provide an index of inclusiveness of built facilities in higher education institutions. The succeeding level is divided into design and management that represent the hardware and the software in disability inclusion respectively. The idea of design here is actually similar to the physical features demarcated in Sawyer and Bright (2007; pp68), while management refers to the acts taken to build and maintain an inclusive environment. Under design attributes are structured under individual areas and facilities. The items in level II to level IV under design are tabulated in Table 2.

Next is the computation of rating for quantitative attributes in the assessment scheme. Individual attributes are rated using a continuous scale from 0 (for exclusive practice, i.e. the worst practice in disability inclusion to 2 (for the best practice in disability inclusion). Contrary to earlier studies which set the starting point for benchmarking the worst practice to the standards prescribed by laws or codes (Ho et al., 2004; Then, 1996), the rating for meeting legal minimum requirements here is 1. Whether an attribute is qualified as the best practice or not is referred to relevant guides and standards. As the actual condition often lies between complete exclusion and the best practice, linear interpolation is used to calculate the rating. If attributes are qualitative in nature, either dichotomous or multinomial classification is adopted to assign a rating (Ho, 2000).

THE BUILDING INCLUSIVENESS ASSESSMENT SCORE (BIAS)

For simplicity's sake, it would be more convenient to present the overall inclusiveness in form of a score or an index. It is called the Building Inclusiveness Assessment Score, or BIAS in short, which is essentially an aggregated figure of the ratings (F) and weightings (w) of all attributes that affect the inclusiveness of built facilities in higher education facilities (Ho et al., 2004):

$$\text{BIAS} = g(w_1, w_2, \dots, w_n; F_1, F_2, \dots, F_n) \quad (1)$$

where BIAS is the Building Inclusiveness Assessment Score;
w_1 (i = 1, 2, … , n) denotes the non-negative weighting of the *i*th inclusive attribute and all w_i's sum to unity;
F_i denotes the (standardised) rating of the *i*th inclusion attribute;
n is the total number of inclusion attributes; and
$g(.)$ is a continuous or discrete function that combines all w_i's and F_i's through the weighted arithmetic mean:

$$\text{BIAS} = \sum_{i=1}^{n} w_i F_i \quad (2)$$

As can be seen in equation (2), it implies a positive relationship between the BIAS and each F_i, given the weightings are positive. In other words, the higher the F_i, ceteris paribus, the higher the score is achieved in the BIAS. Because the computation of rating for quantitative attributes, F_i, has been explained in the last section, the approach to ascertain the weighting of the inclusion attributes, w_i, will be discussed.

THE WEIGHTING METHOD

Irrespective of the approach used to ascertain the weighting of the inclusion attributes, w_i, the outcome should reflect the relative importance of an attribute towards disability inclusion objectively. Owing to the large number of attributes involved, Multiple-Criteria Decision Analysis (MCDA) technique is applied to provide consistent and least biased solution. Among MCDA techniques, the Non-structural Fuzzy Decision Support System (NSFDSS), rather than the commonly used Analytical Hierarchy Process (AHP), is chosen to prioritise the inclusion attributes. Compare with other MCDA techniques, AHP is simple to operate and it enables pair-wise comparison between factors (Ho et al., 2004). When the hierarchy of criteria has been constructed, pair-wise comparison is undertaken and then the consistency level and relative weighting of each criterion are computed (Wu et al., 2007; see Saaty, 1980 for AHP and Chen, 1998 for NSFDSS; also see Ho et al., 2004; pp66 who have explained the procedures of the AHP workshop). An alternative to AHP is NSFDSS which is indeed very similar to AHP. In principle, both AHP and NSFDSS involve three steps namely decomposition, comparative judgement and synthesis of priorities (Tam et al., 2002). NSFDSS is, however, superior to AHP for a simplified scale of importance is used in NSFDSS that enables automatic consistency correction. Besides, NSFDSS can assign more precise priority to the decision criteria for the number of semantic operators used in NSFDSS to measure difference in the magnitude of the first ordered decision and others is greater than that used in AHP (Tam, Tong and Chiu, 2006; Yau and Chan, 2008). It is apparent that

NSFDSS is more desirable and therefore it is chosen to analyse the weightings of inclusion attributes. It is expected that the result of NSFDSS can be delivered by mid July.

DATA COLLECTION

This section describes data collection for assessing the inclusiveness of built facilities in the Main Campus of HKU using BIAS. As one of the purposes of this research sets out to investigate the inclusiveness of built facilities there, on-site assessments of 28 buildings are conducted. The assessments are split into two stages that look into common areas and particular facilities in buildings respectively. At all events they are conducted by at least two assessors who are required to follow the assessment procedures. With intent to minimise the subjective elements, BIAS is created in a way such that the assessors need not to be experienced or professional in the subject. What they need is to be briefed and trained before they conduct actual assessment on-site. Numerical data or yes/no items are the principal data to be solicited, and pictures are taken as record for future reference. In this regard, simple equipment including measuring tape, metal ruler, spring scale and digital camera will be sufficient for the purpose of assessment. The first stage of assessment has been finished in March 2011 and the second stage will begin by May 2011. Preliminary findings from the first stage of assessment will be discussed next.

PRELIMINARY FINDINGS

With regard to the buildings surveyed they are of diverse design and built form. Through the use of BIAS suggested above, their inclusiveness is appraised. Because this research is still ongoing, preliminary findings for the first stage of assessment (i.e. which is confined to the common areas) are presented below.

Lift is not available in a multi-storey building. It means that this building is exclusive to persons with physical or ambulant disabilities. Similar exclusion is caused by the presence of a step(s) in front of entrances that are not bevelled.

Tactile guide path is provided along external access route; however, it is seldom connected to lift zones. Besides, the tactile guide path is usually chopped when it overlaps with channel covers and gratings. In many staircases, tactile warning strips are not provided at landings.

In respect of ease of navigation, room numbers are assigned in an inconsistent manner. Though the layout of buildings is relatively simple, navigation is made difficult as different methods are used to number rooms of the same building.

Handrails fixed at height other than the recommended range are not uncommon (i.e. between 850mm and 950mm). On handrails Braille and tactile information and horizontal extension (of not less than 300mm) at each end are sometimes missing. In some short stairs, handrails are not installed.

Indication and notification for lifts is beyond sufficient. Very often there is no audible signal to indicate arrival of lift, its direction of travel and closing of the doors. Moreover, some lifts do not have visual indication to show acknowledgement message in case of emergency.

Wheelchair users may find it difficult to move out of lift cars for interiors finishes at appropriate height is non-reflective.

No provision of accessible toilet in some buildings is noticed. Where accessible toilets are provided, some of them are cramped with space insufficient for manoeuvring, whilst some are not provided with emergency call bell and alarm.

Accessible car parking spaces are often provided, nonetheless, requirements in dimensions and marking are not often met. Usually the accessible car parking spaces are narrower and the markings are smaller than required.

CONCLUSION
