The argument that disability inclusion is an issue in sustainable design and construction is not false as increasingly more built facilities are obliged to be inclusive under law. In existing buildings, for example, alteration may become necessary. In this regard, disability inclusion is concerned with environmental and economic sustainability rather than merely a social issue. Among accessibility assessment methods that are currently available, they largely rely on assessors' subjectively judgements and are principally qualitative in nature. There have been attempts to improve the process by developing a quantitative assessment model, however, still considerable amount of subjective elements are present in the model. BIAS proposed here prevails for the inclusion criteria of individual areas and facilities are introduced into the hierarchy and subsequently weighted. It gives not only an inclusiveness score but also unearths the perceived weightings of the inclusion criteria. As can be seen in guides and standards, barrier-free design requirements in Hong Kong are relatively less strict. The Multiple-Criteria Decision Analysis technique to be used to analyse the priority of the inclusion attributes was discussed. NSFDSS rather than AHP is chosen for it is less time-consuming and yields more precise result.

The inclusiveness of built facilities in the Main Campus of the University of Hong Kong has been studied. As point out in the preliminary findings there are rooms to make the built facilities more inclusive. More imminent issues are to provide lifts and accessible toilets with emergency call bell and alarm. Other minor improvements such as provision of tactile warning strips at landings and Braille and tactile information on handrails are recommended. Last but not least, the philosophy of disability inclusion in built facilities should be building for all rather than persons with disabilities only. Contrary to that misbelief is inclusion in built facilities benefits everyone. It should be promoted in all societies no matter they are young or aged – a young society also calls for inclusion as parents with infants inside pushchairs want barrier-free passages.

ACKNOWLEDGEMENT

The author would like to thank the financial support given to this project by the HKU 81 Inclusion Fund with utmost gratitude.

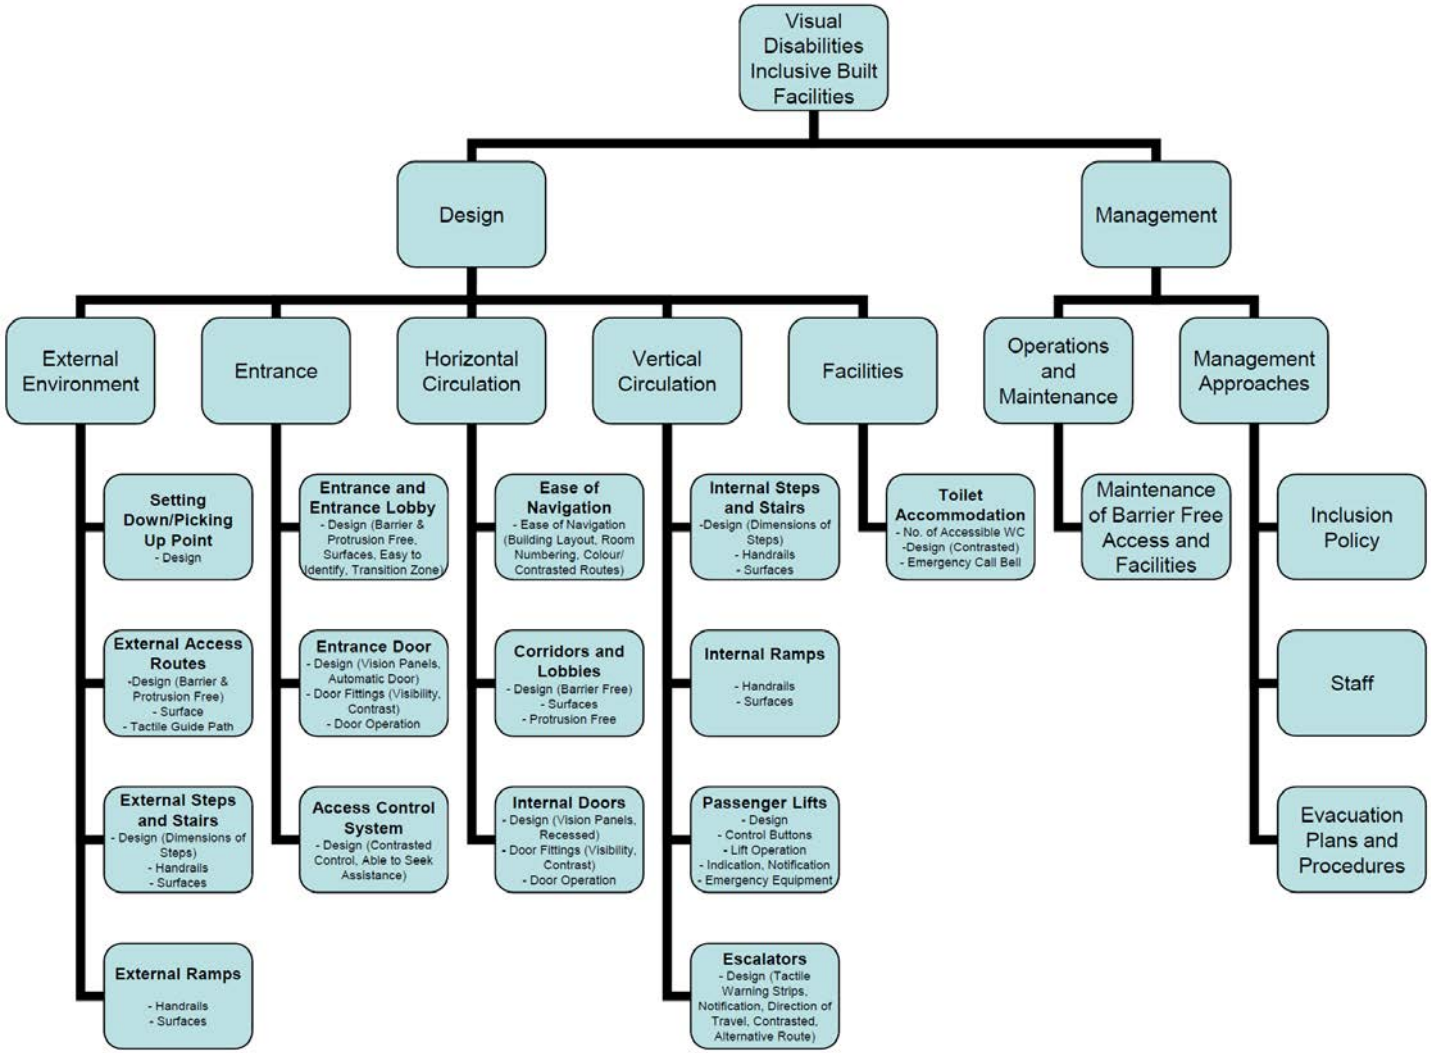

Figure 2: *Improved hierarchy of attributes that affect the inclusiveness of persons with visual disabilities in higher education built facilities*

Level II	Level III	Level IV
External Environment	Car Parking	• No. of Accessible Parking Space • Design of Accessible Parking Space
	Setting Down/ Picking Up Point	• Design of Setting Down/ Picking Up Point
	External Access Routes	• Design of External Access Routes • Surface of External Access Routes • Provision of Tactile Guide Path
	External Steps and Stairs	• Design of External Steps and Stairs • Handrails of External Steps and Stairs • Surfaces of External Steps and Stairs
	External Ramps	• Design of External Ramps • Handrails of External Ramps • Surfaces of External Ramps
Entrance	Entrance and Entrance Lobby	• Design of Entrance and Entrance Lobby
	Entrance Door	• Design of Entrance Door • Door Fittings • Door Operations
	Access Control System	• Design of Access Control System
Horizontal Circulation	Ease of Navigation	• Ease of Navigation
	Corridors and Lobbies	• Design of Corridors and Lobbies • Surfaces of Corridors and Lobbies • Protrusion Hazard
	Internal Doors	• Design of Internal Doors • Door Fittings • Door Operations
Vertical Circulation	Internal Steps and Stairs	• Design of Internal Steps and Stairs • Handrails of Internal Steps and Stairs • Surfaces of Internal Steps and Stairs
	Internal Ramps	• Design of Internal Ramps • Handrails of Internal Ramps • Surfaces of Internal Ramps
	Passenger Lifts	• No. of Accessible Passenger

		Lifts • Design of Passenger Lifts • Control Buttons of Passenger Lifts • Lift Operation • Indications and Notifications • Emergency Equipment
	Escalators	• Design of Escalators
Facilities	Toilet Accommodation	• No. of Accessible WC Cubicles/Accessible Unisex Toilet • Design of Accessible WC Cubicles/Accessible Unisex Toilet • Emergency Call Bell in Accessible WC Cubicles/Accessible Unisex Toilet
	Classrooms/ Lecture Theatres	• Design of Classrooms/ Lecture Theatres • Building Services and Relevant Facilities • Assistive Technology
	(Student) Common Areas	• Design of Common Areas and Fittings • Building Services
	Counter and Service Desk	• Design of Counter and Service Desk
N.B. 1. Design in general is concerned with dimensions and layout of individual areas and facilities. 2. Surfaces are referred to the firmness, the slip resistance, the pattern and the luminous contrast of finishes. Provision of tactile warning strips is also under surfaces. 3. Handrails have to meet requirements in dimensions and shape, fixing position and luminous contrast. It is also necessary to provide Braille and tactile information on handrails. 4. Door: door design is about the dimensions of doors; door fittings are about the furnishings or fixtures on door leaves; door operation is about the opening and the closing of doors.

Abstract

The Open Building concept has been developed half a century ago. Despite the relative potential advantages to society, this concept of Open Building has not been widely implemented in the construction industry. Consequently, it did not lead to a general new approach of designing structures. Why does the construction industry use the Open building concept so rarely among their projects? Using in-depth semi-structured interviews with the 'founding fathers' of Open Building in combination with literature, the inertia which obstructs the implementation of Open building in the construction industry are identified. The study shows that inertia on adopting the principles of Open Building are primarily related to the type of collaboration between firms on construction projects. Only few impediments are of technical nature.

Keywords: Innovation in Construction, Open Building, Implementation of Innovation, Inertia

Introduction

In order to answer the housing problem after turbulent periods in the 20th century, mass production of dwellings offers accommodation to many citizens [Habraken, 1999]. Furthermore, mass production has long been recognized as an effective means of reducing a product's unit cost. The organizational structure and work processes in most construction firms have their roots in these mass production principles [Halman et al, 2008]. However, static mass housing is not capable to adapt easily to changing customer demands, to accommodate more than one program of functions over time. Static building structures causes an increasingly inefficient utilized building stock [Habraken, 1999; Kendall and Teicher, 2000; Thillard, 2004].

To overcome the identified problems with static building structures, the Dutch architect John Habraken proposed the open building system in 1961. In this system, the 'base-building' and its interior are separated, the so-called 'support/infill' approach. Open Building has been of interest for many scholars and has been adopted in the last few decades in countries like Japan, UK and USA. In general, the design customization options include interior and exterior design components, as well as the spatial arrangements that determine the total area of a home [Hofman, 2010].

In the past fifty years many pilot projects have been applied successfully at a small scale. However, it remains a challenge to achieve them at a broad scale. In this paper we will explore for possible reasons why the concept of Open Building has not been widely adopted in the building industry. To this end we first interviewed the founding fathers of Open Building and asked them to reflect upon the development of the concept and the resistance in the building industry to adopt the design principles of this concept. This reflection helped us to identify some important inertia. Based on the insights from the adoption theory of innovation we searched for possible solutions to overcome these inertia. These will be discussed in the discussion section of this paper.
The rest of this paper is structured as follows; in the next section the research method that has been used is presented. The section is followed by a section in which the theory of Open Building is discussed and a section in which the results of the interviews are presented. In the last part of the paper the results of the interviews and limitations and implication for further research are discussed.

Research method

The goal of this study is to identify the inertia on Open Building. To better understand the implications of this specific context a literature study was conducted on Open Building. First, the work of Habraken, the founding father of Open Building, was studied. Secondly more work was studied of the scientific working group 'Open Building Implementation' of the International Council for Research and Innovation in Building and Construction (CIB) and the journal 'Open House International'. Also the work of other scholars in this field in the Netherlands were studied by making use of backward and forward reviewing on the key words 'industrialization', 'flexibility' and 'sustainability' [Webster and Watson, 2002; Short, 2009; Cropanzano, 2010].
From literature was derived that the potential respondents in the Netherlands were (and some still are) associated to Eindhoven University of Technology and Delft University of Technology. With respect to many others who made contributions to Open Building, the following five early promoters of Open Building were interviewed in the autumn 2010: John Habraken, Age van Randen, Ype Cuperus, Jos Lichtenberg and Jouke Post.

Data collected by in-depth interviews were used to explain and explore the inertia of implementation of Open Building in practice. Analysis of the interview data increased the understanding of factors that impede Open Building and what compensation mechanisms are available to mitigate these impediments. The interviews took between one and three hours and with permission the interviews were taped and transcribed within 24-hours after the interview.
Each interview began with explaining the research goal and the role of the researcher. Each respondent was asked to answer a set of structured, open ended questions. These questions where supplemented with questions that came up during the interview.
The interview data were analyzed as follows. First the recurring words and important issues and stories where highlighted in the interview transcripts. These words and issues where clustered for each transcript and the clusters where compared across transcripts. Finally the clusters where labeled.

Literature

The basics of Open Building
The founding father of Open Building is the Dutch architect John Habraken. Already in 1961 he published his book '*De dragers en de mensen*' (Supports: an alternative to mass housing). In his book Habraken argued that mass housing disrupts the age-old 'natural relation' between human being and their built environment. He stated that people will lose interest in things which could not be influenced by them as with mass housing. Furthermore dwellings cannot be understood as products or manufactured objects. Thus, dwelling is a fundamentally human process. Therefore, residents needed to be able to make autonomous decisions on their own behalf concerning their dwelling. Concluding, dwellings provided by units of housing accordingly to mass-housing are inconsistent with the human process [Habraken, 1999].
According to Habraken, Open Building implies a strategy consisting of twofold complementary perspectives. First there is the social perspective that seeks to respond to user's preferences by offering flexibility needed for adaptation of individual units over time. Second there is the technical perspective which seeks ways of building where sub-systems can be installed or changed or removed with a minimum of interface problems [Habraken, 2003]. Furthermore, Open Building comprises the following ideas:

- "There are distinct levels of intervention in the built environment;
- Users (inhabitants) may make design decisions as well as professionals;
- Designing is a process with multiple participants, including different kinds of professionals;
- The interface between technical systems allows the replacement of one system with another performing the same function;
- The built environment is in constant transformation and change must be recognized and understood;
- The built environment is the product of an ongoing, never ending design process, in which environment transforms part by part" [Habraken, 1999].

Habraken distinct basically three levels of decision making: the tissue level (urban planning), the support level (architecture of the base building) and the infill level (design of the interior). Based on Habrakens' 'theory of levels' several other scholars defined more layers based on the differences between the technical and functional life cycle of building systems [Brand, 1995; Duffy, 1998]. However, the theory of levels by Brand and Duffy are based on subdivisions of Habrakens' support and infill level:

- Support level. The base building or the support of a building is the permanent construction with a life span up to 200 years. The support provides service space for

occupancy, the infill. The type, number and size of the individual infill units are primarily not determined by the support, compared with more traditional buildings. Part of the support are all the elements belonging to the public routing (stairs and elevators, corridors and galleries, et cetera) and common used utilities (like foyers, community rooms, et cetera).

The support itself could contain several lots. The lots within the support structure must be connected separately to the services which could be found in the public space of the structure. Based on the thoughts of Habraken, the support should accommodate the infill in an adaptable way. This means that the support determines the capacity of change, based on diverse and changing demands, of the infill leaving the support unaffected. [Habraken, 1999; Kendall and Teicher, 2000]

- Infill level. The infill system consists of many systems and subsystems which could be subdivided in many elements and components. In contradiction to more traditional construction projects the elements are not brought to the site to be processed by its own subcontractor in the building based on the site conditions. The infill is a far more integrated set of products which are basically custom prefabricated off-side for an infill unit. Therefore the infill must be installed as a whole. The infill system constructs a unit (dwelling, office space, et cetera) within the support structure [Habraken, 1999; Kendall and Teicher, 2000].

The main goal of Open Building is to achieve independency between building parts, so buildings can be created that are able to adapt to new user requirements. Despite this clear vision, applying the Open Building principles in practice is challenging. The application of Open Building is still prominent in the Netherlands but also the United States and Japan are known for their efforts.

Research findings

Early promoters of Open Building in The Netherlands, John Habraken, Age van Randen, Ype Cuperus, Jos Lichtenberg and Jouke Post, were asked to describe on their past experience the impeding and stimulating factors towards Open Building as well as the opportunities and threats of further development.

Inertia on Open Building
According to Habraken, the conventional way of designing dwellings can best be characterized as a continued process of "re-inventing the wheel", which hampers Open Building (OB). Van Randen mentioned the uniqueness and one-off characteristics of projects; thinking something new for every project.
Moreover, the traditional project organization itself is the most important impediment of Open building. Lichtenberg explains that innovations, especially Open Building Systems, are implemented in the market through projects. Typically the market consists of projects through which OB must be communicated with the market. Habraken, Van Randen and Lichtenberg mentioned that during the process many firms and actors are involved based on a fragmented and scattered division of roles, responsibilities and decision-making. All the actors need to be convinced of OB and OB innovations before it will be adopted and implemented in the project. And also Post experiences the building process of OB projects as difficult, due to the many layers in the process through which OB must be communicated.
According to Lichtenberg, firms feel very uncomfortable to change towards OB (relationships) because they are programmed for a specific task. When firms are confronted with other tasks, they consider those tasks as risky because they are not adjusted to these new tasks.
Besides the riskiness of financial loss, Habraken and Cuperus mentioned that construction firms are reluctant to relinquish former attainments. For example, architects have to design structures with predetermined Open Building Systems and contractors only erect the support system (and thus not the infill) based on different decision-making levels.
Thus as Lichtenberg generalizes, in construction, a project-based industry, there is a long organizational chain between the innovator and the beneficiary, which impedes diffusion. The challenging task of the innovator consists of convincing all the stakeholders of the advantages of Open Building (or any other innovation).

Habraken explains that conventional projects rely on floor plans. Firms, like financiers, contractors, engineers and architects base their work on floor plans. The involvement of many actors complicates the composition of the floor plan and the complexity increases when the end-users will be involved accordingly to OB. With limited influence of end-users there arises a mismatch between the floor plan and end-users demands. Therefore the 'system' should be reshaped around end-users as suggested by OB.
However, why should construction firms change the system, to which they are used to, when they still make money with conventional floor plan? In addition, Post observed that OB projects, where buildings are assembled in an intelligent user-friendly way, are not of interest of the industry as long as construction firms earn money with conventional projects. Also Lichtenberg came to this conclusion. The willingness of organizations to accept Open Building depends on organizations' attitude towards change. As Lichtenberg mentioned; 'to innovate, organizations need to accept something new, but above all give way old routines'.
Furthermore Post remarked that OB only could be successful when supply and demand are complementary to each other. However, without a client demand about flexibility, the construction industry will not likely invest in the development of interdependent interfaces.

Market demand concerning flexibility failed to occur because adaptability of building structures is esteemed by the market as a hidden quality. Moreover, accordance Habraken organizations need to adapt their collaboration on projects in accordance with the developed system; otherwise the building system has no market potential (because it could not be a competitive alternative). Furthermore, when organizations adapt to the system it will stimulate new developments.

Van Randen mentioned legislation as an impediment of Open Building. However, Habraken en Post both mentioned legislation as an incentive of Open Building. From the interviews with the founding fathers it is concluded that some types of prescriptive based legislation could be inertia on OB like the municipal zoning pan, while some types of performance based legislation could be incentives towards OB.

Other inertia on OB mentioned by the early promoters are:

- The small percentage of total investment in Research and Development;
- Dwelling have a high intensity of installation per square meter and this complicates the development of Open Building in house-building;
- The (inter)dependencies of components hampers the implementation of OB in practice. The interfaces between prefabricated parts are not well developed accordance Van Randen. In addition, Lichtenberg mentioned that interfaces between components within systems require (de)mountability to be flexible or adaptable. However, interfaces are complex due to the many actors involved to realize a particular interface.

Opportunities for Open Building

Habraken claims that the discrepancy of customization between cars, clothing, et cetera versus dwellings will result in a breakthrough of OB. However, programs like IFD-building could not be seen as an initiative which stimulates a breakthrough. Furthermore, these initiatives must be seen as a search for a possible directive of development.

The balance between price and quality was mentioned by the founding fathers as an incentive to OB. Habraken explains that the harmonization between the functional lice-cycle and the technical life-cycle (up to 200 years), means the optimal use of capital. This prevents unnecessary demolishing of building components which could last for many years. In contrast, Post suggests constructing buildings for a limited period of time (20 years), because for short periods reasonable estimations could be made of user demands. After 20 years user demands change dramatically and therefore small changes are not sufficient to meet these demands. Constructing for a period of 200 years is very expensive and the estimation of how the building will be used in this period are hard to make.

Labor could be another incentive accordance Lichtenberg and Post. Lichtenberg explains that increasing labor costs on the construction site stimulates industrialization. In addition, Post remarks that higher quality demands and the ambition to realize buildings in a shorter period of time stimulates industrializations and thus could stimulate dry (de)mountable interfaces. Thus, changing labor circumstances could offer new opportunities to OB. This is clearly described by Van Randen; the objective to create as few as possible (inter)dependencies between systems, so that short-term systems could be replaced without any alterations to the long-term systems. Therefore consciousness is required about the need to consider future use of building structures during the design stage, this life-cycle approach stimulates flexibility accordance Post.

Compensating mechanism

First, Habraken suggests formalizing an infill industry (contracts, norms, recognition, et cetera). Secondly, Habraken proposes single point responsibility, or more specific; make firms responsible for the process, logistics and organization of OB projects. Habraken referred to Sekisui, Japan, as an example of a successful innovative open building system for the home-building industry. The concept is based on a stale framework to which standard components from the market are added to construct a fully customized dwelling. The organizational set up is based on a single point responsibility for a more efficient construction process and to simplify the project organization, especially for the customer.

Also in the Netherlands there are initiatives to simplify the project organization and lower the number of contact points in the construction process. Lichtenberg referred to an initiative called Industrial Building 2015 (IB2015), which aims for an Open Systems Building approach with a central role for the industry. The program focuses at five main principles: 1) decoupling of building components, 2) conceptual solutions, 3) industrial connections (interfaces), 4) Building Information Modeling (BIM) and 5) full-service. The current discussion involves the division of roles; who should coordinate and/or fulfill the pioneering role.

Accordance to Habraken and Post, legislation could be an important incentive to OB when designed properly. The Japanese long-term-housing act, an example to which Habraken referred, stimulates sustainable innovation, the act balances between prescriptive and performance based legislation. The end-user could achieve a considerable fiscal advantage when a constructed building as a whole lasts for 200 years. This stimulates market demand for sustainable buildings which subsequently results in pressure on the construction industry to develop sustainable buildings.

Both Van Randen and Lichtenberg explained that the complexity of interfaces results from the many involved actors which affect the interface design. Van Randen suggests an interface specialist; however another actor in an already fragmented industry could result in a diminished coherence within the interface. Lichtenberg defined an interface as a set of design rules, the virtual interface. However, the interface could also be a physical connection. Anyway, it is the task of actors to agree upon design rules and when there is no agreement among actors an adaptor or intermediary-interface could be a solution.

Market demand could also be an important compensating mechanism to overcome inertia on OB accordance to Lichtenberg and Post. Post claims that no OB developments in the industry will take place when there is no clear client demand. Profit oriented construction firms could be stimulated in developing OB solution by holding out the prospect of future sales or projects, accordance Lichtenberg.

Table 1: Inertia on Open Building

	Respondents				
	John Habraken	**Age van Randen**	**Ype Cuperus**	**Jos Lichtenberg**	**Jouke Post**
Impediments	-It is re-inventing the wheel for every project, a characterization of project-based production that impedes the development of Open Building. -Dwellings has a high intensity of installation per square meter this complicates the development of Open Building in house-building. Construction firms still try to optimize conventional construction methods and believe that Open Building is too complex; the introduction of Open Building means restructuring the division of roles and responsibilities around projects. -The conventional construction process relies on floor plans; financiers, contractors, engineers, architects base their work on floor plans. The involvement of many actors complicates the composition of the floor plan and the complexity increases when the end-users will be involved. Therefore the system should reshape the way towards client involvement. However, why should construction firms change the system, to which they are used to, when they still make money with conventional building? -Construction firms fear the unknown and the risk of losing revenues. -Construction firms are reluctant to relinquish former attainments.	-Construction projects are characterized by improvisation; thinking of something new for every project. -Legislation hampers the development of Open Building. -The complexity of working together with many actors restrains Open Building. -The (inter)dependencies of components hampers the implementation of Open Building in practice. The interfaces between prefabricated parts are not well developed.	-Modular Coordination (MC) (design rules for size and place to formalize Open Building in design) has never been implemented, because: (1) the opposition of architects based on the argument that MC restricts freedom of design, (2) MC focused on industrialization which in that days was open to negative publicity, (3) some firms could apply the design rules with only small adaptations while other had to change / invest heavily, (4) some firms tend to lose the competition because products of competitors where easier applicable, and (5) the design rules where too complex.	-During the building process many firms are involved. The construction process is programmed around fragmented disciplines. Due to this fragmentation alternative organization forms are hard to achieve. - All construction firms involved in a project must be convinced of OB. - Interfaces between components within systems require (de)mountability to be adaptable. However, interfaces are complex due to the many actors involved to realize a particular interface. -Firms are programmed to perform a specific task. When firms are confronted with other tasks, firms consider these tasks as risky. - The innovation inertia: OB is accepting something new, but above all overcoming old routines. - Only a very small part of total investments in construction is spend on research and development. - There are no organizations in the industry with enough importance (like Apple, Toyota) that could, top-down, stimulates OB. There are many small to medium-sized enterprises (SME) which have to collaborate in OB projects (and thus stimulating OB bottom-up).	-The building process of Open Building projects goes very slowly with many difficulties, due to the many layers in the process through which Open Building must be communicated. -Open Building could only by successful when supply and demand are complementary to each other. Therefore it is necessary that construction firms change the way they operate in projects towards Open Building. -The market describes flexibility as a hidden quality; only few demands flexibility in projects. Therefore, legislation could formalize flexibility with respect to sustainability. - Open Building projects, where buildings are assembled in a intelligent and user-friendly way, are not of interest of the industry as long as construction firms earn money with conventional projects.

Table 2: Opportunities for Open Building

	Respondents				
	John Habraken	**Age van Randen**	**Ype Cuperus**	**Jos Lichtenberg**	**Jouke Post**
Opportunities	-The discrepancy between customized options for cars, clothing and suchlike, and the few customized options for dwellings stimulates a breakthrough of Open Building. -Programs like Industrial, Flexible and Demountable (IFD) building could not be seen as body of thoughts which stimulates a breakthrough. However, these programs could be seen as a search for a possible directive of development. -The harmonization between the functional life-cycle and the technical life-cycle (up to 200 years) means the optimal use of capital. This prevents unnecessary demolishing of building components which could last for many years.	-The objective is to create as few as possible dependencies between systems, so that short-term systems could be replaced without any alterations to the long-term system.		-Increasing labor costs on the construction site stimulates industrialization.	-Consciously about the need to consider future use of building structures during the design stage stimulates flexibility (life-cycle approach). -Higher quality demands and ambition to realize buildings in a shorter period of time stimulates industrialization in construction, and thus could stimulate dry (de)mountable interfaces. -Buildings should be constructed for a limited period of time (20 years), because for short periods reasonable estimations could be made of user demands. After 20 years user demands changed dramatically and therefore small changes are not sufficient to meet these demands. Constructing for a period of 200 years is very expensive and the estimation of how the building will be used in this period are hard to make.

Table 3: Compensating mechanisms inertia on Open Building

	Respondents				
	John Habraken	**Age van Randen**	**Ype Cuperus**	**Jos Lichtenberg**	**Jouke Post**
Compensating mechanisms	-Formalization (collaborations, contracts, norms, recognition et cetera) of an infill industry. -Balance between price and quality. -Introduction of 'single point responsibility' like Sekisui (Japan) and Tokoman (Finland). Firms are responsible for the process and they arrange the logistics and organization. -Legislation and governmental policy could stimulates OB: the Japanese long-term housing act, which requires building structures to last 200 years, in combination with fiscal benefits stimulates market demand.	-The many involved actors influence the interface design. An interface specialist could be the solution; however a new role is created in an already fragmented industry. As a result the coherence diminishes.		-The complexity of interface results from the many involved actors. An interface could be a design rule; the virtual interface. The interface could also be a physical connection. It is primarily the task of actors to agree upon design rules. Without this agreement, an adapter or intermediary-interface could be a solution. -The innovation program 'Industrial Building 2015' (IB2015) tries to diminish the number of firms to maximum 4-6 main firms. This is a bottom-up approach of projects towards a more efficient and convenient construction process. -The market consists of a certain collection of projects. And for every project many firms need to be convinced of Open Building. Therefore, a certain sale of Open Building projects, introduced by clients, stimulates Open Building.	

Discussion

Open Building, despite its 50th birthday, is still not applied at a broad scale. However, today there are new opportunities for Open Building. First of all, consumers are more demanding than ever. They want to have a say in the design of their future house and have clear demands about what it is they want. Second, sustainability has become much more important, which in the philosophy of Open Building is a key role. Third, the building process nowadays is expensive due to an increased number of parties involved in the process, resulting in communication problems and higher failure costs that are for the expense of the customer and are calculated in and higher price of the building. Therefore, nowadays more importance is given to the extension of the lifecycle of buildings to be able to spread out the costs over a longer period of time. Fourth, there is an ongoing development of increased willingness of companies to cooperate and develop products and systems together, in which Open Platforms plays an important role.
Conventional buildings are developed in a form of closed (static) systems, due to the fixed integration of technical systems into functional building systems. Due to this high level of functional and material integration, it is usually impossible to remove components in order to replace or exchange them. This is the reason why closed building systems are not suitable for easy transformation and cannot adapt to changes in user requirements. Therefore, to achieve adaptability of buildings, an open system is needed. The main difference between a closed and an open system is the separation and decoupling of sub-assemblies that have different functional and life cycle expectancies [Durmisevic, 2006]. To achieve this, a carefully designed systematization of building components into independent subsystems in a hierarchical order is needed. For such systematization, the design of common interfaces that allow independency between components is required. If this can be achieved, a building can consist of different modules that can be independently upgraded, reconfigured, replaced or added. The different modules together can then form a category of components that can be assembled with standardized interfaces. Open Systems Building (OSB) is a framework to achieve this and can be seen as a realization of Open Building.

According to Gann and Salter, construction should be viewed as a process rather than an industry: ‘it includes designing, maintaining and adapting the built environment, involving many organizations from a range of industrial sectors, temporarily working together on project-specific task’ [Gann and Salter, 2000]. Reasoning for this definition could be the following characteristics of construction: ‘the physical substance of a house is a pile of materials assembled from widely scattered sources. They undergo different kinds and degrees of processing in large numbers of places, require many types of handling over periods that vary greatly in length, and use the services of a multitude of people organized into many different sorts of business entity’[Cox and Goodman, 1956]. Gann and Salter’s definition is emphasized by Habraken’s distinction between support and infill. Besides a physically separation of building systems also a distinction between decision-making units and responsibilities, this clear the way, as Habraken puts it, for a support and infill industry.

Construction projects are a gathering of complex product systems, characterized by (1) many interconnected and customized elements organized in a hierarchical way, (2) nonlinear and continuously emerging properties where small changes to one element of the system can lead to large changes elsewhere in the system and (3) a high degree of user involvement in the innovation process [Winch, 1998]. Dubois and Gadde divided complexity in construction in two main categories [Dubois and Gadde, 2002]. The first category encompasses the uncertainty in the undertaking of individual activities which has four causes, (1) management

is unfamiliar with local resources and the local environment, (2) lack of complete specification for the activities at the construction site, (3) lack of uniformity of materials, work, and teams with regard to place and time (every project is unique), and (4) unpredictability of the environment. As a result, centralized decision-making is difficult to apply and this leads to decentralization of authority. The second category is associated with three factors of operational interdependence in construction [Gidado, 1996], (1) the number of technologies and the interdependence among them, (2) the rigidity of sequence between the various main operations, and (3) the overlap of stages or elements of construction. Furthermore, complex product systems need to be adjusted at the construction site, because of (1) the lack of complete specification, (2) lack of uniformity and (3) an unpredictable environment [Dubois and Gadde, 2002]. This supports the research findings of the interview with the founding fathers of Open Building. It describes in general the inertia on Open Building mentioned by Van Randen, Lichtenberg and Post.

Project-based firms in the construction process are focused on individual projects. The realization of projects is based on combining technical expertise from other organizations [Gann and Salter, 2000; Dubois and Gadde, 2002]. Furthermore, the role of an individual firm is very different among projects; because the division of labor among the actors varies greatly form project to project [Dubois and Gadde, 2000]. As mentioned by Habraken and found by Gann and Salter [Gann and Salter, 2000] it is re-inventing the wheel that characterize project-based production. Gann and Salter found that there are limited links across business units and individual projects. Therefore, the rate of organizational learning of Open Building projects is very low.

According to Gann and Salter firms need to integrate the experiences of projects into their continuous business processes in order to ensure the coherence of the organization, especially according to Open Building projects.

Furthermore, adoption decisions by firms concerning Open Building have to be implemented in projects. As mentioned, projects are collaborative engagements with other firms and as a result Open Building has to be negotiated within the project coalition. A firms' ability to do this, the role of the champion, will be strongly influenced by its role in the coalition [Winch, 1998]. This was also literal mentioned by Lichtenberg.

Open Building needs a champion [Schilling, 2000; Rogers, 2003]. According to Rogers, a champion is 'a charismatic individual who throws his or her weight behind an innovation, thus overcoming indifference or resistance that the new idea may provoke in an organization' [Rogers, 2003]. In construction, the champion can come from every part of the industry. Pries and Janszen and Lichtenberg found that champions typically come from component suppliers [Pries and Janszen, 1995; Lichtenberg, 2002]. This was also suggested by Lichtenberg and Post.

A compensating mechanism for the inertia on Open Building could be *the broker* [Winch, 1998; Rogers, 2004; Winch and Courtney, 2007]. According to Winch and Courtney, a broker is a distinctive type of actor in networks or actor that links other actors in the network [Winch and Courtney, 2007]. However, who should take the broker-role regarding Open Building? As mentioned by the founding fathers as well as several scholars [Dubois and Gadde, 2002; Hofman, 2010] construction firms should look for ways to reconfigure their short-term vision based organizations and project coalitions to long-term setup to encounter the challenges of future construction.

Traditionally, the principal architect or engineer and the principal contractor act as systems integrators, a broker-role between clients, regulators, professional institutions, trade contractors (specialized suppliers), specialized consultants and components suppliers [Winch,

1998; Miller et al., 1995]. The latter three could act as Open Building champions as mentioned before. Typically, construction has two separate system integrators, due to the distinction between the design stage and the construction stage. Therefore, the role is shared by the architect/engineer and contractor. As a result the systems integrator role is less effective. In addition, architects displays competence in regulatory frameworks and clients requirements, but are not equipped to integrate all technical systems into a building. Also the contractor's integration capabilities are typically restricted to the managerial rather than technical level [Winch, 1998]. Thus, the Open Building systems integrator has three functions (1) the skills to integrate interdependent components into a coherent whole, (2) detailed knowledge of client requirements, and (3) knowledge of the rules and regulations governing the industry [Miller, et al.; 1995]. Therefore, and as found in the research date, it is questionable or the architect and/or contractor should fulfill the broker role. However, Nam and Tatum demonstrated that the role of the architect and contractor is decisive in the success of Open Building. The systems integrator, although still questionable or this not could be a specialized supplier for example, must be convinced of the merits otherwise implementation will be slow [Nam and Tatum, 1997].
Winch and Courtney suggests that independent and objective organizations should take the liaison role between firms that are otherwise not connected. They could add value to the development of Open Building by validating new ideas, act as auditor. They could also act as an intermediary between supply and demand site by shaping the definitions of research problems and shaping the practice of implementation. However, almost every discipline is separately represented by a professional body. This weakens their ability to act as a broker of Open Building as they typically threaten the interest of only a particularly set of actors [Winch, 1998]. Thus, until know the Open Building broker did not come forward yet.

Rogers' defined five perceived attributes of innovations, (1) relative advantage perceived by individuals, (2) compatibility with the values and norms of a social system, (3) complexity, (4) trialability, and (5) observability or the visibility of the results of an innovation [Rogers, 2003]. To be adopted Open Building needs a relative advantage regarding conventional building as mentioned by the respondents and several scholars. For example, it solves technical difficulties or meet social requirements better than traditional solutions [Ling et al., 2007; Hartman et al., 2006; Hartmann et al., 2008]. Firms who make efforts to implement Open Building should stress the problem-solving rather than the performance-improvement aspects of Open Building [Ling et al. 2007]. Most importantly, clients' sponsorship is essential for the successful implementation of Open Building [Nam and Tatum, 1997]. In general, without an adequate incentive structure than it is unlikely that Open Building take place. In the case of Open Building Systems it is necessary to develop a long-term gain sharing approach. This means a shift form competitive tendering toward partnering. It is assumed that competitive tendering explains the use of standardized building parts used in conventional buildings.
Therefore, competitive tendering hampers customized solutions [Winch, 1998; Dubois and Gadde, 2002]. However, despite the opportunities for high-involvement relationships, taking the step to strategic partnerships would require modification of some of the basic construction norms, like the current focus on the efficiency of individual projects and competitive tendering [Dubois and Gadde, 2000; Gadde and Dubois, 2010]. Thus, as several scholars indicated project organizations are loosely coupled [Brusoni et al., 2001; Dubois and Gadde, 2002; Hofman, 2010]. In contrary with loose coupling, the development of Open Building requires tight organizational coupling [Brusoni et al., 2001; Hofman, 2010].
The founding fathers believed that legislation could stimulate Open Building. Like the Japanese long-term-housing act, so called performance standards, maybe be an appropriate

form for encouraging systemic technological change. Performance standards specifies minimum building requirements, however they does not prescribe the means or components [Gann et al., 1998].
In addition, compared to manufacturing firms of other industries, traditional construction firms are less open to the external environment, they are less market oriented. The nature of the market strongly influences the potential of Open Building; local markets can often mean undemanding customers. Furthermore, firms do not need to change to Open Building to remain successful or viable at all as long as they meet local needs, responding to regulation and adopt new technologies form their suppliers and customers [Reichstein et al, 2005].

Limitations and implications for further research

Only few interviews (5) were conducted in one country (the Netherlands). No interviews were conducted among scholars and practitioners who are making contributions to Open Building today. Perhaps it is more important to speak with (professional) clients, especially housing corporation, who rejects and/or rejected Open Building in the past. Therefore, a broad survey among stakeholders could gain more complete insight into the inertia on Open Building and its possible compensating mechanisms.
Although the limited interview data was verified in literature, there is no guarantee that the data is complete and unbiased. There is also no insight in the interrelation between impeding factors as well as compensating mechanism. The innovation behavior of construction firms have been subject of several scholars. Only few scholars paid attention to the adoption and implementation of Open Building, where Open Building Systems are hold as systemic innovations. A review of literature around 'innovation behavior of construction firms' and 'adoption and implementation of systemic innovation in construction' could provide more insight in the state of the art concerning the implementation of Open Building Systems and other innovations in practice. Furthermore, only few contributions have been made to formulate 'design rules' for Open Building Systems and its adoption and implementation process and in addition applying and testing those design rules.

Abstract

Is project management developing towards a more human- or culture-oriented discipline? Two recent studies of the Dutch construction industry dealt with this issue, and the results of these studies have led to the conclusion that project management has developed in the opposite direction over the past few years, towards a 'harder', more instrumental approach with an increasing degree of specialisation. This approach works well with relatively simple and repetitive construction assignments, but project managers have noticed that their environment is rapidly increasing in complexity, and that this development limits their effectiveness. Some of these issues include the project's immediate surroundings (for projects in the city centre), legislation, regulations, procedures, the number of parties involved and judicial matters.

The highly instrumental management style described above is not entirely suitable for these increasingly complex construction projects. We have observed that these new construction assignments require new management paradigms, but that the existing paradigms are tenacious in their hold on managers' thinking. The dominant form of management today is still technical, Taylorian and instrumental, and the dominant management culture is still task- and results-oriented.

And yet there are some new developments in the field; lean or agile project management is clearly gaining momentum (or so the trade journals would have it seem). Within this 'movement', the human aspect takes precedence over the structure. The average project manager may be satisfied with his competencies in general, but he gives himself a low score on the 'human' or 'social' side of project management. That is also the facet he would most like to improve about himself; especially with regard to skills such as negotiation, conflict management and leadership.

There is a general trend towards social skills and away from purely technical expertise. This implies that project managers do not necessarily have to be engineers. The project manager of the future will definitely have to have people skills, but according to the project managers themselves, they still have a long way to go.

Keywords: Social innovation, agile project management, lean manufacturing, project management competencies, project management careers, paradigm shift

INTRODUCTION: STRUCTURAL LIMITS?

The quest for success!

The 'holy grail' for much of the research on project management is the search for success factors. What determines the success or failure of a project? An American study by Sloan, based on hundreds of case studies (not limited to the construction industry), shows that 70 to 90% of all projects are considered failures. Some reasons for this include: schedules based on political factors instead of hard facts, lack of support from the project sponsor, stakeholders and senior managers who circumvent formal decision-making processes, risks that are downplayed or ignored and team members who do not show up, do not keep to schedules or are insufficiently competent.

Another study asked project managers about failure factors (Arras People 2010). The results of this study supported the conclusions above and added others: scope creep (the project changes and the scope shifts in a different direction), incomplete requirements and poorly formulated or managed expectations. Similar studies have been conducted in the Prince2 environment (for example: Onna 2007) and PMI (2009). These studies also listed issues such as: confusion as to the client's role, lack of a proper project plan, vague definition of the expected result (both as to what it will be as well as what it should not be), overly optimistic schedules and lack of consideration for delays and changing requirements and principles during the project.

Remarkably, many of the failure factors fall in the category 'structure' or 'instrumental' (control is more important than involvement, a great deal of confidence in procedures and checklists, making plans and then rigidly executing them). The answer to failure can be found in the project management methods used, as they all resemble one another. The two most common in the Netherlands are:

- Prince2 (Projects IN Controlled Environment by the Office of Government Commerce)
- PMBOK (the PMI's Project Management Body Of Knowledge (2009))

Problem statements and objectives

This study deals primarily with the 'hard' side of project management; *"if your only tool is a hammer, all your problems look like nails"* (Maslov, 2011). Project managers usually approach problems by applying more structure to the project. This is only to be expected in a sector dominated by engineers: 95% of the managers in the construction industry have a technical background (Pries, 2005). However, it remains to be seen whether the use of even more structure and instruments is effective. Where one project suffers under the burden of too much structure when creative interaction is needed, another project may benefit from a rigid structure. Van Aken (1996) notes that in general:

- Use of instruments has a negative correlation with success;
- Working style correlates strongly with success;
- Few instruments are necessary to achieve success with goal-oriented work processes;
- In many projects, too much structure stands in the way of success.

This paper was drafted with the above discussion in mind. In it, we will discuss questions such as:

- Is project management a discipline that is primarily characterised by a hard, instrumental approach?
- Are there indications that project management is developing towards a more human- or culture-oriented approach?

This study is based on literature research and presents the following two studies;

- The first study (Pries, 2009) describes, examines and when possible quantifies various aspects of culture in the Dutch construction chain. This study is based on literature on the subject, an Internet survey of 241 individuals in the construction industry and 14 interviews.
- The second study (Everts, 2008) analyses the existing and desired competencies among project managers. The conclusions of this study are based on an Internet survey of 150 project managers and six interviews.

DEVELOPMENT TOWARDS AGILE PROJECT MANAGEMENT?

From 'instrumental-Taylorian' towards 'agile' project management

Projectmanagement and organizational management are sometimes seen as the same fields of expertise, but studies show a clear difference between needed competences (Turner, Muller & Dulewicz, 2008). It has been argued that project management is going through the same learning cycle as management all be it with a time lag (Krahn, 2005). Even though both organizational management and project management now claim that they can be 'agile', this paper focuses purely on the latter. Meredith (2006) notes that traditional, hierarchical management is increasingly being replaced by 'consensual management'. One could see this as a form of 'social innovation', in that it deals with the emancipation of workers at all levels. Without treading into the sensitive area of definitions, we can describe this as an increased involvement of employees and clients in formulating policy and of the organisation in implementing that policy.

The world of project management also pays increasing attention to the human side of management (Pries, 2011). In the literature on project management, the concept of 'agile' management is clearly very popular. This agile management approach is especially popular in the field of ICT project management, but we have not yet observed it in the Dutch construction industry.

Agile originated in the world of ICT and software development. It displays many of the characteristics of 'lean thinking'. "Lean Software Development; an agile toolkit (Poppendieck, 2003)" is an example of the concept that originated in Japanese Lean Manufacturing. The Manifesto of the Agile Alliance (http:/www.agilealliance.org/) states: *"We are uncovering better ways of developing software by doing it and helping others do it. Through this work we have come to value: individuals and interactions over processes and tools; working software over comprehensive documentation; customer collaboration over contract negotiation; responding to change over following a plan. That is, while there is value in the items on the right, we value the items on the left more".*

Agile stands for individual interaction rather than procedures and tools; results above paper predictability and reacting to change instead of rigidly following the original plan. In this sense, agile seems to better suit the current zeitgeist than traditional project management due to the dramatic increase in environmental turbulence and complexity in the construction industry (Pries, 2011). In a simple, stable world, traditional project management would suit

just fine; plans are drawn up based on relatively predictable variables and the manager can simply follow the plan. However, in a complex and rapidly changing world, this method is no longer sufficient. Manoeuvrability and flexibility are vital, as managers must be able to adapt to inevitable changes. There is no room for bureaucratic organisations and rigid procedures. Aspects that do fit into this paradigm include (Pitagorski, 2008):

- Self-managing or self-organising teams
- Plenty of interaction with the client, "even when there isn't a problem to be solved!" (Blais).
- Balance between 'top-down' and 'bottom-up'
- Motivated individuals; according to the Agile Alliance: "Build projects around motivated individuals. Give them the environment and support they need, and trust them to get the job done". But Pitagorsky does raise some doubts about this method. It is useless to ignore the fact that there is a great deal of variation in the competencies of different individuals. Blind confidence is counter-productive; some kind of balance must be found.
- A leader should become more of a coach and facilitator, clearing obstacles from the team's path.

INTERLUDE: A CONTROVERSY BETWEEN AGILE AND TRADITIONAL PROJECT MANAGEMENT?

The academic literature on the subject suggests that there is a conflict between the two approaches to management, but in practice the difference is more subtle. As Pitagorsky (2008) explains: *"The challenge is to stay lean and agile and to satisfy the control needs (…) by blending the wisdom of the traditional and Agile PM approaches. The right blend of formality and flexibility is essential for ongoing success"*. The difference may seem black-and-white in theory, but in reality there are several shades of grey. This is an opinion that the authors find easy to live with. The challenge is to select the right project management model for each specific project. When the project is absolutely unique and displays a high level of complexity with many parties and interests involved (and therefore many potential conflicts), then the manager should not implement a hierarchical and bureaucratic project management model. However, if the accent lies more on implementing a relatively simple plan that enjoys broad consensus among all parties, then such a plan would be ideal. Of course, every project progresses through different phases. The earliest phases of the project demands a more agile approach (exploratory, conceptual, value-adding, interaction), while the later phases will often require a more traditional approach to project management (managing, technology, focus on costs).

Is structure unnecessary then?

We often hear people in the construction field saying 'that culture nonsense' may all be well and good, but that there are still too many fundamental mistakes being made. Contracts and procedures are drawn up wrong and technical design mistakes frustrate the builders. There is of course truth in all of this. Managing the structure is vital in a technical world. Structural thinking is far from nonsense; attention to the structure is absolutely necessary. However, it is much easier to work within a structure if attention is also paid to the culture of cooperation. After all, a person with two legs doesn't hop around on one all his life. It is in this field of culture, or the 'human side' of project management that we are falling behind, and it is on this point that we must innovate as a sector (Pries, 2009). We must invest more in the cultural dimension.

INTERLUDE: THOUGHTS ON ORGANISATION AND COMPLEXITY

How fragmentation has become our worst enemy!
Building used to be much easier in the Netherlands. There was a client, an architect and a contractor. The architect was the boss and the contractor had all-round craftsmen in service. High-quality buildings were assembled by high-quality labour using low-quality materials. After World War II, the focus was on quantity production. These uniform construction tasks offered plenty of opportunities for series production. At that time, especially in the 1960s in the Netherlands, our sector went through large-scale innovations (Pries, 2005; Doree, 2005). Large-scale use of concrete, large elements, modular high-rise buildings; all were phenomenal innovations. Those were also the days of the time-and-motion study. Using a stopwatch, managers could measure productivity and construction increasingly became a science.
The number of specialists also began to increase. The leading role once played by the architect has exploded into 10 specialised consultants, and the average building site now has 30 to 40 subcontractors getting in each other's way.

What about the theory?
This development corresponds with what we find in the literature on the subject. When we examine operations research (as in Daft, 2006; Pries,2009; SBR, 2005; SBR, 2007), then we see a relationship between the serial nature of the production (or its complexity) and the size of the series. Small, difficult series result in piecework, while large, simple assignments are ideal for series production or even mass production (although this does not apply to the construction industry). Piecework requires high-quality labour and craftsmanship, little specialisation, few formal procedures and decentralised decision-making, a well-trained craftsman is only hampered by procedures and checklists.

The times have truly changed!
In today's Dutch construction industry, we are still confronted with the assumption that we can continue with series production. We are faced with countless sub-contractors, a large number of specialists at the construction site (each chosen by lowest bid), coordination problems, but also a fundamentally changed building assignment. Just five years ago, 70% of all homes were built on the edges of the city, where it was relatively easy to build. But today 70% of our assignments are in the complex existing built environment (Pries, 2010). This existing environment comes with its own residents, interest groups and logistical challenges. On top of that, 50 cents of each Euro spent on construction goes to renovation, management and maintenance, and those types of production are much less predictable than new construction. There are no projects involving thousands of homes any more, today's homes must all be unique and consumer-oriented. Moreover, we are faced with any number of sustainability regulations that will fundamentally change our building process. All together, these changes present us with all of the ingredients for chaos. We are faced with a difficult, small-scale assignment that we still want to approach with a simple, large-scale solution.

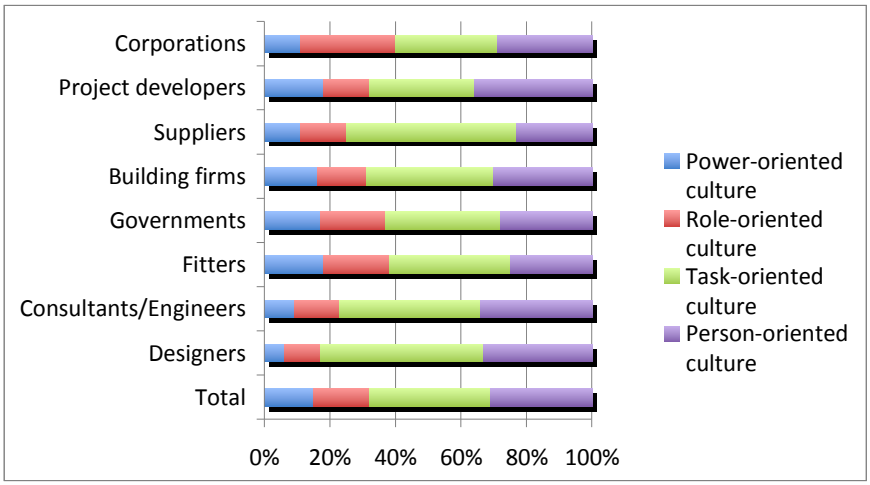
CULTURE WORKS!

Introduction

We have noticed that people in the construction industry find the culture of cooperation extremely interesting, and they suspect that it may be very important, but that they lack the knowledge and skills necessary in order to implement it (Pries, 2009). We have therefore defined, studied and when possible quantified the various aspects of culture in the building chain.

The importance of culture

Much has changed in the construction sector in recent years. The complexity of the rules and interests pertaining to building projects is here to stay; construction will never go back to the simplicity of yesteryear and we will have to get used to the fact. The natural reaction of the construction industry has been to adopt more bureaucracy and systems like ISO 9001, VCA and a focus on documenting every exception. Our real challenge is to learn how to work together better, but that is not an automatic process (Pries, 2008).



- Cooperation between people with different organisational cultures is by no means a matter of course;
- People often lack any conception of 'other' cultures, and this impedes understanding. Note that this brings an extra problem in the field of project management, because some terms may even have different meanings: goal/result, project charter/project plan/plan of attack, etc. This definitely does not help us understand one another;
- There is often a lack of tolerance for other cultures;
- Dominant parties expect other parties to adapt to their culture;
- The consequences of these issues may include: mistrust, tension and conflict.

Results of the study: task-oriented culture dominates

In a power-oriented culture (Harrison, 1972), people want to make quick decisions. In a role-oriented culture, people want to make careful decisions. In a task-oriented culture, the higher goal is the priority and in a person-oriented culture, the person's own goal is the priority. The task-oriented culture dominates the building chain (37%), but other cultures exist as well. Cooperation among the parties should produce few problems, as they generally share the dominant culture. And yet we observe that the minor differences can lead to misunderstandings in practice;

- Project developers, consultants and designers are more likely to have a person-oriented culture;
- Suppliers, designers, consultants and builders are more likely to have a task-oriented culture;
- Corporations, fitters and governments are more likely to have a role-oriented culture.

Distribution of organisation culture types in the building chain

The good news is that the differences are relatively minor. With just a little effort, we should be able to understand the other parties.

Cooperation in the construction industry graded C-

Symbols, heroes and rituals are expressions of a particular culture (Hofstede, 1993). These aspects do not determine the culture and can change relatively easily. This study provides an overview of these cultural expressions by the various parties. The construction industry is generally an informal sector. People in the industry generally address one another by their first names. Informal meetings are relatively common in the industry. With the exception of project developers, few people wear suits.

Values are the core of any culture. The construction industry is an ambitious sector; almost 90% of the respondents state that they consider ambition to be healthy. Other results of the study are often entirely predictable:

- Meetings often last too long;
- We communicate a great deal via E-mail and not enough face-to-face;
- Internal political hassles are common;
- Managers are promoted from within the sector itself;
- The result is not the only thing that matters (with the exception of project developers (75%), suppliers (58%) and fitters (57%));
- We do not always understand other parties in the building chain. We give ourselves a satisfactory score, but designers and the government are known for understanding other parties poorly. ***We understand one another to a certain extent, but we do not fully understand one another's working methods;***
- ***We feel that we understand other parties better than they understand us.***

THE ENGINEER AS A TYPICAL PROJECT MANAGER?

Introduction: the engineer as a typical project manager?

In the previous section, we saw that construction management is dominated by a technical, Taylorian and especially instrumental approach. The culture is primarily results- and numbers-oriented and cooperation is hindered by exaggerated misconceptions of one another. The industry is beginning to realise this fact (Pries, 2009), and people are recognising that the old way of working is no longer sufficient; we are becoming aware of our limitations.

If this is true, then it should also reflect in the opinions of the project managers themselves. Do our project managers consider themselves well-equipped for their job? Using a survey of 130 project managers, we worked to find the answers to these questions. This was an emphatically introspective study of the self-image of a representative group of project managers, clients, builders and consultants.
In the following section we will argue that project managers will have to adapt to agile project management as the focus shifts from technical knowledge to culture and social skills. As stated before, agile can be applied to organizational management as well, but in this paper only agile project management is discussed.

From technical competencies to social competencies?
Competencies consist of characteristics, knowledge and skills (van Doorn, 2008). Characteristics are not easy for people to acquire or discard; either you have it or you don't. Remarkably, this category gets the highest score. Apparently, project management is not something that anyone can learn (see table below for details).

Project managers consider themselves able to deal with stress, honest, technically proficient (83% of the respondents has a technical background) and persistent. The average project manager is satisfied with his competencies; none of the competencies were rated unsatisfactory. Especially older project managers indicate that they have little that they still wish to improve about themselves.

Results for competencies (purple: characteristic. green: skill. blue: knowledge).

Which competencies do you consider important? Scale:		**Grade average project manager: Scale:**		**Which competencies would you like to improve? Scale:**	
Proactive	4.7	Deal with stress	7.5	Negotiating	3.4
Decisive	4.5	Honest	7.4	Managing conflicts	3.3
Communicative	4.4	Persistent	7.4	Risk management	3.3

Social competencies: the male engineer as typical project manager?

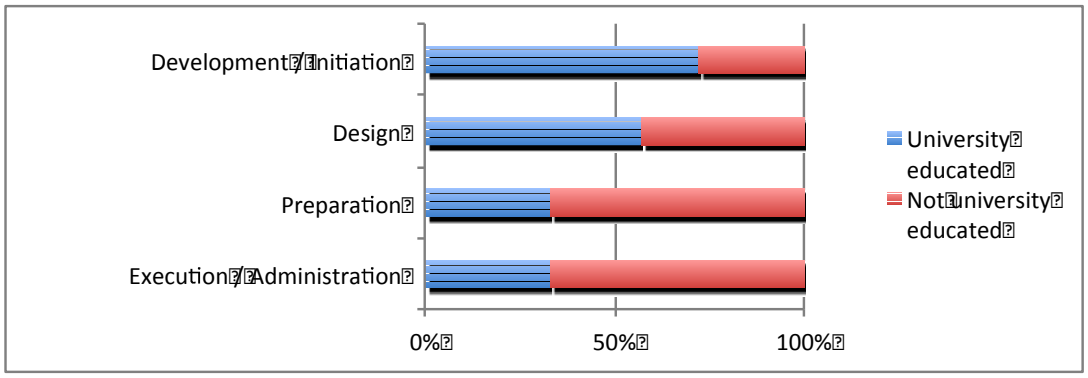
Project managers give themselves a low grade for 'ability to listen', conflict resolution, empathy and ability to inspire. They also consider themselves poor team builders and mediocre leaders. This ‘human‘ or ‘social' side of project management is also the side that they would most like to improve about themselves, especially with regard to skills such as negotiation, conflict management and leadership. Older project managers in particular place more value on a proper technical background, and men consider it more important than women.

Which developments do project managers observe in the sector?
Project managers see that their environment is rapidly becoming more complex and that this development impedes their performance. Some of these issues include the project's immediate surroundings (for projects in the city centre), legislation, regulations, procedures, the number of parties involved and especially judicial matters.
More than 60% of the respondents have practical experience with an integrated contract, and almost 40% have experience with an even more intense form of cooperation. According to this study, older managers are more likely to implement innovative types of contracts than younger managers. This may seem logical, but younger managers generally consider themselves to have better social skills than older managers, and it is that competency that is vital for construction organisational models that require cooperation.

What differences in vision exist among the various project managers?
Do male project managers give different answers than female managers, and are there differences between younger and older project managers? Remarkably, there is a significant degree of consensus among the different project managers. Only a few points showed any significant differences. These will be dealt with per category below.

Young-Old (experienced-inexperienced)
Young managers prefer the human side of project management. They value communication more highly and think that good people and teams contribute the most to successful projects. They also prefer working for public organisations. As the graph below shows (1=100%), more than half of all young project managers work for public organisations, while only around 25% of the older managers work in public organisations.

Do women have better social skills?
Here we observed a number of remarkable differences. For example, men would like to improve their environmental management skills and their discipline, while women would like to be able to deal with stress and improve their leadership skills. The results indicate that women place a higher importance on, and give themselves higher scores for, 'social' competencies. They also indicate that their social competencies help them realise successful projects. However, when asked what they would like to improve, they state that they would like to improve their more technical competencies. Men answered this question in the exact opposite.

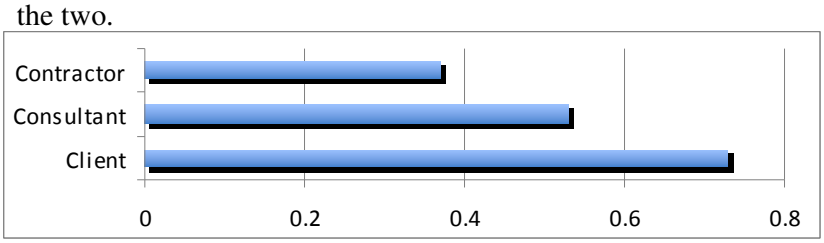


Women are more likely to work for clients; in fact, there was not a single woman in this study who worked for a contractor. The study also indicated that there were more female respondents in the younger categories. This may indicate that the percentage of female project managers in the construction industry is increasing, but it may also indicate that the more experienced women are leaving the industry. The women working as project managers today state that they are planning on remaining employed in the construction industry.

Clients vs. contractors.
Contractors are more likely to value expert knowledge and time management more highly than communication. Project managers working for clients give themselves a higher grade for managing their surroundings and communication. Contractors also think that ICT solutions will become more important to the construction industry in the future. As a result of the increase in innovative contract types, we might expect contractors to become increasingly interested in the competencies related to the design phase and cooperation. Some examples of these competencies include: interest in the end user, negotiation, communication and listening ability. However, the results point to the contrary.

Differences between the building process phases?
Project managers in the preparation phase place less emphasis on pro-activity and more on risk management. They also give themselves higher scores for managing their surroundings, organisation and quality control.

The question as to which factors contributed most to success did not produce significant differences; a remarkable unanimity of opinions across the board. The only extraordinary result was that project managers place a higher value on detailed procedures during the execution phase. In general, the managers do not differ significantly in their thoughts on project management competencies in the different phases of the project. Whether they work in the development or in the execution, they all had similar ideas of the function of project management. This may be one of the reasons why so many of the respondents can work in several phases of the project, or even all of the phases, at the same time. When we differentiate between the level of education in the different phases, it is clear that university-



educated managers are more common at the start of the realisation process, while those educated at universities of applied sciences are more common at the end.

From the comparison between the project phases and the different age categories, we noticed the remarkable difference that older managers (50+) make up only a small percentage in the early phases, while the age differences are less pronounced in the preparation and execution phases. This corresponds to the results in that we have shown that older project managers place a higher value on technical expertise and less on the social skills required in the earlier phases.

How do project managers develop their competencies?
A number of questions in this study dealt with how the project managers developed their competencies. The section below will deal briefly with the results of these questions.

- Only 34% of the respondents works for an organisation that spends more than one day per month on personnel development. It would be interesting to compare these data with data from other sectors, such as the service sector. Only 18% of the respondents have a mentor.
- Project managers throughout the construction industry state that practical experience is by far the most important factor in their personal development. Remarkably, training courses receive higher scores than their own academic education.
- More than 30% of the project managers expect to move up to general management within their own organisations. Aside from the question of whether this is a realistic goal, we can ask ourselves if it is a desirable one. Should good project managers be promoted away from producing successful projects? We should make careers in the project management field more attractive.
- Managers are more likely to visit their superiors' projects than those of their juniors.
- The chart below shows that project managers working for a client are more likely to have a personal development plan (PDP) than their colleagues. This may be an indication that clients place a higher priority on developing their personnel. This difference was also observed between public and private employers. Aside from these categories, the study showed that approximately half of the respondents do not have a PDP. We should note, however, that a PDP is no guarantee for actual personal development, as there is no literature that shows any actual correspondence between the two.

- Despite the problems involved, the complexity of the work and the responsibility involved, project managers as a whole enjoy their work. They give their job an average score of 4.4 out of 5. 80% of the respondents state that they hope to continue working in the sector, 20% are undecided and none have any concrete plans to leave the construction industry in the future.

Some recommendations

The study was primarily descriptive, providing a sketch of the most important job in the construction industry - the project manager. And yet we can still formulate the following recommendations:

- A good project manager does not always have to be a male engineer! Women function well in innovative contract forms and in complex project environments. Organisations that do not recognise this fact are not doing themselves a favour.
- Contractors in the construction sector should pay more attention to developing their personnel. This may include more internal training courses, mentorships and personal development plans. Only 34% of the respondents work for an organisation that spends more than one day per month on personnel development. Only 18% of the respondents have a mentor.
- Educational institutions should examine whether they provide people with the proper competencies. Technical training has traditionally been very important in the sector, but the reality in the field shows that it may be desirable to reconsider the skills necessary for success. Notably: industry tends to critique the PBL forms, which especially train people skills.

CONCLUSION

In this paper, we asked whether project management is a discipline that is primarily characterised by a hard, instrumental approach and whether there are developments toward a more human- or culture-oriented approach.

We realise that this paper does not provide any definitive answers to this question, as the scope is too broad and the subject is too new. We then examined the literature on the subject and presented two studies. These studies, how valid they may be, are applicable only to the Dutch context. We are curious as to the experiences in other countries correlate with our findings. Based on the information above, we can present the preliminary conclusions below:

- In the years of reconstruction following World War II the project management field developed towards a hierarchical, instrumental management model. Procedures, systems and checklists were combined with a Taylorian management style; PRINCE2 and PMBOK are still popular project management models. One could say that this was a logical development considering the serial, quantitative assignments then common.
- Building has rapidly become more complex and project managers see that their environment has rapidly become more complex as well, which has made their job more difficult.
- An instrumental management model is ideal for simple, serial production methods, but this method is less suitable for more complex assignments. Project managers must be able to adapt to changing circumstances.

- One can conclude that these new construction assignments require new management paradigms, but that the existing paradigms are tenacious in their hold on managers' thinking (Doree, 2005). The dominant form of management is still Taylorian, hierarchical and instrumental. The dominant culture is still task- and results-oriented.
- The study shows that people from different cultures working within the same project still do not automatically cooperate well. There is often a lack of tolerance for other cultures. In fact, managers are often completely oblivious to the existence of other cultures. Each party expects the other to adjust to their culture, resulting in less than optimal cooperation.
- And yet there are some developments in the field. 'Lean' or 'agile' project management is clearly on the rise, at least in the literature on the subject. Within this 'movement', the human aspect takes precedence over the structure. Interaction is more important than process management and tools. Agile management is best coupled to the complexity of the project.
- The average project manager is satisfied with his competencies. Project managers on average give themselves a low score for the 'human' or 'social' aspects of project management. That is also the facet they would most like to improve about themselves; especially with regard to competencies such as negotiation, conflict management and leadership. This indicates a general trend towards more social competencies and away from purely technical expertise. Older project managers in particular place more value on a proper technical background, and men consider it more important than women. The issue is not who has the right idea. The technical side is and will remain important, but it is no longer the only solution. This implies that project managers do not necessarily have to be engineers. The project manager of the future will also have to have social skills. According to the project managers themselves, they still have a long way to go to achieve this goal.

SUSTAINABLE RETROFIT POTENTIAL IN LOWER QUALITY OFFICE STOCK IN THE CENTRAL BUSINESS DISTRICT

Sara Wilkinson
Business & Law, Deakin University, Melbourne, Australia
s.wilkinson@deakin.edu.au

ABSTRACT

Given the relationship between energy consumption, greenhouse gas emissions and climate change, the built environment has significant potential to lessen overall emissions. With around half of all greenhouse gas emissions attributed to the built environment; it has a significant role to play in mitigating global warming. With large percentages of office stock structurally vacant in some city centres and only 1 or 2% of new buildings added to the total stock each year; the scope for reductions lay with adaptation of existing buildings. The stock with the highest levels of vacancy and obsolescence offers the highest potential of all.

Many cities are now aiming to become carbon neutral. Successful retrofit demands that social, technological, environmental, economic and legislative criteria are addressed. Buildings have to meet user and community needs. City centres comprise a range of different type of office stock with regards to age, size, location, height, tenure and quality. All buildings present challenges and opportunities with regards to retrofit and sustainability and integrating retrofit measures that reduce energy, water and resource consumption.

Using a selection of low grade office buildings to develop retrofit profiles, this paper addresses the questions; (a) what is the nature of retrofits in relation to low quality office building stock in the Central Business District (CBD) and, (b) what is the extent and scope for sustainable retrofits to low quality office buildings. Using Melbourne CBD retrofit events of low quality office buildings were analysed between 1998 and 2008 to identify the scope and extent for integrating sustainability into retrofits projects.

Keywords: office buildings, sustainability, refurbishment, building adaptation, Australia

Introduction

Building owners increasingly look to retrofit existing stock as a means of delivering sustainability in the built environment. Akin to many developed countries, Australia needs to increase the retrofit of existing office stock to reduce building related greenhouse gas emissions (Garnaut, 2007). This is recognised by the City of Melbourne who aim to bring about a carbon neutral city by 2020 with a goal of 1,200 building retrofits to deliver greenhouse gas reductions through sustainability measures (AECOM, 2008). Clearly not all buildings are the same, for example there is a great variance in building quality and some properties may experience greater levels of retrofit and greater frequency of adaptation (Wilkinson & Remøy 2011). The questions this paper addresses are: *(a) what is the nature of retrofits in relation to low quality office building stock in the CBD and, (b) what is the extent and scope for sustainable retrofits to low quality office buildings.*

Defining Retrofit

The definition of retrofit is derived from Douglas's (2006) definition of adaptation as: "*any work to a building over and above maintenance to change its capacity, function or performance' in other words, 'any intervention to adjust, reuse, or upgrade a building to suit new conditions or requirements";* it is a broad definition. Retrofit can occur to a whole building or to part of a building; for example, to one or more floors of high rise buildings. The definition encompasses within use and across use retrofits. The term 'retrofit event' includes all activity related to individual building permits on existing buildings. In the case of tenanted buildings, events can be referred to as alterations and extensions, upgrade, change of use and renovation; as such multi-tenanted buildings will experience multiple events in the one building. High rise buildings experience a greater number of retrofit events, though the value of scope of those events may be smaller. There are a plethora of terms used to cover retrofit such as adaptation, refurbishment, upgrade, conversion, renovation – all of which often exist in a 'state of happy confusion' (Markus 1979, Mansfield 2002). This paper examines the lower quality office buildings, the need to retrofit existing stock and the scope for enhancing sustainability through retrofit. One reason buildings are retrofitted is to meet tenant and owner requirements and low grade office buildings particularly need to adapt to changing preferences if they are to compete with newer sustainable buildings.

Building quality and office stock in the Melbourne market

Office stock comprises a wide range of different attributes such as size, age, space plan, configuration and physical condition which are taken as measures of quality. Office buildings are classified in the Australian market using the Property Council of Australia building quality matrix. The matrix uses different measures such as size of floor plate, number and speed of lifts; environmental rating under Green Star and or NABERS, quality of the entrance foyer and so on to determine the level a building is rated at. Buildings are rated from Premium, the best quality, sequentially through A, B, C and D. The lowest levels of building quality measured in the matrix are C and D grade. 'Premium' office buildings typically attract the highest rental levels with the highest capital values. However many office buildings do not have the Property Council of Australia rating and such buildings are likely to be owned by private individuals and do not form part of property investment portfolios. Initial analysis of retrofit activity in Melbourne CBD showed that action is largely focussed on the superior quality offices and that the C and D grade stock has the least activity (Wilkinson & Remøy, 2011). Given that C and D grade office buildings typically have the lowest levels of building quality, equipment and amenity there is a great scope for stakeholders to implement sustainability improvements The Melbourne CBD office market contains 3,608,258 square metres of lettable space, of this, 55.6% is Premium and A Grade quality, with 26.4% of Grade B quality with the remaining 18% being Grade C and Grade D (Savills, 2010). The situation is that a significant minority of offices is lower grade and less likely to undergo retrofit than its contemporary higher grade offices.

Sustainable retrofit measures

Sustainability is defined in the context of the triple bottom line where three components of economic, environmental and social sustainability are perceived as equally important. With buildings the emphasis is placed often on the environmental sustainability of the structure and fabric and the operational phase of occupation, with thought also to deconstruction and recycling opportunities at the end of the building lifecycle. Langston (2010) noted building

retrofit can deliver economic, environmental and social benefits to society, which should be at the forefront of thinking about existing stock.

The key environmental sustainability measures that can be considered in the retrofit of office buildings are energy efficiency, water efficiency, the reduction of waste, recycling and waste management, specification of low environmental impact materials and effective building operation and facility management (GBCA, 2010). Energy efficiency and reductions in building related greenhouse gas emissions may be improved by using high efficiency luminaires, high frequency ballasts and energy efficient lighting controls and purchasing 'green power' (Arup, 2008). Tenancy sub-metering enables the improved management of energy use. Depending on the individual building substantial improvements can be made with minimal costs through a housekeeping review, energy purchase, improved maintenance and re-commissioning building's services (Arup, 2008). Furthermore reusing existing buildings allows owners to capture the embodied energy already invested in the existing structure and fabric of the building, rather than commit new resources.

Water economy measures include installation of waterless urinals and 3/6 litre dual flush toilets, water efficient fixtures and water tanks to collect rainwater to flush toilets (GBCA, 2010). Such measures can reduce the environmental impact of buildings and are recognised by their inclusion in the environmental assessment tools used to evaluate the sustainability achieved in green buildings such as Building Research Establishment Environmental Assessment Method and the World Green Building Council's Green Star (Langston, 2010).

Other sustainability measures that may be adopted include reusing timber and using timber from renewable certified sources. Furthermore using carpets, paints, sealants, glues and adhesives with low Volatile Organic Compounds incorporates sustainable materials into buildings (GBCA, 2010). The provision of bicycle storage and shower facilities promotes the adoption of more environmentally friendly transportation. Clearly there are a range of measures which may be adopted and the list above is not exhaustive, however each building has to be assessed on its merits to identify specifically those parts which may be retrofitted with sustainability measures.

Social sustainability is a broader concept and relates to society, the community and /or individual people. The social sustainability of the building is considered by stakeholders and within environmental assessment tools. An illustration of social sustainability is the notion that sustainable buildings are healthier for users due to the specification of materials that do not contain chemicals detrimental to human health (Clements-Croome, 2006). Another example of social sustainability is building aesthetics where buildings having pleasing aesthetic qualities enhance surrounding areas and the environment in which they are sited (Ohemeng 1996, Zunde 1989).

A powerful argument for economic sustainability is the view that sustainable buildings are healthier buildings which result in less employee absenteeism due to sickness and higher productivity thus increasing the overall profitability of business occupiers (Clements-Croome, 2006). Given that typically businesses attribute about 85% of all costs to staffing; it is a powerful case. Lower operating costs within sustainable buildings are a further driver and potent reason for implementing sustainability, given increasing energy costs. It is evident that there is a close and often overlapping relationship between the three components of the triple bottom line.

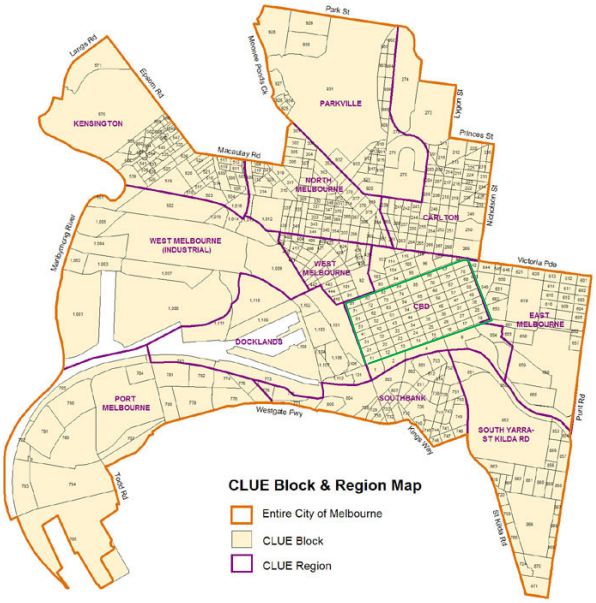
Whilst it is possible, with a well planned retrofit, to increase the office quality grade and simultaneously increase the rental and capital value of the building; previous studies concluded that this is largely dependent on the condition and location of the building (Boyd et al 1993, Sinclair, Isaacs *(in Baird et al)* 1996, Swallow 1997, Snyder 2005, Kersting 2006). With regards to sustainability improvements, one UK study showed that post retrofit office buildings typically had lower running and operating costs than prior to the retrofit even if the retrofit did not have sustainability as a priority (Kincaid, 2002). Kincaid (2002) confirmed Wilkinson's global study of thermal improvements in office refurbishments (Wilkinson, 1997). The lower running costs accrue as a benefit of technological advances in building services since the original installation was provided. This reduction in running costs is a positive economic outcome for the party which pays for the operating costs, which can contribute to higher rental levels or higher capital values (Kincaid, 2002). Lower running costs result in less greenhouse gas emissions thereby reducing the overall environmental impact of the building. The potential for integrating a broad range of economic, environmental and social sustainability measures are explored in the context of the type and extent of retrofits that have been undertaken to C and D grade buildings from 1998 to 2008 in the Melbourne CBD.

Building attributes in retrofit

Earlier work identified attributes which are important or affect retrofit (Kincaid 2002, Snyder 2005). For a fuller discussion on building retrofit and building attributes readers are referred to Wilkinson et al (2009). This paper focuses on selected important attributes in the context of C and D grade buildings, sustainability and retrofit; the number of retrofits overall, trends over time, age, location, building quality, aesthetics, plan shape and operating and energy costs. Some of these attributes are associated with sustainability such as building quality as defined by the Property Council of Australia and described above. Premium grade offices typically have the best quality services for example the fastest lifts and air conditioning which results in high operating costs per metre squared and consequently high greenhouse gas emissions. However it is also true to say that lower grade offices with older services installations can have higher running costs on a per metre squared basis (PCA, 2008). Aesthetic qualities are a measure of social sustainability in the context of this research.

Age has an important affect on retrofit; as buildings age they wear out and need components repaired or replaced (Douglas, 2006). Barras & Clark (1996) and Baum (1991) argued the correlation between time and building obsolescence, establishing that as time passes retrofit of some form is necessary to avert a decline which otherwise leads to demolition. Previous studies considered location and its affect on retrofit as important; with some properties sited in favourable locations which enhances the frequency and likelihood of retrofit (Kincaid, 2002; Douglas, 2006; Highfield, 2000). Building location within a geographical area can be interpreted into zones, in Melbourne the CBD has five zones from Prime, Low Prime, High Secondary, Low Secondary to Fringe. The best location is Prime where the highest rental and capital values are found and there is a view that buildings in better locations are likely to undergo more retrofit (Swallow 1997, Ball 2002). Building quality is measured in various ways, it can be either provision of a greater number of amenity features, attributes and, or a higher standard of services, features, fixtures and fittings.

Ohemeng (1996) found that aesthetics was an important attribute in determining whether or not a building was adapted in his UK study of 400 building owners. Plan shape was an important attribute in retrofit and that some plan shapes such as deep plan shapes were easier



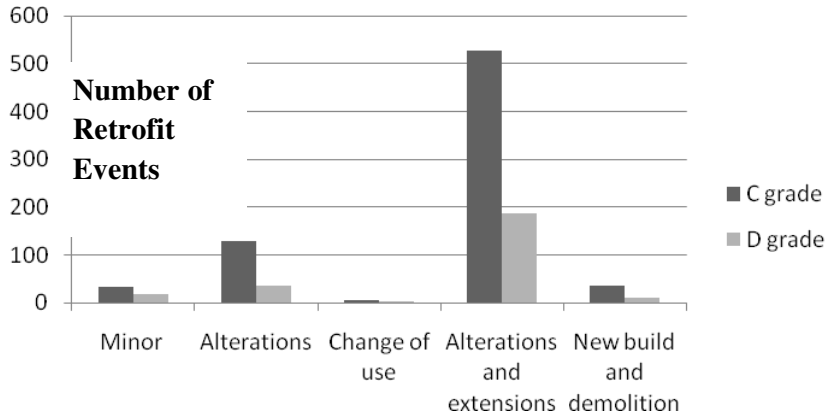
to adapt than others such as irregular shaped ones (Kincaid, 2002; Povall & Eley *in Markus*, 1979). Building height or the number of storeys in a building was found to effect retrofit in studies conducted by Povall & Eley (in Markus 1979) and Gann & Barlow (1996).

Research Approach

A database of office buildings was compiled to appreciate the nature of retrofit and the extent and scope for sustainable retrofit using multiple sources such as the commercial database Cityscope, and public databases such as PRISM (Victorian Government) and the Heritage database. In addition data from the Property Council of Australia, Google Earth and Google Streetview (www.google.com.au/maps) was used to gather building related data (PCA 2007). Information relating to retrofit events was derived from the records for building permit applications. Visual inspections and photographic records of CBD office buildings were carried out. The database contains records for 13222 retrofit events to commercial buildings from 1998 to 2008 and allows the researcher to provide an overview of what has happened on a CBD scale with retrofits to commercial C and D grade buildings.

Given the objectives; to understand the nature of retrofits to C and D grade office stock and the extent and scope for sustainable retrofit to C and D grade office buildings this stock only was extracted for analysis. The criteria used to examine the scope and the potential for sustainability in the retrofit were number of adaptations, location, building quality, aesthetics, plan shape and costs in use. As this study determines the nature of and the scope and extent for adopting sustainability in retrofits within the Melbourne CBD, details on the individual characteristics of the buildings is not examined or discussed. The results are a uni-variate and a bi-variate analysis of the data. The answer to the first question; *what is the nature of retrofits in relation to low quality office building stock in the CBD,* is given on the basis of a quantitative statistical analysis derived from the database and reflects the empirical reality. The answer to the second question is derived from the literature outlining different types of sustainable retrofit measures and their impact on building performance.

Figure 1 CLUE block and region map Melbourne



The research investigated activity in a developed, mature commercial market; the Melbourne CBD which was first set out in 1834 and has been continuously occupied. It is the most mature property market in Victoria with a diverse range of stock. The streets bounding the CBD area are as Flinders Street, Spencer Street, Spring Street and La Trobe Street highlighted in green in figure 1.

Results and discussion

All retrofit events to C and D grade buildings were analysed to ascertain the level of retrofits undertaken. A total of 978 retrofit events occurred to 197 C and D grade buildings from 1998 to 2008. Minor retrofits accounted for 5.8% of works, alterations 16.8%, change of use retrofit 0.8%, alterations and extensions adaptations, the most extensive level 72.8% and new build and demolition work accounted for 4.5% of works. This pattern maps closely figures for retrofits to all building grades. The most frequent level of work undertaken was 'alterations and extensions' retrofits which indicates a high level of confidence in the market to recoup the costs involved in the construction works, as well as the loss of income during the works in order to achieve higher rental levels post retrofit. It is indicative of the prevailing median age of 31 years of the building stock during the time period which means that buildings are at an age where retrofits are required to bring them up to market expectations (Jones Lang LaSalle 2005, Duffy in Brand 1994).

Examining the amount of all retrofits by Property Council of Australia building quality grade, Premium quality stock accounted for 12.9% of the works, with A grade at 20.7% and B grade recording the highest amount of activity at 27.3%; therefore 60.9% of the work is undertaken to the highest quality stock. Unclassified office buildings accounted for 24.2% of work, leaving work to the lowest quality stock the C and D grade stock accounting for 11.1% and 3.8% respectively. Within the Melbourne market there are lower vacancy rates for the prime quality office stock (Knight Frank, 2010) which implies that work undertaken results in higher levels of stock occupancy. Reviewing the retrofits to C and D grade stock to ascertain what level of retrofits are undertaken, more work occurs to the C grade stock overall and that alterations and extensions retrofits are most popular.

Figure 2 Retrofits to C and D grade offices and Property Council of Australia building quality grade.

Characteristics of the stock

Overwhelmingly the C and D grade stock has an irregular plan shape (48.2%), followed by deep plan configurations at 28.4%, with 17.1% having a narrow frontage and the remaining 6.3% being of a wide frontage to the street. The buildings retrofitted were purpose built for commercial usage, with only 13.8% having undergone a change of use prior to current use.

Brick was the primary façade or envelope material for 72.7% of buildings, followed by curtain walling (9.8%) and with concrete cladding and stone at 8.6% each. Opportunities exist for making changes to openings with brickwork construction and with overcladding for brick and concrete clad buildings. Brick and stone construction has high thermal mass and are relatively effective at heat retention and resisting rapid thermal gain when temperatures increase. There is scope for overcladding externally or retrofitting internally with insulated panels to improve thermal performance. Curtain walled buildings typically have poor thermal performance on the other hand, and great opportunities exist for improving energy efficiency with this stock. Significantly when visually inspected, 92.8% of the external envelope or cladding of the stock was in good or very good condition with only minor surface imperfections noted. There is little in the physical condition to drive owners to undertake alterations externally that could provide an opportunity to improve thermal performance. Furthermore when building appearance is evaluated 65.8% of events happened to buildings classified as aesthetically pleasing, with 17.2% classed as neither 'beautiful' nor 'ugly'. This result confirms Ohemeng's (1996) study that more attractive stock is retrofitted compared to less attractive buildings. However given that 17% of retrofits were undertaken to buildings classed as 'ugly'; there is scope in around one in five C and D grade retrofits to update and improve external appearance and thermal performance.

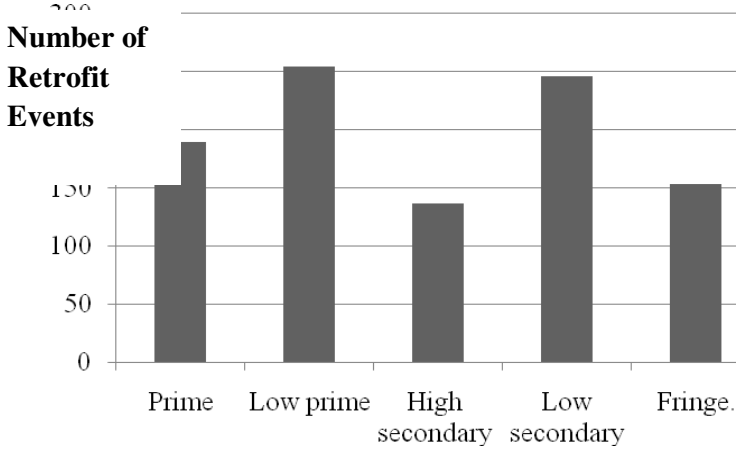
When the location of the vertical services core is considered, 48.8% of events occurred in buildings with multiple services cores, followed by 31.6% with central locations. This implies that these buildings undergoing the highest frequency of retrofit are those which are more amenable to different configurations of space plan on individual floor levels, a finding supported by (Arge, 2005).

The C and D grade stock is predominately of single land use; that is 63.5% of events occurred to buildings classed solely as offices. However a large minority of 35.3% were office and retail land use, with the remaining 1.2% classified as office and residential land use. Ownership of mixed use properties can make retrofits to the external envelope complex particularly with residential land use. Here buildings without a mixed land use undergo more frequent levels of retrofit possibly because less negotiation is required with co-owners and other stakeholders. This has implications in future as more mixed use buildings appear in city centres; especially under planning policies encouraging mixed land use combining residential and office uses.

Where regulatory requirements are concerned, 67.7% of retrofits occurred to buildings with no listing or heritage overlays. Owners of non listed stock are more likely to undertake retrofit and municipal authorities need to consider programmes to incentivise owners of heritage stock to adapt. Having stated this, older heritage stock has high levels of embodied energy and were constructed using traditional methods and materials likely to have high thermal mass and relatively good thermal performance.

Given that as buildings age, they require retrofit (Barras & Clark 1996, Langston et al 2007), the age of buildings undergoing retrofit was examined with 20.4% of all events occurred to buildings less than 25 years of age. The largest number of events occurred to buildings aged 26 to 50 years, where 48% of events were undertaken. Buildings aged 51 to 75 years accounted for 12.6% of events, with 11.3% occurring to buildings aged 76 to 100 years and the remaining 7.7% of events occurred to buildings aged 101 to 152 years. Clearly C and D grade stock undergoes most retrofit activity during the 26 to 50 year period. It is possible that owners of this lower grade stock are inclined to wait as long as possible before paying for retrofit works as opposed to being keen to maintain a position within the market place. When the whole stock is analysed the median age for retrofit was 19 years. 15.8% of events occurred to 40 year old C and D grade stock.

Arge (2005) found that the potential for lateral and vertical extension of a building greatly enhanced it's desirability for retrofit. Not surprisingly none of the Melbourne stock had potential for lateral extension because entire sites were built out. Scope for vertical extension was based on an analysis of the structural frame type and condition of the property and 25.9% of retrofit events could support vertical extension, planning permission permitted. Depending on planning density requirements there is scope to increase net lettable floor area of CBD offices in over a quarter of retrofits to C and D grade stock, whilst retaining original structure and fabric and the associated embodied energy.



Arge (2005) noted that the degree of attachment to other buildings was important in determining the level of disruption to tenants of adjoining properties during retrofits. Most retrofits occurred to buildings attached on two sides (34.4%) closely followed by 31.9% to detached buildings. Only 15.4% of events took place to buildings which are attached on three sides and Arge's (2005) finding is supported. The authorities could consider incentivising retrofits to buildings which are enclosed by others to increase retrofit activity within this type of stock.

Access to the building was important in determining the ease of delivery of construction materials and retaining tenants in situ where necessary during retrofits (Arge 2005). No C and D grade retrofits occurred to buildings with access on all sides. Most retrofits occurred to buildings with access from the street front and side (35.2%), followed by street only access (27.3%) which contradicts Arge's (2005) findings. Fewer than one in five (19.2%) events took place to buildings which have access from street, side and the rear of the property. Finally 18.3% of events occurred to buildings having access from the street and rear of the building.

Building location is perceived as important in determining whether retrofit occurs (Swallow, 1997). Interestingly most events (25.9%) occurred in the Low Prime location which suggests that owners are conscious of the benefits of the location and strive to keep up with retrofit activity in higher quality stock (figure 3). Events in the Prime location accounted for 19.3% of all retrofits which is likely to be associated with the higher levels of activity generally in these areas. There is a distinct drop in High Secondary location activity where 14% of events occurred. However the activity rate increases in Low Secondary locations where 25.1% of retrofits took place; it is likely that these retrofits are what Chandler (1991) termed 'distress' retrofit where owners are obliged to undertake works to meet statutory requirements and to attract and retain tenants. Finally activity in the least desirable location of all, 'fringe' showed only 15.6% of events indicating that the lowest quality stock is largely unworthy of retrofit. The implication for policy makers is that incentives should target improving the stock quality

in the fringe locations where there is clear scope of improving building performance and reducing building related greenhouse gas emissions.

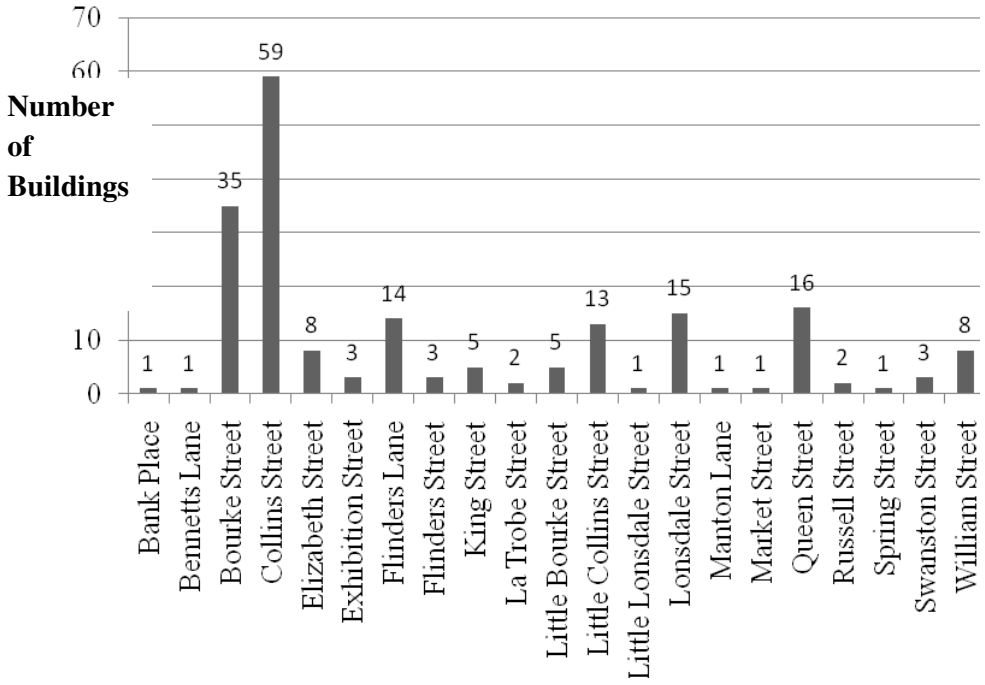


Figure 3 C and D grade building retrofits and location

CBD Location

Another way of examining location and retrofit activity is to investigate activity by street address. In this instance, the retrofits happen primarily in two streets; Collins Street and Bourke Street. Figure 4 shows retrofits to individual buildings by street address; note that many buildings experienced multiple retrofit events from 1998 to 2008.

Figure 4 C & D Grade buildings adapted by street

Street Address

Sustainable retrofit

On the basis of Property Council of Australia building quality grade, it is possible to assess cost in use. The Property Council of Australia publishes data with regards to median gross income, and the costs of operating expenses, energy and water consumption based on grade (Property Council of Australia 2008). As expected gross income on a per metre squared basis is correlated to building quality with C grade stock grossing $274.01 per square metre compared to $395.92 per square metre for Premium and A grade stock and $300.95 per square metre for B grade stock (Property Council of Australia, 2008). No data is available for D grade buildings. The gap between income for C and B grade is narrow compared to the gap between B and A / Premium stock and possibly deters owners of C grade stock from high capital expenditure on improvements which may not lead to a substantial increase in gross income.

When operating expenses are examined no data is available for D grade stock, however C grade stock is more expensive to operate on a per metre squared basis at $73.35 per square metre compared to $62.11 per square metre for Premium and A grade and $54.17 per square metre for B grade (Property Council of Australia, 2008). Clearly there is scope to retrofit the buildings with energy efficiency measures to reduce these high operating costs. It is clear that any retrofit replacing worn out services will result in significant energy saving simply because the quality of replacement fittings far exceeds that of existing fittings (Wilkinson, 1997. Kincaid, 2002).

The costs of electricity consumption is highest in C grade stock at $25.93 per square metre, compared to $21.70 per square metre for Premium and A grade buildings and $19.72 per square metre for B grade stock. Even though the level of building services amenity, such as air conditioning and high speed lifts, is lowest in C grade stock; the cost of electricity consumption is highest. This is a result of the age, condition and efficiency of existing installations. Clearly there is an opportunity to reduce electricity consumption per metre squared to levels significantly below the higher quality stock with their intensive use of building services (Property Council of Australia, 2008). A similar picture emerges where gas consumption is considered. The costs of consumption is highest in C grade stock at $3.33 per square metre, compared to $1.29 per square metre for Premium and A grade buildings and $1.55 per square metre for B grade stock. Retrofit aimed at improving efficiencies in the existing gas installations will lead to lower levels and costs of consumption. Where water consumption is concerned a similar situation exists. C Grade stock has the highest costs associated with consumption at $3.51 per metre squared, compared to Premium and A grade at $3.34 per metre squared and B grade at $2.49 per metre squared (Property Council of Australia, 2008).

Swallow (1997) stated the type of building owner was an important factor influencing retrofit. Over 60% of events occurred to C and D grade stock in private ownership, where the breadth and depth of professional advice offered to and taken up by owners is unknown. Institutionally owned stock is likely to be professionally managed and accounted for 37% of events. It is considered these owners are more likely to consider sustainable retrofit compared to private owners. There is a significant opportunity to develop a programme to educate owners of C and D grade about the benefits of sustainable retrofit in terms of increased capital and rental values and to assist them financially to implement measures. No C or D grade buildings in the database had NABERS, Green Star or ABGR environmental ratings highlighting the environmental quality gap in this stock. This gap needs to be addressed by

policy makers as it will further encourage the evolution of a two tier market of buildings perceived to be either sustainable or non sustainable.

Conclusions

The questions this paper addresses are: *(a) what is the nature of retrofits in relation to low quality office building stock in the CBD and, (b) what is the extent and scope for sustainable retrofit to low quality office buildings.* There are some clear findings from this analysis;

a) Most retrofits are extensive; alterations and extensions adaptations,
b) C and D grade is least likely to be adapted,
c) Vacancy rates are higher in C and D grade stock,
d) Most retrofits occur in Collins Street and Bourke Street,
e) Retrofits largely occurred to buildings with irregular plan shapes, brick facades and envelopes, with multiple service core locations, classed as office land only, without heritage listing or overlay issues, aged between 26 and 50 years, attached on two sides or detached and in private ownership.

With the C and D grade stock there is scope to;

a) Overclad brick facades and envelopes to improve thermal performance, though given the good condition of stock overall building owners will need encouragement.
b) Reduce the relative high operating costs, electricity and gas consumption costs through sustainable retrofit.
c) Decrease water consumption costs through sustainable retrofit.
d) Over a quarter of retrofits could support vertical extension, planning permission permitted, to increase total area whilst retaining existing embodied energy.

Additional issues raised in this study are;

a) Owners of non listed stock are more likely to adapt and authorities need to consider programmes to incentivise this group.
b) Buildings with office land use only undergo more frequent adaptations. This has implications in future as more mixed use buildings appear in city centres.
c) The gap between gross income for C and B grade is narrow compared to the gap between B and A / Premium stock and possibly deters owners of C grade stock from capital expenditure on improvements which may not result in substantial increases in gross income.
d) To educate owners of the benefits of sustainable retrofit in terms of increased capital and rental values and to assist them financially to implement measures.
e) Authorities could incentivise retrofits to buildings which are enclosed by others to increase the rate of adaptation.
f) Incentives could be targeted at stock in fringe locations where there is scope to improve performance while reducing building related greenhouse gas emissions.

There are distinct differences in the patterns of retrofit based on building quality, as there are similarities, such as the level of retrofit and the locations in which work is undertaken. Sustainable retrofit measures have been identified on a CBD wide scale with specific stock characteristics offering the best potential for retrofit affirmed. The characteristics embody the facets of the economic, social and environmental aspects of the triple bottom line identified previously. Finally the results reveal clear evidence that an environmental quality gap is

appearing in the C and D grade stock which needs to be addressed as part of an all encompassing approach to improving the entire building stock.

PARTNERING AND THE TRADITIONAL: INSTITUTIONAL DETERMINANTS OF GOVERNANCE IN DANISH CONSTRUCTION

STEFAN CHRISTOFFER GOTTLIEB

jsti@man.dtu.dk

Abstract
Projects have traditionally been constituted by contracts, whose enforcement is held in place by governance mechanisms that involve high degrees of surveillance. In this light, partnering is advocated as a project specific, communicative alternative to this traditional legal coordination process of the construction industry. In a Danish context partnering has, however, so far not been able to offer a well-defined alternative to this traditional regulatory governance frame. However, rather than providing a well-defined alternative, in this paper we argue that partnering can be seen as a nullification of the traditional, i.e. as a counter-concept to a juridico-discursive conception of project governance that otherwise has been instrumental in organizing and coordinating various aspects of the construction process according to a more or less taken-for-granted regulative schemata of institutional order. Accordingly, it is suggested that the effects of partnering in the first instance stem from a series of interventions in the institutional and regulative context of the construction process, and that future case studies could benefit by paying closer attention to the institutional determinants of management thinking and practice.

Keywords: Collaboration, partnering, institutional history, governance, the traditional.

INTRODUCTION: PARTNERING AND THE TRADITIONAL

In this article, we explore how the concept of partnering has emerged and become institutionalized as a certain governance form in Danish construction. Our main argument is that partnering should be seen as a thoroughly historical phenomenon that constitutes a counter-concept to a 'traditional' *juridico-discursively* institutionalized way of governing project delivery, which rests on a strong technical-rationalistic thinking. By means of an institutional history approach, we trace the development of partnering and point to the processes through which partnering has become problematized, articulated and institutionalized.

In Denmark as well as in the rest of Europe, the last two decades have seen a proliferation of change initiatives and new ways of working that have taken as their starting point and main objective to improve the industry's productivity and level of innovation by changing traditional ways of working. Flanagan *et al.* (1998: 15) have thus argued that: "*[e]veryone agrees the industry must respond to the customer's demands instead of continuing to offer the*

traditional approach" and (Fernie et al., 2006: 94) have argued that new management ideas (*cf.* Bresnen and Marshall, 2001) or change reforms are continuously and increasingly launched in an attempt to abolish: *"…the 'illnesses' of the sector […] [and the] 'traditional bad ways of both thinking and practice'"* (Fernie et al., 2006: 94).

However, what this notion of the 'traditional' refers to is somewhat difficult to get a firm grasp of, especially if we are on a quest for unambiguity and clear-cut definitions. Taking much contemporary construction management related literature as a starting point, we would argue that there are just as many understandings of the 'traditional' as there are concepts and new management ideas proposed. In fact, it would appear that each of the solutions to the construction industry's problems, *i.e.* each of the proposed treatments to the industry's illnesses, carries along with it a diagnosis and problem representation that is more or less explicitly formulated and valid in terms of its ability to mirror an actual social problem. Paraphrasing Cohen *et al.* (1972), we would argue that new management ideas at large whether BIM, partnering, lean, Business Process Reengineering (BPR), etc., are solutions looking for or indeed defining a problem.

As an example, Green and May (2003) argue that the BPR wave of the 1980s and early 1990s addressed the construction industry as a backward industry compared with other industries and constituted 'the traditional' in terms of an unresponsiveness towards the "*...customer in the marketplace."* (Green and May, 2003: 104). In the case of partnering, we are faced with a situation in which trust, openness and mutuality are constituted as the cure to the adversarial, conflict-ridden nature of the industry, where time-honored practices, process technologies, qualifications and forms of organization have established a cultural and social hegemony, which has to be broken for the sector to advance into the 21st century (ATV, 1999).

Even though we can argue that new management ideas and concepts shape industry discourses and are constitutive of social practice they do, however, not just appear from nowhere. Several different models of explanation can be applied. Some would argue that the emergence of new concepts in a given institutional field can be understood analytically as a result of a transition from one institutional 'logic' to another (Friedland and Alford, 1991), whilst others would opt for more structural or evolutionary explanations (*cf.* Geels, 2010). In this paper, we take an institutional history approach to the study of the emergence and institutionalization of the concept of partnering in a Danish context.

While there might be consensus on what partnering as a surface phenomenon entails, e.g. trust, openness, economic incentives, etc. (cf. Nyström, 2005), this paper aims at providing an understanding of how such concepts and elements in the first instance become part of an institutional vocabulary. Thus, the objective of the paper is to provide an input to how regulatory industry change takes place, and how the determinants of a certain management/ governance knowledge and practice become institutionalized in a certain context.

INSTITUTIONAL HISTORY

We take as a starting-point the notion that society and all its subsystems, including and most relevant for this paper the various national construction business systems, should be seen as institutional constructions. Following March and Olsen (1984), we observe political institutions not just as the aggregate consequences of individual behavior, but as ordering and constitutive forces; that is as shaping mechanisms for conditions of possibility and thus positions from which subjects can observe themselves as rational actors (Andersen, 1995). In

this paper we will not discuss the question of why to apply institutional theory, but address how an institutional analysis can be conducted on a specific field. In doing so, we have chosen to follow an institutional history approach as advocated by e.g. Andersen (1995; 2003).

In essence institutional history is an approach to the observation of the institutional construction and the possibilities and limitations it entails (Andersen, 1995: 258). The crux of the argument is that institutions are endowed with a certain taken-for-grantedness: *"...Institutions are taken for granted, then, in the sense that they are both treated as relative fixtures in a social environment and explicated (accounted for) as functional elements of that environment."* (Jepperson, 1991: 147).

Institutional history therefore becomes an approach with which to problematize and question contemporary institutions by referring them to the conditions of hegemony and power under which they are established (Foucault, 2001). Institutional history consists of two juxtaposed analytical constituents: a diachronic and a synchronic analytical perspective. With the diachronic analysis, we are interested in establishing the system of transformations that constitutes change, whereas the synchronic analysis is concerned with describing the unity of the system at a given point in time.

Two perspectives: diachronic and synchronic analysis

The diachronic analysis is concerned with the analysis of the constitution of institutions. Inspired by Andersen (1995) and Kjær (1998) we observe the analytics of institutional history as consisting of the following processes and elements:

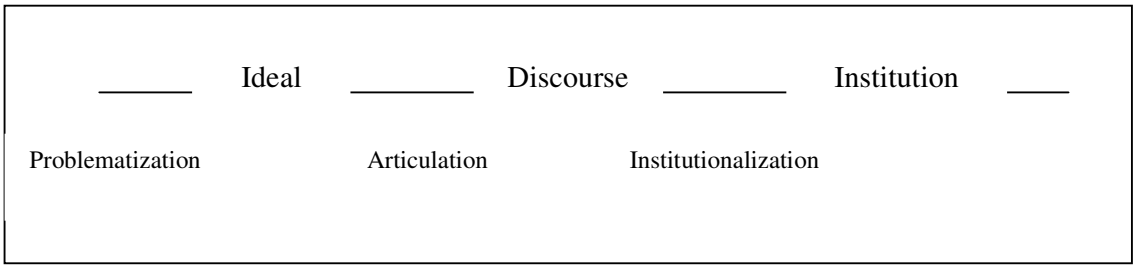

Figure 1: *Three steps in institutional history (adapted from Andersen, 1995: 263).*

An *ideal* is an anchorage point for a discourse. It is the point of convergence for the processes of problematization, or in other words, the creation of mutual awareness of a common enterprise (*cf.* DiMaggio and Powell, 1991: 65). An ideal is an idealized conception of a social field on the basis of a set of constitutive distinctions (Kjær, 1998: 7). A *discourse* is based on an ideal. The transition from ideal to discourse takes place through processes of articulation and discursive formation. A discourse can be seen as a set of rules that govern the formation of subjects, objects, concepts and strategies and constitutes: *"…the stuff beyond the text functioning as a powerful ordering force."* (Alvesson and Kärreman, 2000: 1127). The transition from ideal to discourse entails a process of autonomization of the ideal in which the relations between objects, subjects, concepts and strategies that otherwise have been articulated from another discourse become reordered. Finally, an *institution* is seen as a stabilization and formalization of the relations of power and authority constituted by discourse. According to Scott (2003) institutions can be seen as social structures that have attained a high degree of resilience and are able to inform social interaction. Institutions consist of both regulative, cognitive-cultural and normative elements. Institutionalization, then, denotes the process through which discursively articulated ideals are authorized, attain a

basis of legitimacy and secure resources. The diachronic analysis thus becomes an analysis of how new ideals are formed, articulated and institutionalized, and how of breaks and ruptures in an established discursive order take place.

Where the diachronic analysis is concerned with the deconstruction of differences, the synchronic analysis seek to create unity and pinpoint the mechanisms at play in in given social fields. The synchronic analysis of institutions, then, is the analysis of how historically constituted institutions function as a pattern or principle of organization. Or as Kjær (1998) puts it: Where the diachronic perspective *"…may bring to the fore "the conflict-laden processes that define fields and set them upon trajectories that eventually appear as "natural" developments to participants and observers alike" (DiMaggio, 1991: 268)""* (Kjær, 1998: 5), with the synchronic analysis we are interested in identifying field level mechanisms that produce sub-field effects.

Below we will apply these two perspectives of institutional history in an analysis of the development partnering. The paper sets out to analyze how partnering in Denmark the last 15-20 years has developed as a counter-concept to a traditional hegemonic *juridico-discursive* institutionalization of construction project governance. This is accomplished through a diachronic analysis of debates and controversies from 1990 to present day. Then, in conclusion, we shift focus to a synchronic analysis how a new institutional order is shaped as a result of a negation of the traditional institutional ordering of the construction industry. In the analysis, we focus first and foremost on the regulative context and on how partnering has become a legitimate practice in Danish construction while downplaying questions of how partnering become taken-for-granted on an everyday project level. These more normative and cognitive-cultural elements of the institutionalization process will, however, be illustrated by pointing to how certain hegemonic discursive elements become problematized and reordered in the development of partnering.

AN INSTITUTIONAL HISTORY OF THE DEVELOPMENT OF PARTNERING

The Danish partnering policy development was formally launched in April 1998, when the Ministry of Housing and Urban Affairs published their construction policy action plan (BM, 1998), which for the first time mentioned the term partnering as a new form of cooperation in an official government document. However, the emergence of partnering dates back a few more years, at least to 1990 where a number of actors attempted to put the inter-linked problem of cooperation of productivity on the political agenda. The following analysis will thus start in 1990 and continue up to 2007, where partnering has become rather stabilized and formalized as a regulative phenomenon. The analysis will focus exclusively on the Danish establishment of partnering, and not take into consideration the progress in other Nordic or European countries, neither when discussing international influences on the Danish development, nor in relation to the 'cultural traffic' of national principles and recipes across nation states.

The analysis will be presented in three sections, analogous to the analytical framework presented above. First, an analysis of the policy development in the early 1990s leading to a description of how productivity was problematized and collaboration seen as an ideal. Second, we highlight how certain conceptions of the solutions to the problems were articulated and established. This account will also point to the central actors in the national debate on new forms of collaboration. Third, we focus on how various institutional

arrangements have been set up and become stabilized to deal with the problems of collaboration in guise of the concept of 'partnering.'

Problematizing productivity and the 'traditional'

The last 20 years the Danish construction industry has been subjected to a series of industry level development initiatives, one of which is partnering. The precondition for the different initiatives was an industry level problematization in the early 1990s, which framed the Danish construction industry as a coherent institutional field in need of strategic intervention.

This problematization was initiated by the Danish Building Development Council (BUR, 1990) who released a report on the productivity of the Danish construction sector. This report, which played an integral part in the following year's debate on the problems of the sector, documented that the resource use in the construction of a housing project had almost doubled from 1969 to 1986. Based hereon, it was concluded that although the complexity of the construction process had drastically increased, something had to be wrong with the way in which the construction industry in its totality was organized. The report thus rejected more local interpretations of the productivity problem, by framing productivity as a problem pertaining to the overall sectoral organization of the industry.

This field level problematization was further strengthened in 1993, when a series of working groups under the Ministry of Business and Industries published eight resource-area analyses, which said to: *"…draw a picture of the Danish business conditions and put the development opportunities in the 90's into perspective."* (EfS, 1993: 7). The aim of these analyses was to establish a new and forward-reaching basis for the future business policy in Denmark. The work triggered a series of attempts to put productivity and innovation on the agenda, and perhaps more important: to do so from a resource area perspective. The construction/housing area was identified as one of these resource areas, and it was described as rather peculiar or idiosyncratic when compared to other industries, most prominently the manufacturing industry.

A distinctive trait identified in the analyses was that the production in the on-site construction-market segment was said to be characterized by fragmentation and discontinuity in the form of changing collaborative constellations at different locations each time. The construction sector was furthermore characterized as a distinct home-market business with great dependency of the public sector both as a purchaser and as regulative authority. The analysis therefore pointed to the need of increased competitiveness of the industry through a streamlining of the construction process and vertical collaboration in the delivery system (EfS, 1993: 13). In summary, four central problems were identified pertaining to:

- Internationalization: Companies lack competencies and capital strength to enter foreign markets.
- Transition: Companies lack the abilities and production methods to operate within more than one market segment.
- Collaboration: Increasing future price competition leads to demands to increased long-term collaboration between companies in order of developing the industry's productivity.
- Innovation: Limited strategic process and product development and collaboration between manufacturers and construction firms.

In essence, the problematization processes of the early 1990s established a distinct industry level perception of the innovation and productivity challenges, and in the following decades

this problematization framed and catalyzed multiple activities aiming at producing coherent industry level solutions to the four challenges.

One of the most influential political measures utilized in these activities was the idea of the public sector as purchaser. The public sector was envisioned to use its collective buying power to force new technologies onto the market, as the current technological totality of the construction sector, comprising *"…the complex of scientific knowledge, engineering practice, process technologies, infrastructure, product features, qualifications, and procedures"* (EfS, 2001b: 71, own translation), had created a lock-in situation, which the primary actors themselves were unable to exceed. A prevailing conviction was accordingly the need for strong governmental involvement, and rather than working from the premises that the market could regulate itself, the basic point-of-departure was that there was the need for strong public intervention - much as it was the case in the immediate post-WW2 period (Gottlieb, 2010).

Articulating the ideal of collaboration

While the problematization processes of the early 1990s succeeded to establish a distinct industry level perception of the innovation and productivity problems, more challenges were encountered as the industry level diagnosis had to be translated into organized development efforts at local levels. The immediate effect of the industry level problematization led to a proliferation of largely uncoordinated and experimental articulation and development processes, and although these activities represented largely uncoordinated responses in relation to the industry level problematization, they also generated a series of discursive elements, which later became a resource for the articulation of more coherent responses to the problematization.

Utilizing the discursive elements as resources, several ideals thus were mobilized - each claiming to deliver an integrated industry level response to the challenges of productivity and innovation. Beside the ideal of collaboration, which is analyzed in more detail below, the elements included different types of industrialization and digitalization efforts. The immediate effect of the industry level problematization was, however, a strategy to launch three large scale development programs: Project Refurbishment, Project House, and Project Productivity with the below foci:

	Project Refurbishment	**Project House**	**Project Productivity**
International market development			
Demonstration projects	x	x	
The public sector as purchaser			
Development contracts	x		x
Development projects		x	x
R&D and information-infrastructure			
Strategic research program for construction	x	x	x
Other ministries	x	x	
Integrated business promotion			
Business support	x	x	x

Figure 2: *Main areas of action in the three core programs (EfS, 1993: 16).*

In effect, the most important of these programs turned out to be Project Productivity whereas the other programs had less effect. Project Refurbishment was highly experimental and

consisted of approximately 100 individual demonstration projects; however, due to the experimental design of the program, the strategic effects were marginal. Product House, on the other hand, was oriented towards a large-scale strategic intervention, but was never fully realized, and after an initial idea phase, the initiative was terminated.

It was therefore Project Productivity, whose 'public sector push' strategy, combining issues of productivity with collaboration that paved the road for the initial development of partnering as a strategy for increasing the productivity of the sector. This initiative was initiated in March 1994 when the Ministry of Housing and Urban Affairs invited the actors of the building industry to take part in a competition on process and product development (Clausen, 2002: 108). By November 1994 four consortia were appointed to participate in the program and carry out the suggested development programs and demonstration projects.

One consortium in specific can be seen as the paradigmatic case for the introduction and development of partnering in a Danish context: the so-called PPU-consortium. This consortium set out to make the building process more efficient by realizing vertical integration between project designers and contractors (EfS, 1997: 5). The central contribution from the PPU-consortium was the development of a new 3-stage phase model (see Figure 3) to replace the traditional phase-model, which was introduced by the association of engineers and the architect's association in a white paper in September 1968 as a response to the Ministry of Housing's launch of a fixed price/time circular that effectively subordinated the engineers and architects to the control of the client (Gottlieb, 2010: 172).

Traditional process	PPU-process
Construction client's program	**Construction client's program**
1. Project disposition suggestion	**1. Program project**
Collaboration between client, consultants and authorities	Collaboration between client, consultants, contractor and authorities
2. Project proposal	**2. Project proposal**
Collaboration between client, consultants and authorities	Collaboration between client, consultants, contractor, subcontractors, manufacturers, suppliers and authorities
3. Scheme design	**Contracting**
Collaboration between consultants and authorities	
4. Final design	**3. Execution project**
Collaboration between consultants	Collaboration between consultants, contractor, subcontractors, manufacturers and suppliers
Call for tender – Award – Negotiation	
Contracting	
Execution	**Execution**

Figure 3: *Differences between the traditional project design process and the PPU-process (EfS, 2001b: 29)*

The 3-phase model was formulated as an attempt to establish an overarching and systematic frame for all relevant parties in the project design phase. This included e.g. a staged contract formation with the construction client and most importantly a focus on economic clarification in the very early parts of the project. In contrast to the traditional phase-model, the recast 3-phase model was articulated as a means to ensure integration between the consulting and the

producing parties and as a means of involving clients and contractors more actively in the design process.

In the debate of this new conceptual model concerns were, however, raised by clients, contractors and architects alike in relation to areas of responsibility (EfS, 1998). The 3-phase model was articulated as a dilution of the certainties required for rational governance that had been the rationality of the traditional phase model with its unequivocal assignment of roles, tasks and responsibilities. Thus, where the traditional phase-model, with its fixed and *juridico-institutionalized* responsibilities, previously had been seen as the ideal political technology needed for the unequivocal and effective production of projects, the proposed 3-phase model was put forward as an attempt to recast the functionally differentiated construction industry that had evolved as a consequence hereof. Other principle concerns were, however, also raised towards the consortium's remuneration scheme, price formation model and use of open project finances, which were said to bypass all safeguarded 'good practices' of project governance.

Moreover, where the PPU-consortium succeeded in empowering the contractor in the early phases of the process, to such an extent that vertical integration was articulated as turnkey contracting in a new guise (EfS, 1998: 3-7), the client was not placed in the central role envisioned from the outset of the program. The reason for this was argued to rest on the fact, that the client's role was not formulated in binding terms (EfS, 2001a: 6). In contrast to the 1950s and 1960s construction development agenda, which to large extent had dictated the clients' room for maneuver through laws, executive orders and circulars, requiring the clients to conform to certain requirements and conditions in order to achieve finance (*cf.* the 1953 circular on state loans for non-traditional buildings (Indenrigs- og Boligministeriet, 1953)), a turn can be observed in the Project Productivity program. Here the client was discursively constituted as an active player in the creation of new markets and products. This turn was instigated as a response to the drastic decrease in public expenditures for social housing, which was experienced from the 1980s onwards, where the ratio of social housing to total building volume dropped from 26 pct. to 10 pct. Thus, productivity could not be coded in terms of capital intensification, mass production and expansive economics in the housing segment as was the case previously. Rather, with the absence of a regulated market absorbing mass commodities, a strategy of co-production was articulated as a way of breaking the deadlock.

Interestingly, all of the above discursive elements that were articulated as cause and solutions to the lock-in situation represent a move away from traditional, safeguarded *juridico-discursive* governance mechanisms. As such, we argue that the discourse underlying the development process was based on discursive negation of the hitherto predominant practices of construction.

Partnering: institutionalizing collaboration

Based on the preceding analysis of the problem of productivity and the articulation of the ideal of collaboration, in this section we discuss how the institution of partnering has emerged. We outline three events in the institutionalization of partnering in Denmark: (i) the Construction Policy Action Plan from the Ministry of Housing and Urban Affairs from 1998; (ii) the establishment of 'Project New Forms of Collaboration' in 2001; and (iii) the development of a governmental guide to partnering for public clients and the passing of a statutory order on partnering in 2004. These three events are chosen as they provide a view

into the process through which the discursively articulated ideal of collaboration was authorized, secured resources and attained a basis of legitimacy.

Authorizing collaboration: The ideal of collaboration opened up for a process of articulation in which it was made possible for a variety of different actors to discuss and account for the problem of productivity from a common conceptual ground and theorize the relationship between productivity and collaboration. This grounded the current institutional basis for partnering in Denmark. Based on the work conducted in the wake of the 1993 business economic analysis of the construction sector, the government presented a policy action plan in April 1998 highlighting the practical implementation of the political initiatives within the construction political area in the years ahead. A total of 13 specific initiatives were specified, three of which located within the area of 'The construction sector's productivity and collaborative conditions.' Here it read that the future efforts to increase the productivity of the sector should be focused on the development of new, more flexible forms of collaboration and precautions to improve the planning and management of the building process. In the description of actual initiatives, the term 'partnering' was mentioned for the first time in a public policy report. Partnering was presented as one of three new modes of collaboration, which were to be tested through a series of demonstration projects. The other two collaborative models proposed in the action plan was 'horizontal industrialization', focusing on better collaboration and organization at site level through use of planning principles from the stationary industry, and 'in-between tender' being a form of tender procedure based on outline proposal rather than on main project proposal as most often is the case in design and build contracts. Both of these other collaborative models have later been articulated as elements in the Danish partnering and Lean Construction discourse, where the latter often is argued to be an extension of the former at a craftsman-level, notwithstanding that partnering could be argued to represent a substantive rationality whereas Lean Construction is basically procedural.

Securing resources: In order to pursue the objectives in the governmental action plan, resources were given to a series of demonstration projects under a newly established program was instigated in 2001. These projects build on the foundation laid in the Project Productivity program and focused more specifically on the concept of partnering. During the four years of operation, a total of nine projects were completed and documented, however, in addition to these projects the report concluded that the construction sector had undergone a quite substantial change, in that the use new forms of collaboration had increased remarkably. Partnering was here used as a collective designation for a series of new forms of collaboration (*i.a.* framework agreements and strategic partnerships) in which dialogue and trust played a decisive role. The report noted that 'Project New Forms of Collaboration' had documented the following results:

- Substantial economic savings (5 – 20 pct.) in design and construction coupled with the prospect of increased contribution margins for the companies.
- Increased product quality through closer and more trustful collaboration.
- Fewer resources tied in disputes and no settlements in arbitration.
- Better working climate throughout the entire construction process.

On this basis, it was concluded that the good results were positively correlated with a change in the mode of collaboration towards dialogue and trust instead of the traditional opposition and distrust. Thus, to further extend and capitalize on these argued benefits on a wider sectoral level, a construction clients' network was established in 2001. This network, consisting of major construction clients within the public sector, was in the following six year

responsible for the completion and evaluation of 30 demonstration projects testing new forms of cooperation. The results from the 30 projects were used in the development of a series of guidelines on the topic of new forms of collaboration and procurement that eventually formed the basis for the development of a governmental guide to partnering for public clients in 2004 (EBST, 2004). This will be discussed further below.

Basis of legitimacy: Let us, however, first observe why a *quasi-public* organization could provide the basis for the formulation of a governmental guideline and later a statutory order on partnering. Following the Danish 2001 national election, the newly elected government chose to abolish the Ministry of Housing and Urban Affairs that otherwise had been the cornerstone in the efforts to develop the Danish construction sector since WW2. Instead, the collective construction/housing resource area was split up and placed at several independent ministries and authorities each governing their own discrete part of the complex. Thus, in order to secure some kind of concerted action across the different segments of the construction industry, a new brokering agent or institution had to be established. Accordingly, it was envisioned that the development activities by the construction clients' network should provide the 'nodal point' in a partnership between the Danish Enterprise and Construction Agency, the Ministry of Social Affairs and construction clients from the public, private, and social housing sector.

The primary drivers of this partnership were the administrative authorities commissioning various demonstration projects to be evaluated and 'translated' into policy proposals or recommendations by the construction clients' network. As an example of this process we can turn to the aforementioned governmental partnering guidelines to public construction clients (EBST, 2004), which was developed on the basis of the work of the network. The partnering guidelines stipulate the legal as well as practical foundations for the completion of partnering projects within the public sector. The purpose of the guidelines were to (EBST, 2004: 7):

- Provide the public client with an outline of the contents of partnering.
- Assign a systematic basis on which to assess whether a project should be completed under a partnering scheme.
- Assign a set of practical procedures and describe tools that can be used to support a partnering process.

Furthermore, the guidelines provide the legal implications of a partnering approach, including the linkages to the statutory orders and consolidated acts that have been passed as a result of the activities conducted in this network. The most important of these are statutory orders no. 1135, 1394 and 948 (OEM, 2003; 2004; 2006) and consolidated act no. 338 (OEM, 2005). Speaking from the perspective of the traditional regulative foundations of project procurement and execution, we argue that all of the above legal documents can be seen as regulative mechanisms, which exempt the actors from certain safeguarded *juridico-discursive* obligations that otherwise frame their actions. We thus argue that the formal rationality of the traditional governance mechanisms is substituted with a substantive rationality in which an orientation towards values, performativity and actorial pluralism is preferred over correspondence, surveillance and standardization (*cf.* Clegg *et al.*, 2002: 324-326). This can e.g. be seen in the remarks to consolidated act no. 338 on framework agreements, where it reads that strategic partnerships and framework agreements will lead to a more efficient process and lower prices as suppliers will have economies of scale and the opportunity to learn from one another as well as from project to project. Importantly, the act does, however, not contain any explicit procedures for how to develop innovative capabilities in firms, nor does it promote any specific construction technologies or standard procurement methods and

procedures to follow. The primary actors of regulation are, in other words, expected to be able to act autonomously in order to realize any benefits of establishing collaborative relationships.

In summary, it can be said that the construction clients' network assumed a pivotal role in acting as a nodal point in relation to construction process development and innovation within the field of new forms of collaboration. The network was central in the process of authorizing, securing and delegating resources and providing a basis of legitimacy for partnering. This *i.a.* included overseeing the transition of partnering from a policy focus area, in need of strong governmental intervention and control, to a more or less well-established regulative phenomenon, which has achieved a specific conceptual form and direction based on a turn away from *juridico-discursive* governance mechanisms towards a much more dispersed image of rational agency.

CONCLUSION AND FUTURE DIRECTIONS

So far, we have focused on the diachronic dimension in the institutionalization of partnering in Denmark, illustrating how the ideal of collaboration has been articulated as partnering discourse that has become institutionalized as a regulative macro-level phenomenon. We will now turn our attention towards pinpointing the mechanisms at play in construction, when observed from the perspective of partnering.

In the foregoing diachronic analysis:

1. We have shown how partnering since 1990 has emerged as a response to a sectoral problematization of the construction industry's insufficient productivity development due to a lock-in to *traditional* ways of thinking and practicing.
2. It is demonstrated that the discourse on partnering is based on an ideal conception of collaboration as a means of breaking the lock-in.
3. We have attempted to illustrate that even though the various activities in the development of partnering have focused on providing tools with which to manage and facilitate collaboration at a project-level, partnering has primarily been stabilized and formalized in the legal and regulative apparatus of the Danish construction industry.
4. We have argued that this institutionalization of partnering has followed a trajectory based on a discursive negation of the notion of the traditional, which has constituted partnering not as a new well-defined operational alternative, rather as a regulative mechanism with strong normative and cognitive-cultural underpinnings (Scott, 2003).

On this basis we conclude that the central element in the institutionalization of partnering has been a specific de-institutionalization or rather politicization (cf Laclau and Mouffe, 1985), of the notion of the traditional as a *juridico-discursive* governance phenomenon. This problematization of has taken several forms: both as (i) an ideal in favor of a new order of project governance based on negotiation and trust, and as (ii) a series of negations to the *juridico-discursive* institutionalization of project governance.

Observed in a diachronic perspective, partnering seemingly forms a *counter-concept*, i.e. a concept that is in constitutive opposition to another concept from which it obtains its meaning. In this particular case, we suggest that partnering forms a counter-concept to what we have termed *juridico-discursive* governance. We further argue that the predominantly regulative-institutional (Orr, 2004) constitution and stabilization of partnering as a continuous critique and negation of *juridico-discursive* means of project governance entails a series of

distinct consequences for how expedient governance and management is thought and understood in a project practice setting. In essence, we argue that the emergence of partnering has radically altered the basic "*rules of the game*" (North, 1990: 3) in the very institutional foundations or determinants of management and governance:

The development of partnering does thus not represent an institutionalization of a new practice. Rather, partnering should be seen as an institutionalized critique of the traditional in guise of the *juridco-discursive* complex of project governance. In this perspective, partnering has not emerged, once and for all, on the horizon of management thinking as a finite or *centered* system of signs. Partnering like any other concept should be seen as a condensation of a wide range of social and political meanings that only through a historical awareness and deconstruction can be unraveled. Based on such a conceptualization of the institutional determinants of partnering, we believe that further synchronic studies, e.g. ethnographic case studies, can shed renewed light on several 'sticky' as well as topical problems in partnering research, including questions of what partnering actually involves, why it is so difficult to implement partnering in practice, and not least how to understand the relationships between macro-level industrial change and local project-practices.

Abstract
It has long been recognised that the role of the construction industry in socio-economic development goes beyond its share in national output. A number of studies have focused on the issue of employment creation others have emphasised its multiplier effect on other sectors of the economy. The role of construction infrastructure in the process of development has gained a new stimulus following the United Nations Millennium Declaration at the Millennium Summit in New York in September, 2000. Eight Millennium Development Goals (MDGs), measured through 21 targets, were devised. According to international development agencies, the services provided by infrastructure have a pervasive effect on the economic and social targets related to the MDGs. Using data obtained from World Bank and United Nations publications, and making use of an analysis developed in previous works, this study presents some prospects of the pattern of development of the construction industry in two groups of countries in Sub-Saharan Africa, according to their level of economic development. Some insights for the growth strategies of the construction industry in the groups of countries are also presented.

Keywords: construction industry, economic development, MDGs, Sub-Saharan Africa.

INTRODUCTION

The relationship between a country's stage of development and the level of activity in the construction sector is one, which has received great attention at the macroeconomic level for a number of years. For instance, Turin (1973), World Bank (1984) and Wells (1986) have attempted to model the relationship and found a positive correlation between several measures of construction output and the level of income per capita. These findings have been the subject of much argument due to problems related with the reliability of data, limitations of the coverage and methods of analysis employed.

Existing paradigms on the structural change in the construction industry, as a national economy develops over time tend to be based on cross-sectional data across countries rather than longitudinal studies based on one country's time-series statistics. However, longitudinal studies pertaining to developing countries of Africa have been developed in Lopes and Ruddock (1997) and Lopes *et al.* (2002). Bon (1990) also made use of a longitudinal analysis to present a development pattern for the industry, at a global scale, also based in the stage of economic development of a country's economy. Bon's 1990 study covers the period 1970-1985 and a vast number of countries from all the continents. The arguments were further developed in Bon (1992). An important aspect of the proposition was that, in the early stages of development, the share of construction increases but ultimately declines, in relative terms, in industrially advanced countries - and even at some stage, the decline is not only relative but also in absolute terms i.e. 'volume follows share'.

The positive association between construction (indeed physical infrastructure) and economic growth has been subject of debate for the part of the proponents of endogenous growth theory and international organisations such as the World Bank in the *Structural Adjustment Programme* for Africa. Indeed, in the aftermath of the 1979-980 oil-shock and the international financial crisis that followed in 1981, most of Sub- Saharan African countries experienced until the late 1990s a decreasing growth in per capita income (see Table 1) despite heavy investment in construction and other physical capital over the period 1970-1980. World Bank (1994) posited that rather than the quantity of infrastructure the main concern in developing countries should be the improvement of the quality of infrastructure. It could be argued according to this reasoning that this would be achieved through an adequate maintenance and upgrading of existing infrastructure stocks and by prioritising investments that modernise production and enhance international competitiveness.
The argument above brings about the other side of the construction sector and ancillary industries. Construction projects, particularly public infrastructure projects, require a vast amount of national resources. In less developed countries, quite often, the "real costs" of a major construction work are understated if one looks at the figures presented in the national account tables. Technical assistance (usually paid in foreign currency) and some other unexpected costs can inflate significantly the costs of a construction project. Thus, it could be argued that in the resource-constrained developing countries, part of the scarce resources available devoted to construction investment projects could alternatively be used in other important sectors of the economy (e.g. health, education and agriculture).Thus, African governments and their development partners shifted economic policies away from infrastructure investment to macroeconomic stabilisation accompanied by social intervention.

In the early 2000s, international organisations and development agencies started to become aware of the important role infrastructure would play for attaining all the Millennium Development Goals (MDGs) in Sub-Saharan Africa (Organisation for the African Unity, 2001; Commission for Africa, 2005, cited in World Bank, 2009a). An important question which should be the concern of the construction economics research community and national and international development agencies is how a well functioning construction industry could contribute to a sustainable economic growth and development (Lopes, 2011, forthcoming).

The structure of this paper is as follows: the next section discusses the role of the construction sector in the process of economic growth and development. The third section presents quantitative analyses of the relationship between the measures of construction output and those of the national aggregate in two groups of countries in Sub-Saharan Africa according to their stage of economic development: Low Income Countries (LICs) and Middle Income

Countries (MICs). The statistical sources and data are presented and commented on, and the analysis and discussions of the results are elaborated upon. The fourth section explores the link between construction investment and economic and social targets related to the Millennium Development Goals (MDGs). A concluding remark finalizes the analysis presented in this paper.

THE ROLE OF CONSTRUCTION IN ECONOMIC DEVELOPMENT

The construction industry has historically been linked with the process of industrialisation and urbanisation, particularly since the advent of the Industrial Revolution. Railways systems and canals played an important role in the connection of different regions of Europe, North America and in some parts of Latin America (Rostow, 1963). Transport infrastructures facilitated trade and co-operation between countries and also the diffusion of technical innovations from the most advanced to the less advanced areas of the globe. The construction industry played a key role in the reconstruction of the war-ravaged Europe. The heavy programme of construction improvement of housing and social infrastructure, beside its contribution to the national output, was also a reflex of a better re-distributive economic policy in Europe post World War II. The importance of the construction industry has also been recognized in the context of countries affected by natural hazards (Ruddock *et al*, 2010; Amaratunga and Haigh, 2010). Besides its multiplier effect on other sectors of the economy, a well-devised reconstruction programme of building and community service infrastructure can contribute to sustainable development and protect the natural and built environments.

With regard to the relationship between construction and economic development, Turin (1973), using cross-country comparisons, found an association between construction investment and economic growth. That finding was consistent with the classical approach in growth theory in which physical capital formation is the main engine of economic growth and development. Turin's argument about the pattern of the construction industry contrasts with the argument advanced by Bon (1992; 2000). In Bon's 1992 paper, the link between economic development and construction is discussed and Bon points out the problem with Turin's analysis, which is largely focused on developing countries. As the share of construction in total output first increases and then decreases with economic development, this is called the inverted U-shaped relationship, following Maddison, who, in his seminal study of economic development (Maddison, 1987), tracked several key advanced industrial countries (AICs). Bon's 1992 argument concerns the entire path from LDC (least developed countries) to NIC (newly industrialised countries) to AIC status.

In the aftermath of the 1979-980 oil-shock and the international financial crisis that followed in 1981, most of Sub- Saharan African countries experienced until the late 1990s a decreasing growth in per capita national income, despite heavy investment in construction and other physical capital over the 1970-1980 period (Lopes, 1998). Following the *Structural Adjustment Programme for Africa* that started in the mid-1980s, World Bank (1994) took the view that, for the developing countries, the emphasis should be on the improvement of the quality of infrastructures rather than the quantity of infrastructures. Thus, it is reasonable to argue that this would be achieved through an adequate maintenance of existing infrastructure stocks and by prioritising investments that modernise production and enhance international competitiveness. Lopes (1998), discussed the role of construction in the economic development of countries in Sub-Saharan Africa. The development patterns of construction and related sectors were modelled based upon data from the period 1980-1993 and a sample

of 15 countries comprising two different patterns of growth in that period. It was argued that construction and the national output grow at the same rate only in a declining economy, and that in a growing economy, the volume of construction, typically, would not grow faster than the rest of the economy.

THE CLOUT OF THE CONSTRUCTION INDUSTRY IN SUB-SAHARAN AFRICA

Data Sources and Methodological Issues

The main statistical sources used in this analysis are the 2010 edition of the *Yearbook of National Account Statistics: Main Aggregates and Detailed Tables* from the United Nations, *Africa Development Indicators 2008-2009* and *World Development Report 2010* from the World Bank. The internet site of the UN statistical office presents data on gross domestic product (GDP) and its components both in the expenditure and production approaches. This publication presents various sets of economic series detailing the evolution of GDP and its components in different statistical formats over the long period 1970-2008, at the world, world regions and country levels: at current prices in national currencies; constant 1990 prices in national currencies; current prices in US dollars; and constant 1990 prices in US dollars.

The indicators of economic activity analysed are: GDP and construction value added (CVA) both in constant 1990 prices in US dollars. Unfortunately, data on gross fixed capital formation in construction (GFCFC) are not provided in the UN publication. Thus, CVA is used as a proxy for analysing the evolution pattern of construction investment in two groups of countries in Sub-Saharan Africa. As CVA is roughly a half of GFCFC, it appears reasonable that the former indicator can be used as a surrogate measure of construction investment. In order to facilitate international comparisons as well as for aggregation purposes, constant 1990 prices in US dollars are used. In order to place the two country groups in the economic development arena, gross national income (GNI) per capita for the bench mark year 2008 has been chosen. This is provided by *The World Development Report 2010* (World Bank, 2009b). This report presents the following definitions of the income groups of countries according to the 2008 GNI per capita: low income countries (LICs), US$ 975 or less; lower- middle- income (LMICs), US$ 976-3,855; upper-middle-income (UMICs), US$ 3,856 -11,905; and high income countries (HICs), US$ 11,906 or more.

Data on the evolution of economic indicators in the period 1980-2006 were obtained from the *Africa Development Indicators 2008-2009* (World Bank, 2008). Thus, because of data consistency, the quantification of the relationship between the construction sector and GDP is only analysed for the period 1980-2006. Using data obtained from the *UN Yearbook of National Accounts Statistics* (United Nations, 2010 internet edition), data are presented for the share of construction in GDP (at constant1990 US dollars) for the period 1980-2006. GNI per capita is presented for the year 2008. The evolution of GDP per capita, both of Sub-Saharan Africa as a whole, as well as excluding two important economic players of that region, South Africa and Nigeria, are presented for the period 1980-2006 (Table 1).

Cross-matching sources, data are available for 45 countries and these can be split into two groups according to the level of GNI per capita in 2008. Tables 2 and 3 illustrate these two groups: Group I - low income countries (LICs); Group II- middle income countries (MICs). Thus, Group II comprises both LMICs and UMICs, and only Equatorial Guinea could, in theory, be considered a HIC, owing to its high GNI per capita.

Analysis and Discussion

Table 1 shows the evolution of GDP per capita in Sub-Saharan Africa as well as that of Sub-Saharan Africa excluding South Africa, and then Sub-Saharan Africa excluding South Africa and Nigeria. The division shown in Table 1 is a reflection of the clout those two countries represent in the Sub-Saharan African economy. According to World Bank (2009b), South

Africa's and Nigeria's GDP in nominal prices comprised over fifty percent (51.4 percent) of Sub-Saharan Africa's GDP. The reasons for this dominance are not the same for the two countries. Nigeria plays a big role because it is, by far, the most populous country in the region, whereas South Africa is important owing to its unmatched industrial structure and technological development that makes it the economic pole of Sub-Saharan Africa.

Table 1 shows that both the region and its subdivisions, in terms of GDP per capita, experienced decreasing growth in the period 1980-2000 and a reasonable upturn in the period from 2000 onwards. According to data constructed from World Bank (2008), the LICs, as a group, experienced dramatic decreasing growth in GDP per capita in the period 1980-2000, and an average annual rate of growth of almost 2% in the period 2000-2006. The striking aspect worthy of note concerning Group 1 is that GDP per capita in the LCIs in 2006 (measured as an average for the group) was lower than that in 1980. Again, data constructed from World Bank (2008) show that the countries comprising Group II (MICs), in terms of GDP per capita, grew slightly in the period 1980-2000, with an average annual growth rate of about 1%, and notched up a spectacular rate of growth of an annual average rate of more than 4% in the period 2000-2006.

Now, looking at the relationship between the construction sector and the national economy, Tables 1 and 2 show that the evolution pattern of the share of CVA in GDP in the developing countries of Sub-Saharan Africa is markedly different according to the country's stage of economic development as determined by GNI per capita. The share of CVA in GDP in the low-income countries (Group I), despite differences across countries as well as taking into account annual fluctuations, varied, in general, from 4% to 5% of GDP, as is illustrated in Table 2. In terms of the evolution in the period, the share of that indicator was in line with the development pattern of GNI per capita: it decreased in the period 1980-1990 (from 4.49% to 4.03 % b, measured as an average for the group), remained practically stagnant in the period 1990-2000, and grew at a reasonable rate in the period 2000-2006 (from 4.19% to 5.08%, again measured as an average for the group). It is worth noting that in the latter years of the period, the share of CVA in GDP was higher than that in the earlier years of the same period. That is, in the first stages of economic development, and in an increasing growth pattern, the construction industry tends to grow faster than national output. Conversely, in an economic downturn, the industry tends to decrease not only absolutely but also relatively.

Regarding the middle-income countries (Group II), Table 3 shows that the share of CVA in GDP varied, in general, from 5.0 % to 6.5% in the period 1980-2006, also disregarding differences across countries as well as annual fluctuations. Table 3 also shows that the share of CVA in GDP decreased from 6.43% in 1980 to 5.47% in 1990 (measured as an average for the group) despite a growth in GDP per capita, as already pointed out, at an average annual growth rate of about 1% in the period 1980-1990. From then onwards, the share of construction in GDP remained practically stagnant at around 5.5% of GDP. The pattern experienced by the MICs is worthy of note: despite a significant increase in national income per capita, particularly in 2000-2006, the share of CVA in GDP in the late years of the period did not reach the value attained in the beginning of the period. It could reasonably be said that the construction industry activity in the MICs reached a peak, in relative terms, in the early 1980s. These results presented here seem to corroborate those of a previous work concerning the developing countries of Africa (Lopes, 1998) that found that in the developing countries of Africa that have middle-income status or are in a sustained process of reaching it, and have achieved a certain level of the construction industry activity (say 5 to 6 percent of GDP, depends upon the year taken as basis), the proportion of construction in GDP tends to remain

stagnant, i.e. the rate of growth of construction volume follows that of the national economy.

CONSTRUCTION INFRASTRUCURE AND THE CHALLENGE OF THE MILLENNIUM DEVELOPMENT GOALS

This section considers the role of construction in socio-economic development, particularly by exploring the link between construction infrastructure and economic and social targets related to the Millennium Development Goals (MDGs). Much of the material in this section is drawn from Lopes (2011, forthcoming).

As pointed out earlier, the construction industry has historically been linked with the process of industrialisation and development. Railway systems and canals played an important role in the connection of different regions of Europe, North America and in some parts of Latin America. Transport infrastructure facilitated trade and co-operation between countries and also the diffusion of technical innovations from the most advanced to the less advanced areas of the globe (Rostow, 1963). The construction industry played a key role in the reconstruction of war-ravaged Europe: the heavy programme of construction improvement of housing and social infrastructure, besides its contribution to the national output, was also a reflex of a better re-distributive economic policy in Europe after World War II. Following the UN Millennium Declaration in 2000, the Heads of State and Government of Sub-Saharan Africa have emphasised the role transport infrastructure can play in enhancing inter-regional cooperation and foster economic and social development (Organisation of African Unity, 2001).

In the early 2000s, the physical infrastructure in Sub-Saharan Africa was in a very poor state. External capital flows (particularly from donor countries pertaining to the Development Assistance Committee of the OECD) for African infrastructure had reached a historic low. As already mentioned, African governments and their development partners sharply reduced, over the 1990s, the share of resources allocated to infrastructure, and in the aftermath of the Asian financial crisis, in the early 2000s, private capital flows declined sharply. The Commission for Africa, in 2005, in line with another policy shift on the part of the international development agencies, singled out infrastructure as one of the continent's central development challenges (World Bank, 2009a). In the same line, a report of the UN Millennium Project (UN, 2005, cited in Easterly: 2006, p. 290) argued that poor countries were in a poverty trap: Escaping the trap requires:

"A big push of basic investments between now and 2015 in public administration, human capital (nutrition, health, education) and key infrastructures (roads, electricity, ports, water and sanitation, accessible land for affordable housing, environmental management)"

The Group of Eight summit at Gleneagles in 2005 called for action by the major economies and multilateral donors in the financing of Sub-Saharan African infrastructure. This led to the formation of the *Infrastructure Consortium for Africa.* This consortium would constitute a forum where major donors could work with continental and regional institutions to spearhead economic integration (World Bank, 2009a). One of the practical results of this political arrangement was the publication of the flagship report "*Africa's Infrastructure: A time for Transformation*" in 2009. This publication diagnosed the infrastructure needs of Sub-Saharan Africa, addressing the twin challenges of financing and sustainability, particularly the attainment of the millennium development goals (MDGs).

Table 4: *Overall Infrastructure Spending Needs for Africa, 2005-2006*
(US$ billions annually)

Sector	Capital expenditure	Operation and maintenance	Total needs
ICT	7.0	2.0	9.0
Irrigation	2.7	0.6	3.3
Power	26.7	14.1	40.8
Transport	8.8	9.4	18.2
WSS	14.9	7.0	21.9
Total	60.4	33.0	93.3

Source: World Bank (2009a)
Note: ICT- information and communication technology; WSS- water supply and sanitation

Table 4 indicates that the estimate for the overall cost to build, maintain and operate Africa´s infrastructure is US$93 billion annually over the period 2006-2015, approximately 15% of Sub-Saharan Africa's GDP in 2006. Of this total, about two thirds are for investment and about one third for operation and maintenance. In sectoral terms, about 40% is allocated to the power sector. The second-largest component is water and sanitation – a key sector for meeting the MDGs – with about 23% of the total and the third largest share of the cost is associated with transport, which is approximately 20% of the overall spending needs. In terms of regional groups, the burden of the price tag relative to the countries' GDP is markedly different across groups (World Bank, 2009a). For middle-income countries and resource-rich countries, the amount is in the range of 10% to13% of their respective GDPs. For low-income countries, as much as 25% of GDP would be needed, and for a particular sub-group of the latter-fragile states (war-ravaged countries), the burden would be an astonishing 37% of GDP. If one takes into account that the middle-income countries already spend a reasonable share of their wealth in investing in infrastructure and the spending needs are almost equally divided across groups, one can envisage the implausibility for the poorer countries in Africa to finance the funding gap of their estimated spending needs. As Table 5 shows, the funding gap for the infrastructure in Sub-Saharan Africa is US$ 31 billion or about 5% of GDP, taking into account efficiency improvements. About US$ 23 billion a year, or over 70% of the funding gap, is for the power sector. The other significant component of the gap, representing a shortfall of US$ 11.4 billion is associated with water supply and sanitation (WSS). The funding gap in the latter sector in the low-income countries, particularly in fragile states looks like an unattainable target in the foreseeable future in the light of the present economic situation and prospects of the countries themselves, and the challenges posed to the development partners by the recent global financial crisis.

***Table 5.a**: Funding Gaps, by Sector and Country Group*
(US$ billion annually)

As pointed out above, international development agencies and bilateral donors have underscored infrastructure (more precisely the services provided by the infrastructure) as the key factor for the attainment of the MDGs. The MDGs are the world's time-bound and quantified targets for addressing extreme poverty in its many dimensions – income poverty, hunger, disease, lack of adequate shelter, and exclusion – while promoting gender equality, education, and environmental sustainability (UNDP, 2005). Following the adoption of the UN Millennium Declaration at the Millennium Summit in New York in September 2000 (UN, 2000), eight MDGs, measured through 21 targets, were devised. Most of the MDG targets have a deadline of 2015, and 1990 is the baseline against which progress is quantified.

Restricting here the analysis for those infrastructure items which incorporate mainly construction investment (WSS, transport and electricity – note that a significant part of the investment in the power sector is for multi-purpose use), construction infrastructure has an important role to play in the process of attaining the MDGs in Sub-Saharan Africa. The MDG Goal 7 – ensure environmental sustainability – is particularly relevant to the construction industry. This goal is translated into the following targets: i) integrate the principles of sustainable development in country policies and programmes and reverse the loss of environmental resources; ii) halve, by 2015, the proportion of people without sustainable access to safe drinking water and basic sanitation; and iii) have achieved by 2020 a significant development in the lives of 100 million slum dwellers.

Table 6: *MDGs in Sub-Saharan Africa: Goal 7- Ensure Environmental Sustainability*

Source: United Nations (2010b)

Table 6 suggests that Sub-Saharan Africa, as a whole, is unlikely to achieve, by the deadline of 2015, the targets related to access to safe drinking water and basic sanitation. However, some middle-income economies of Africa such as Cape Verde, South Africa, Botswana, Namibia, Seychelles and Mauritius are either on track or experiencing good progress towards achieving the targets, particularly in access to safe drinking water (WHO/UNICEF, 2010). Regarding the urban population living in slum areas, whereas some progress was noticed in relative terms, the absolute number of slum dwellers has actually been growing and will likely continue to increase in the near future.

With respect to the emission of CO2, Sub-Saharan Africa registered 0.9 metric tons per capita in 2007 compared with 12 metric tons per capita in the developed world, and, in deforestation, the rate of increase started to decelerate in the period 1990-2010.

The WSS sector, besides its direct effect on the provision of water and sanitation services, has a pervasive impact on other social targets, namely in the prevention of disease, improvement in education and promotion of gender equality so that women save time when they begin using an improved water source. Transport fosters trade by reducing the cost for transporting goods and passengers, reduces child/maternal mortality and improves access to education services. Electricity enhances productivity, eradicates poverty by fostering economic growth and reduces child/maternal mortality.

One important area related to the construction industry which needs special attention on the part of government agencies is urban planning. The rate of urbanization in Sub-Saharan Africa is increasing sharply. This has its merits. For example, higher population densities lower the per capita costs of providing safe water, sewer systems, waste collection, and most other infrastructure and public amenities. Moreover, sound urban planning restricts development in flood-prone areas and provides critical access to services, and infrastructure developments can provide physical protection for the natural environment. On the other hand, most of the urban areas have been unable to cope with the increasing populations, and large numbers of their inhabitants have a poor quality of life. As pointed out by the World Bank (2009b), overcrowding, insecure tenure, illegal settlements sited in landslide- and flood-prone areas, poor sanitation, unsafe housing, inadequate nutrition, and poor health exacerbate the vulnerabilities of the population in urban slums. These are the realities for millions of people in Sub-Saharan African countries. An efficient construction industry can contribute to the efforts to tackle these problems. For example, it can address the vulnerabilities of slum dwellers by devising labour-intensive and cost-effective technologies, and by implementing practical sustainable measures in the framework of the *Agenda 21 for Sustainable Construction in Developing Countries* (International Council for Research and Innovation in Building and Construction (CIB) and United Nations Environment Programme (UNEP), 2002) This framework for a coordinated response to the challenges of limiting the impact of construction puts an emphasis on collaboration among different stakeholders of the construction industry. Indeed, it is the flexibility of the construction industry in being able to adjust to different framework conditions that makes it such a great contributor to the process of economic development.

CONCLUDING REMARKS

The picture that emerges from the analysis of the evolutionary process of the construction industry and its role in national socio-economic development suggests that the share of construction in gross domestic product tends to increase with the level of per capita income in the first stages of economic development. When countries reach a certain level of economic development, the construction output will grow slower than national output in the later stages of their development. That is, it decreases relatively but not absolutely. Thus, it is reasonable to assume that when a certain level is achieved (say the share of CVA in GDP at around 5% to 6%) and countries enter into a path of sustained economic growth and development, the construction output tends to grow, in general, with the same rate of growth as that of the general economy.

The results of the study also underlie the twin challenge of finance and sustainability in Sub-Saharan Africa in the effort towards attaining the MDGs, and the situation is particularly acute in the low-income countries in the light of the countries' own economic circumstances and prospects, and the current global financial crisis. The results of the study may have some implications for public policies. Given the experience of the growth process in Sub-Saharan Africa, what should be the focus of growth-enhancing policy in the two groups of countries? How can the construction industry contribute to this end, and help a country in Group 1 to move to Group 2? For example, further investment in construction infrastructure might be recommended for countries in Group 1 but might not necessarily be a growth priority for countries in Group 2. Most recent data indicate that there is no significant funding gap in infrastructure investment in the middle-income countries of SSA in order to achieve the economic and social targets of the MDGs. These countries should prioritize their investment projects by balancing economic and financial factors with social targets. For the low – income countries, taking into account the dire financial stress facing these countries, the analyses suggest that most of the effort should be directed at construction investment projects in order to achieve a level of the construction industry activity of, say, 5 to 6% of GDP which is required for a reasonable functioning of the economy. The priority should be given to construction investment projects that have high multiplier effects in the economy, particularly transport and multi-purpose (power and water) infrastructures. A concerted effort to implement sub-regional infrastructure projects seems also to be the way forward.

PATTERNS OF STRUCTURAL CHANGES IN CONSTRUCTION?

Abstract

The changing role of construction at various stages of development has been at the core of debate in the field of construction economics. It has been argued that the construction industry should follow the pattern of manufacturing, its primary supplier, rather than services, even if early studies suggested an S-shaped relationship with GDP per capita. The presented analysis stems from this well known literature and again it focuses on the link between construction share in value added and development measures. The conventional view that GDP per capita suffices is critically discussed and new variables that help the explanation of such a relationship are introduced. Discussion builds upon the comparison of standard cross country regressions in the 1970 and in 2005. Even if explicative power is quite weak it is shown that in recent years construction has been linked with new variables such as market size and population density.

Keywords: Construction, development stages, structural change.

INTRODUCTION

Structural analysis is a central tenet in growth economics since the seminal work by Lewis (1954) and the many contributions by Kuznets (1956, 1957), and Chenery and his collaborators (Chenery, 1960, Chenery and Taylor, 1968, Chenery and Syrquin, 1975). One research thrust follows a micro approach that focuses on market structure, income and resource allocations among individuals or price differences (Leamer, 1984). Differently most of early literature focused on macroeconomics and long run processes (Chenery, 1986). Chenery and Syrquin referred to development pattern as "any significant aspect of the economic and social structure associated with a rising level of income or other index of development" (1975, p. 4). For instance, Agénor and Montiel (2008) argue that developing countries tend to be more open and capital importers, while advanced ones have a larger public sector. Furthermore, as development develops further, current account deficits and capital account surpluses usually decrease, while openness increases. Value added and employment growth and shares, in addition, have been extensively analyzed. Fisher (1939) and Clark (1940) predicted a sequence of stages in the course of development. First of all, the share of agriculture should decrease as industrialization takes place. The primary sector produces basic goods whose demand is quite income inelastic. When an economy takes off

Engel curves show how demand is diverted from basic to luxury goods as durables. The potential of service industries in modern society is also reputed to be very good. Therefore even in the early stages of development, manufacturing and informal sectors begin rapidly to grow as a result of the rural-urban migration. Some sectors can absorb this new urban labour supply in basic service and manufactured good production. In this embryonic stage, food production and housing should meet most of the basic needs of these low income migrants. At the intermediate stage, a network of production and consumption linkages start developing with increasing final and working capital demand. Agglomerative economies push urbanization further. Construction would continue to play a relevant role in this phase, maybe with a decreasing rate of growth. Only in the last stage, when deindustrialization takes place, smokestack industries start moving to less developed regions or countries, and urban areas change their shape with new landscapes and construction technologies.

BASIC MODELS AND STYLIZED FACTS

The very first issue is to define economic development. The most widely used measure is either GDP or GNI per capita. Country data can be made comparable by converting them into in a single currency, say US dollars, by using exchange rates. Current exchange rates are an imperfect measure of the purchasing power of the various national currencies. The alternative to market rates is to re-price the local components of income in every country at a uniform set of prices. Hence, non tradable goods are reflected in these conversion factors. This approach uses the Purchasing Power Parity (PPP) that is the weighted average of the ratio of domestic price to the price of the very same good in the considered country, say the USA. An alternative is the Atlas conversion factor, which uses the three-year average of exchange rates to smooth the effects of transitory exchange rate fluctuations, adjusted for the difference between the rate of inflation in the considered country (using this country's GDP deflator), and that in a set of developed countries (using the weighted average of the countries' GDP deflators in Special Drawing Right terms). According to the World Bank differences between PPP and Atlas figures are not remarkable.

Nonetheless, the use of GDP as a measure of development has been widely questioned (Stigliz and Fitoussi, 2009). The best alternative perhaps is the Human Development Index (HDI) developed by the United Nations (2010) or the Physical Quality of Life Index (PQLI) by Larson and Wilford (1979). The HDI was created to emphasize that people and their capabilities should be the ultimate criteria for assessing the development of a country, rather than economic growth alone. For instance, the Bahamas and New Zealand have similar levels of income per person, but life expectancy and expected years of schooling differ greatly between the two countries. HDI is a composite index that measures progress in the three basic dimensions: health, knowledge and income. At first, health was measured according to life expectancy at birth; education according to adult literacy rate, and income or standard of living according to GDP per capita adjusted for purchasing-power parity (PPP US$). Currently level of education is measured according to the expected years of schooling for a school-age child in a country today with the mean years of prior schooling for adults aged 25 and older. Income measurement also has changed from purchasing-power-adjusted per capita Gross Domestic Product (GDP) to purchasing-power-adjusted per capita Gross National Income (GNI). However problems remain. Consistency is hardly achieved among countries and over time. The availability of comparable time series and likely correlation between in built variables pose well known statistical problems. The PQLI is the average of basic literacy rate, infant mortality, and life expectancy at age one, all equally weighted. This is not a meaningful alternative as there is a considerable overlap between infant mortality and life expectancy and there is no measure of income.

Defining economic structure is far from being easy. We follow the traditional approach stemming from the path breaking Clark's contribution (1940), who considered labour force, consumption patterns and income distribution, while Kuznets (1957) added the shares of GDP. We address the latter by focusing on the contribution of construction to value added. This study revisits the classical analysis that was initiated by Turin (1969) and Strassman (1970). According to this last scholar, construction is a major force that replaces manufacturing in driving economic growth after the first stage of development (the so called "middle-income country bulge"), while Turin postulated a causal relationship between construction and economic growth. In his first study Turin (1969) did not find any statistically significant link. This result perhaps reflected the rather small considered sample (46 countries in 1958). In his subsequent study (1978) Turin claimed that an S-shaped curve fitted better the new data set (87 countries). This is to say that construction share in GDP is always positively related with GDP per capita, initially at an increasing rate and later on at a decreasing pace. Size matters too as construction accounted for between 3 and 5 per cent of GDP in most developing countries, whilst it was twice as much (5 - 9 %), in advanced ones. Lewis (2009), however, shows that this pattern is no longer the case, while Bon (1992) argued that the inverted U-shaped relationship should hold for both the share of construction in GDP and its volume. In other words, there is an absolute decline of this industry in the very long haul. These issues have been extensively discussed in the literature and there is a growing consensus about Bon's conjecture. Analyses by Wells (1985), Crostwaite (2000) Yiu, et al. (2004), Ruddock and Lopes (2006) support his view. Most of these contributions are rather descriptive and only few consider an appropriate statistical model in the Chenery's style. This model is based on a reduced form of a general equilibrium where domestic production in each sector is due to intermediate and final demand, including net export. Since a large sample is needed and each demand component is a function of income level Chenery decided to adopt single functions of income and population. His main specification is a linear logarithmic regression equation as the following one:

$$\ln C = \beta_0 + \beta_1 \ln Y + \beta_2 (\ln Y)^2 + \beta_3 \ln N + \beta_4 (\ln N)^2 + \beta_5 \ln X \qquad (1)$$

where C is the dependent variable that, in our case, is construction value added over GDP, Y is the income level measured as GDP per capita, N is the country's population and X is another exogenous variable to be addressed later on in the paper. If we eliminate the quadratic terms, parameters β1 and β3 can be interpreted as growth and size elasticities. When these factors are considered, multi-collinearity and parameter interpretation arise, but β2 and β4 are useful to detect non linear income and size effects and assess upper and lower asymptote in Turin's fashion. Crostwaite (2000) presents a similar specification where construction spending over GDP is regressed over income alone. Actually Crostwaite acknowledges that there is no linear relationship between C (he does not take into account ln C) and ln Y and only when the quadratic term is included, both parameters become (weakly) significant at 5% confidence. However the model specification suggests that the least square estimator provides biased and inconsistent results by casting doubts on parameter estimates and, above all, the coefficient of determination (R^2) is close to zero (only 2,7%). It is pretty clear that more regressors were needed in his sample. The most obvious one is the population that was supposed "to allow for effects of economies of scale and transport costs on patterns of trade and productions" (Chenery and Taylor, 1975, p. 17). Actually controlling for size

through population is questionable as the size of a country can be measured by land area o resource availability. However, population appears to be an important source of housing demand, thus it should be included in our setting. Kessing and Sherk (1971) suggested that population density serves as an imperfect proxy for the availability of natural resources per head. According to these authors, densely populated countries are expected to have economies more oriented toward manufactured than primary goods, along the lines of a land-labour Heckscher-Ohlin theory. Even if this statement is disputable, there is no doubt that land scarcity can constrain building activities and we include it as a candidate regressor. Economic deepening, in fact, differs from primary factors availability. Hence we would like to differentiate between large and small countries by using another size variable, not including population. A simple solution is to introduce an output measure. Lastly we follow Branson et al. (1998) and regress separately an equation with quadratic terms only in order to avoid multi collinearity. This is to say that the explanatory variables, ln Y and $(\ln Y)^2$, are in two separate regression specifications, as our task is to provide evidence about non linear elasticities only.

DATA AND FEW SIMPLE EXAMPLES

In the past empirical research was constrained by data availability. Early studies assessed of long-term series in developed countries and later on shifted the focus on cross country analyses of less developed economies. In comparing the results of time series and cross countries it is customary to interpret the latter as partial short term adjustments and the former as long term changes in exogenous variables. However, lack of data forced scholars to use a sample of countries in a given year with the hope that it was a good substitute for relations within countries over time, as they add "an insight into current structural differences, viewed partly as points in the process of growth, caught, as it were, at different stages and phases" (Kuznets, 1959, p. 174). Kuznets himself was aware that cross section estimates tend to underestimate inter-temporal trends because they "are not likely to provide a firm basis for estimating the relevant inter-temporal pattern (1959, p. 197). This is due to the "vast and rapidly changing flow of innovations in material and social technology (1959, p. 179). Additional reasons for these differences are institutional settings, the impact of varying policies and, above all, omission of dynamic effects as propagation mechanisms. These differences explain diverse levels of development. Since the task of this study is to provide a stylized fact and not to clarify why more advanced countries have larger or smaller construction sectors, the Kuznets methodology is used. In a future paper the authors will focus on the joint estimation of cross-section and time series analysis in order to improve the efficiency of estimates and develop a dynamic model. For time being, only the two extremes of the considered sample are considered to test differences that are to be explicated in future research. Population, construction and total gross value added are obtained from the UN data developed by the United Nations Statistics division. Urban population and population density are drawn from the WorldBank database, while GDP per capita (in constant terms) is based on the PennTables. As stated above, only cross section data of the years 1970 (or 1971 when 1970 are not available) and 2005 are used. The first data consists of 139 countries. First of all, it is difficult to detect any relationship between the (log) of GDP per capita and value added construction share. Actually only when advanced countries are considered, a negative relationship seems to appear (Quatar being an outlier).

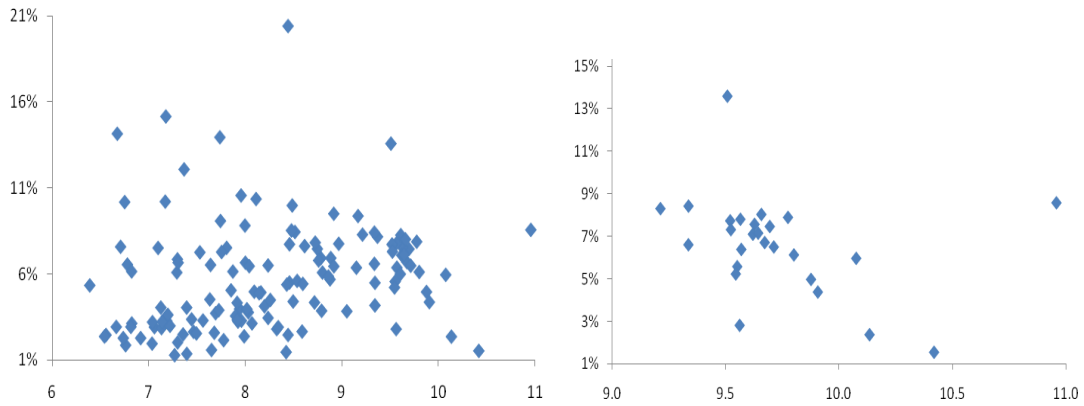

Figure 1: *Const. shares and GDP per capita,1970* ***Figure 2:*** *Only advanced countries, 1970*

Several regressions, none of which was satisfactory were executed. The ”best” one is the following:

$$\ln C = -1.689 + 0.1580 \ln Y - 0.0511 \ln N \qquad (2)$$
$$(-9.642) \quad (3.648) \qquad (-2.380)$$
$$\text{Adj } R^2 = 0.112; \ F[2,136] \text{ (prob)} = 9.69 \ (.0001)$$

The coefficient of determination is very small, even for cross section analysis and most of the variability of construction share is left unexplained. However, all the variables are statistically significant, according to t values (shown in brackets) and F test, but surprisingly population has a negative effect. As put forward by Branson et al. (1998), the quadratic term have been verified in the following way:

$$\ln C = -1.484 + 0.0213 (\ln Y)^2 - 0.0073 (\ln N)^2 \qquad (3)$$
$$(-16.489) \quad (3.573) \qquad (-2.399)$$
$$\text{Adj } R^2 = 0.1089; \ F[2, 136] \text{ (prob)} = 9.43 \ (.0001)$$

Elasticities seem to be not linear. The shape is not the one advocated by Bon (1992) but quite the opposite. Only the negative relationship with population is lessened. These signs do not change if the share of urban population and/or population density is added. The results are not presented, as estimates are not significant at 5% confidence. Finally, dummies are used to differentiate Less Developed Countries , Lower Medium Countries, Upper Medium Countries and advanced ones, but, as expected, the model performance is poor. Hence GDP per capita is enough to identify stages of development. Population, in addition, was replaced with value added to assess economic size, but the negative relationship persisted.
The equivalent analysis for the year 2005 was then addressed. The considered sample is larger with 176 records, but no clear pattern is recognizable in the scatter plots of Figure 3 and 4, even in the subsample of advanced countries is considered.

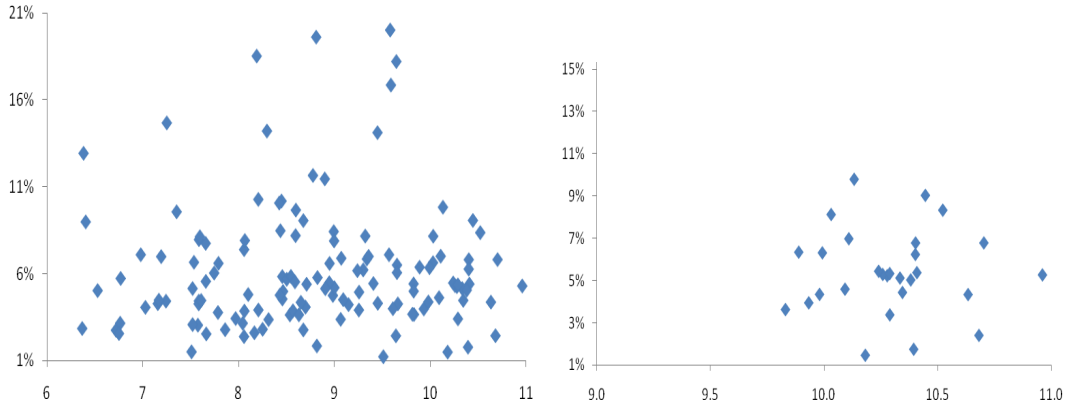

Figure 3:*Const. shares and GDP per capita,2005* ***Fig 4:*** *Only advanced countries,2005*

According to the same regressions that were presented earlier, the outcome is surprising:

$$\ln C = \underset{(-7.353)}{-2.727} + \underset{(0.965)}{0.0335} \ln Y \; \underset{(-3.029)}{-.0607} \; \ln N \qquad (4)$$

$$\text{Adj } R^2 = 0.06; \; F[2,173] \text{ (prob)} = 5.52 \; (.0048)$$

The coefficient of determination is smaller, but GDP per capita is no longer an explicative variable, as shown by the t and F tests. The estimated quadratic form is:

$$\ln C = \underset{(-14.61)}{-2.872} + \underset{(0.977)}{0.002} (\ln Y)^2 - \underset{(-2.542)}{0.003} (\ln N)^2 \qquad (5)$$

$$\text{Adj } R^2 = 0.033; \; F[2, 173] \text{ (prob)} = 4.03 \; (.0195)$$

Thus, it is doubtful that development can explain construction share. However GDP per capita can be included with another specification that has at least the same (weak) power than the 1970 data. Moreover we tried several specifications using variables discussed in the previous section. Unfortunately just a few proved satisfactory. Actually value added appears to be a better measure of economic size and only population density is statistically significant:

$$\ln C = \underset{(-6.511)}{-2.634} + \underset{(2.641)}{0.1064} \ln Y \; \underset{(-3.435)}{-0.0652} \; \ln VA + \underset{(2.342)}{0.0673} \ln \text{PopDensity} \qquad (6)$$

$$\text{Adj } R^2 = 0.103; \; F[3,173] \text{ (prob)} = 6.61 \; (.0002)$$

This equation performs much better than the “standard” model seen above. Hence this very exploratory analysis appears to show that non classical variables, such as population density, i.e. people per sq. km of land area, and market size, measured by valued added, should be considered to explain the behavior of the construction sector in the year 2005, while total and urban population are not significant.

CONCLUSIONS

Even if the interest in structural analysis has considerably decreased in the last decade due to new endogenous growth models, classical structural analysis is the core of development theory. Patterns of economic development are indeed a key issue during transition from a low income, rural economy towards an industrialized urban one with a large income per capita. Accumulation of physical capital has always been at the core of these analyses, but construction often has been neglected as a driver of sustained growth. Maddison's remarkable book on long run performance by 16 advanced capitalistic countries since 1820 (1991) should be considered. This author states "there are three main kinds of physical capital: non-residential, residential, and inventories. The first is the biggest and has the greatest influence on growth; the second is substantial, but much more limited in its impact" [Maddison 1991, p. 65]. Moreover Maddison presents interesting data about gross residential capital stock per head and as a ratio to GDP in leading economies from 1950 to 1987 (table 3.11 and 3.12) but he does not provide any attention at all to the remarkable data of Germany and Japan. The field of construction economics filled this gap. Turin postulated a causal relationship between construction and economic growth, while Strassman argued that building activities can even replace manufacturing after the initial stage of development. Since these fundamental contributions there has been a significant debate about the role of construction in a given economy. It has been argued that building technology is shifting towards the service sector. Bon has argued that construction per se is less dynamic than other major economic industries, when abundant physical capital is already in place (Bon, 1992). Little statistical analysis has been put forward in this regard. In this paper this old debate has been revised by providing same explorative regressions that link construction value added share to GDP per capita. The contribution of this paper is the introduction of new variables, such as total value added and population density, that should help the understanding of these relationships. Our outcome is still tentative, as explanatory power is quite weak. Additional longitudinal analysis is needed, but this very preliminary analysis shows that the worldwide construction role in the Seventies appears to be very different from the current one and, therefore, new variables should be used for analyzing this changing role.

Abstract
Local and national Governments must deliver the public facilities that citizens need and, at the same time, select private firms that are able to build these facilities according to the best possible compromise between available resources (money, time...) and the quality of the required work/service. Consequently, multi-criteria evaluation schemes, such as the Most Economically Advantageous Tender (MEAT) scheme, are often used by tendering committees in public projects. The used procedure has to meet the requirements of full transparency and to assure competitiveness among bidders. Many MEAT award related models have been proposed in the specialized literature. This paper presents a classification of these models. Their strength and weakness are illustrated. The assessment of some of these models builds upon their application to an example of public procurement. The presented analysis can be used by Governments and public firms in the selection of the tendering mechanism that best meets their requirements, needs and expectations in bid evaluation.

Keywords: public tender, Most Economically Advantageous Tender, supplier selection, bid evaluation

INTRODUCTION

One of the main tasks of local and national Governments is to deliver the public facilities that communities need. This activity involve many challenges, such as gaps in the required financing, need for facilities that meet different qualitative requirements fully, need for their timely delivery, the large number of involved stakeholders and so on.
Consequently Public Procurement has received increasing attention in the specialized literature. This activity has a significant economic relevance. In 2003 the European Public Procurement accounted for more than €1500 billion, equal to about 16% of the EU Gross Domestic Product (Lewis, 2007). In order to implement efficient investment policies, Governments have to encourage competitiveness among candidate suppliers (Malmberg, 2003). In this way, it is possible to build more environmentally friendly public facilities at lower prices and with better quality.

The implementation of efficient Public Procurement procedures is challenged by bid rigging, i.e., the collusion among bidders or between a bidder and a corrupt public officer (Tanaka and Hayashi, 2011). The awarding committee (usually a commission of experts selected by the public authority) must follow prescribed procedures and maintain transparency in public tenders in order to prevent these situations (Panayiotou et al. 2004). Definitively, any given Government aims at obtaining the best possible public goods or services and avoiding collusion: specific laws exist in this regard. In order to meet this goal, a public client must find private firms that can build the required facilities according to the best possible compromise between available resources (money, time...) and the quality of the required work (e.g., in terms of post delivery service, technical features, etc.). Consequently multi-criteria evaluation schemes often are used by tendering committees in this kind of public works.
The European Union Public Procurement Directive 2004/18/EC imposes the use of the Linear Weighting technique (when possible) in the public tenders to be awarded according to the MEAT criterion. This practice is limited by the lack of an optimal choice of weights to be assigned to the evaluation criteria. Moreover, when MEAT is used, public officers can favour a given bidder by assigning a high weight to a criterion that only that competitor is expected to meet fully. Consequently this method is characterized by some subjective choices which make corrupt behaviours possible. In the last few years many models, related to the multi-criteria evaluation of bids, have been proposed in the specialized literature.

Some of these models have been developed for the specific purpose of public construction projects, while others, although aimed at a more general application, can be also applied to evaluating construction bids. Some of these methods address the optimal choice of the weights for the linear weighting. Others are based on the qualitative comparison between alternatives. Another set of methods is based on the estimation of the utility coming from each bid. Lastly, another approach aims at determining the social costs of completion time and the quality of the final work. These costs are added to the submitted bid price.
A classification of several published bidding mechanisms for public projects is proposed in this paper. Their strengths and weaknesses are illustrated. The analysis aims at informing Governments and public agencies the type of mechanism that best meets their requirements, needs and expectations in bid evaluation.
The paper is structured as following. The next section describes the multi-criteria bid evaluation, as proposed by the European directive, and it presents a classification of the considered models, while the following section presents an application of these models to an example of public procurement practice. A final section concludes the paper.

THE MULTICRITERIA SELECTION IN PUBLIC PROCUREMENT

Background

In most countries, public procurement is ruled by specific legislative requirements. In the European Union, this matter is regulated by the 2004/18/EC Directive (European Parliament and Council, 2004), also known as Public Procurement Directive. This law sets the application of one of the two following award criteria: the Lowest Price (LP) or the Most Economically Advantageous Tender (MEAT). The LP criterion is typically used in conjunction with pre-qualification requirements (Lorentziadis, 2010). In this case, money saving is one the main goals of the tender, because the features of the supplied product, service or work are standardized and price is the only element that differentiate offers (Piga and Zanza, 2005). Differently, when the contract is awarded on the basis of the MEAT criterion, various (quantitative and qualitative) factors are considered simultaneously. In this

last case, scores for different factors are synthesized into an overall score by using of the linear weighting method (European Parliament and Directive 2004/18). In this regard, the committee has to assign a weight to each criterion before the submission of the offers. These weights are to be specified in the request for proposals (Lorentziadis, 2010). The literature on supplier selection suggests many methods for weights determination (for an overview see De Boer, 1998), but the Public Procurement directive does not impose any specific procedure in this regard. Consequently, weights could be set on the basis of subjective judgments that, of course, create consistency and validity problems in the evaluation process (Lorentziadis, 2010 and Borcherding et al., 1991). In fact, there is no absolutely optimal choice of weights (Dulmin and Mininno, 2007). In addition, when this awarding scheme is used, public officers can give an unfair advantage to a given bidder by assigning a high weight to a criterion that only she can meet fully (Søreide, 2002).

Literature review

In order to overcome these limits, several studies have proposed the adoption of vendor rating methods that are used in the private sector. These instruments can be a valid alternative to the simple linear weighting of performance values that is based on the weights allocated by public officers.

The methods can be classified in five categories:

- *Linear Weighting-based methods*. These use specific algorithms to find weights to be used for scoring each bid
- *Comparison-based methods*. Each bid is compared to all others in a quantitative or qualitative manner. With this procedure, a final score is assigned to each offer through techniques such the Analytic Hierarchy Process (AHP)
- *Cost-Benefit Analysis*. The cost and benefits of each offer are estimated. The weighted sum of these indicators determines the final score.
- *Utility-based methods*. Specific utility curves, as a function of different criteria, are defined to estimate the overall utility of each bid.
- *Costing-based methods*. The cost consequences of non price related performance are determined and summed to the bid cost. The resulting overall cost is the indicator used for award.

Table 1 shows examples of the models that characterize the above illustrated categories.

Linear Weighting-based methods

Lorentziadis (2010) proposes linear programming for evaluating criteria weights by suggesting the choice of the average of the least or most favourable set of weights for all candidate suppliers. All weights range according to the limits established by the public client. Suppliers can be assigned differing degrees of importance provided that the related criteria are known in advance when the request of proposal is announced.

Even if there is no direct definition of weights by public officers, this model is still subject to discretionary choices about weights range and degrees of importance of candidate suppliers.

Comparison-based methods

Many approaches use performance indices as inputs to the Analytic Hierarchy Process (AHP) for defining the best offer among alternative bids (Sipahi and Esen, 2010). AHP determines a ranking of evaluation criteria through their pair-wise comparison first, and then uses this rating to define the ranking of bids. The pair-wise comparison of all alternatives is performed according to their degree of satisfaction of each criterion. This method sometimes is employed in conjunction with the Simple Multi-Attribute Ranking Technique (SMART) (Padhi and Mohapatra, 2009a). Other techniques use fuzzyfied input data (Padhi and Mohapatra, 2009b). Costantino et al. (2011), for example, determined the best offer in a public tender through a Fuzzy Analytic Hierarchyic Process (FAHP) that was based on pair-wise comparison of alternatives according to different factors and on fuzzyfication according to specific membership functions.

These methods allow the peer evaluation of all bids, however qualitative comparisons could still be made in a discretionary way. At the same time, membership functions in fuzzyfied models cannot be chosen in a univocal way.

Cost-Benefit Analysis

Many authors have argued about the need for differentiating cost and benefit criteria in the evaluation of bids. For instance, Topcu (2004) proposes a model according to which, after the pre-qualification of contractors with weights determined by AHP, each bidder receives a score that results from the weighted sum of the normalized overall pre-qualification score (estimated benefits) and bid price. A similar, but more complex, approach is proposed by Bana e Costa et al. (2007). Cost and benefits are evaluated in different ways. Cost is considered with the use of an adequate coefficient, while benefit is determined by a set of qualitative sub-factors. The shift to a quantitative scale and the definition of a set of weights for the sub-factors is obtained through a pair-wise comparison that is based on the MACBETH method (Bana e Costa and Vansnick., 1994). In this case the trade-off between cost and benefit scores is obtained by a weighted sum (where the weights are selected by decision makers).

These analyses allow the differentiation between the required price and offered benefits of each bid, but do not take into account other non-monetary requirements for completing a

project, such as completion time. Moreover, discretionary choices can still affect these models.

Utility based methods

Other authors have focused on evaluating the utility of the overall bids. Holt et al. (1993, 1995), for instance, defined a three-stage evaluation procedure for construction related tenders. After a prequalification phase on the basis of non-subjective criteria, all bids are assigned a score according to the utility resulting from pre-defined project criteria and, successively, a second score is assigned to each offered price. A weighted sum of these two indicators determines the final ranking. Differently, Hatush and Skitmore (1998) use six evaluation criteria (bid value and a set of attributes related to a given bidding company, such as financial strength, technical ability, management capability, health and safety records, and reputation). For each of these attributes, a score is determined. The corresponding utility is given by a curve that is developed after bid opening and reflects all offers. The bidder with the highest overall utility is awarded the contract. A similar method has been proposed by Lambropoulos (2007), with two fundamental differences: the considered criteria are cost and delivery time discounts and the utility curves are defined before the request for proposals and known a priori by all bidders. The main drawback of the utility function is its difficult estimation.

Costing based methods

In the last twenty years, the MEAT award scheme has been also adopted in the United States, namely in the construction sector. Ellis and Herbsman (1991) have proposed bid price and completion time as the basis for awarding highway projects. In the initial formulation of the method, the bid price of each competitor is summed to the cost value of each day of incompletion of the project. For each proposal a factor, known as the Road User Cost per day, is estimated. This includes the client's contract administrative costs and the cost to road users for the unavailability of the road (or lane) during construction. The Road User Cost per day is then multiplied by the completion time (in days) proposed by the bidder and the result is added to the bid price. The contractor with the lowest total bid is awarded the project. The same authors (Herbsman and Ellis, 1992) extended their model by considering also the quality of the work (e.g., in terms of roughness index of provided road asphalt). The analysis of 101 highway projects (that had been awarded with the MEAT method) has showed substantial benefits in terms of time savings in comparison with similar projects awarded with the Lowest Price method (Herbsman, 1995).

The cost estimate of completion time or quality allows the quantification of comparable performance indicators and, at the same time, the use of true values in selecting the best bid. The limit of this method is the difficult estimate of the User Cost.

The literature review shows that the above outlined methods have some limits, notwithstanding their benefits, particularly in the case of highway projects. Most of them are based on some subjective selection criteria, such as the interval between weights or membership functions (to be chosen by public officers). Other methods require the subjective estimation of the bid (i.e., in the pair-wise comparison). The qualitative scores, as defined by a given evaluation committee, can still favour a corrupt bidder (Lengwiler and Wolfstetter, 2006). Consequently, this type of arrangement can undermine the transparency of the process. The distinction between the cost and benefit of each bid, furthermore, does not take into account that any given project requires other resources (e.g., time and maintenance services), in addition to money.

Lastly, some of these methods do not respect the EU legislation, because the awarding conditions are not known before the bid opening (Lambropoulos, 2007).
Consequently there is no absolutely a best method when the bid award according to multiple criteria is considered. A public client should select the method which best fits his expectations and established procurement procedures.

THE APPLICATION OF SELECTED MODELS TO PROCUREMENT PRACTICE

In order to verify how different methods can affect the awarding outcome of a public project, three of the outlined models are applied to a case of procurement practice, namely the renovation of a facility at the Politecnico of Bari, Italy (Costantino et al., 2011). In this public project the target price of the auction $\overline{d}_1$ was € 148500 plus VAT and the maximum project duration $\overline{d}_2$ was 35 weeks. The winning bid was selected according to the MEAT criterion.
The number of bidding suppliers was m=45. Each bid (see Table 2) was evaluated according to n=4 criteria, as specified in the request for proposals. The considered criteria were: 1) Price c_1 (with the corresponding performance value d_{i1} measured in € for the i-th supplier and i=1,…,m); 2) Reduction of project completion time c_2 (with d_{i2} measured in weeks and i=1,…,m); 3) Duration of post delivery free maintenance c_3 (with d_{i3} measured in months and i=1,…,m); 4) Quality of enhancement plans c_4 (with d_{i4} and i=1,…,m to be evaluated according to a 0-10 scale that reflect the quality of changes proposed for the design plans and/or material and component substitution). The criteria used for the award were of quantitative (c_1, c_2, c_3) and qualitative (c_4) nature.
The bids of Table 2, are evaluated according to three different ways: the fuzzy AHP (FAHP) (Costantino et al., 2011), a utility based method and a costing-based method.

As far as the FAHP is concerned, the criteria for weights and membership function can be found in Costantino et al. (2011). This method takes into account all the four decision criteria proposed in the tender.

Lambropoulos's model (2007), as an example of the utility-based method, is used in this application. The inputs to this model are the cost and time discounts proposed by each bidder. Because the required duration of the free maintenance period is not specified in the request for proposal, the application cannot consider this performance value. This is also true for the quality of enhancement plans, which cannot be determined on the basis of a purely quantitative scale. Consequently, the offer that maximizes the overall utility function (1) is to be selected

$$U(s_i) = KU(\lambda_{ci}) + XU(\lambda_{ti}) \quad (1)$$

where $U(s_i)$ is the overall utility of the offer of bidder s_i; $U(\lambda_{ci})$ □ [0,1000] is the utility of the price discount by s_i; $U(\lambda_{ti})$ □ [0,1000] is the utility of the time reduction offered by s_i; K and X are the weights of $U(\lambda_{ci})$ and $U(\lambda_{ti})$. The utility functions $U(\lambda_{ci})$ and $U(\lambda_{ti})$ used in this application are expressed by (2) and (3)

$$U(\lambda_{ci}) = \begin{cases} 3000\lambda_{ci} & \text{for } 0 \le \lambda_{ci} \le 0.2 \\ 400 + 1000\lambda_{ci} & \text{for } 0.2 \le \lambda_{ci} \le 0.4 \\ 667 + 333 * \lambda_{ci} & \text{for } 0.4 \le \lambda_{ci} \le 1 \end{cases} \quad (2)$$

$$U(\lambda_{ti}) = \begin{cases} 200\lambda_{ti} & \text{for } 0 \le \lambda_{ti} \le 0.2 \\ -167 + 1333\lambda_{ti} & \text{for } 0.2 \le \lambda_{ti} \le 0.8 \\ 500 + 500 * \lambda_{ti} & \text{for } 0.8 \le \lambda_{ti} \le 1 \end{cases} \quad (3)$$

The parameters λ_{ci} and λ_{ti} are determined according to (4) and (5) respectively.

$$\lambda_{ci} = \frac{\overline{d}_1 - d_{i1}}{\overline{d}_1} \quad (4)$$

$$\lambda_{ci} = d_{i2} \quad (5)$$

The values of the weights used for the two utility functions are respectively $K = 0.55$ and $X = 0.45$.

As far as the costing based method is concerned, the following evaluation approach is proposed. The user benefits that result from the time reduction (*tub*) and the free maintenance (*mub*) are subtracted from the bid price. Thus the total bid cost b_i (6) is obtained through

$$b_i = d_{i1} - tub \cdot d_{i2} - mub \cdot d_{i3} \quad (6)$$

In this case, the time reduction benefit has been assumed to be equal to *tub* = 800 €/day, while the free maintenance is equal to *mub* = 50 €/week.

Table 3 shows the scores of all offers according to the three considered methods.

Table 3: *Bid scores according to the three considered methods*

The data of Table 3 shows different results depending on the type of awarding method. According to FAHP, the utility-based and costing based method the winning bid would be s_{39}, s_{19} and s_{37} respectively. Table 4 shows that each method determines very different rankings of the offers.

Table 4: *Top 10 bids according to the three considered methods*

Rank #	FAHP	Utility-based	Costing-based
1	s_{39}	s_{19}	s_{37}
2	s_{10}	s_{23}	s_{9}
3	s_{29}	s_{33}	s_{32}
4	s_{12}	s_{15}	s_{28}
5	s_{25}	s_{27}	s_{20}
6	s_{14}	s_{38}	s_{2}
7	s_{33}	s_{42}	s_{22}
8	s_{7}	s_{26}	s_{8}
9	s_{36}	s_{3}	s_{6}
10	s_{41}	s_{17}	s_{30}

Moreover, the variability in the final rankings of bids is not determined by the choice of the awarding method only, but also by the parameters used in the evaluation. The same method can lead to very different results by changing its parameters. Thus there is the possibility that a given competitor is favoured over the others. This problem has been addressed in specialized literature (e.g., Telgen and Schotanus, 2010).
Consequently, the selection of an awarding method by local and national Government or governmental agencies should take into account two factors: the availability of useful information for setting the evaluation parameters and the possibility of corrupt behaviour.

CONCLUSIONS

The delivery of public projects is one of the main tasks of local and national Governments (or governmental agencies). These facilities must meet a set of economic, technical and environmental requirements. In this regard, the Most Economically Advantageous Tender is increasingly used as the award method of public projects. The literature review has shown that many models can be applied to the MEAT tenders. This paper has addressed and discussed some of these models. Five types of awarding mechanisms have been outlined. All of them require the setting of some selection parameters and sometimes they are based on the subjective evaluation of offers.
Three of these methods have been applied to evaluating the bids for the renovation of a facility at the Politecnico of Bari, Italy. The data show different outcomes depending on the considered method. The correct evaluation of bids depends on a method that is characterized by fair air and precise parameters and minimizes the possibility of anticompetitive behaviour.
Future research should address the development of an awarding method that is based on objective evaluation and without the need for selecting parameters for ranking.

Abstract
Paper presents first findings, assumptions and initial results of the two innovative projects for construction industry: Leonardo da Vinci Projects (TRAIN.CON, 2010-2012) – "Augmented Reality Applied to Machinery Maintenance from Construction Sector" and Norwegian Instrument Project (NORW, 2009-2011) - "Distance Learning within Management in Construction".

Keywords: augmented reality, distance learning, management, machines operators.

INTRODUCTION

Author is the member of research teams for two EU funded projects connected with education of construction personnel in Europe: MAIN.CON project (No: 2010-1-ES1-LEO05-20930), titled: "Augmented Reality Applied to Machinery Maintenance from Construction Sector", related to the creation of innovative system facilitating construction machinery maintenance, with use of the augmented reality basis. NORW project (No: FSS/2008/X/D5/W/0005/U/0013), titled: "Distance learning within management in construction", is the part of the Development of Polish Universities Program, donated by Norway, Iceland and Lichtenstein within the Norwegian Financial Instrument project. NORW project is related to development of modern, blended learning types of studies for Polish and Norwegian construction managers. Logos of the Norwegian Financial Instrument and Leonardo da Vinci programs are presented in fig. 1.

Figure 1: *Logos of FSS and Leonardo da Vinci projects.*

ASSUMPTIONS FOR THE MAIN.CON PROJECT

Introduction

The effectiveness of construction processes implementation today depends on the production capacity of sets of construction machines and equipment. An equipment contains a mechanism or a set of mechanisms aimed at processing of energy or conducting of works, while a machine is a device containing an engine of any type. Nowadays, mechanization of

various construction processes requires application of leading machines, complemented by machines parts, to establish the mechanized construction work lines. The term 'mechanization' encompasses the production-related operation of machines performing tasks related to particular technology. Production-related operation pertains to performance by machines of mechanical works under varying conditions at the building site. The activities of the technical service for any machine include the planned preventive measures, aimed at preventing the excessive use and damages of machines and repairs, restoring the original technical conditions of machines.
Generally speaking, mechanization and automation are forms of technological progress. Significant features of mechanization and automation include recognition of any organizational relations, which take place within the technological operation sequences (storage, transport, production and assembly, operation and maintenance) and using them in the common production process, using the increasingly mechanized lines of machines.
Mechanization is a process related to the development of machines. Progress in the field of mechanization of construction trade depended on technological progress with regard to construction machines. At present, in association with the quick development of industrial automation devices, it is becoming increasingly dependent on the progress of IT science and computer techniques. Regardless of technical progress, the development of the basic theory of mechanization in construction trade was observed relatively recently. In the fifties of the 20th century, the first principles of mechanization of construction works were formulated in Poland, and in the sixties - the principles of complex mechanization.
The gradual automation of processes on the construction sites will depend on the changes in the way of thinking about the building techniques. While the main problem in mechanization of processes is the technology and the technical works equipment (a properly selected set of machines), for automation and then robotics of processes, the problem lies in control (management) of the entire processes or great systems, using the appropriate automatic devices or computer software. Augmented reality can be a vital part of construction technology development

Basis for the project

MAIN.CON project partners are as follows: Labour Foundation for the Construction Sector, Spain (the Promoter), Polish British Construction Partnership, Poland, BZB, Germany, Centro Edile Andrea Palladio, Italy and Ente Scuola per la Formazione delle Maestranze Edili, Italy. The aim of the Leonardo da Vinci MAIN.COM project is to design and apply a training system in basic machinery maintenance using a new technology called augmented reality. This system will improve the basic skills of machinery operators related with a safe maintenance of their machines and not only with their operation. Main assumptions for the project are presented at fig. 2.

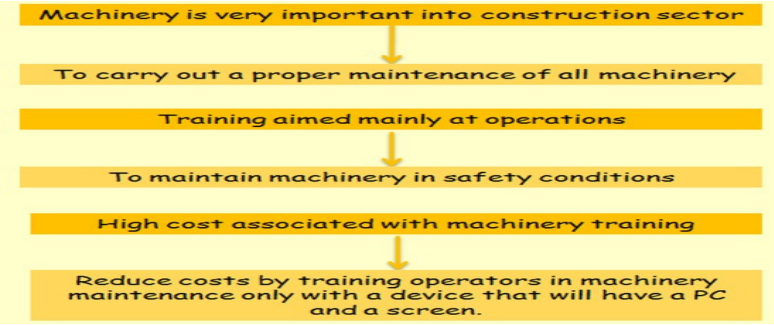

Figure 2: *Main goals of the MAIN.CON project [2].*

The Augmented Reality (AR) is the term to define a direct or indirect view of the physical environment in the real world, which elements combine with virtual elements in order to create a mixed reality in real time. So, it consists in a group of devices which add virtual information to real information. This is the main difference with virtual reality, because it doesn´t replace physical reality, but superimposes virtual data on real world. This project is going to be focused in excavation works for two reasons. Firstly, because of intensive work, which emphasizes the necessity of preventive maintenance. Secondly, because of the enormous quantity of self-employers and SMEs, who own, for example a digging machines and are working for others companies. This project is going to be based upon the outcomes obtained in the project "Training system for mechanical digger operators", in which one of the most important developments was maintenance training. Furthermore, it included an experimental system based on personal digital assistants (PDA) of which function was to support the learning through the use of checklists. The system pretends to enhance the training of operators in the field of maintenance, through the use of Augmented Reality. To reach this aim, the project will provide a system which will allow to select maintenance operations by means of a interface easy to use by the operator. One of the first attempt for use of augmented reality was conducted by car producer – BMW, for easy maintenance of cars. Fig. 3 presents screenshot from BMW movie showing general maintenance of the car engine – replacement of the cooler duct.

Figure 3: *BMW system of cars maintenance with use of augmented reality screenshot [4].*

Classification of chosen construction machines

Every machine consists of three basic elements: undercarriage, bodywork and working equipment. The type of each of these elements serves as a basis for classification of machines. The MAIN.CON project will base on the standard ISO/TR 12603, which provides the European classification of construction machines according to their use within the framework of individual work groups. For example - group 100 will be the subject of MAIN.CON project. This group consist of earth-moving machines and equipment: (for preliminary earthworks and wide excavations: 110 - bulldozers: wheel, caterpillar, 120 - loaders; wheel, caterpillar, 130 - digger-loaders; wheel, caterpillar; 140 - diggers; hydraulic, drag line excavators, bucket wheel diggers, bucket chain excavators; demolition equipment; transport of soil: 150 - articulated dump trucks, tipper trucks; for earthworks finishing: 160 - scrapers, 170 - graders; narrow and pit excavations: 180 - ditch diggers, 190 - pipe-laying machines) [1].

The process of machine operation is an entire set of organizational and technical tasks, which are aimed at performance of production tasks using machines in accordance with their technical parameters, as well as maintenance of the technical capacity of machines enabling them to perform work.
In the operation process, the following two (A and B) states of machines are recognized:
A). Production-related operation of machines – it is a state of capacity of machines to perform mechanical works (in relation to rented machines, the applicable term is – the state of production-related use of machines). In the state of production-related operation of machines, two significant sub-states can be identified: the sub-state of machines waiting for implementation of tasks and the sub-state of production-related tasks implementation by machines (performance of mechanical work). The basic tasks performed during the production-related operation of machines include:

- formal and legal activities associated with driving machines on public roads,
- transport of machines to construction sites (conditions, securing of transport),
- preparation of machines for work (location of machine, connecting of the power supply),
- performance of tasks and mechanical work of machines (position-related limitations, occupational health and safety),
- disassembly of machines and transport to another work site or to the place of storage.

The time of waiting for task performance is an inevitable time of production-related operation of machines and it amounts to 5 to 15% of their production time. The structure of activities performed in the state of production-related operation of machines and auxiliary equipment is presented in table 1.

Table 1: *The structure of construction machines maintenance activities [1].*

The structure of activities performed in the state of waiting and performance of production tasks for machines and sets of auxiliary equipment (boarding, scaffolds, templates, etc.)					
Transport arrangements	■			■	
Transport of the machine to the construction site	⇨				
Assembly and setting for operation		●			
Period of the machine works			▬		
Disassembly and transport of machine				⇨	
Maintenance and repairs after completion of works			*Random events (breakdowns)*		●

B). Technical maintenance status of machines - is the status of prevention of breakdowns, repairs or renovation of machines and control of their ability to perform production tasks. The basic tasks performed in the technical maintenance status of machines are as follows:

- washing of working elements of machines and lubricating of those components, which are most sensitive to damages after the end of each working shift,
- periodical inspections, technical and transport servicing of machines and auxiliary equipment after the end of the cycle of works or all works on the building site, as well as the planned repairs and renovations of machines and auxiliary equipment.

The typical features of the process of construction machines operation include:

- frequent changes of the place of operation and the associated frequent transfer of machines between construction sites or places of operation on the site,
- a wide scope of changeability of the conditions of operation due to external conditions (weather, terrain) or technological conditions of works,
- a relatively high frequency of technical maintenance due to sensitivity of drives and auxiliary systems of machines to work overloads.

Depending on the intensity of operation, the production capacity and efficiency of machines lowers as a result of wear of the structure elements and the process of ageing of machines. Restoration (regeneration) of the original technical capacity of machines, that is, their full ability to perform tasks, depends on a number of organizational and technical activities, belonging to the appropriate system of technical maintenance of machines.

System of maintenance and repair of machines

Machines, which have the status of technical maintenance, are either reparable or irreparable. Irreparable machines include those, which are technically unfit or which are reparable from the technical perspective, but their repair is not profitable. The issue of technical maintenance of machines is associated with the concept of repair capacity of machines.

Repair capacity of a machine – is the component of the concept of reliability and it is the adaptation ability based on prevention, identification and elimination of damages (inspections and repairs of the machine), which may arise during operation of the machine or as a result of ageing of the materials and the structure.

The basis for planned operation of machines and technical devices is a schedule of technical maintenance and repairs of machines and devices. The system provides for obligatory technical maintenance and major (general) repairs after the machine performs a specific number of hours of work.

Periodical technical maintenance includes the planned preventive measures, preventing the early damage of the machine. The following types of maintenance can be identified:

- everyday technical maintenance – a set of maintenance tasks: washing, lubrication and inspection of some mechanisms (components of the hydraulic system, bolts, flat runners etc.), which are performed every day, usually after the end of each working shift. Lubrication of the machine mechanisms is based on addition or replacement of lubricant in the lubrication points within specified time intervals. Everyday maintenance is considered to be one of the most significant tasks, decisive for maintenance of the machine in the proper technical condition and for reliability of its work.
- periodical technical maintenance – a set of maintenance tasks: control of the condition of the machine and replacement of some parts or small sub-assemblies, performed prior to each summer or winter season or prior to transfer of the machine to the new construction site. Periodical inspections, apart from the ordinary maintenance tasks, such as replacement of oil, include checking of the main mechanisms of the machine (the gear, clutches, breaks, bearings, hydraulic systems etc.) and determining of the medium-level repair date.
- transport-related technical maintenance – a set of special tasks performed in order to prepare and secure the machine during transport. The transport maintenance may include a partial disassembly and safeguarding of the machine for the transport period.

Planned and preventive repairs are technical tasks, aimed at restoring of the original technical condition of the machine. The following types of repairs can be identified:

- medium-level repair – is a set of maintenance and repair tasks performed after a specific number of hours of work of the machine (e.g. about 2.5 thousand hours for a loader); it includes elimination of defects or replacement of sub-assemblies of the hydraulic and

electric system, mechanisms of work tools, etc. The most significant inspection tasks include: measurement of clearances in the machine driving mechanisms and work tools (gear wheels, bearings, bolts etc.), inspection of rubber seals of pumps, cylinders and hydraulic pipes, checking of wear of electric sub-assemblies and parts, etc.

- major repair – a set of renovation tasks performed after a large number of working hours of the machine (e.g. about 5 thousand hours for a loader); it includes verification of all parts and sub-assemblies, repair or replacement of the main sub-assemblies of the machine. The most significant tasks include: replacement of seals and flexible pipes, hydraulic pumps and manipulators, main electrical sub-assemblies, disassembly and repair of the main machine assemblies, the engine, the gearbox, the driving mechanisms and work tools, replacement of parts and sub-assemblies.
- breakdown repair – it includes the full scope of repairs resulting from damage.

Initial results of the project

MAIN.CON project consist of several general work packages (WP), leading to the achievement of project goals:

- WP I - analysis of construction earthworks machinery. In this work package Partners will carry out a Focus Group in each partners' country in which they will analyze and select the most appropriate machine for its implementation under Augmented Reality (AR). First meetings with construction personnel in Poland showed that the most used machinery for earthworks are medium size diggers.
- WP II - definition and establishment of a map of basic skills in machinery maintenance. This work package consist of: analysis of machinery operators, definition of key functions and main functions, definition of the elements of the operators' skills, identification of performance evidences, definition of the implementation criteria, identification of knowledge evidences, establishment the different levels of the skills. Fig. 4 shows possible connections between real world and artificial reality.

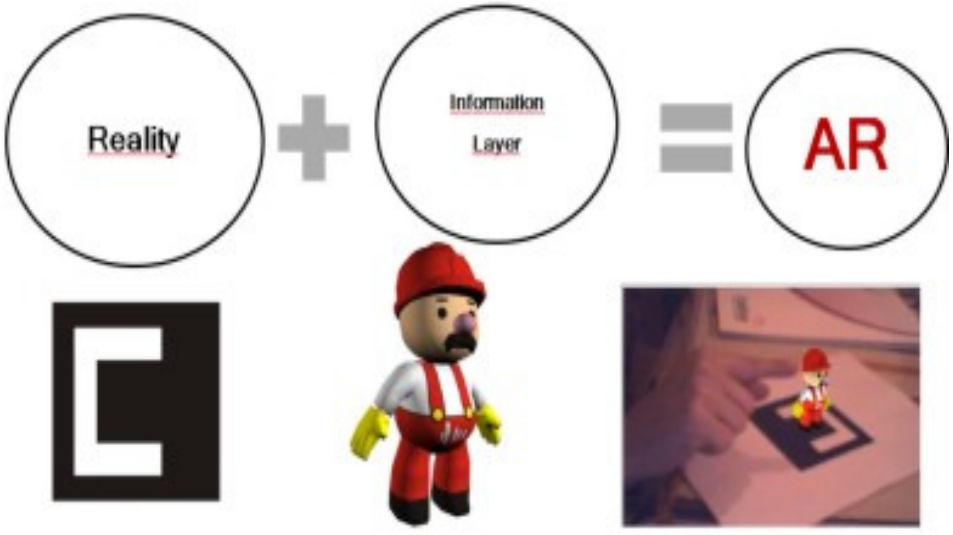

Figure 4: *Ramon (in Poland – Roman) - animated PDA - character facilitating operators training created in the MAIN.CON project [2].*

- WP III - development of the software and hardware based on Augmented Reality for maintenance training. This work package consist of: development of the contents, make graphic design, building the graphics under Augmented Reality rules, design of the training system, design of assessment system, make the needed devices to carry the hardware. Fig. 5 shows possible elements of the future training system.

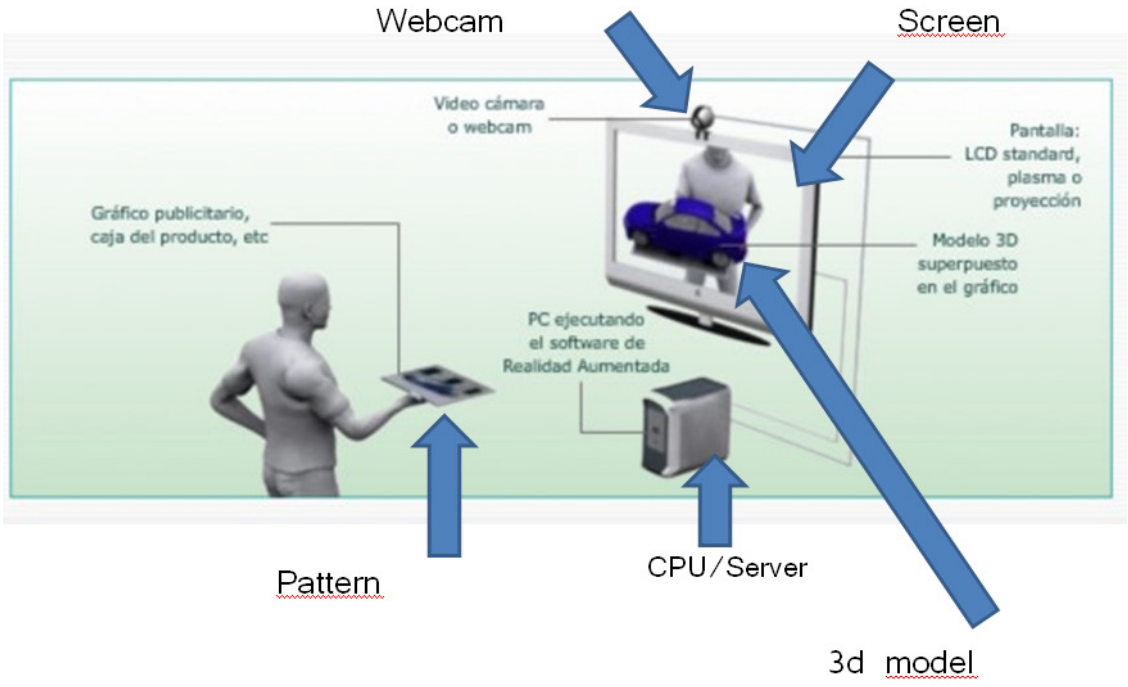

Figure 5: *Augmented Reality of the MAIN.CON project [2].*

All products of the project will be tested and evaluated. Full, usable version of the Augmented Reality system for machines operators should be ready at the end of the year 2012.

Initial results of the survey held in Poland

The survey was made among Polish operators of the construction machinery, to find what excavators are the most useful / popular in the country and what kind of maintenance operations could be run at the building site by themselves.

Focus Groups in Poland took place on 19.02.2011, during weekly meeting of excavators operators course, organized by "LEKTOR" – Centre for Continuous Education of Drivers and Machine Operators, ul 1-go Maja 7, 05-250 Radzymin, Poland. Each focus group was composed by 10 to 15 experts in the field of machinery maintenance. The duration of the focus group was around 2 hours. The focus group was managed by a moderator who follow the following steps (as agreed with Partners and Promoter of the Main-Con project):

Step 1: Overview about the project.
Step 2: Explanation about the aims of the focus group.
Step 3: Asking opened questions included in the questionnaire. Recording and moderation of the debate.
Step 4: Provide the questionnaire with closed questions to the experts.
Step 5: Collect the questionnaires and closure.

Results shows that operators can perform chosen maintenance operations on site. Summary of the results are shown in table 2.

Table 2: *Results of the survey in Poland (*first five most popular answers – yes)

CONTROLS:	YES	NO
Oil leakage from hydraulic system	39	2
Proper running of bucket	38	0
Proper running of indicator lights and instrumentation	36	2
Condition of hoses and metal pipes	35	3
Abnormal noise of axles	35	3
Oil leakage from transmission and reductors	35	2
Tires wear and tear	35	5
INSPECTION REGISTRATIONS:	YES	NO
Cleaning of electrical poles and battery terminals	24	12
Cleaning of the filter element of engine vent	23	11
Cleaning of plug and filter fuel tank	14	19
Empty sediments from fuel tank	10	24
Empty sediments from reservoirs	10	24
FILTERS AND LUBRICANTS:	YES	NO
Check of hydraulic oil level	38	1
Check coolant level	36	2
Inspection and cleaning of cabin air filters	25	11
Inspection and cleaning of secondary air filter	20	14
Replacement of air primary filter	19	16
Cleaning of air pre-filter and check of turbine pre-filter	19	16
LUBRICATION:	YES	NO
Greasing of loader unit	37	3
Backhoe greasing	36	3
Greasing of oscillator of front axle	25	9
Greasing of rear axle support	23	11
Supports and cross pieces of drive shaft	22	13
SAFETY:	YES	NO
Proper running of lighting devices	37	1
Proper running of parking brake	37	1
Proper running of auxiliary brake	36	2
Proper running of the wiper	34	1
Proper working of rear-view mirrors	33	3

The following (few chosen as the example) questions were asked during debate:

1. Which heavy machine is the most used for carrying out the excavation?

Caterpillar or wheeled excavator are the most useful machines – 8 answers; 6 persons are convinced that JCB excavator are the most popular machines (medium size, for example JCB JS130W); one person mentioned VOLVO excavators; all agreed that backhoes are the most useful (both on wheels or caterpillars).

2. Which are the typical works for maintenance and services that can be made on the machine by the operator?

Lubrication (10 persons fully agree); checking the oils and fluids (5 persons fully agree); technical check of tires; checking the wires and electrical equipment; minor reviews before and after the work (battery, cables, tires); checking the state of the petrol tank and other tanks.

3. Which operations are done daily? All agreed:

Checking the hydraulic ducts; lubrication; checking the possible leakage; checking the blades; checking the tires and wheel clamping; exchange the filters.

4. Which operations are done monthly?

Overall clearing; checking and changing the tires; technical review; checking the wires / hydraulic; checking and cleaning / exchange the filters; conservation of electric wires; checking the lubricates / exchange.

5. Which of the listed operations are particularly uneasy to fulfill?

Checking the levels of lubricates and exchange of lubricates and filters; checking and changing the tires; exchange of wires / hydraulic ducts; conservation of electric wires.

6. Do you think that "Augmented Reality" could be useful for training operators on maintenance works?

All courses are important for better professionalism; 16 answers YES (one – very useful); 3 answers NO; 10 answers – NOT SURE.

Focus Groups show interest of machinery operators in finals results of the project - Augmented Reality distance learning courses and didactic materials - which will be the final results of the project.

FINDINGS OF THE FSS NORWEGIAN PROJECT

Introduction

The NORW project is related to development of studies in English for construction managers in Poland and Norway (English as a language of instruction for the lectures and workshops). The project will develop some new courses, modules and curriculum as well as modify the existing ones.

New curriculums were created in cooperation with sector of small and medium - sized enterprises. The project will create two first courses organized in the blended learning mode of teaching (face to face mixed with e-learning):

- "Economy and Financial Management in Construction" and
- "Construction Management".

Need for the courses was confirmed during numerous research works and projects and contacts with Polish, Norwegian and other European construction companies. Operational goals of the project are: increasing the attractiveness of teaching at Universities and increasing the professionalism of construction managers running the European funded projects in construction infrastructure (roads, bridges, airports, water and waste water treatment plants, sewage networks, etc.). Detailed goal of the project is creation of the didactical internet platform for teaching elements of management in construction together with didactical materials and methodology, both in English and Polish. Partners of the project are: Department of Construction Engineering and Management, Civil Engineering Faculty of Warsaw University of Technology (the Promoter), Poland, Polish British Construction Partnership, Poland, Norwegian University of Science and Technology (NTNU) in Trondheim and SINTEF in Oslo (Norway). Results of the project – distance learning courses – will be used in Poland and Norway for postgraduate study and then transferred to other EU countries.

For the distance learning courses, created in the NORW project, the It's Learning platform located at NTNU will be used. General website of the platform is shown at the figure 6.

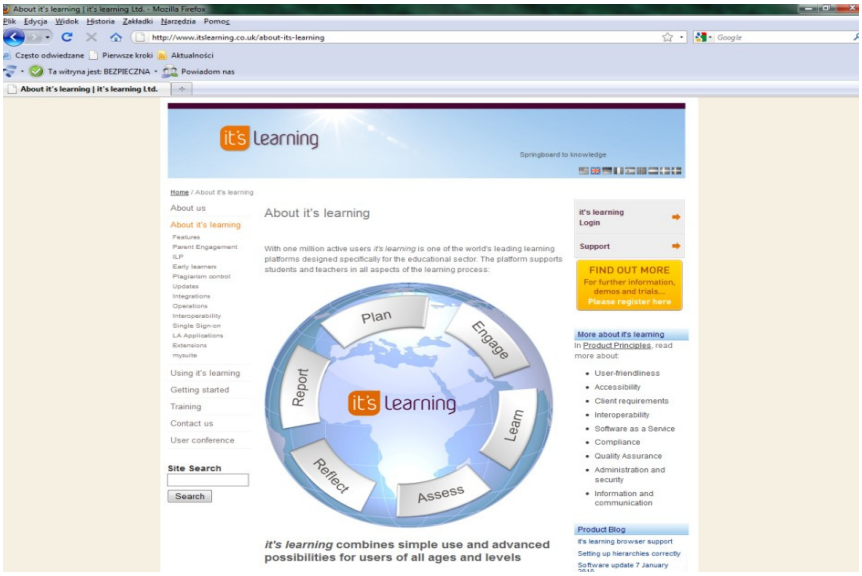

Figure 6: *Main It's Learning website screenshot [5].*

Main content – related assumptions of the NORW project's courses

Economy and Financial Management in Construction Course

The process of decision making is not an individual but iteration process, conducted from general to detailed approach in three stages of preparatory procedure:

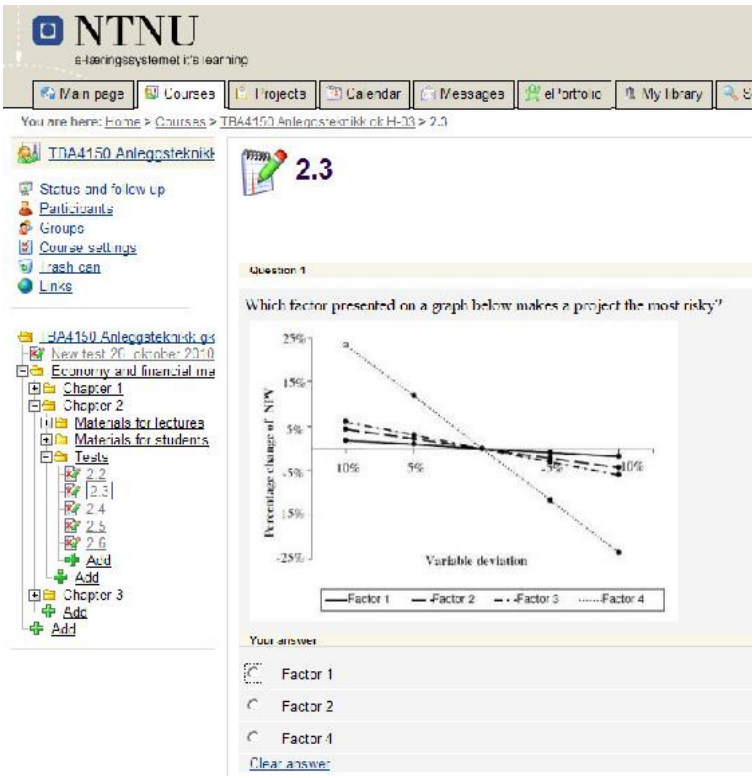
- opportunity study,
- pre-feasibility study,
- feasibility study.

All three stages employ, to a larger or smaller extent, methods and analyses which were presented in the first manual converted into distance learning mode of study. The manual "Economy and Financial Management in Construction" consist of the following elements [6]:

- the basic method is the method of determining the present net value (NPV). It is based on discounting cash flows from the future periods to the present period. Discount rate has to be usually at least equal to the percentage rate of the capitals in banks increased by appropriate percentage rates connected with inflation and applicable risk. Percentage rate where the NPV value is equal to zero is called the boundary internal rate of return (IRR). Obviously while making investment decisions various scenarios should be taken into account (optimistic, neutral, pessimistic) in order to gain attitude towards the project's behavior in various economic situations. In these scenarios it should be specified which of the factors for analysis of cash flows have the biggest influence on the final result of the NPV value.
- capital asset pricing method (CAPM) - determining discount rates, trends concerning rates of return from other projects and the will to bear risk by potential investors should be taken into account. All such research may be conducted including the strategy of games and the risk, which means establishment of a large group of operation research methods and probability-static methods.
- the unique application of the Fuzzy Theory for the analysis of NPV method value is emphasized.

- financing methods of investment projects and methods of organization structure selection for management of investments, especially covering the structures useful for launching projects in the public private partnership (PPP) are also analyzed.
- the basic principles of Value Management Method are presented. The Value and Risk Management method (V-RM) may also analyze risks and related probability of achieving the expected advantages.

For all the issues presented above – set of over hundred different exercises were created. Example of such an exercise from NTNU It's Learning platform is shown on fig. 7.



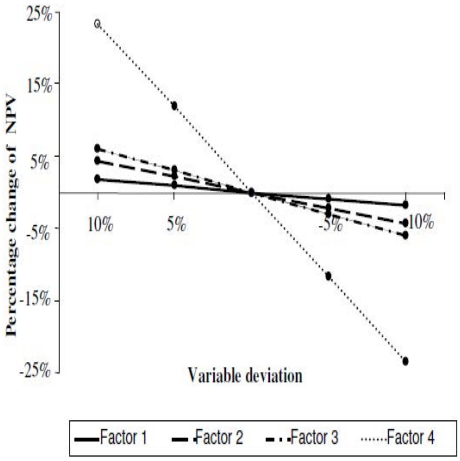


Figure 7: *Example of the "financial" exercise on It's Learning NORW Platform – screenshot from the prepared course.*

Example of the exercise "sensitivity analysis" is presented below.

> "SENSITIVITY ANALYSIS - Introduction - Sensitivity analysis is an analytical method indicating how NPV and IRR change together with modification of a single variable and other factors remaining unchanged. The starting point for this analysis is the basic presented during lectures. Then a few or more than ten variants of calculations are conducted. Each time the same variable is changed by the same percentage below and over the expected value, for example –10%, –5%, +5%, +10%. The other factors remain unchanged. Therefore it is possible to answer the question what would happen to a given project if the variable assumed in the analysis was different. Thanks to the sensitivity analysis by single changes new NPV values are obtained. Then charts picturing dependence of NPV on the changed factors are prepared, which enables obtaining sensitivity curves. Inclination of the curves shows how a given project is sensitive for the course of a given variable. The

bigger is the NPV curve inclination, the more a given project is sensitive to the analyzed factor. A project with a bigger curve inclination is considered more risky. After presenting all sensitivity curves on one chart it is possible to assess which data is the most sensitive and should be estimated in the most detailed and probable way at the stage of budgeting the investment. Try to answer the question below:
Which factor presented on a graph below makes a project the most risky?

a) Factor 1,
b) Factor 2,
c) Factor 4.

Figure 8: *Exercise on the sensitivity analysis [3].*

Solution
Factor 4 has a bigger curve inclination, therefore it makes a project the most risky. Answer c) is correct."

Construction Management Course
The manual "Construction Management" consist of the following elements [7]:

- chapter 2 introduces the construction industry in general. The chapter also gives data on construction in the European Union and presents the construction company, including some of their traditional organisational hierarchies, and the link between the firm and the construction site.
- chapters 3 and 4 examine the contractual documents and the different agents that appear in the construction phase. Documents of the design project and tendering documentation are analysed. Chapter 4 introduces other interesting issues such as communications, decision making and negotiation.
- chapter 5 analyses information flow, documentation and record keeping. It develops mainly the daily logs, the reports, the diary and the meetings.
- next chapters explain basic issues related to the execution of works, such as: machinery and equipment (6), productivity and performance (7), site setup and planning (8) and technology and quality (9). Chapter 6 takes into consideration the selection of machinery, the calculation of its cost and, finally, the machinery maintenance. Chapter 7 presents the study of works, techniques of work measurement, equipment performance and productivity assessment; two fresh concepts are also introduced: value engineering and

benchmarking. Chapter 8 considers constrains of the site and the equipment, storage of materials, temporary facilities, jobsite offices and jobsite security. Finally, chapter 9 summarises construction processes and procedures in building and civil works, and it explores the temporary works, innovation and quality management at the construction site.

- chapter 10 is focused on health and safety in the construction site. Taking into account the European Union directives, the general principles of prevention and the involved agents and their duties are explained. Site specific safety plans and incidents during the execution of works are also considered.
- chapter 11 shows the environmental management at the construction site; the issue of sustainability is also explained. Chapter 12 analyses supply chain management in construction, introducing the issue of lean construction.
- chapter 13 describes resources management, investigating the scope of activities, the assignment of resources to activities, their sequence, duration and monitoring. It develops the bar and network diagrams, cost of resources and cost control.
- chapter 14 considers changes and claims during the construction phase.
- chapter 15 focuses on progress payment procedures.
- chapter 16 describes the closeout process of the construction works and also the construction contract. It analyses the testing and commissioning procedures, handover and occupation. It introduces the operation and maintenance manual and the as-built documents.

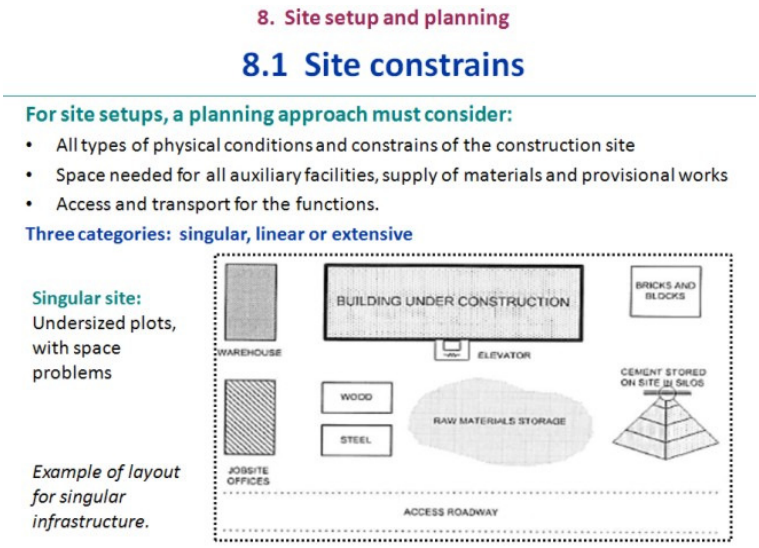

Figure 9: *Example of the exercise on It's Learning NORW Platform – Construction Management Course.*

For all the chapters presented above, as for the previous course - set of different exercises were created, for example - the exercises connected with design of different building site layouts for different types and sizes of the construction project. Example of the exercise is presented on figure 9 (exercises for Chapter 8: "Site setup and planning", subchapter 8.1: "Site constraints").

SUMMARY

Results of both projects presented above should significantly improve education system of construction industry personnel. NORW project will allow to take a part in the postgraduate

study in construction project management for those engineers, who are very busy at infrastructure construction project, having no time to gain their knowledge via stationary, face to face courses. E-learning will allow them distance learning mode of study – from home or from the site office. Results of the MAIN.CON project will improve daily work of construction machines operators. Transport works (including earth moved with excavation preparation) in construction are important element of building process, for example for 1 m2 of apartment there is a need for transport of 1800 – 2400 kg of materials and elements. (depends on the technology and materials). [1]. Better maintenance of the construction machinery will significantly improve work capacity. Training provide with augmented reality system will decrease costs of construction machinery maintenance courses for operators.

ACKNOWLEDGEMENTS

Author would like to express his sincere thanks to Warsaw University of Technology, Civil Engineering Faculty, Poland, Norwegian University of Science and Technology and SINTEF from Norway for help in preparation of FSS project and to promoter of MAIN.CON project: Fundacion Laboral de la Construction, Spain.

Abstract
The analysis proposed is aimed at a detailed risk review for a given project at the stage of value engineering of the integrated value and risk management. On the basis of the cost estimate and the time schedule established, for individual groups of works, the cost or time deviations for each task are specified. Expert knowledge is used for this purpose. In order to transform the input information, it is necessary to introduce fuzzy modeling, which includes fuzzification, inference and defuzzification processes. The procedure proposed allows for automatic determination of optimistic and pessimistic project scenarios with regard to both time and cost, using simple math operators like the arithmetic average and the center of mass. In this way, we obtain the quantified risks associated with time and cost of the project, which allows for comparison of several technologies for implementation of the same project and selection of the most optimum variant.

Keywords: risk, analysis, project management, construction, fuzzy sets

INTRODUCTION

A key stage of every construction project is its implementation, or the moment of creation of the facility. This is associated with selection of the contractor, technology of performance of works, the implementation cycle. All of these aspects influence to a specific extent the two key project parameters, which are the cost and deadline of implementation.

In the article, we present the method of introducing the risk associated with a given investment at the implementation stage, using the experience and knowledge of independent experts. We used the fuzzy set theory as a tool. Fuzzy set can be presented as a set of pairs, which assigns to each element in space a degree of membership: from non-membership, through partial membership, to full membership [1]. Thus, we can see that apart from the alternative "membership – non-membership", typical for a conventional set, there are cases of partial membership here. The fuzzy set theory is a theory of classes, in which going from membership to non-membership is not incremental, like in a conventional set, but graded.

In order to transform the input information, we used fuzzy modeling, which includes fuzzification - presentation of input data (information) in form of fuzzy sets, inference- transforming several input functions into a resulting function and defuzzification- obtaining of an acute value, which reflects a given fuzzy set.

This approach towards the investment project implementation allows the investor or the general contractor to obtain knowledge on the potential changes in the time and cost of implementation.

DESCRIPTION OF THE METHOD

The example used involved the following project. The facility under concern is an apartment building, and the estimated construction cost is PLN 28 346 000. The entire project consists of seventeen groups of works, such as preparatory works, earthworks etc. Specific costs, determined by the author of the cost estimate, are associated with each group of works. These have been presented in table 1.

No.	Name	Costs
	APARTMENT BUILDING	28 346 000
1	Preparatory, background works	450 000
2	Earthworks	1 640 000
3	Raw state – underground level	2 250 000
4	Raw state – above ground part	5 300 000
5	Brickworks – external walls	950 000
6	Brickworks – internal walls	825 000
7	Roof insulation	1 320 000
8	Windows	3 120 000
9	External plaster + heat insulation	1 950 000
10	Wall lining – clinker brick	823 000
11	Interior finishing works	4 220 000
12	Passenger elevators	758 000
13	Power supply and low current installations	1 800 000
14	Sanitary installations	1 350 000
15	Building service lines	260 000
16	External works	1 150 000
17	Preparation of the facility for final acceptance	180 000

Table 1: *A tabular breakdown of costs for individual groups of works.*

The groups of works presented in table 1 constitute the time schedule of the project planned. Presented below is the Gantt chart for the project examined. The schedule below presents the planned time of implementation of individual tasks, defining the correlations between them. Apart from the sixteen groups of works, presented in table 1, the schedule includes some control points and activities that do not generate costs directly. For the needs of the method presented, we focused on analysis of deviations, associated with seventeen groups of works specified in table 1. Nevertheless, the total time of implementation of the investment is a result of twenty three tasks included in the schedule.

No.	Task name	Cz. trw.
1	APARTMENT BUILDING	488 d
2	Takeover of site	0 d
3	Preparatory, background works	35 d
4	Earthworks	104 d
5	Raw state - underground level	74 d
6	Raw state - above ground	118 d
7	Brickworks - external walls	140 d
8	Brickworks - internal walls	130 d
9	Roof insulation	77 d
10	Windows	118 d
11	External plaster + heat insulation	120 d
12	Elevation wall lining	101 d
13	Deadline for residential changes	0 d
14	Finishing interior works	253 d
15	Passenger elevators	93 d
16	Power supply and low current installations	323 d
17	Sanitary installations	366 d
18	Building service lines	140 d
19	External works	114 d
20	Preparation for final acceptance	26 d
21	End of works, filing of application for a certificate of occupancy	1 d
22	Acceptance by the Acceptance Commission	12 d
23	Obtaining of the binding permission for occupancy	1 d

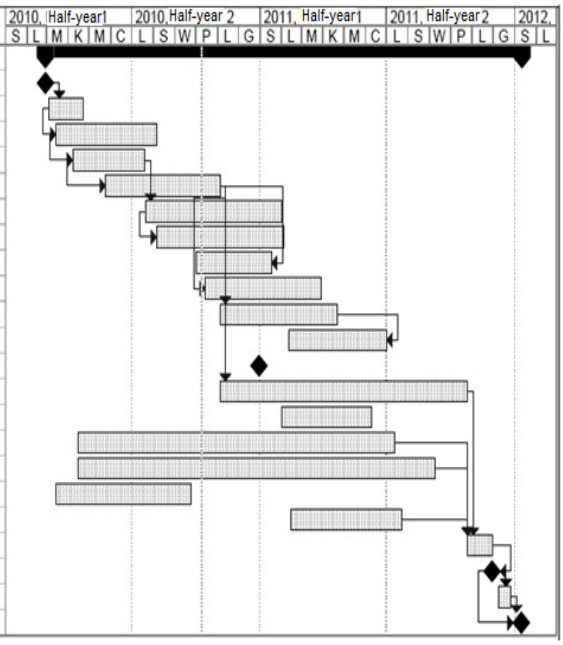

Figure 1: *Gantt chart for the project planned.*

During implementation of the project, there are various deviations from the cost or time planned. The objective of this article is to present a method of determining these prior to commencement of the project. It was assumed that information in this regard would be presented by Experts in form of 3 answers to the following questions:

What is the most probable cost/time value for task „x" and its probability (level of membership)?
What is the minimum cost/time value for task „x" and its probability (level of membership)?
What is the maximum cost/time value for task „x" and its probability (level of membership)?

For the needs of analysis, it was assumed that knowledge on deviations was obtained from 3 independent experts, using the issues associated with fuzzy modeling. At the same time, it was assumed that the probability of occurrence of deviation would be expressed as the so-called membership level. In fuzzy modeling (inference), three stages of the operating block can be distinguished: fuzzification, inference – creation of the resulting membership function, defuzzification – sharpening of the fuzzy set. The diagram has been presented in figure 2.

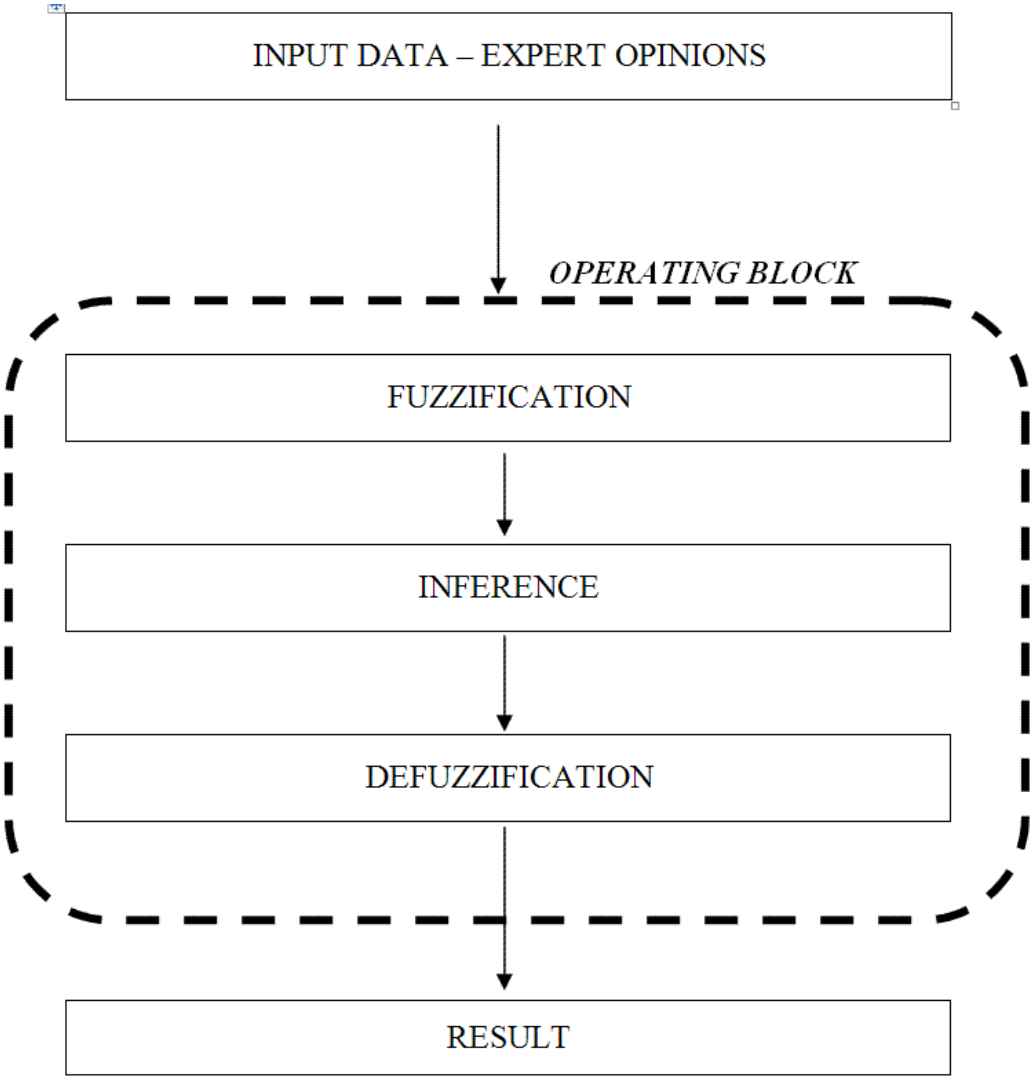

Figure 2: *A fuzzy model diagram.*

The input model data consists of answers to three questions from three experts. The first stage of the operating block is fuzzification. It is based on presentation of input data (information) in form of fuzzy sets. For the needs of this study, it was assumed that the input function of membership of the fuzzy set has the form of a linear piecewise function. The space of sets corresponding with one task of the investment has been presented below:

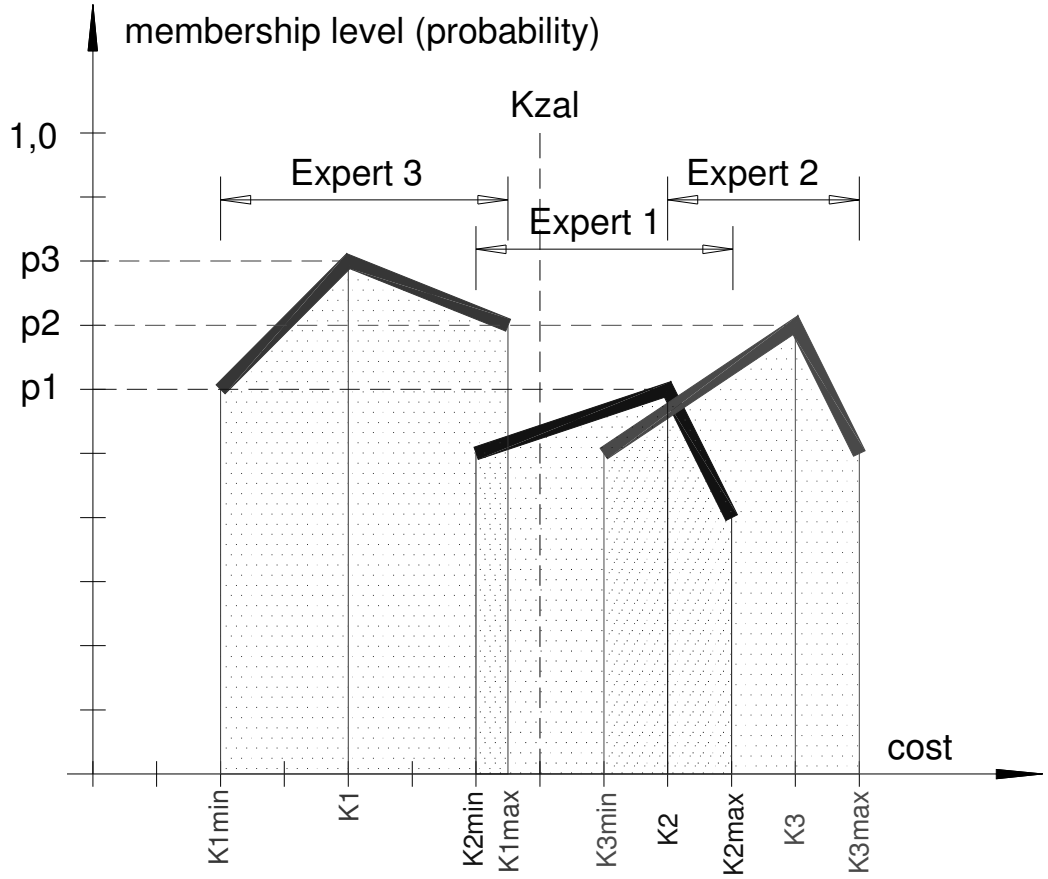

Figure 3: *Representation of input information (expert opinions) in form of fuzzy sets*

Each of the three experts has presented the most probable cost (K1, K2, K3) and its probability (p1, p2, p3). Apart from this, the experts gave answers concerning the extreme values, that is (K1min, K2min, K3min, K1max, K2max, K3max) and the corresponding probability values (p1min, p2min, p3min, p1max, p2max, p3max). As it has been mentioned, the probability of emergence of a specific cost was expressed by the membership level. The chart also shows the Kzal, or the assumed cost. Analogically, the fuzzification process was conducted for the time of implementation of each group of works. This representation of expert knowledge presents three fuzzy sets, in which the central point is the most probable value, and the extreme values are, accordingly, the acceptable minimum and maximum values. Figure 3 depicts the fuzzy representation of input information for only one task (group of works), e.g. the preparatory/ background works. In table 2, input data on cost deviations for all investment tasks can be found.

Table 2: *A breakdown of input cost data for all investment tasks.*

In the fuzzy sets theory, Figure 3 simply presents 3 fuzzy sets. This is input information. For further use of the knowledge of 3 experts, information presented by them was consolidated to one set representing the cost (time) deviations for a given task. In other words, the so-called resulting membership function was presented. The process transforming several input functions into a resulting function in fuzzy modeling is known as inference. There are many operators used to determine the resulting membership function. In this article, we used the arithmetic average operator. The value of the resulting membership function is equal to the average level of membership of each input set, which can be recorded according to following formula:

$$f_{wynik}(k) = \frac{\sum_{i=1}^{n} f_i(k)}{n},$$

where:

$f_{wynik}(k)$ – the resulting membership function (function determining the probability of occurrence of events),

k – function argument – cost or time

n – number of experts (number of fuzzy sets), n=3,

i=1, 2, …, n.

Upon the assumptions made, the formula can be recorded as follows:

$$f_{wynik}(k) = \frac{f_{EKS1}(k) + f_{EKS2}(k) + f_{EKS3}(k)}{3},$$

where:

$f_{EKS1}(k)$ – membership function determined on the basis of data from expert 1,

$f_{EKS2}(k)$ – membership function determined on the basis of data from expert 2,

$f_{EKS3}(k)$ – membership function determined on the basis of data from expert 3.

Using the MS-Excel spreadsheet, the resulting function was established for each investment task, presenting the potential risk information.

Figures 4 and 5 below present the operation of inference, using as an example the first group of works in the project or „Preparatory, background works”

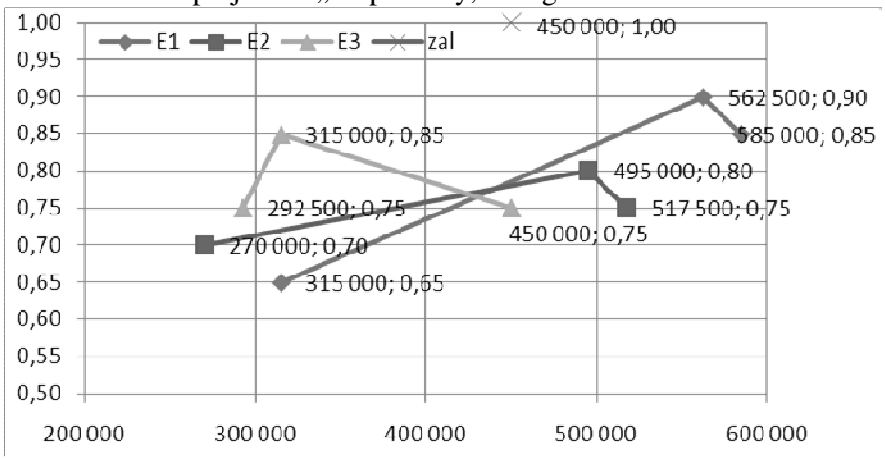

Figure 4: *Input functions – opinions of three Experts concerning risk for the task „Preparatory, background works”.*

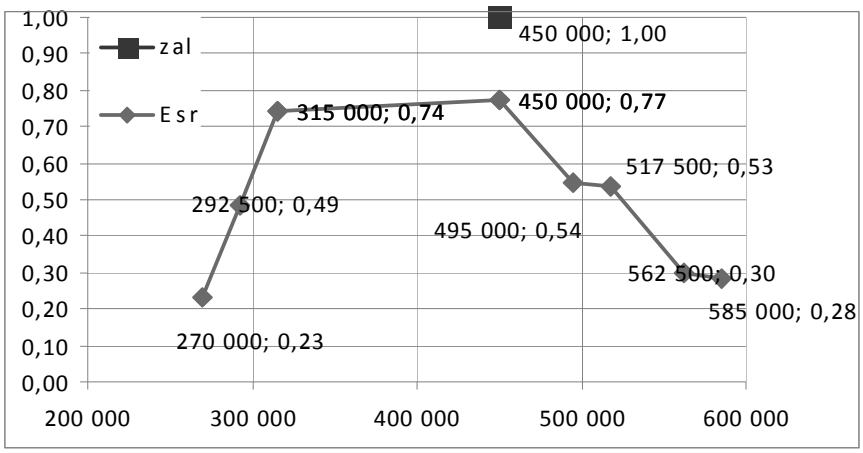

Figure 5: *Resulting risk function for task „Preparatory, background works".*

The defuzzification process leads to obtaining of an acute value, which reflects a given fuzzy set. Having the resulting function of the expert opinion, we established two points, dividing the set of results into the optimistic and pessimistic part. These points were established using the center of mass method. The acute value was calculated on the basis of following formula:

$$k_{wyn} = \frac{\int k \cdot u_{wyn}(k)dk}{\int u_{wyn}(k)dk},$$

where:

k_{wyn} – the acute costs value (input value),

$u_{wyn}(k)$ – the resulting membership function,

k – the cost (argument) of the membership function.

In the presented case, the resulting membership function is in form of a broken line. The center of mass of the broken line, e.g. ABCD, was determined by replacing each line section with a material point, placed in the middle of the section, of the mass equal to the section length [2]. The coordinates of the center of mass of the broken ABCD were determined on the basis of following formulas. According to Figure 6 symbols d_1, d_2, d_3 represent lengths of sections AB, BC, CD, and $S_1(k_1,u_1)$, $S_2(k_2,u_2)$, $S_3(k_3,u_3)$ are centers of these sections.

$$k_0 = \frac{d_1k_1 + d_2k_2 + d_1k_3}{d_1 + d_2 + d_3},$$

$$u_0 = \frac{d_1u_1 + d_2u_2 + d_1u_3}{d_1 + d_2 + d_3}.$$

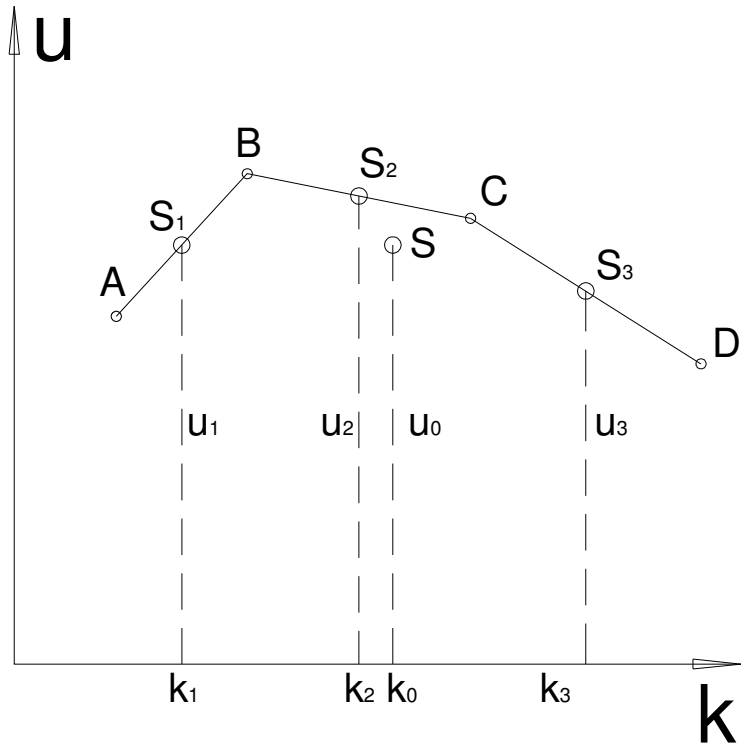

Figure 6: *Graphic representation of determination of the center of mass of a broken line.*

On the basis of the above formulas and using the Excel spreadsheet, for each group of works, optimistic and pessimistic centers of mass were established. For the first group of costs, the "Preparatory, background works", were presented in Figure 7.

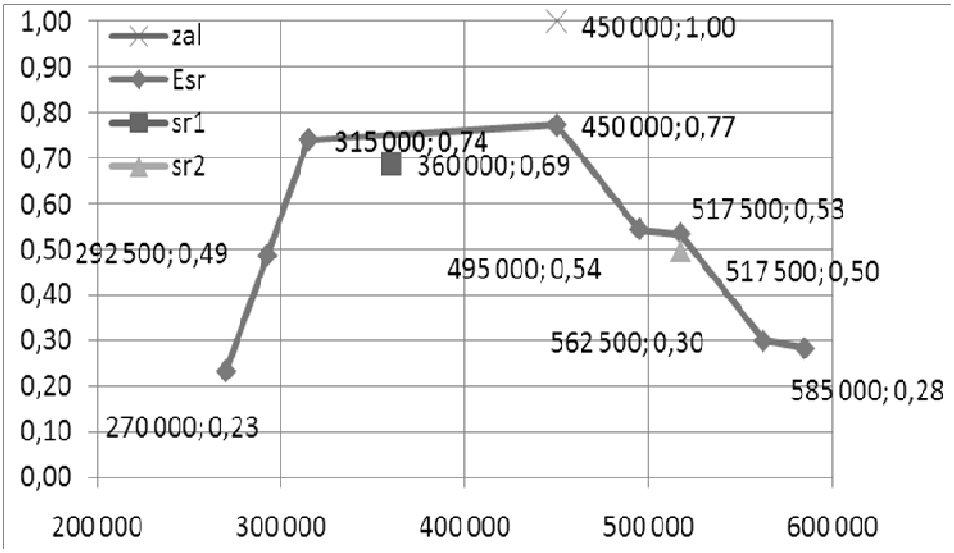

Figure 7: *Graphic representation of establishing of the center of mass for the first group of costs of „Preparatory, background works".*

The same operations, that is, fuzzification, inference, defuzzification were conducted for all groups of investment costs. The results obtained were presented in table 3 for cost values and in table 4 for time values.

Table 4: *A breakdown of pessimistic and optimistic time values with probability.*

In the analysis presented, the measure of risk applied was the ratio of the value of deviation to its probability. Thanks to the above analysis of each investment task, it is possible to establish the summarized deviations associated with the entire project. Figures 8 and 9 present the resulting estimated, pessimistic and optimistic values of cost and time. They were based on aggregation of individual values for investment tasks, using the MS-Project software to create 3 scenarios of the task implementation: optimistic, estimated and pessimistic. The resulting probability of summarized values has been established as a weighted average.

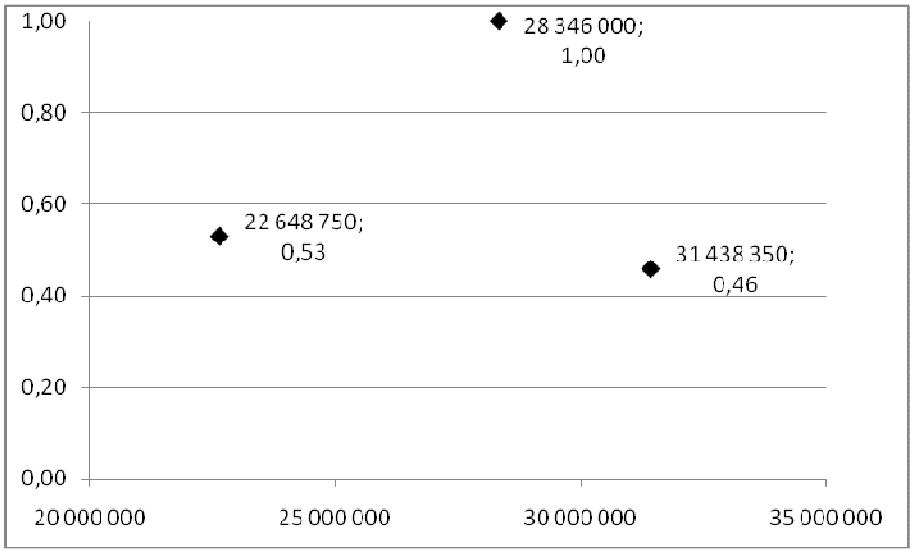

Figure 8: *Graphic representation of risk for the investment cost*

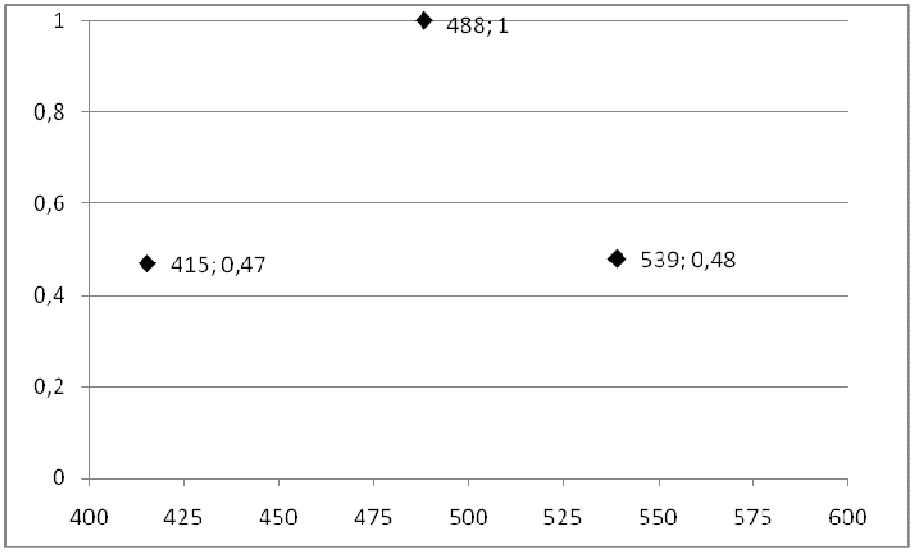

Figure 9: *Graphic representation of risk for the investment time.*

Thanks to this representation of the cost and time of implementation, the general project risk, as function of probability and deviation value was determined on the basis of following formulas:

$$R_k^{pes} = \frac{\left(K_{pes} - K_{zal}\right)/K_{zal}}{1 - p_{pes}} = \frac{\left(31438000 - 28346000\right)/28346000}{1 - 0{,}46} = 0{,}202$$

$$R_k^{opt} = \frac{\left(K_{zal} - K_{opt}\right)/K_{zal}}{1 - p_{opt}} = \frac{\left(28346000 - 22648750\right)/28346000}{1 - 0{,}53} = 0{,}428$$

On the basis of the same formulas and according to figure 9 it is possible to determine risk values for the investment time.

CONCLUSIONS

The method presented provides the general contractor or the investor with knowledge on the potential deviations, cost and time associated risks. This method uses expert knowledge associated with individual stages of works, which are very diversified. Expert knowledge has been used separately for each stage, at the same time obtaining the risk associated with the entire project.

On the basis of quantification of risk, investor or contractor obtain the possibility of responding quickly to unexpected scenarios. Thanks to this analysis, commencing the investment, they are aware of the potential threats associated with a failure to meet the deadline or exceeding of the budget planned. Moreover it is possible to compare several possible projects on the basis of cost and time deviation and its probabilities.

The analysis proposed makes it possible to control the project further during its implementation. It is possible to use the data obtained to control the project e.g. using the

earned value method [3]. Thanks to time and cost analysis, at the level of individual tasks, it was possible to determine cash flows in the time function for different variants.

In this way, at any time during the project life cycle, the investor or the general contractor is able to determine whether the threshold values of the earned value method indicators have not been exceeded. At the same time, at the stage preceding decision-making, the investor is able to determine the possible risk (variance) of the assumed implementation cost or time.

Having the knowledge on the time and cost variances so far, the general contractor will find it easier to plan the financing of the project, without exposing the project to additional problems, associated with delayed payments.

THE PROCEDURE ALGORITHM – A BLOCK DIAGRAM

Presented below are the general rules of the procedure in form of a block diagram.

CONSTRUCTION PROJECT SCHEDULING WITH IMPRECISELY DEFINED CONSTRAINTS

JANUSZ KULEJEWSKI

Abstract
This paper regards to the scheduling of a construction project under ill-defined constraints of time and resources for the execution of works. Fuzzy numbers are used for modelling the imprecision of constraints. Two methods of the measurement of fuzzy constraints satisfaction are presented. The first method uses the possibility measures based strictly on the assumptions of the fuzzy sets theory. The second method uses the measure based upon the concept of the α-cuts of a fuzzy number and the probability theory. The numerical examples are given for the comparison of both methods. The results confirm that the use of the probabilistic measure provides the neutralization of the assessment of the fuzzy constraints meeting and improves the construction schedule.

Keywords: construction schedule, imprecision, possibility measure, probability measure.

INTRODUCTION

The planning data used in the scheduling of construction projects are often imprecisely defined with regard to the required project completion time and the availability of renewable resources (key personnel and construction equipment) required for the project execution. This is caused by the various circumstances, e.g.:

- the uniqueness of the any given construction project makes it difficult or even impossible to use the statistical methods for the assessment of the project makespan;
- the acquisition of contracts in the tendering procedure does not allow for the precise planning of the owned renewable resources distribution to the individual projects;
- conditions of contract provide for a time interval between the completion time preferred by the client (due-to date) and the completion time required by the client under the penalty of the contract termination of contractor's fault (deadline); the existence of such a time interval allows the contractor for the flexible planning of the sufficient time for the completion of the works.

As a result, the planning data for the planner are often defined imprecisely [3], with the use of a natural language, e.g.: "*about two weeks*", "*about two to three weeks*," "*a little over two weeks*", "*about fifteen to twenty workers*" and alike [14]. In the literature dealing with the problems of project scheduling on the basis of imprecisely defined planning data, there is a common approach to use the fuzzy sets theory for modelling the imprecision of project data, in conjunction with the various schedule optimization methods, as for example the branch-and-bound method, e.g. [16], priority heuristics, e.g. [4], [15], [18] and metaheuristic methods, e.g. [5], [11], [15], [18]. However, the most of the literature under

consideration take into account only the imprecision of durations of works and the imprecision of time available for the execution of works. The availability of any renewable resource is treated as well-known, which in the case of a real construction project rarely holds true. The assessment of the fulfilment of imprecisely defined time constraints is done with the use of possibility measure for the comparison of two fuzzy numbers or the real number and the fuzzy number, one representing the planned project makespan and the other representing the project makespan limit. The comparison is done with the Hurwicz criterion, e.g. [8], [17], [18] and the result is highly affected by the specific risk attitude of the assessor. In result, two or more persons may express different opinions about the degree of meeting the fuzzy limit of the project makespan.

In this paper, the principles of the fuzzy modelling of imprecisely defined planning constraints and the principles of the assessment of the fuzzy constraints satisfaction are presented. The problem of the neutralisation of the assessment of meeting the fuzzy time and resource constraints is resolved with the use of the α-cuts of a fuzzy number and the probability theory. The paper also presents a numerical example showing the advantages of the use of probability measure for the optimization of the construction schedule with regard to the imprecisely defined time and resource constraints.

THE MODELING OF THE PROJECT CONSTRAINTS USING FUZZY SETS

To model the imprecision of the availability of the *k*-th resource, a planner can use a trapezoidal fuzzy number $\tilde{R}_k$ in the form of the ordered four $\tilde{R}_k = (r_k^{(1)},\ r_k^{(2)},\ r_k^{(3)},\ r_k^{(4)})$, where real numbers $r_k^{(i)}$ (i = 1, …, 4) should satisfy the condition: $0 \le r_k^{(1)} \le r_k^{(2)} \le r_k^{(3)} \le r_k^{(4)}$. Fig. 1 shows an example of a trapezoidal fuzzy number modelling imprecisely defined resource constraints, expressed as "*from about* $r_k^{(2)}$ *to about* $r_k^{(3)}$, *but not less than* $r_k^{(1)}$ *and not more than* $r_k^{(4)}$".

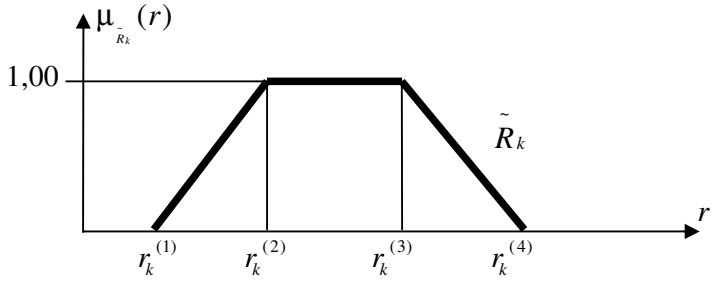

Figure 1: *An example of using a trapezoidal fuzzy number for modelling the imprecisely defined availability of the renewable resource constraints. Source: Own*

In the more specific case, a planner is able to narrow the area of imprecision and to express his opinion about resource constraints as "*about* $r_k^{(2)}$, *but not less than* $r_k^{(1)}$ *and not more than* $r_k^{(3)}$". To express this imprecision mathematically, a planner can use a triangular

fuzzy number $\tilde{R}_k$ in the form of the ordered three $\tilde{R}_k = (r_k^{(1)},\ r_k^{(2)},\ r_k^{(3)})$ or a trapezoidal fuzzy number $\tilde{R}_k$ in the form of the ordered four $\tilde{R}_k = (r_k^{(1)},\ r_k^{(2)},\ r_k^{(2)},\ r_k^{(3)})$.

Similarly, to model the imprecision of the project makespan limitation one can use a trapezoidal fuzzy number $\tilde{T}_d = (t_d^{(1)},\ t_d^{(2)},\ t_d^{(3)},\ t_d^{(4)})$, where real numbers $t_d^{(i)}$ (i=1, …, 4) satisfy the condition: $0 \le t_d^{(1)} \le t_d^{(2)} \le t_d^{(3)} \le t_d^{(4)}$. One can determine the components of this ordered four, assuming for example:

- as the real number $t_d^{(1)}$: the shortest feasible project makespan, determined as the result of the network model analysis without the renewable resource availability constraints;
- as the real number $t_d^{(2)}$: the lower limit of the project makespan, evaluated by the scheduler as having the greatest chance under the given circumstances;
- as the real number $t_d^{(3)}$: the upper limit of the project makespan, evaluated by the planner as having the greatest chance under the given circumstances;
- as the real number $t_d^{(4)}$: the project completion time required by the client.

ASSESSMENT OF THE PROJECT FUZZY CONSTRAINTS SATISFACTION

Application of the possibility measures

If the maximum consumption of the *k*-th renewable resource must not exceed the imprecisely defined resource availability limitation, the schedule must satisfy the following relation:

$$r_k^{\max} \le \tilde{R}_k \qquad (1)$$

The satisfaction of the relation (1) means that the maximum consumption of the *k*-th renewable resource, expressed by the real number $r_k^{\max}$, should not exceed the limit, which is the unknown (yet) output of the fuzzy number $\tilde{R}_k$.
Similarly, if the works must be completed within the imprecisely prescribed time period, the schedule must satisfy the following relation:

$$t \le \tilde{T}_d . \qquad (2)$$

The satisfaction of the relation (2) means that the planned project makespan expressed by the real number *t*, will not be longer than the time limit, which is the unknown (yet) output of the fuzzy number $\tilde{T}_d$.

Using the theory of possibility [1], one should assess the degree of fulfilment of the relation $r_k^{\max} \le \tilde{R}_k$ and evaluate of the veracity of the statement: "*the real number* $r_k^{\max}$ *will not be greater than the unknown* (*yet*) *output of the fuzzy number* $\tilde{R}_k$" using the necessity measure $\mathrm{N}(r_k^{\max} \le \tilde{R}_k)$ and the possibility measure $\Pi(r_k^{\max} \le \tilde{R}_k)$. The necessity measure is used to assess how much the occurrence of the relation $r_k^{\max} \le \tilde{R}_k$ is obvious throughout the

state of the knowledge of the planner of the circumstances which are limiting the availability of the *k*-th renewable resource. The possibility measure is used to assess how much the occurrence of the relation $r_k^{\max} \le \tilde{R}_k$ remains in compliance with the state of knowledge of the planner of the circumstances which are limiting the availability of the *k*-th renewable resource. According to [1] and [8], the appropriate formulas are as follows:

$$\Pi(r_k^{\max} \le \tilde{R}_k) = \sup_{r \ge r_k^{\max}} \mu_{\tilde{R}_k}(r), \tag{3}$$

$$\Pi(r_k^{\max} \ge \tilde{R}_k) = \sup_{r \le r_k^{\max}} \mu_{\tilde{R}_k}(r), \tag{4}$$

$$\mathrm{N}(r_k^{\max} \le \tilde{R}_k) = 1 - \Pi(r_k^{\max} \ge \tilde{R}_k), \tag{5}$$

where $\mu_{\tilde{R}_k}(r)$ is the membership coefficient of the fuzzy set $\tilde{R}_k$.

It should be noted that the possibility measure $\Pi(r_k^{\max} \le \tilde{R}_k)$ does not have the property of complementarity, i.e. $\Pi(r_k^{\max} \le \tilde{R}_k)$ does not have to be equal to $1 - \Pi(r_k^{\max} \ge \tilde{R}_k)$.

Using the necessity measure and the possibility measure for assessing the credibility of the statements given above, one should consider the cases shown in Fig. 2.

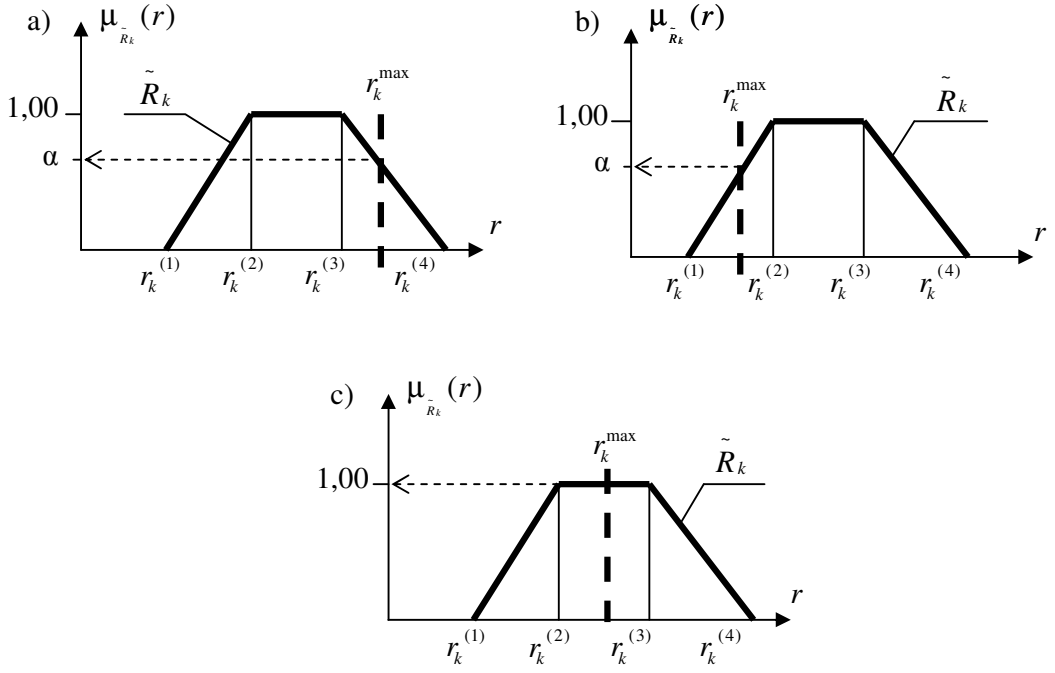

Figure 2: *The alternative schemes of relations between the fuzzy number* $\tilde{R}_k$ *and the real number* $r_k^{\max}$. *Source: Own*

On the basis of the formulas (3), (4) and (5), one can conclude that:

1) For the case shown in Fig. 2a: $\Pi(r_k^{\max} \le \tilde{R}_k) = \alpha$, $N(r_k^{\max} \le \tilde{R}_k) = 0$; the evaluated statement may be true to a degree of α, but the obvious truth of this statement is zero;

2) For the case shown in Fig. 2b: $\Pi(r_k^{\max} \le \tilde{R}_k) = 1$, $N(r_k^{\max} \le \tilde{R}_k) = 1 - \alpha$; the evaluated statement is possibly true, but the obvious truth of this statement is $1 - \alpha$,

3) For the case shown in Fig. 2c: $\Pi(r_k^{\max} \le \tilde{R}_k) = 1$, $N(r_k^{\max} \le \tilde{R}_k) = 0$; the evaluated statement is possibly true, but the obvious truth of this statement is zero.

The meaning of the assessment presented above may be sometimes difficult to understand for the planner. Therefore, for the assessment of the degree of fulfilment of the relation $r_k^{\max} \le \tilde{R}_k$, there is a sought after the synthetic measure (marked here as ST), having – in line with the intuition of the planner – the property of complementarity:

$$\mathrm{ST}(r_k^{\max} \le \tilde{R}_k) = 1 - \mathrm{ST}(r_k^{\max} \ge \tilde{R}_k). \tag{6}$$

Using the approach shown in [4], [17] and [18], one can implement the Hurwicz criterion for the assessment of the degree of domination of the fuzzy number $\tilde{R}_k$ over the real number $r_k^{\max}$:

$$\mathrm{ST}(r_k^{\max} \le \tilde{R}_k) = \beta\,\Pi(r_k^{\max} \le \tilde{R}_k) + (1-\beta)\,N(r_k^{\max} \le \tilde{R}_k), \tag{7}$$

where $\beta \in (0.0;\ 1.0)$ is the *coefficient of optimism*, which characterizes the risk attitude of the planner. For example, assuming the neutral risk attitude of the planner ($\beta = 0.5$), one can obtain:

$$\mathrm{ST}(r_k^{\max} \le \tilde{R}_k) = \begin{cases} 1{,}0 & for\ r_k^{\max} \le r_k^{(1)}, \\ 0{,}5 + 0{,}5(1-\alpha) & for\ r_k^{(1)} \le r_k^{\max} \le r_k^{(2)}, \\ 0{,}5 & for\ r_k^{(2)} \le r_k^{\max} \le r_k^{(3)}, \\ 0{,}5\alpha & for\ r_k^{(3)} \le r_k^{\max} \le r_k^{(4)}, \\ 0{,}0 & for\ r_k^{\max} \ge r_k^{(4)}. \end{cases} \tag{8}$$

In a similar way one can assess the degree of fulfilment of the relation $t \le \tilde{T}_d$.

As can be seen from the formula (7), the result of the assessment of the degree of fulfilment of the relations $r_k^{\max} \le \tilde{R}_k$ and $t \le \tilde{T}_d$ strongly depends on the value of coefficient β, which characterizes the risk attitude of the planner.

Application of the probabilistic measure

It should be noted, after [2], that the necessity measure and the possibility measure determinate the lower bound and the upper bound of the probability:

$$N(r_k^{\max} \le \tilde{R}_k) \le P(r_k^{\max} \le \tilde{R}_k) \le \Pi(r_k^{\max} \le \tilde{R}_k), \tag{9}$$

$$N(t \le \tilde{T}_d) \le P(t \le \tilde{T}_d) \le \Pi(t \le \tilde{T}_d). \tag{10}$$

This arises the question whether it is feasible to neutralize the assessment of the fulfilment of relations $r_k^{\max} \le \tilde{R}_k$ and $t \le \tilde{T}_d$, through the direct use of the probabilistic measure. The resulting problem can be described as follows:

– there are two numbers given: (1) a real number *m*, representing the maximum consumption of some renewable resource or the planned project makespan, and (2) a fuzzy number $\tilde{N}$, modelling the limit of resource availability or the limit of the project makespan;

– assess the probability $\mathrm{P}(m \le \tilde{N})$ that a real number *m*, resulting from the construction project schedule, will be not greater than the unknown (yet) output of a fuzzy number $\tilde{N}$.

The idea of the assessment of the probability $\mathrm{P}(m \le \tilde{N})$ presented below is based upon the use of the α-cuts of a fuzzy number $\tilde{N}$ for a finite number of levels of certainty of the imprecise estimation of the given constraint. For the any given α-cut of a fuzzy number $\tilde{N}$, an interval number $\overline{N}_{\alpha_i} = [n^{\mathrm{l}}_{\alpha_i}, n^{\mathrm{u}}_{\alpha_i}]$ is obtained. Symbol *i* is an index of a sequent α-cut. An example of an interval $\overline{N}_{\alpha_i}$ is shown in Fig. 6.3.

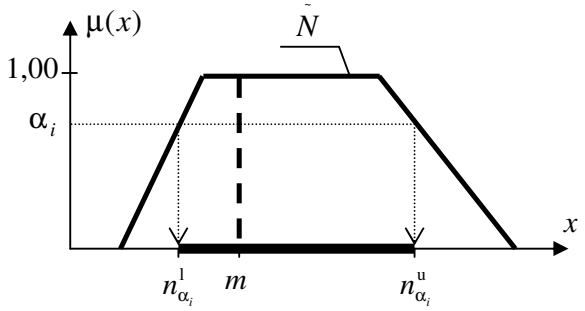

Figure 3: *An example of an interval* $\overline{N}_{\alpha_i}$ *. Source: Own.*

On the basis of Fig. 3 one can conclude that if $n^{\mathrm{l}}_{\alpha_i} < m < n^{\mathrm{u}}_{\alpha_i}$, then an interval $\overline{N}_{\alpha_i}$ is divided further into subintervals $[n^{\mathrm{l}}_{\alpha_i}, m]$ and $[m, n^{\mathrm{u}}_{\alpha_i}]$. The probability that a real number *m* will be not greater than the unknown (yet) output of an interval number $\overline{N}_{\alpha_i}$ can be determined geometrically as:

$$\mathrm{P}(m \le \overline{N}_{\alpha_i}) = \frac{n^{\mathrm{u}}_{\alpha_i} - m}{n^{\mathrm{u}}_{\alpha_i} - n^{\mathrm{l}}_{\alpha_i}}. \tag{11}$$

If $m \le n^{\mathrm{l}}_{\alpha_i}$ then $\mathrm{P}(m \le \overline{N}_{\alpha_i}) = 1$ and if $m \ge n^{\mathrm{u}}_{\alpha_i}$ then $\mathrm{P}(m \le \overline{N}_{\alpha_i}) = 0$. The aggregation of probabilities $\mathrm{P}(m \le \overline{N}_{\alpha_i})$ for the finite number of α-cuts of a number $\tilde{N}$, leads to the following formula:

$$\mathrm{P}(m \le \tilde{N}) = \frac{\sum_i \alpha_i \, \mathrm{P}(m \le \overline{N}_{\alpha_i})}{\sum_i \alpha_i}, \tag{12}$$

where $i = 1,\ldots, I$ is an index of sequent α-cut of a number $\tilde{N}$.

SCHEDULE OPTIMIZATION PROBLEMS FORMULATION

In this paper, an *activity–on–node* network model with *finish–to–start* relations between activities is adopted to represent the construction project. The start date of the project is set to zero. Only the imprecision of the schedule constraints is considered. Therefore, the formula for calculating the scheduled project makespan can be expressed as:

$$t = \max\{s_i + d_i\}, \quad i = 1, \quad 2,...,n,$$

where s_i is the start date of activity i, d_i is the duration of activity i, and n is the total number of activities.

The following two alternative optimization problems can be formulated, based upon the two alternative measures of the compliance with the fuzzy limit of the project makespan:

– find the start dates of activities so as to maximize the degree of compliance with the fuzzy limit of the project makespan:

$$\max \mathrm{ST} : \mathrm{ST} = \mathrm{ST}(t \le \tilde{T}_d), \tag{13}$$

– find the start dates of activities so as to maximize the probability of compliance with the fuzzy limit of the project makespan:

$$\max \mathrm{P} : \mathrm{P} = \mathrm{P}(t \le \tilde{T}_d), \tag{14}$$

where t is the real number, representing the planned project makespan, and $\tilde{T}_d$ is the fuzzy number, modelling the imprecisely specified constraint for the project makespan.

Taking into account the relations of type *finish–to–start* between the activities, the solution of the problem (14) or of the problem (15) must fulfil the following condition:

$$s_j \ge s_i + d_i \big| i \in \{Prec(j)\}, \tag{15}$$

where $Prec(j)$ is the set of predecessors of an activity j in the project network model.

The solution of the problem (14) or of the problem (15) must also take into account the fuzzy constraints of the renewable resources availability. The maximum consumption of the k-th resource can be determined as:

$$r_k^{\max} = \max\{\sum_{p \in \{A(\tau)\}} r_{kp\tau}\}, \tag{16}$$

where $\{A(\tau)\}$ is the set of operations executed in a time period τ, $\tau = 1,...,t$, $r_{kp\tau}$ is the consumption of the k-th renewable resource for the execution of an activity p in a time period τ, and t is the planned project makespan. According to the two alternative measures of the compliance with the fuzzy resource constraints, the planner should assess the required degree ST_{kr} of compliance with the fuzzy constraint of k-th resource availability or the required probability P_{kr} of compliance with the fuzzy constraint of k-th resource availability. This leads to the following conditions:

– for the solutions of the problem (14): the condition of meeting the required degree of compliance (ST_{kr}) with the fuzzy limit of availability of the k–th renewable resource:

$$\mathrm{ST}(r_k^{\max} < \tilde{R}_k) \ge \mathrm{ST}_{kr}, \tag{17}$$

– for the solutions of the problem (15): the condition of meeting the required probability of compliance (P_{kr}) with the fuzzy limit of availability of the *k*–th renewable resource:

$$P(r_k^{\max} < \tilde{R}_k) \geq P_{kr}. \tag{18}$$

SCHEDULE OPTIMIZATION PROBLEMS SOLVING

Despite the specific measure adopted for the assessment of the fuzzy constraints satisfaction, optimization problems presented above are the resource – constrained project scheduling problems, which belong to the class of NP-hard problems [4]. For solving such problems, the use of heuristic or metaheuristic methods is well justified. Their detailed description is omitted here. The surveys appropriate for the construction project scheduling has been done by the others, e.g. [6], [7], [9] – [13], [16]. In this paper, the considered schedule optimization problems were translated into numerical optimization problems solved with the use of Genetic Algorithm (GA). To preserve the required technological precedence relationships among activities in the project network model, the general idea was to use the GA technique to establish the additional resource relationships among some activities. Those additional relationships were based upon the selected priority rules. On the basis of the solution presented by the *m*-th chromosome, the start dates s_j of each activity were calculated using the following formula:

$$s_j(m) = \max_{i \in \{Prec(j)\}} \{s_i(m) + d_i\}. \tag{19}$$

The following fitness functions were used to assess the resulting construction schedule:

1) for the problem of maximization the degree of compliance with the fuzzy limit of the project makespan:

$$f(m) = ST(m) - \sum_{k=1}^{K} F_k, \tag{20}$$

2) for the problem of maximization the probability of compliance with the fuzzy limit of the project makespan:

$$f(m) = P(m) - \sum_{k=1}^{K} F_k, \tag{21}$$

where:

$f(m)$ – the value of fitness function for the solution presented by the *m*-th chromosome;

$ST(m)$ – the degree of compliance with the fuzzy limit of the project makespan, resulting from the schedule drawn upon the solution presented by the *m*-th chromosome:

$$ST(m) = ST(t(m) \leq \tilde{T}_d); \tag{22}$$

$P(m)$ – the probability of compliance with the fuzzy limit of the project makespan, resulting from the schedule drawn upon the solution presented by the *m*-th chromosome:

$$P(m) = P(t(m) \leq \tilde{T}_d); \tag{23}$$

$t(m)$ – the planned project makespan, resulting from the schedule drawn upon the solution presented by the *m*-th chromosome;

F_k – the penalty (large enough positive real number) for the failure to meet the required degree of compliance with the fuzzy limit of availability of the *k*-th renewable resource;

G_k – the penalty (large enough positive real number) for the failure to meet the required probability of compliance with the fuzzy limit of availability of the *k*-th renewable resource;

K – the number of types of renewable resources with limited availability.

NUMERICAL EXAMPLES

The scope of the exemplary construction project covers modernization of an existing housing estate. This includes the renovation of existing buildings A and B, the renovation of the existing estate road, car parking, and the construction of new buildings *C* and *D* with the ancillary facilities. The network of the project activities is shown in Fig.4. The network data are given in Table 1.

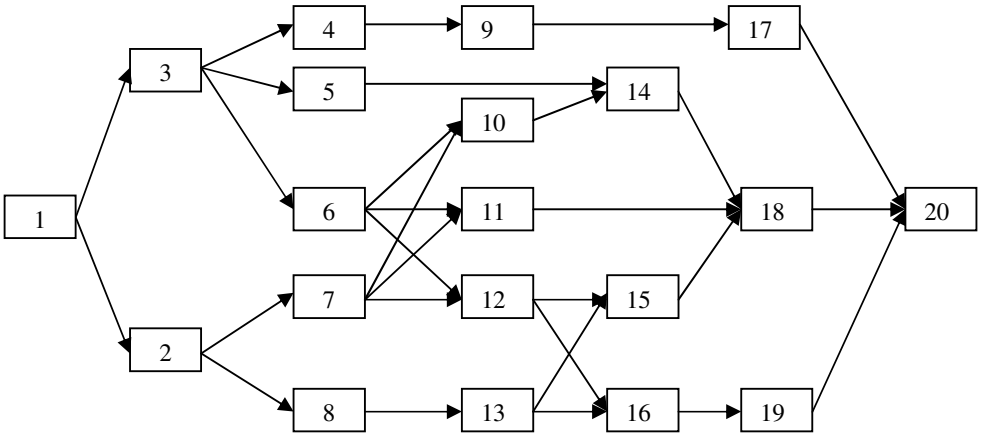

Figure 4: *An example of a construction project network model. Source: Own*

Neglecting the limit of workforce availability, the shortest feasible project makespan is t_s = 37 weeks, with the maximum employment of $r^{\max}$ = 49 workers per week. The contractor assumes that the number of available workers will be probably limited to 30 – 35 workers. In any case it will be not less than 25 and not more than 40 workers. The imprecisely specified limit of workforce availability can be modeled by the fuzzy trapezoidal number $\tilde{R}$ = (25, 30, 35, 40).

The client requires that the project has to be completed within a maximum period of 50 weeks from the date of commencement. On the basis of his past experience, the contractor assumes that he should be technically able to execute the works within about 40 – 42 weeks. Due to the commitments of the contractor to the other clients, the project makespan should not exceed 45 weeks, and the owner of this project will absolutely not accept the project makespan exceeding the period of 50 weeks. The imprecisely specified limit of time available for the execution of the works can be modeled by the trapezoidal fuzzy number $\tilde{T}_d$ = (37, 40, 45, 50).

Table 1. *Data for the project network model shown in Fig. 4. Source: Own*

Activity No	Description	Dura-tion (weeks)	Required number of workers	Earliest feasible	
				start date	finish date
1	Construction site preparation	4	8	0	4
2	Earthworks for buildings C and D	4	17	4	8
3	Renovation of foundations of building A	3	12	4	7
4	Renovation of an existing estate road	3	8	7	10
5	Renovation of the roof of building A	4	10	7	11
6	Renovation of internal services in building B	5	11	7	12
7	Foundation of building C	6	9	8	14
8	Foundation of building D	6	11	8	14
9	Renovation of the existing parking	3	6	10	13
10	Renovation of internal services in building A	6	9	14	20
11	Redecoration of building B	5	10	14	19

14	Redecoration of building A	4	9	20	24
15	Internal services in building C	5	10	20	25
16	Internal services in building D	5	11	20	25
17	Repair of auxiliary facilities	3	6	13	16
18	Finishing works in building C	7	6	25	32
19	Finishing works in building D	4	8	25	29
20	Construction site removal	5	9	32	37

In the first example, the planner is obliged to schedule the project to the highest degree of compliance with the imprecisely specified time limit for the execution of the works.

The planner is risk–neutral ($\beta = 0{,}5$). Moreover, the schedule should guarantee the degree of compliance with the fuzzy limit of workforce availability not less than $ST_{wr} = 0{,}50$.

The problem given above is described by the formula (13):

$$\max \mathrm{ST} : \mathrm{ST} = \mathrm{ST}(t \le \tilde{T}_d),$$

with the condition (15), concerning the *finish–to–start* relations among the activities in the project network model:

$$s_j \ge s_i + d_i \big| i \in \{Prec(j)\},$$

and with the condition (17), concerning the required degree of compliance with the fuzzy limit of workforce availability:

$$\mathrm{ST}(r^{\max} \le \tilde{R}) \ge 0{,}50.$$

The resulting construction schedule is presented in Fig. 5. The planned project makespan is $t = 44$ weeks and the degree of compliance with the fuzzy limit of time available for the execution of the works is $\mathrm{ST}(t \le \tilde{T}_d) = 0{,}50$. The maximum workforce employment is 35 workers per week and the resulting degree of compliance with the fuzzy limit of workforce availability is $\mathrm{ST}(r^{\max} \le \tilde{R}) = 0{,}50$. It should be noted that the resulting degree of compliance with the fuzzy limit of time available for the execution of the works is rated significantly higher by the more optimistic planner (see Fig. 7). It should be also noted, that the shortening of the planned project makespan to the level of 40 weeks does not change the resulting degree of compliance with the fuzzy limit of time available for the execution of the works (see Fig. 7). Similarly, the reduction of the maximum workforce employment to the level of 30 workers per week does not change the resulting degree of compliance with the fuzzy limit of workforce availability.

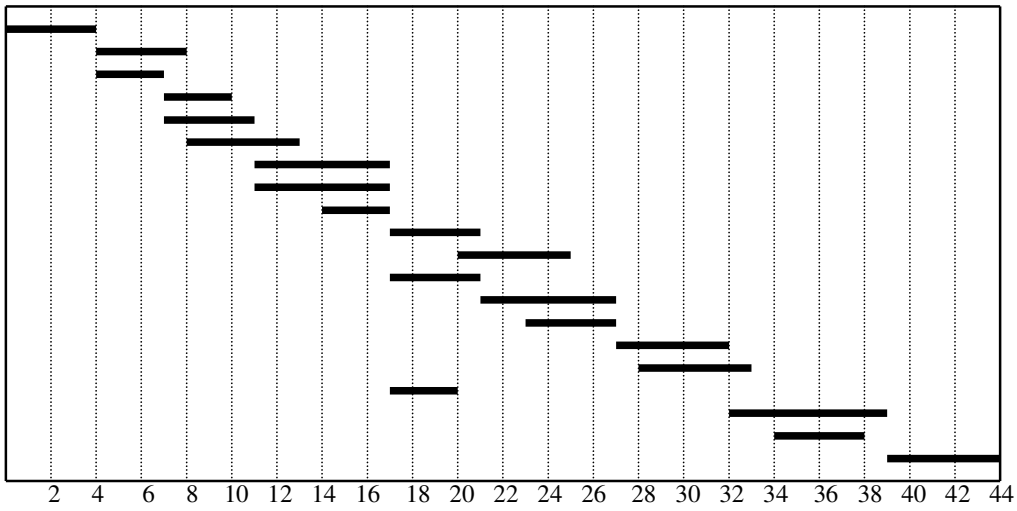

Figure 5: *Construction schedule ensuring the highest degree of compliance with the imprecisely specified time limit for the execution of the works. Source: Own*

In the second example, the planner is obliged to schedule the project to the highest probability of compliance with the imprecisely specified limit of time available for the

execution of the works. Moreover, the schedule should guarantee the probability of compliance with the fuzzy limit of workforce availability not less than P_{wr} = 0,50. This problem is described by the formula (14):

$$\max P : P = P(t \le \tilde{T}_d),$$

with the condition (15), concerning the *finish–to–start* relations among the activities in the project network model:

$$s_j \ge s_i + d_i \big| i \in \{Prec(j)\},$$

and with the condition (18), concerning the required probability of compliance with the fuzzy limit of workforce availability:

$$P(r^{\max} \le \tilde{R}) \ge 0{,}50.$$

The resulting construction schedule is presented in Fig. 6. The planned project makespan is t = 41 weeks and the probability of compliance with the fuzzy limit of time available for the execution of the works is $P(t \le \tilde{T}_d) = 0{,}70$. The maximum workforce employment is 32 workers per week and the resulting probability of compliance with the fuzzy limit of workforce availability is $P(r^{\max} \le \tilde{R}) = 0{,}56$. It should be noted that any shortening of the planned project makespan improves the probability of compliance with the fuzzy limit of time available for the execution of the works (Fig. 7), regardless the risk attitude of the planner. Similarly, any reduction of the maximum workforce employment improves the probability of compliance with the fuzzy limit of workforce availability.

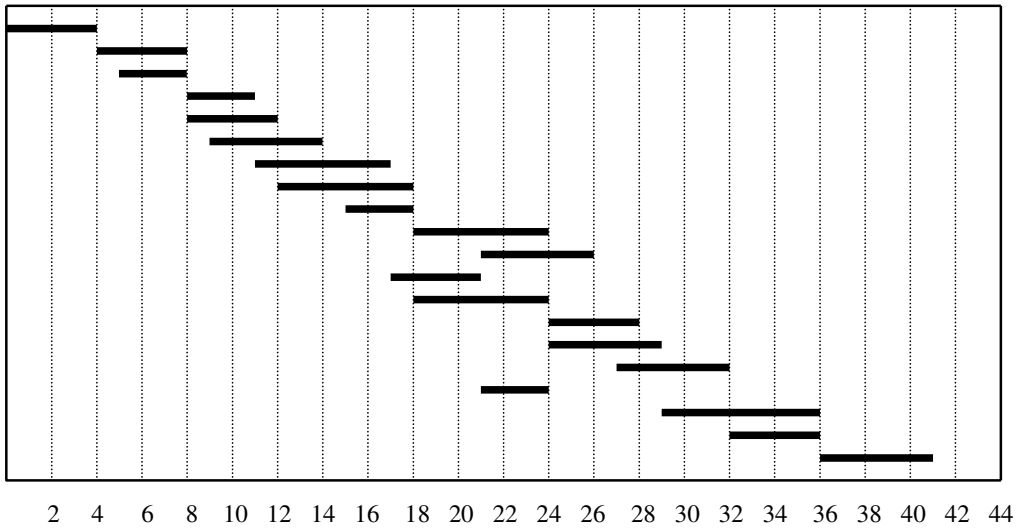

Figure 6: *Construction schedule ensuring the highest probability of compliance with the imprecisely specified time limit for the execution of the works. Source: Own*

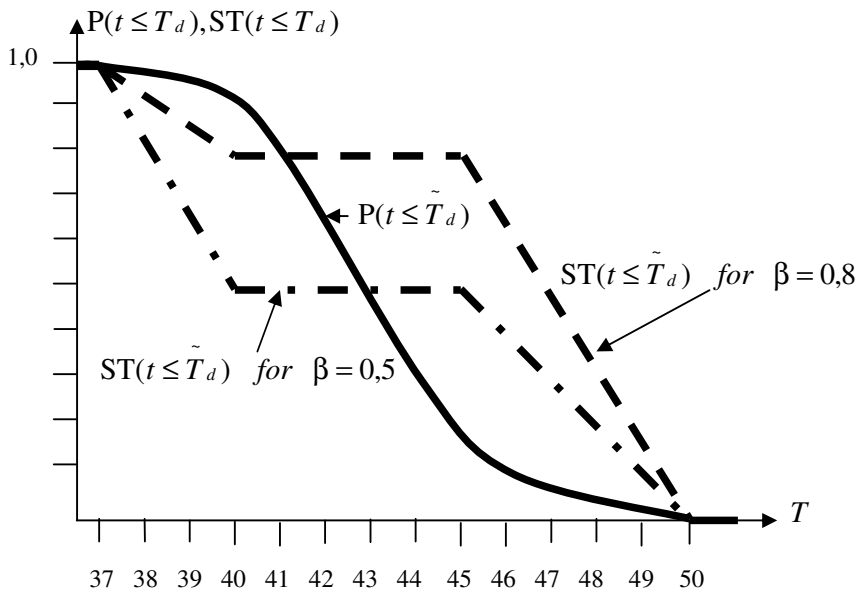

Figure 7: *Comparison of the functions* $ST(t \le \tilde{T}_d)$ *and* $P(t \le \tilde{T}_d)$. *Source: Own*

Suppose now that the workforce is divided into two main trades: construction workers (Trade I) for items 1 – 5, 7 – 9, 11 – 14, 17 – 20 and installers (Trade II) for items 6, 10, 15, 16.

The imprecisely specified limit of construction workers availability is "*about* 30", but not less than 28 and not more than 32 workers. This limit can be modelled by the fuzzy trapezoidal number $\tilde{R}_{\mathrm{I}}$ = (28, 30, 30, 32). Furthemore, the imprecisely specified limit of installers availability is "*about* 20", but not less than 18 and not more than 22 workers. This limit can be modelled by the fuzzy trapezoidal number $\tilde{R}_{\mathrm{II}}$ = (18, 20, 20, 22). The imprecisely specified limit of time available for the execution of the works remains as before: $\tilde{T}_d$ = (37, 40, 45, 50).

The planner is obliged to schedule the project to the highest probability of compliance with the imprecisely specified limit of time available for the execution of the works. Moreover, the schedule should guarantee the probability of compliance with the fuzzy limit of construction workers availability not less than $\mathrm{P}_{\mathrm{I}r} = 0{,}50$ and the probability of compliance with the fuzzy limit of installers availability not less than $\mathrm{P}_{\mathrm{II}r} = 0{,}50$. This problem is described by the formula (14):

$$\max \mathrm{P} : \mathrm{P} = \mathrm{P}(t \le \tilde{T}_d),$$

with the condition (15), concerning the *finish–to–start* relations among the activities in the project network model:

$$s_j \ge s_i + d_i \big| i \in \{Prec(j)\},$$

and with the conditions (18), concerning the required probability of compliance with the fuzzy limits of construction workers and installers availability:

$$\mathrm{P}(r_{\mathrm{I}}^{\max} \le \tilde{R}_{\mathrm{I}}) \ge 0{,}50,$$

$$P(r_{II}^{max} \leq \tilde{R}_{II}) \geq 0{,}50.$$

The resulting construction schedule is presented in Fig. 8.

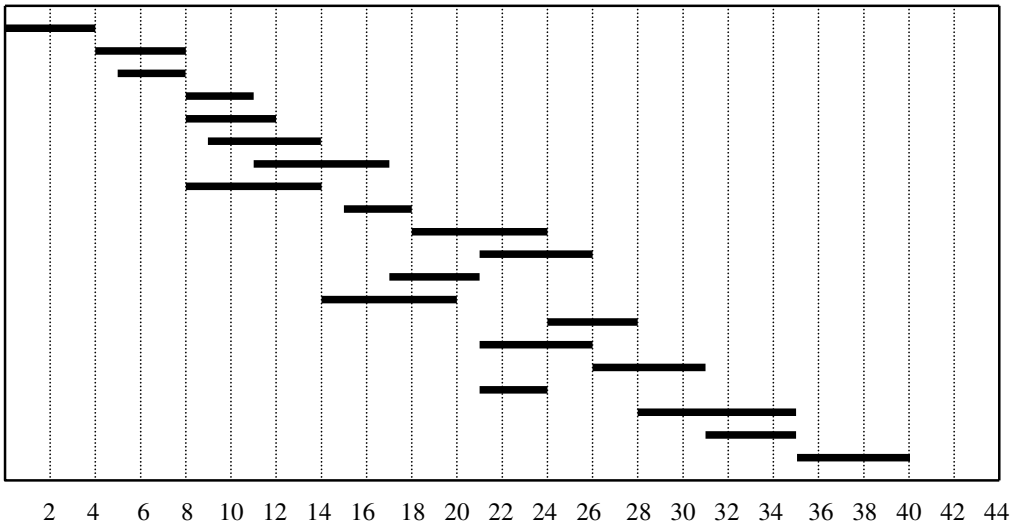

Figure 8: *Construction schedule ensuring the highest probability of compliance with the imprecisely specified time limit for the execution of the works in the case of two trades with limited availability. Source: Own*

In this case, the planned project makespan is t = 40 weeks and the probability of compliance with the fuzzy limit of time available for the execution of the works is $P(t \leq \tilde{T}_d) = 0{,}84$. The maximum employment of construction workers is 30 workers per week and the resulting probability of compliance with the fuzzy limit of workforce availability is $P(r_I^{max} \leq \tilde{R}_I) = 0{,}50$. The maximum employment of installers is 19 workers per week and the resulting probability of compliance with the fuzzy limit of workforce availability is $P(r_{II}^{max} \leq \tilde{R}_{II}) = 0{,}97$.

CONCLUSIONS

The theory of possibility allows for the modelling of imprecisely defined planning constrains by means of trapezoidal or triangular fuzzy numbers. If trapezoidal fuzzy numbers are used, some difficulties arise in determining the proper numerical value of coefficient β characterizing the risk attitude of the assessor. This may cause the different assessments of the degree of satisfaction of fuzzy planning constraints, formulated by planner and by the decision maker. In addition, the result of evaluation remains constant when the planned project makespan or the planned resource consumption takes the value from the core of the trapezoidal fuzzy number, modelling the given planning constraint. This adversely affects the optimality of solutions to scheduling problems with imprecisely defined constraints. If triangular fuzzy numbers are used, there still remain difficulties in the numerical

characteristics of the attitude towards risk. The approach presented in this paper combines the elements of the theory of possibility and the elements of theory of probability. The imprecision of project constraints is modelled by fuzzy numbers, while the level of satisfaction of fuzzy planning constraints is assessed by the use of probability measure. It has been demonstrated that the use of probability measure neutralize the assessment of compliance with the fuzzy constrains. Moreover, the results of the optimization of construction schedule are improved. The approach presented in this paper can be adopted when also the uncertainties of project activity durations are modelled by fuzzy numbers.

Abstract

The paper presents an empirical study of investment activities on existing buildings and their dependencies on corporate strategic factors. The study is based on almost 3000 activities carried out from 2003 to 2007 on a typical characteristic housing stock in Germany. The stock is managed by a strategically positioned housing company.
First the state of the art in the research field is presented. The research concept is introduced. Using the methods of descriptive statistics key cost values of the investment activities are presented in accordance with the company's strategic factors. The cost values are compared with the investments of appropriate other German housing companies. In compliance with the obligations of the technical management, strategic recommendations are derived to control costs. The benefits of the strategic recommendations are evaluated with the identification of potential cost savings. The investment minimum of technical management is derived from the key cost values minus the cost saving potential. The minimum investment is discussed in comparison with the investment of other representative German housing companies. The strategic recommendations are incorporated in a concept for the selection of future activities.

Keywords: technical management, housing stock, strategies, existing buildings

INTRODUCTION

The investment activities on existing residential buildings are an important business sector in the German housing industry. As a research field, these residential buildings have been underestimated so far.

Since 2000, the volume of the investment on existing residential buildings is higher than the volume of the investment on new residential buildings (DIW Berlin, pp. 30-31). In 2007 the members of the Association of German Housing Companies (GdW) invested 77 % of their investments in the activities on existing residential buildings (GdW 2008, p. 154). These activities indicate construction work performed to maintain or modify the residential properties (residential building, outdoor areas) and their elements (Figure 1) (Kalusche 2007, pp.128-129).

By focusing on the existing residential buildings, the technical management of housing stock has become the most important task of the construction departments in German housing companies. The technical support of new construction plays only a minor role.

Basis for a rational and cost-effective technical management of the housing stock is the knowledge of the characteristics of the investment activities on existing buildings and their dependencies on corporate strategic factors. Rußig (2006, p. 20) notes, however, that in Germany as well as in other European countries there are only few reliable data concerning the performed technical investment activities and their dependencies.

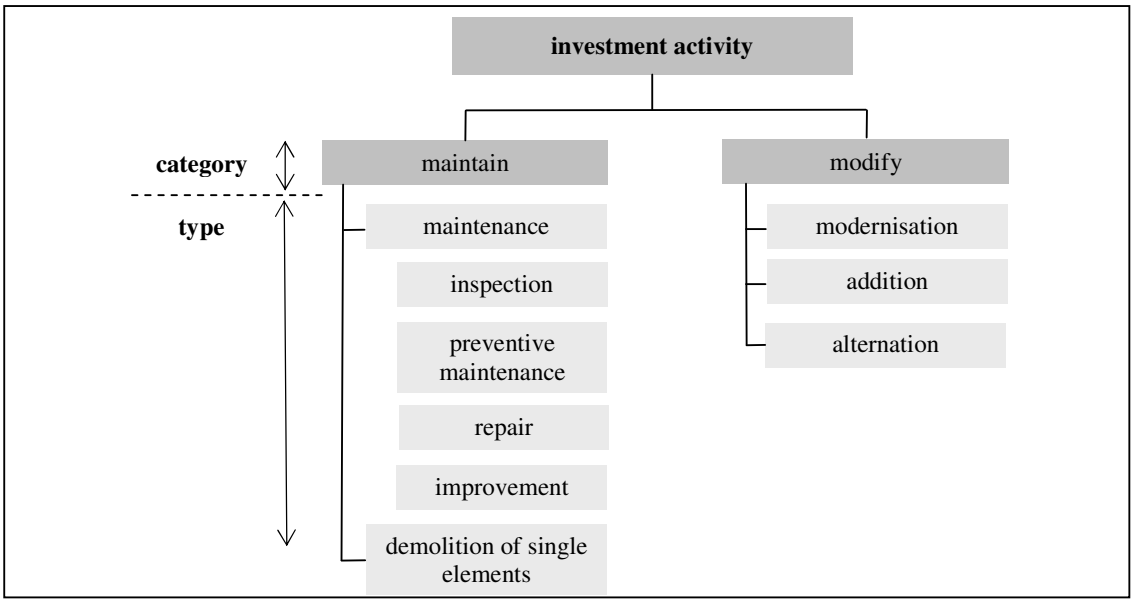

Figure 1: categories and types of investment activities

Lohse and Pfnür (2009, pp. 35, 50, 56-60, 101, 104) show in a survey that the implementation of strategic investment activities on existing residential buildings is one out of five key challenges for the German housing companies.

Currently, there are no scientific studies that use the experience from past activities (Figure 1) on existing residential buildings for a rational and systematic selection of future activities. Therefore the objective of the study is to develop strategies for the cost-effective technical management of housing stock.

STATE OF THE ART

The empirical study on investment activities on existing residential buildings is an emerging research field. First studies were conducted in the 1960s and 1970s by Mrosek (1972) and Zschirnt (1975). To date, there is quite a number of research projects available.

Still those projects show some deficits concerning their method or their content. The investigations have limited significance and are only qualitative. This results from the specific samples, the individual operationalizations, or the consideration of selected single criteria. The qualitative character is given for example in the research by the Statistisches

Bundesamt (2009), Klingenberger (2005), Aikivuori (1994) or Leather et al. (1998).

The novelty of the presented approach is characterized by a thorough multi-criteria analysis of the investment activities on a typical housing stock sample. The gained knowledge is used in order to systematically select appropriate future investment activities.

So far, the development of strategic recommendations is focused on the user-oriented management, the economic management and the damage (structural damage, personal injury) prevention and removing.

Up to now the recommended strategies for user-oriented management refer to user requirements in general and to some very specific requirements like accessibility, energy efficiency or sustainability. They refer to certain owner segments or to special age groups of the buildings. They are mostly based on case studies, expert interviews or surveys. Examples are found in Finkenbusch (2008) or Kirchhoff and Jacobs (2005).

The strategies for the economic management seek to find an economic alternative instead of the minimum investment level. They can be derived by cost-benefit analysis, by methods of investment analysis or by the adoption of entrepreneurial activities. The data are usually obtained by the analysis of case studies or surveys. The statistical analysis of in-company data is rare. The strategies are designed for specific user groups. Examples are found in Kirchhoff and Jacobs (2007), Veser et al (2007) or Kortmann (2008).

Strategies to prevent and repair damage (structural damage, personal injury) are developed component-based or process-related. They are mostly based on the analysis of case studies, expert interviews or the statistical analysis of damage cases (structural damages, accident reports, insurance claims). Examples are the investigations of Schrepfer and Gscheidle (2007), Rizkallah et al. (2003) and Schüler and Röbenack (1996).

The novelty of the presented approach is to meet the obligations of the technical management and to ensure an appropriate minimum investment level.

RESEARCH METHODOLOGY

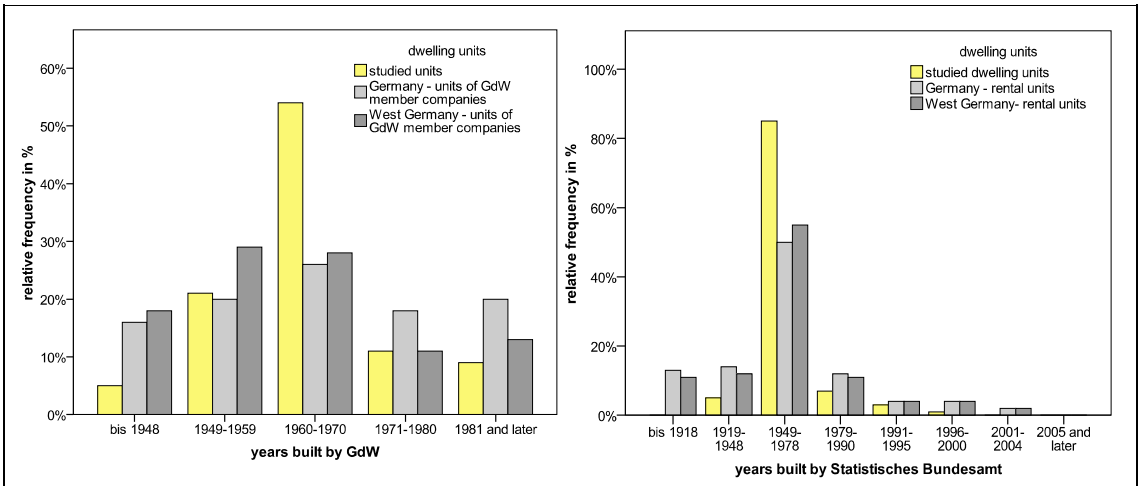
The research is structured into the following steps:

- Sample selection
- Operationalization of the investment activities
- Data collection
- Data analysis

Sample selection

The study focuses on the analysis of investment activities carried out on a typical housing stock of one housing company. The in-depth study provides a thorough and detailed analysis of all its activities. The investigated period is from 2003 to 2007.

In the study 2939 investment activities have been investigated, which were managed by the technical department of the company. Therewith, about 90 % of all executed activities had been recorded.



For the realization of these activities, according to DIN 276 (2008), preparation, planning and construction work are required. In this study, only the construction items are considered. According to VOB/A (2010), § 1, construction work is defined as work of any type to create, maintain, modify or remove a structure.

The housing stock includes 2164 dwellings with a total living space of 152.755 m². The dwellings are located in 251 multi-family houses of different age in major cities in West Germany.

The comparison of the dwellings of the research sample with the unit distribution within the member companies of the GdW shows that the years "1960 to 1970" are overrepresented in the sample (Figure 2). In all other regards, the examined housing stock shows the typical age distribution of the dwellings of the GdW member companies in West Germany. The typical West German age distribution is confirmed by the comparion of the studied units with the rental units recorded by Statistisches Bundesamt (Destatis) (GdW 2006, pp. 153-154; Statistisches Bundesamt 2008, pp. 12-13).

The analysed housing company is privately owned. Private owners manage 4.06 million dwellings. These are approximately 47 % of the 8.69 million professionally owned dwellings and about 10 % of all dwellings in Germany (BBR, 2006, p. 23; Veser et al., 2007, p. 26.).

The housing stock is managed by a housing company, which has adopted to changing market conditions by diversification (Kühne-Büning, pp. 123-124; Nordalm 2003, pp. 34-36). Since the late 1990s, the business segments management and marketing of existing housing stocks were supplemented with the segments purchase, sale and privatisation of existing housing stock as well as the management and marketing of purchased and privatized housing stock.

(Source: GdW 2006, p. 211; Statistisches Bundesamt 2008, pp. 12-13)

Figure 2: comparison of dwelling units

Operationalization of the investment activities

As part of the operationalization, the recorded investment activities have been classified by the following six features:

- Category

- Investment package
- Management concept
- Area
- Cause
- Cost (€)

The variables and their categories are defined on the basis of participant observation and by literature review. Their definitions and categories are described as follows:

Variable category of activities
According to Figure 1 the investments are classified in maintenance and modification activities. Maintenance activities secure the functional use of the objects. They lead to retain, restore or improve the required functions of the objects and their elements. Modification activities are usually associated with a distinct change in building design (DIN 276 2008, p. 3; Kalusche 2007, pp. 128-129; Zeitner 2006, p. 137).

Variable investment package
The investment activities fit into the three investment packages shown in Table 1.

Table 1: variable investment packages

no	package	explanation
1	**immediate measures**	day-to day activities carried out straight after the notification of dysfunction or failure
2	**planned actions**	predetermined activities carried out in accordance with a yearly prepared action plan
3	**complete renovations**	a bundle of activities carried out in the temporarily unoccupied or lately added units

Variable area
The technical management of the housing stocks is different for the dwelling and for the common areas. The definition of the area categories is chosen following the Condominium Act (WoEigG 2009).

The *dwelling area* includes the spaces and building structures that are privately owned property.

The *common area* includes the spaces and building structures that are common property.

Variable management concept
The investment activities can be derived from the strategic perspective on different management concepts. The concepts are focused on the three management approaches (Hegewald et al 2009, pp. 19-20):

- *Renting*: sustain the letting and liveability of the residential property
- *Privatisation*: sales design of the residential property (increasing the quality for the sake of marketing, meeting the requirements of future users)
- *Condominium*: sustain the use of the privately and individually owned residential property

The management concepts are applied in the dwelling and common areas. The application depends on the different ownership status as shown in Table 2.

To study the influence of the company's strategy on the entire property, the management concepts in the dwelling and common areas (e. g. renting + renting) are taken together.

Table 2: variable management concepts by area

area	management concept	owner status/responsibilities	explanation
dwelling area	renting	housing company is the only owner of the tenement (all dwellings and common area)	preparing the dwelling areas for renting
	privatisation	housing company owns unit in condominium	preparing the dwelling areas owned by the housing company for sale
	condominium	housing company owns unit in condominium	preparing the dwelling areas owned by the housing company for renting
common area	renting	housing company is the only owner of the tenement (all dwellings and common area)	preparing the common areas for renting
	privatisation	housing company changes the form of ownership from tenement to condominium	preparing the common areas for privatisation
	condominium	housing company manages the common property of the condominium	preparing the common areas for the condominium management in connection to the privatisation

Variable cause

The cause of an activity describes the event leading to that activity (Table 3).

Table 3: variable causes

	no	cause	explanation
material	1	maintaining functionality and usability	Functionality and usability are verified. Small changes in functionality and usability are removed.
	2	limited functionality and usability	Damages, limiting the functionality and usability are fixed.
	3	component failure	Failed components are retained in a functional and usable state.
immaterial	4	user demands	Functional, environmental and hygiene requirements are met. Architectural trends are realized.
	5	changed and new laws, standards and codes of practice	Legal or technical constraints or health issues are met (requirements of the Energy Conservation Act, health hazards due to asbestos).
	6	increase profitability, balance sheet aspects	Activities are carried out to increase the earning capacity of the housing stock.
materiell + immaterial	7	limited functionality and usability and user demands	Same as no 2 and no 4
	8	user demands and increase profitability, balance sheet aspects	Same as no 4 and no 6
(Source: Möschwitzer 2008, pp. 95-96)			

The causes can be divided into three groups:

- material cause (due to material wear)
- immaterial cause (due to non material wear)
- material/immaterial cause (due to material and non material wear)

Variable costs
The costs of the studied activities describe the expenses for the building work (Möller 2001, pp. 98-99) in accordance with DIN 276 (2008, p. 4). The costs of the activities are recorded as billed gross building work.

Data collection
The data have been collected in two steps: in the first step, secondary in-company data were collected. In the second step, the compiled data have been supplemented with additional variables by assignment and assessment.

Data analysis
Using the methods of descriptive statistics, key cost values (€ per m² of living space) of the investment activities are presented in accordance with the management concepts. The values are calculated for each investment package in the dwelling areas as well as for the common areas (Table 2).

The derived values of the housing company are used to calculate comparative figures (whole property = dwelling and common area) in total and by management concept. The values are used to compare the investment behaviour of the housing company with the investment of comparable other German housing companies.

The benefits of strategic recommendations are evaluated with the identification of potential cost savings (€ per m² of living space). The investment minimum of technical management (target key cost value) is calculated from the key cost value minus the cost saving potential per m².

The determined minimum investments are used to calculate the target comparison values. The target comparison values are used to compare the investments of the studied housing company with the investments of selected other German housing companies.

RESULTS

Key cost values

The investment activities lead to total costs of € 25,878,492.32 (Table 4). According to the definition of the different action packages in Table 1, the *complete renovations* (€ 4,639,083.53) represent the cost situation for the *dwelling areas*. The *planned actions* (€ 20,528,593.94) represent the cost situation for the *common areas*. The *recorded immediate measures* (*dwelling and common areas*) lead to relatively low costs (€ 710,814.85).

Table 4: costs of all studied activities (2003 to 2007)

area	cost							
	total		immediate measures		complete renovations		planned actions	
	total (€)	(%)	total (€)	(%)	total (€)	(%)	total (€)	(%)
dwelling area	4,960,333.77	100.0	321,250.25	6.5	4,639,083.53	93.5	0.00	0.0
common area	20,918,158.54	100.0	389,564.60	1.9	0.00	0.0	20,528,593.94	98.1
total cost	25,878,492.32	100.0	710,814.85	2.7	4,639,083.53	17.9	20,528,593,94	79,3

The key cost values in the *dwelling and common areas* vary depending on the management concept (Table 5, Table 6).

The highest key values occur, when the management concept *privatisation* is applied (Table 5, Table 6). Here it is more likely to invest in expensive maintenance and modification activities in order to increase the quality and to meet the requirements of future users (Hegewald 2009).

Table 5: key cost values of complete renovations by management concept (dwelling area) (2003 to 2007)

management concept	total costs (€)	costs (€/unit)	key cost value (€/m²of living space)
renting	1,321,739.27	8,418.72	133.84
privatisation	3,052,823.99	9,393.30	149.34
condominium	264,520.26	4,007.88	63.72

Table 6: key cost values of planned actions by management concept (common area) (2003 to 2007)

management concept	total costs (€)	key cost value (€/m² of living space)
renting	2,346,226.72	20.29
privatisation	18,046,603.08	176.23
condominium	135,764.14	1.33

The key cost values of the management concepts *renting* and *condominium* are significant lower than the values of the concept *privatisation*.

Within the *renting* management more cost-effective maintenance and modification investment activities are carried out. They are used to remove wear, adjust the property to the technical standards or fulfil tenants' requirements (Hegewald 2009).

In the *condominium* management especially cost-efficient maintenance investment activities are carried out. They focus on guaranteeing the habitability. The cost-intensive activities are or will be carried out only in connection with the *privatisation* strategy (Hegewald 2009).

Investments in comparison

The investment activities of the housing company (*dwelling* and *common area*) can be compared with the investment activities of the GdW member companies in West Germany and also with the investment activities of the member companies of the Association of North German Housing Companies (VNW) (Veser et al. 2007, pp. 61-62).

When comparing with those appropriate values from literature, the calculated key cost values are well above the benchmark (Figure 3). Overall, the analysed housing company is investing twice as much in its housing stock as the representative housing companies on average. The high level of investment is mainly due to the concept *privatisation*. The investment in *privatisation* is 2.3 times as high as the investment of the average GdW member company in West Germany.

This raises the question, which investment activities must be carried out on the existing housing stock and which not.

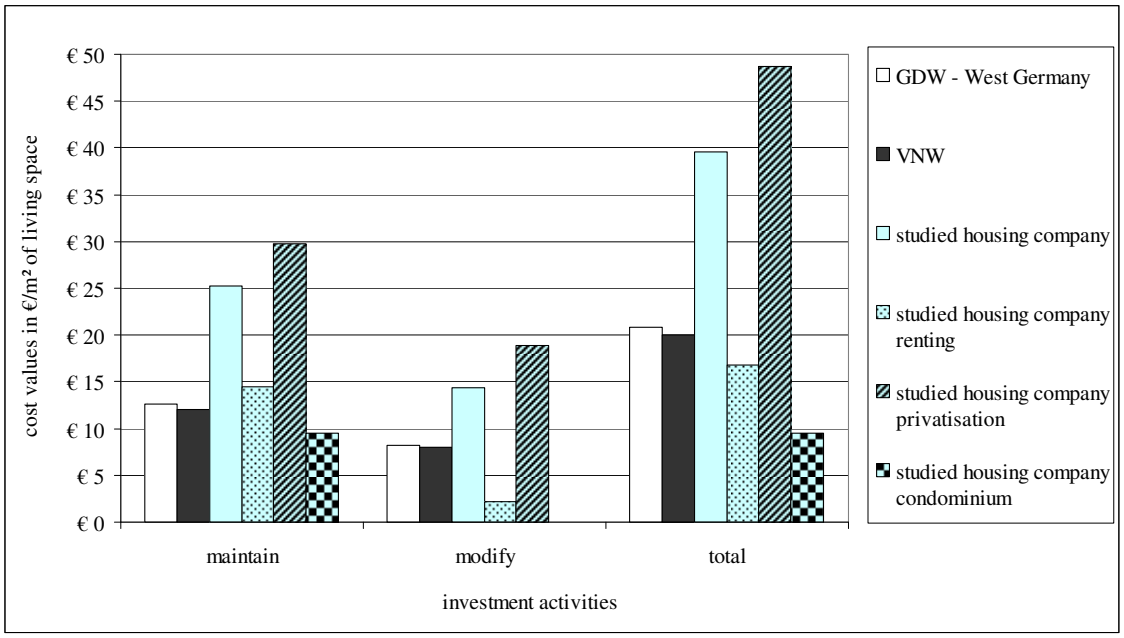


Figure 3: comparison of the investments (key cost values per year)

Duties of the technical management

With the investment activities the duties of the technical management have to be met. The duties are divided into the maintenance and adaptation requirements.

The maintenance requirements include the duty to obtain the housing stock in a functional and hazard-free condition. They can be derived from the law of tenancy, condominium law and the duty to implement safety precautions and to ensure upkeeping of the property.

The tenancy's maintenance requirements are defined in the Civil Code (Bürgerliches Gesetzbuch) (BGB, 2009). They result out of § 535 (1) Civil Code (BGB, 2009) (TÜV

Rheinland Group 2008, p.28). According to it it's the duty of the landlord to keep the tenant's property in a suitable, contractually fixed condition.

The committed maintenance investment activities of the law of tenancy include, as stated by Blank (2005, p. 397-399) and Palandt/Bassenge (2009, pp. 728-729):

- activities to prevent and remedy structural defects
- activities to maintain and restore the contractually fixed condition
- preventive maintenance
- improvements, that result from the maintenance and restoration of the contractually fixed condition

The maintenance requirements for property owners and their managers are derived from the Condominium Act (Wohnungseigentumsgesetz – WoEigG) (WoEigG 2009). They are described in §§ 14, 21 and 27.

The committed maintenance activities are, as written by Stürzer (2007, pp.65-66), the work done to conserve and restore the original condition or functionality of the residential property.

The duty to implement safety precautions and to ensure property upkeep results from § 823 (1) Civil Code (BGB, 2009) (Damm 2005, pp. 4, 6). It is the owner's duty to eliminate threats posed by the residential property or counteract them to prevent injury to others (Blankenstein 2008, p. 736).

Monitoring obligations arising from the implementation of safety precautions and property upkeep can be fulfilled by certain activities. These monitoring obligations and activities are derived e. g. from laws, regulations, or from the general state of the art (Damm 2005, p. 4). Detailed descriptions can be found in Damm (2005).

The adaptation requirements arise, when the protection of the existing use is restricted or has been repealed. They include the duty to adapt the residential property to changed or new legal regulations.

The protection of the existing use secures the residential property owner's right to use and maintain its property, even if it does no longer reflect the current applicable building regulations (Frankenstein 2006, p. 1081). The protection of the existing use is derived from article 14 (1) of the German Constitution (Grundgesetz) (Harlfinger 2006, p. 25).

On one hand, the protection of the existing use is limited or omitted by carrying out activities that implement a significant change in stocks or change in use, according to the wording of the building law (Harlfinger 2006, pp. 25-26). In these cases, an adjustment is required to meet the current building regulations. Maintenance activities are in general covered by the protection of the existing use. Möschwitzer (2007, pp. 21-26) describes this in detail.

On the other hand, the protection of the existing use is limited by the planning law, the building law (fire and safety measures) and others (energy measures (EnEV)). This requires an adjustment to meet the current legal regulations (Harlfinger 2006, p. 26-27).

Strategies

The investment activities are considered technically necessary, if they meet the maintenance and adaptation requirements of the management. Cost reduction potentials have those investment activities that reach beyond the responsibilities of technical management. These are named technically unnecessary investments.

The requirements for the technical management can be assessed with reference to the causes of the activities (Table 3). The assessment of the causes leads to the following strategies:

- Respond to those causes that are associated with the duties of technical management: the duties will be secured with the response to the three material causes, the material/immaterial cause and the immaterial cause "changed and new laws, standards and codes of practice".

- Do not respond to those causes that are not associated with the duties of the technical management: cost saving potential is evident in the response to the immaterial causes "user demands" and "user demands plus increase profitability, balance sheet aspects".

Cost saving potential

The cost saving potential is calculated for the two in Table 1 defined investment packages *complete renovations* and *planned actions* by cause (Table 7). The *immediate measures* are not considered, because they only meet maintenance requirements.

Table 7: cost saving potential of the investment packages by causes (2003 to 2007)

cause	complete renovations		planned actions	
	cost (€)	(%)	cost (€)	(%)
maintaining functionality and usability	26,547.38	0.6	613,556.54	3.0
limited functionality and usability	1,643,592.38	35.4	7,391,453.84	36.0
component failure	64,958.07	1.4	108,434.81	0.5
limited functionality and usability + user demands	2,660,269.38	57.3	2,289,717.63	11.2
changed and new laws, standards and codes of practice	118,421.42	2.6	1,498,623.50	7.3
user demands	*54,830.10*	*1.2*	*449,013.95*	*2.2*
user demands + increase profitability, balance sheet aspects	*70,464.80*	*1.5*	*8,177,793.68*	*39.8*
total	4,639,083.53	100.0	20,528,593.94	100.0
Cost saving potential is in grey and italics				

The cost shares of the technically unnecessary investments are typical for the management of the *common areas* (Table 7). In the management of the *dwelling areas*, the costs of those investments are low. Thus the cost saving potential focuses on the *planned actions*. 42 % of these total costs can be saved from a technical perspective, whereas only 2.7 % of the total costs of the *complete renovations* belong to the technically unnecessary investments.

In the management of the *common areas* the cost saving potential differs depending on the management concept (Table 8).

The cost shares of the technically unnecessary investments are typical for the management concepts *renting* (37.7 %) and *privatisation* (42.9 %) (Table 8). The response to those investments shows a cost saving potential up to 7.66 €/m²of living space for *renting*. For *privatisation* the cost saving potential is up to 75.60 €/m² of living space.

Within the management concept *condominium*, no technically unnecessary investments occur. Here no cost-reducing opportunities exist.

Table 8: cost saving potential of the planned actions by management concept (2003 to 2007)

cause	renting		privatisation		condominium	
	costs €/m² of living space (€)	(%)	costs €/m² of living space (€)	(%)	costs €/m² of living space (€)	(%)
maintaining functionality and usability	0.81 (93,404.78)	4.0	4.95 (506,532.84)	2.8	0.13 (13,618.92)	10.0
limited functionality and usability	7.59 (877,060.70)	37.4	62.57 (6,407,421.62)	35.5	1.04 (106,971.52)	78.8
component failure	0.45 (52,267.01)	2.2	0.40 (40,994.10)	0.2	0.15 (15,173.70)	11.2
limited functionality and usability + user demands	1.56 (180,000.90)	7.7	20.60 (2,109,716.73)	11.7	0.00	0.0
changed and new laws, standards and codes of practice	2.23 (257,885.93)	11.0	12.12 (1,240,737.57)	6.9	0.00	0.0
user demands	*0.15 (17,039.39)*	*0.7*	*4.22 (431,974.56)*	*2.4*	*0.00*	*0.0*
user demands + increase profitability, balance sheet aspects	*7.51 (868,568.01)*	*37.0*	*71.38 (7,309,225.66)*	*40.5*	*0.00*	*0.0*
total	20.29 (2,346,226.72)	100.0	176.23 (18,046,603.08)	100.0	1.33 (135,764.14)	100.0
Cost saving potential is in grey areas and in italics						

Minimum investment of the technical management

In the management of the *dwelling areas* only low cost saving potential is shown. The determined key cost values (Table 5) of the *complete renovations* are therefore equivalent to the minimum investment of the technical management.

In the management of *common areas*, the application of the strategic recommendations results in a significant cost reduction potential of 42 %. The minimum investment differs from the determined key cost values (Table 6).

The minimum investment is characterised by the values of the management concept *privatisation* (Figure 4). The target key cost value of the concept *privatisation* is 100.63 €/m² of living space. The target key cost value of the concept *renting* (12.63 €/m² of living space) is eight times lower than the value of the concept *privatisation*. The target key cost value of the concept *condominium* (1.33 €/m² of living space) is almost 10 times lower than the corresponding value of the concept r*enting*.

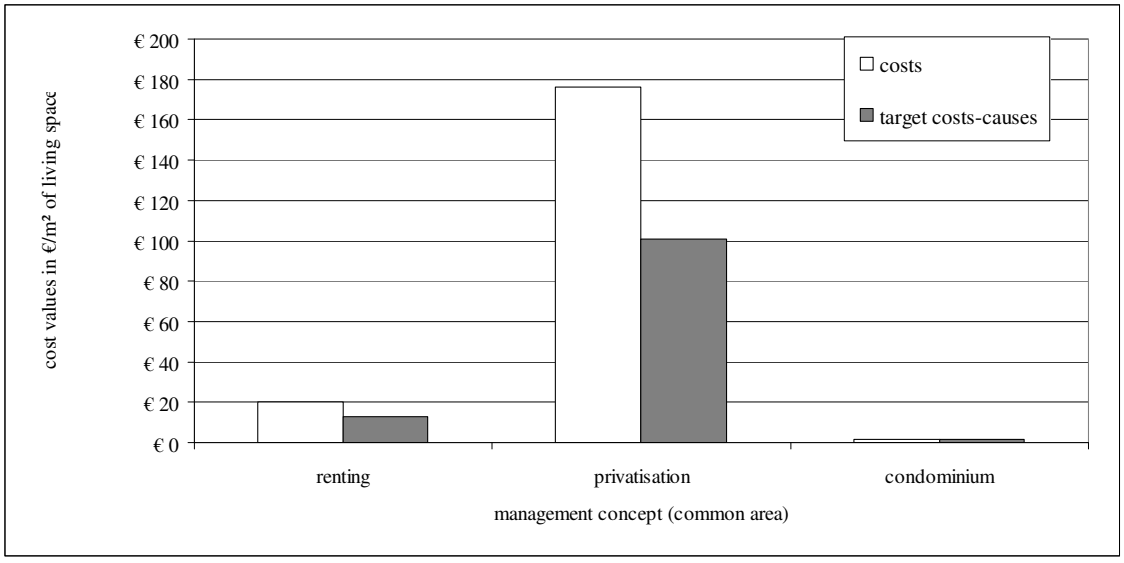

Figure 4: key and target key cost values of planned activities by management concept (2003 to 2007)

Minimum investment in comparison

The minimum investment (dwelling and common area) is higher than the representative member companies' average investment (Figure 5). The minimum investment is about 35 % higher than the average investment of the GdW member companies in West Germany. It is about 40 % above the average investment of the member companies of the VNW.

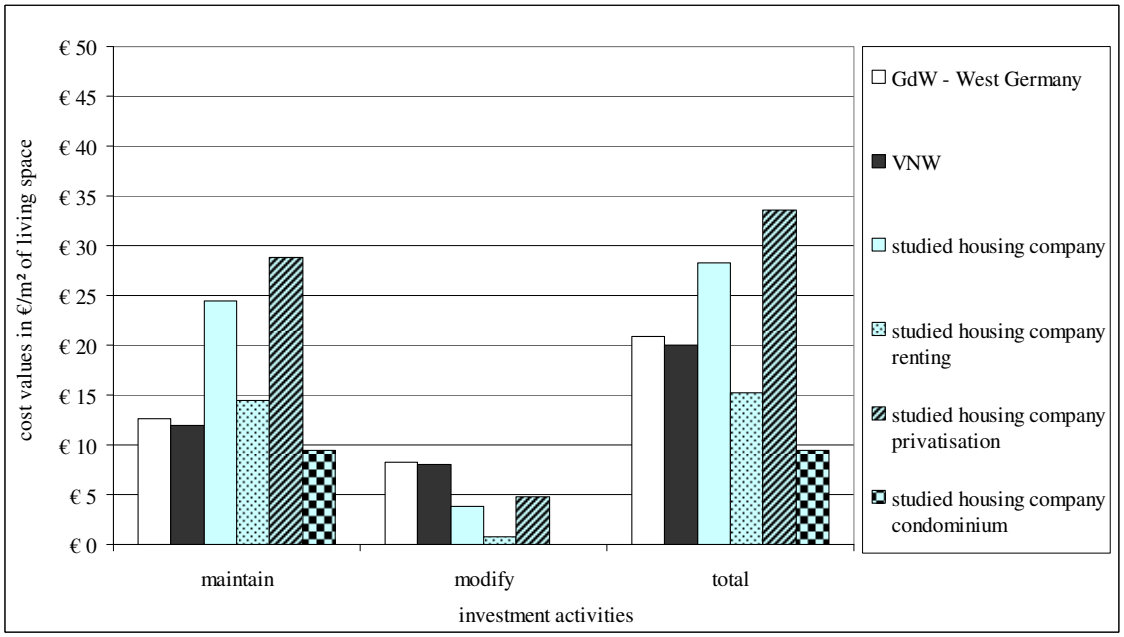

Figure 5: Comparison of the investments (target key cost values per year)

It might be supposed that the investment level of the representative companies could be too low for a long-term guaranteed housing stock quality. But Morgan Stanley mentions in Veser et al. (2007, p. 62) 16 to 20 €/m² of living space as sufficient for this purpose. The comparative values are 20.87 €/m² of living space (member companies of GdW) and 20.00 €/m² of living space (member companies of VNW).

Instead, it can be assumed that the studied housing company's proactive role, particularly in the context of *privatisation*, causes a considerably higher investment level. The technically necessary investment is performed more extensively as needed in order to avoid further investments. Therefore, the minimum investment in *privatisation* is 1.6 times higher than the investment of the GdW member companies on average.

The minimum investment of the concepts *renting* and *condominium* is lower than the average investment by the compared housing company members. Compared with the data from Morgan Stanley in Veser et al. (2007, p. 62) the investment in *renting* (15.22 €/m² of living space) is sufficiently high to ensure to keep the stock in a good quality. Even so, the investment in the concept *condominium* (9.46 €/m² of living space) is classified as adequate at the transition to an intensive phase of *privatisation*.

CONCLUSION – CONCEPT FOR THE RATIONAL SELECTION OF ACTIVITIES

To identify potential cost reductions by thorough analysis of the cost distribution is an important opportunity to derive a concept for the rational selection of the investment activities on housing stock. The analysis is able to answer the question, which investment activities have to be carried out and which not.

The derived concept refers to the investment activities classified as belonging to the *planned actions* (Table 1), whereas investment activities classified as belonging to the *immediate measures* and *complete renovations* are generally recommended to be carried out. They are realized in the context of the ordinary duties of the technical management.

The *planned actions* can be categorized into technically necessary and technically unnecessary investments. For the assessment of the recorded *planned actions* the causes and the resulting strategies can be used.

The technically necessary investments are generally recommended to be carried out. A temporary interruption of the technically unnecessary investments is possible without the risk of considerably damaging the stock values. But the general omission of the technically unnecessary investments is deemed critical for long-term user-oriented operation.

With the technically necessary investments all security and functional requirements are met, whereas the technically unnecessary investments customize the housing stock. They fulfil personal, social, aesthetic and efficiency demands (Preiser 1983).

To avoid possible vacancy, additional technically unnecessary investments might be appropriate to be carried out. Therefore, it is proposed that these unnecessary investments are evaluated by using a multi-criteria decision making model (AHP and cost-effectiveness analysis). With the help of the model, then the investment activities with the best cost-benefit ratios are candidates for implementation according to the available overall budget of the company.

Abstract

The drive for more sustainable built environment in the United Arab Emirates (UAE) received a significant boost in the period 2006-2008 supported by new legislations from the government and increased interest from major stakeholder especially municipalities. The absence of locally developed frameworks for evaluating sustainable design of buildings has created opportunities for the introduction of foreign ones. LEED has become popular in industry and has even influenced the current attempts to develop a local framework. The paper will report the findings of a research that, first, evaluated the effectiveness of LEED framework in dealing with local issues. Secondly the paper will examine two case studies where LEED was used in only one of them while both cases aimed to ensure the project development is sustainable. The analysis shows that "responsible design" produced more effective solutions for sustainability.

Keywords: Sustainable development, LEED, UAE, Responsible design.

INTRODUCTION

The construction boom in the United Arab Emirates has created significant pressures and raised concerns about the impact of such boom on the environment and energy. This has prompted the local governments to issue directives and new regulations requiring all buildings in the major cities, such as Abu Dhabi and Dubai, to adhere to strict green standards prescribed worldwide

It is argued that global climate concerns can be largely alleviated by responsible design, may it be automotive, product, machinery or building design. Wann (1990) explains in his book *Biologic* that "environmental deterioration is a lack of relevant information [and that] poor design is responsible for many, if not most, of our environmental problems." It is not surprising that attention has focused on developing green building practices to substantially reduce or eliminate negative environmental impact of construction and operational practices. Reviewing design practices to that end may also contribute to reduce operational costs, enhance building marketability, increase worker productivity and reduce potential liability

resulting from indoor air quality problems. Thus green design can have environmental, economic and social elements that benefit all building stakeholders.

Building design is heavily influenced by its geographical location and where architecture varies vastly from place to place in response to its regional context. The focus of this study is on designing sustainably and responsibly for the arid regions of Dubai. The inculcation of green design strategy made mandatory by governmental regulations in Dubai and the appropriate way of introducing and infusing them, into the pre-existing system is perceived as a challenge.

There is an opportunity to extrude applicable techniques from already developed practices elsewhere and identify opportunities for application in this region, taking into consideration the local, cultural and ecological conditions International rating systems like LEED have been used widely in Dubai and is seen by many, especially foreign consultants, as a valid tool to initiate the green journey

This study main objective is to evaluate the effectiveness of current effort to design buildings that are seen to be more environmentally friendly. Two case studies will be examined where in one of them LEED framework was used while the second case study worked without a reference to a rating framework.

SUSTAINABILITY DECISION DRIVERS IN THE UAE

The unprecedented growth in the UAE construction industry in the late years coupled with its massive fossil fuel energy consumption has not escaped media attention. The LIVE PLANET report in 2006 revealed that UAE was responsible for the world's largest ecological footprint. World Wildlife Fund revealed that UAE was five times more unsustainable than any other country in the world.(Anon 2007, WSP 2009) It was observed that UAE had an Ecological Footprint of 11.9 hectares/person, while the global average is at 2.2 hectares/person and the sustainable average should be at 1.9 global hectares/person (Oehme, 2008).

In 2008, Dubai government released a directive proposing a regulation that requires all buildings in Dubai to adhere to strict green standards prescribed worldwide.(Sell 2007). Greening the future was the message delivered by the government of Dubai in its DM Circular 161 which underlines the fact that all buildings constructed in Dubai from the beginning of year 2009 shall conform to green standards.

The introduction of sustainability metrics should assist in turning the generic concept of green development into action. However, one must keep in mind that the fabric of the construction industry in Dubai is made up of a mix of small, medium and large sized local and foreign contractors, consultants and investors. The industry functioning under time and cost constraints largely depends on the cohesive symbiotic functioning of all of these diverse segments complementing each other to get the job done within desired project frameworks. Getting the message of the need for green development through, to these varied types of people involved, tagged with its high financial perception would be a matter of concern during actual implementation.

The difficulty also arises with the fact that LEED solutions were never designed to be used across multiple countries and often have features with a significant 'local' flavour. Hence the impact and effectiveness of the LEED system, which forms the basis of the proposed green regulations, needs to be critically analyzed as to whether these prescribed design

requirements suit the local context of Dubai. The next section will examine the applicability of LEED guidelines and their implementation in Dubai's construction projects.

EFFECTIVENESS OF LEED IN DEALING WITH LOCAL ISSUES

Climate responsive design has been the underlying principle while identifying green building design elements. By understanding climatic conditions that are specific to a project's location, design teams are able to develop climate responsive sustainable building designs. Positive climatic attributes are enhanced and unwanted impacts are eliminated through careful design consideration. The result is a building that utilizes less energy and provides high quality and a comfortable environment for the occupants. Broadly, the UAE is defined as having a tropical desert climate, with high humidity. It experiences two distinct seasons: a hot summer at 50ºC (120 ºF) (May to October), and a milder winter ranging from 10ºC (68 ºF) to 25ºC (77 ºF) (November to April). Wind speed is generally quite high, and its direction variable (Arup, 2004). This air movement can be enhanced through responsible design to create desirable comfort conditions.

Sustainability criteria defined in LEED are evaluated in the local context and each of these parameters is explained in below.

Environment and Planning criteria

The selection of an appropriate site has the biggest impact on a sustainable design. LEED stresses upon the utilization of previously developed land and brown fields for new developments and discourages new land development. Most of Dubai's land is undeveloped and only 20% of the emirate has been occupied so far (WSP, 2008). Hence it is not appropriate to restrict development to previously developed sites as against virgin land. However, preference should be given to developed sites as their infrastructural requirements will be limited leading to minimal environmental disruption. The availability of land in Dubai makes brown fields unattractive for development.

In Dubai, site selection is often based on the commercial viability of the location. Though connectivity is an important aspect it is not always a driving factor for site selection as most of the city commutes through privately owned vehicles. Besides care should be taken not to exploit the natural ecology by restricting developments along Creek area, land connecting to the mangroves which form habitat for migratory birds; along the beachside which are already over developed, desert zones with wildlife and such sensitive zones.

Building orientation in Dubai is in response to the adjacent development like roads or natural/manmade beaches to maximize commercial viability. The lack of natural landforms and expansive desert land has restricted the articulation of the building's architectural form. This is where the need for climate responsive design becomes critical and LEED pointers come in play. Accordingly landscaping should be planned to enhance the design and utilize natural resources to create comfort zones in design. Monotonous desert sprawls in the UAE are often landscaped mainly with turf grass lawns and high maintenance plants in discontinuous patches providing little relief from the building mass. The concept of a thoroughly thought building footprint has never been relevant. Much help can be sought by following the LEED principles. LEED credits for building orientation, planting hardwood trees, north facing windows, native vegetation, shadow profiling to mention a few could be most popularly used and are apt to be applied in Dubai.

LEED propagates minimal environmental disruption from a building footprint onto a site. Common issues faced in the region like heat island effects, reflected glare etc can be reduced by designing the building with underground parking hence reducing the building footprint. LEED suggests placing parking under cover like multistory, subterranean or shade structure or utilizing a parking deck. Parking facilities and roadways have negative impacts on the environment because impervious surfaces increase storm water run-off while contributing to urban heat island effects. Encouraging the use of mass transit reduces the demand for transportation thereby reducing the space needed for parking lots, which encroach on green space on the building site (USGBC, 2007).

Dubai also has the highest rate of car ownership in the world. LEED advocates various strategies to reduce the impact of vehicles, promote fuel efficient cars, car pooling and other alternative travel options. Alternative transportation are currently being reviewed and promoted by the government. One among them is the encouragement for the use of bicycles, as most new communities are being designed as being bicycle friendly. RTA has been instrumental in setting up Bicycle Network Master Plan that will be implemented in stages from 2008 (Noort, 2008) providing 1300 kms of cycling paths, as part of the 2015 strategic vision. To ensure the success of this strategy, it is important to provide amenities like bicycle storage and showering areas as support facilities as advised in LEED.

UAE has large urban sprawls of paved area under constant sunlight. In addition, hot air released from air conditioning units contributes to warming up of built spaces, leading to Heat islands (WSP,2008). The LEED point for Green roofs can be used efficiently here to reduce heat island effect by replacing heat absorbing surfaces with plants, shrubs etc for their insulating and aesthetic benefits. In the UAE this point can be altered to form Cool roofs wherein plant matter is substituted with photovoltaic panels or solar hot water collectors to utilize the enormous heat energy available.

Similarly photo pollution is a problem, arising from the reflection of excessive building lighting utilized commonly seen in this region. LEED suggests to classify projects as per lighting zones and to design accordingly. This should be adopted at design and a regional sensitivity to determine the type of environment the project falls under and then the design evaluated. Carefully designed exterior lighting solutions can reduce infrastructure costs and energy use.

Water efficiency

UAE has one of the highest water consumption levels in the world due to climatic conditions and high per capita income (Chaudhury, 2005) though the country has virtually no natural supply of fresh water. Per capita demand in the UAE has been estimated at 378 litres/day compared with the international benchmarks of 189 – 265 liters per day. LEED water efficiency credits aims at reducing potable water consumption and generated wastewater volumes which can be applied effectively to this region.

Desalination, an expensive and energy intensive process, provides much of the potable water. Considering the extensive amount of energy and infrastructure invested in providing potable water, the careful use of water should be enforced through policies and awareness should be brought about amongst the public about water conservation. LEED credits on high-efficiency fixtures, use of automatic fixture sensors, metering controls, occupant sensors, flow restrictors, reduced flow aerators on lavatory, low consumption fixtures for sink and shower, dual-flush water closet and ultra low flush urinals, dry fixtures such as composting toilet systems and non water using urinals, should be employed to cut down wastewater volumes.

In the arid region of UAE where fresh water is scarcely available LEED advocates the need for reusing recycled gray water for non potable activities, which is now actively taken up by the government. The Dubai Municipality (DM) has an established network to distribute treated sewage effluent (TSE) and has undertaken, in conjunction with Dubai Electricity Water Authority (DEWA), to provide TSE to any new district cooling plants and community landscaping if required (DM, 2009). Building design should incorporate gray and storm water for non-potable applications such as toilet and urinal flushing and custodial uses. Similarly all car washing facilities can recover and reuse their wastewater.

The high humidity in Dubai results in significant amounts of condensate being produced by air conditioning equipment. Rather than draining this water into the sewer system, condensate can be captured and used for irrigation and other various non-potable water applications on site. One of the largest condensate recovery systems in the world has been incorporated into the design of the Burj Dubai (WSP,2008).

In Dubai, large amount of potable water is consumed in irrigation practices. Plants which are better adapted to hot arid climate, better known as Xeroscapes, consume less water and should be incorporated in the design along with night time irrigation with the help of experts in the field. Design should minimize the amount of land covered with turf due to its high water requirement. A large number of golf courses proposed in the UAE, are with expanses of green water-consuming turf.

Energy efficiency

Dubai has the world's highest per capita energy consumption at 20,000kWh per year (Sinclair, 2008). Ventilation and air conditioning in Dubai's buildings has been shown to account for up to 60% of the total energy consumed in buildings (DM, 2009). The thermal performance of the building envelope is one of the main drivers in determining what the cooling load and resultant energy use will be. Hence it is important to consider the design of building envelope with primary significance. LEED, as well as DM, prescribes strict U values to adhere to, for Building thermal insulation.

The energy use of buildings are closely related to their size, use, the way they are operated, their construction characteristics, shape and of course the climate. The hot temperatures and humidity in UAE, necessitates that all buildings require air conditioning and mechanical ventilation to be installed. Mixed mode systems combining natural and mechanical ventilation should be encouraged as for five winter months of the year the weather is pleasant and air conditioning can be optional.

In Dubai's humid climate insulation plays an important part in reducing the heat exchange between the inside and the outside environment as well as the formation of condensation. Building envelope requirements should be based on UAE's climate zone 1A classification and must meet the minimum insulation and maximum U value and *Solar Heat Gain Coefficient* (SHGC) requirements listed by the DM. Better thermal performance by incorporating building entrance vestibules and thermal bridges at floor junctions and connection points of the building envelope will reduce the energy demand for cooling and prevent energy losses.

On the onset of a design programme it is essential to set minimum energy efficiency requirements for the project, for all the proposed building systems by complying with the mandatory provisions of ASHRAE Standard 90.1-2004 for the climate zone of 1A (Rogers, 2008). Design to accomplish energy demand reduction by optimizing building form and

orientation. Strategic planting can shade the building which can decrease cooling loads during warm months.

Due to the large temperature differential between the incoming and outgoing airstreams, such as that exists in Dubai, abundant waste energy can be recovered through exhaust air energy recovery systems, gray water heat recovery systems and cogeneration. Ducts, supplying conditioned air must be insulated to minimize heat loss and prevent condensation. TSE provided by the Municipality should be used for water cooled HVACs.

There is a growing demand for economical cooling alternatives in the UAE, such as District Cooling towers (Dubai News Online, 2008).The incorporation of district cooling should be an integral part of the building design. It helps to displace bulky equipment from the building facade and roofs as is often seen on Dubai. Thermal storage systems should be included inorder to offset energy demands from peak to off-peak periods and reduce electrical costs. Refrigerant management is often a concern with high volumes of air conditioning. The design should avoid the use of CFC-based refrigerants as CFC causes depletion of the Ozone layer.

Onsite renewable energy is gaining popularity worldwide. However there are difficulties associated with implementing it here in Dubai, as the technology is not developed sufficiently for it to be more cost effective than conventional energy sources, making it difficult to convince the market to invest in it. While companies like MASDAR are aiming at using an array of renewable sources, mainly PVCs for electricity generation to utilize the potential of the hot summer sun. The maintenance of Photovoltaic cells should be considered at the design stage and provisions made for the same. In the desert conditions of UAE, with high dust content and high humidity in the air there is a buildup of dust on the solar collector panels. This requires regular cleaning as the dust reduces the efficiency of the system.

Similarly, solar water heaters can be widely used. Solar Hot Water systems are the most cost effective means of using the power of the sun. Residential buildings, hotels, villas and labour accommodation with consistent need for hot water, and their large roof expanses can make the most of this technology. Design should consider incorporation of solar hot water systems as this will have a significant reduction on electricity usage.

Materials & Resources

Dubai is facing significant challenges associated with waste generation and disposal. Design of individual buildings should facilitate the appropriate collection and disposal of waste by sorting and reusing at preliminary levels. All efforts should concentrate on minimizing waste. Recognize that there is no such thing as waste, only resources out of place.

Along with the regulatory guidelines from DM, LEED construction credits for diverting waste from landfills, recycled content and the reuse of materials in design should be applied. Waste should be segregated at disposal and central collection and storage facilities provided during design. Provide sorting and storage facilities for recyclable materials. Involve local haulers to provide waste management services. Hazardous waste should be disposed as per regulations with authorized agencies.

Identify opportunities to incorporate salvaged materials into building design. Establish a project goal for recycled content materials and identify material suppliers that can achieve this goal.

LEED encourages the use of locally sourced materials to promote local economy and provides impetus for growth. This may not seem very relevant now in UAE, but with the

proposed development envisaged for the manufacturing units, it may be a potential design consideration in time to come. Some of the regional materials available here in the UAE are glass, cement, concrete, ceramics which should be locally sourced.

Similarly Forest Stewardship Council's (FSC)certified wood for wood building components and lower grades of wood (grade 2 or 3 for lumber or veneer rather than grade 1) should be specified in design to reduce pressure on forests.

Air quality management

Dubai faces high levels of pollutions from man-made sources like motor vehicles and fossil fuel burning power stations, dust from construction and other such activities. Particulate matter, suspended in air found in desert regions are typically higher during the summer months due to more unsettled weather conditions and higher air temperatures. During building design high level filtration system should be employed in air handling units processing both return air and outside supply air. Design permanent architectural entryway systems to limit the entry of pollutants into the building.

With enclosed buildings and recirculating air in Dubai, it is necessary to monitor and improve indoor air quality with adequate ventilation requirements. Design should provide adequate ventilation with focus on cross ventilation. All naturally ventilated spaces shall be manually operable openings. CO and CO2 should be constantly monitored in car parks with constant outdoor air supply to car parks.

A governmental regulation has restricted smoking in public places and smoking rooms must obtain permit to allow smoking. Locate exterior designated smoking areas at least 25 feet away from entries, outdoor air intakes and operable windows inorder to prevent ETS intake during outside air intake. Locate designated smoking rooms to effectively contain, capture and remove ETS from the building.

Rooms with pollutants like ETS, chemical storage room, printing area etc must be directly exhausted to the outdoors with no re-circulation of return air and enclosed with impermeable deck-to-deck partitions.

Specify low- VOC materials in adhesives, paints and coatings and sealants. Assemblies that contain no added urea-formaldehyde resins are preferred.

A typical Dubai building has glazed facades with no shading structure. This results in higher cooling loads and increased energy consumption. In addition, excessive brightness contrast between externally lit surfaces and building interiors causes visual discomfort. This is altered by switching on internal lights permanently, leading to unnecessary energy consumption.

A well considered daylighting approach in buildings will not only reduce the incidence of glare and discomfort but also reduce the need for electrical lighting if part of an integrated daylight strategy with lighting controls and external shading devices. Blinds and shading fins helps in reducing solar gains in the buildings and is an old popular and efficient technique used in building design of all temperate regions. LEED recommends direct line of sight to the outdoor environment via vision glazing to achieve a minimum glazing factor of 2% in regularly occupied areas. This needs to be carefully incorporated along the north facade in Dubai considering the heat gains from exposed glazing and high occupant loads. Also allow for comfort control adjustments to suit individual needs or those of groups in shared space. Integrate individual controls with occupancy sensors.

Vernacular design features

The architecture of today calls for 'a modern vernacular that is inspired by a responsive and sensitive balance between the knowhow and wisdom of the past and that which is sustainable, yet modern.' Vernacular design critically examines the possibilities of implementing local know-how in both a developmental and modern context. In response, contemporary Gulf architecture should be about applying tradition, culture and modernity in equal parts, to create something that is undeniably 'Gulf' yet clearly modern.

A traditional design takes advantage of the existing natural resources. Passive building design and material choices that avoid absorption of the sun's heat to promote thermal comfort and energy conservation, are traditional methods used by early inhabitants of UAE. Dubai's traditional buildings, like the ones at the Bastakiya have light coloured exterior finishes and they help in reducing energy use. Light exterior colours with high SRI are highly recommended.

It is common to see water features in the UAE used for aesthetic enhancement. Well maintained water features checked regularly for Legionella bacteria prevalent in this region due to high humidity, can be incorporated to promote passive cooling during the hot summer months. Water bodies add to the humidity levels during the summer months, causing further discomfort, hence their usage thoughtfully designed.

Courtyards provide relief by creating negative pressure zones hence attracting air movement as well as creating interesting interactive spaces. These along with wind catchers can be positioned to trap and filter breezes aiding natural ventilation during the cooler months of the year. Mechanical controls can be incorporated to shut off or promote air circulation.

THE CASE STUDIES

Case studies are carried out in an attempt to understand the application of the principles and ideas reviewed above elements in project design and execution. Vast amount of information and project management techniques can be learnt from the practical experience gathered in case studies. Two projects were taken up to evaluate the current practices in green design and identify good practices.

The first project is a five star luxury beach resort in Dubai proposed to be a LEED accredited building. This is analyzed against evaluated LEED principles and compared against the list of green elements compiled from the study. A check list with reasoning for each of the elements was prepared and sustainability measure of the project verified. As the building is designed to be LEED rated, various design credit elements have already been incorporated. However, from the check list responses it was noticed that the five star nature of the project and the associated security and quality issue perceived has, in certain cases made it difficult to address a number of the sustainability criteria.

The case study revealed that a large number of design and execution points learnt in the planning techniques have been implemented to the design process of this resort building. A number of procedures have been put in place through an integrated design process to ensure the successful implementation right from the design stage. Careful execution forms a very important part for the success of the green initiatives endeavored in this project. A few

notable design measures implemented to increase the sustainability credentials of the Project include

- Translocating trees for reuse rather than removal;
- The use of native, desert adapted plants
- Cool roofs with solar thermal water heaters
- Graywater recycling through water saving shower heads, taps and low flush toilets etc;
- Energy saving technologies, such as insulation, building orientation, shading and energy saving bulbs;
- Use of locally sourced materials where possible,
- Waste management strategies during construction and operation;
- Sourcing of local and sustainably grown goods
- Sustainable transport linking of public transport systems to the Project
- Using savings on road and service infrastructure to invest in more energy efficient buildings, renewable energy systems and sustainable water management.

The need for no new infrastructure to be placed, due to the existence of the prior resort facility, has been a bonus to the site as no major excavation and laying of infrastructure lines is now required. The large expanse of building footprint spread all across the site necessitated by the nature of resort buildings, has disturbed the natural state of the site. Though this sort of spilling of building masses is dictated by the typology of resort building, careful addition of native planting and the restoration of existing site plant material being wisely incorporated in the landscaping scheme has added value to the quality of natural eco system created within the resort premises. An attempt is made to minimize disturbance to the eco system and factors to sustain and promote the existing system are put in place. Pointers from the sun and wind directions study have been utilized to enhance interior occupant comfort levels, which is seen through the in-corporation of architectural elements like a cascading roof providing shelter from the south sun, permanent manually adjustable wooden louvers and blinds, intermitted water bodies positioned in the flow of wind etc. Due to the lack of practice of sustainability elements within the region, there are no suppliers to provide specific green products. Local materials are very few and those available are not cost-effective.

It is noticed that sustainable design elements form an overarching component of the Project, and is considered in all aspects of the project design and execution. LEED is used to guide the Sustainable design process in which water, energy and resource demands as well as waste are attempted in being reduced without affecting the overall experience of the building and surrounding landscaping. To ensure efficient co-ordination between all team members, an integrated design approach was employed and LEED design workshops were help frequently. A LEED coordinator was essential in facilitating the progress of the design. The most difficult aspect was to reach at an environmentally friendly design while making sure that the commercial benefits were not impacted. On the whole this project is a good example of sustainable building design in practice in Dubai.

In the second case study sustainability was driven by what was considered to be “responsible” design. This project is a resort shopping destination (figure 1) within the urban city sprawl. It is a low rise building with a canal forming a central water body and smaller fragmented building masses connected to the main building through bridges facing the creek which ultimately culminates as the quayside.

This project was conceived in 2003; before the trend of green architecture and sustainability came about to Dubai. Nevertheless it was still considered as an excellent example of the use of passive elementary architectural features, which are easy to maintain and operate. Many systems and architectural elements were specifically designed to accommodate local conditions and create comfort zones.

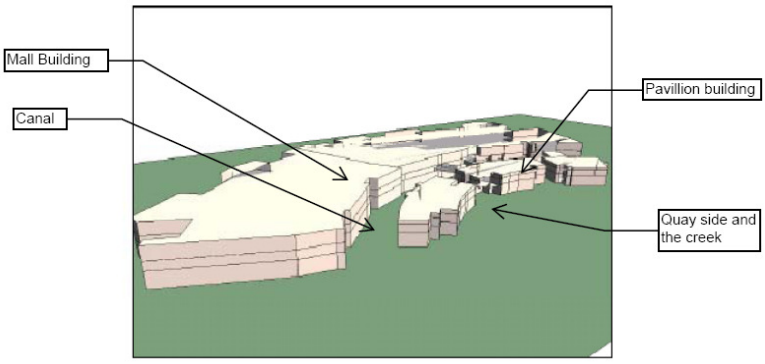

Figure 1: Mall Building Composition

This case study was compared against the green elements shortlisted through the study of sustainable techniques. Some of the outstanding sustainability elements incorporated are discussed in below.

The creation of Microclimate by intelligent planting, features like cool walls, topiary misting, waterfalls, shading devices like Teflon coated canopies, building mass shading, drop down shades and temporary screens, green roofs and wind shield structures is highly notable. Modifying factors like the air and radiant temperatures, wind conditions and humidity helps create microclimates for comfortable external spaces.

The microclimate zones are provided with fully shaded walkways (figure 2) with reflective canopies that provide shelter from occasional rainfall. By providing additional surfaces such as cooling walls, planting and grass cover, the resultant temperature has greatly improved. In addition, high thermal mass of surrounding walls aid the pre-cooling process keeping the outdoors ambient.

To encourage air exchange, lightweight fans are situated below holes in canopy frame reducing heat sensation significantly. The traditional internal courtyard provides good shading by virtue of the enclosing buildings, and is aided by relatively small overhangs. Water features and planting provide local evaporative cooling, and are most effective when the relative humidity drops, typically mid-afternoon. The courtyard effect is achieved in between the building masses, at the canal walk and between building blocks, where shading is provided by the buildings and air movement is triggered by the stack effect.

In order to protect the space from uncomfortable wind conditions, planted trellises are used as wind breaks. High levels of planting and a green roof used reduces surface temperatures and offer shading.

Water features used intermittently and abundantly throughout the project provides relief from hardscape. Light coloured deep shaded pools help to lower the temperature of the water body. Sun protection is provided by building overhangs after a computer generated shading model

was studied. Drop down shades, temporary screens, awnings and trellis have been used to mitigate the sun.

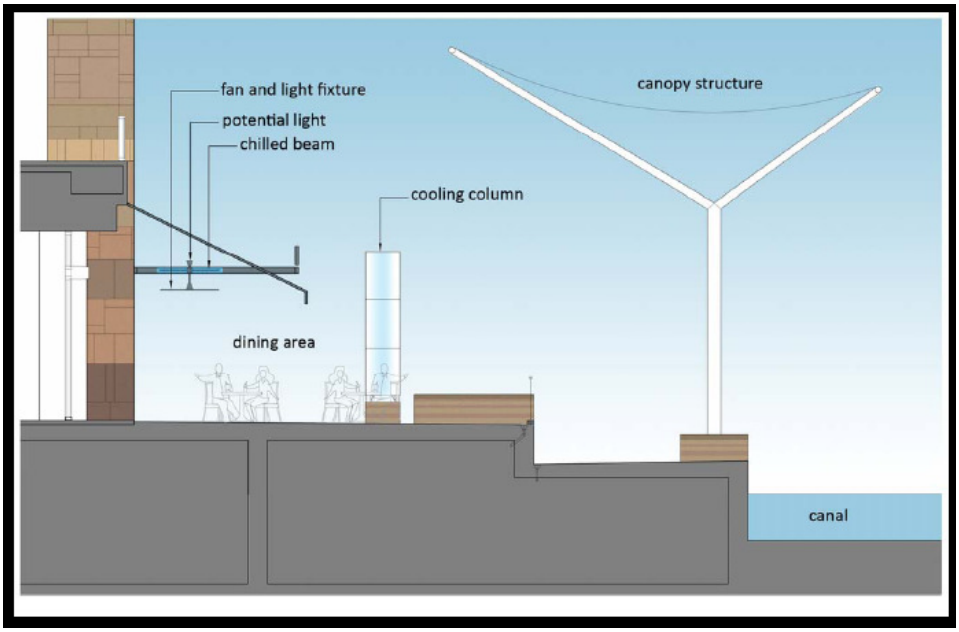

Figure 2: Cooling of the canal side

The external envelope consists of high performance insulating glass units with solar control tempered glass and ceramic fritting where required to reduce glare. External walls are of natural stone, ceramic tiles, terracotta tiles used to reduce energy losses. Most of the components can easily be recycled at the end of their design life for reutilization.

The analysis shows that sustainability was not a guiding factor during the planning stages neither was it not considered as one of the primary aims of the project, yet best practices were employed in all sectors of design which in itself incorporated sustainability elements. No benchmarks for green building design were set at the conceptual design stage, however a design in response to climatic conditions was a part of the design brief. Enhancing the comfort level of occupants and providing a comfortable pleasant outdoor and indoor ambience was a design need. This necessitated the need to consider the environmental impact while designing unlike typical Dubai buildings. A detailed climatic study with the movement of sun, temperatures, wind, the impact of the large creek water body and associated humidity factors were considered.

Creation of a controllable Microclimate is an effective strategy that can be implemented in Dubai. Passive techniques, inspired from vernacular local architecture should be implemented as being a low-tech, low maintenance sustainable design feature. Though not all aspects of green design are considered in this project a variety of design recommendations found in LEED design submittals are covered. The mall, currently operational since 2 years, is very popular with heavy footfall and high retail sales. The popularity of this recreational destination speaks in itself about the success of comfortable sustainable design conditions that the consultants have attempted to create and succeeded.

This case study demonstrates that the use of a rating system is not essential to ensure that sustainability factors are achieved. Responsible design along with an awareness of the deteriorating environment and concern for minimizing consumption is the need of the hour. The project inculcates basic design criteria for good responsible design with worldwide best practices being adhered to. Along with it are age old proved and recommended techniques of wind catching, courtyard effect, water body enhancement and passive shading elements infused into the design to suit the contemporary context of a modern shopping mall. The resultant is a user friendly, eco-friendly sustainable development which responds to its duty of environmental wellness.

DISCUSSION AND CONCLUSION

The case studies showcase that when we talk about green buildings, we are really talking about redesigning the design process – rethinking everything from the place to the schedule and pace of design.

Lessons learnt include that additional time and procedures need to be invested to formulate procedures and systems customized to individual site conditions. Thoughtful specification forms an important part of design development. It was also learnt that the Municipality procedures and infrastructure in place, like hazardous waste treatment facilities, an extensive TSE network to name a few, are very beneficial and aid the Green building design intent. The propagation and popularity of such projects will gradually tune the supply market too, for obtaining local and fair trade materials and stimulate the usage and market for green products and eventually successful green buildings.

Both the case studies highlighted the need for input from all members of the design and construction team. Building design requires the integration of many kinds of information. The construction industry is commonly characterized as technically and organizationally fragmented (Kaatz et al.2005 cites Egan,1998). This fragmentation is a key factor preventing a tangible transition to sustainable construction (Kaatz et al.2005 cites Sheath et al., 1996; Lee et al., 2000). In integrated design, process stakeholders are brought together at the earliest practical point in order to develop and execute a common project vision. These meetings create a communication space, where stakeholders work in close co-ordination and develop mutual understanding and trust. Integrated design clarifies client goals, design options and solutions, which allows for achieving the intended building performance.

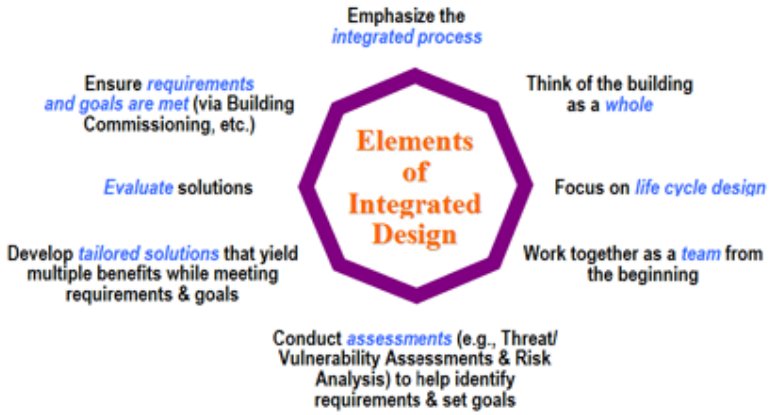

Figure 3: Elements of an Integrated Design (WBDG Aesthetics Subcommittee, 2009)

Good buildings result from an appreciation by all involved of the importance of formal consistency throughout the design. Every successful mission, in any field of work, relates to the consistent sincere commitment of all members of a team towards an integrated goal. The same holds true for our buildings.

ABSTRACT
The complex and dynamic nature of project environments presents both opportunities and challenges for the empowerment of individuals and teams. Yet, empowerment is a complex concept in its own right, taking on multiple forms across people, is contextually embedded and shifts over time. As research on empowerment in projects continues to grow, pertinent questions are emerging aimed at promoting the growth of empowerment theory and its applicability in practice. For example, how do organizations empower employees at different levels and still be able to achieve goal congruence across the organization?; how does empowerment manifest itself across project phases?; and how does empowerment manifest across co-located or geographically/physically spaced individuals on the same or different projects/teams across the same organization? The multiplicity and dynamism of empowerment in projects across three aspects - space, time and levels, and their intersections are examined within the context of the complex, dynamic and uncertain operational realities of projects. It is argued that such a spatiotemporal agenda is better understood through the lens of chaos and complexity theory, a perspective that reveals the way in which empowerment is intertwined with other managerial interventions and business strategies for the successful delivery of projects.

Keywords: chaos theory; complexity theory; empowerment; spatiotemporal

INTRODUCTION

The nature of work is changing rapidly and the impact is evident across all levels of business organisations (Conger 1988, Gray 2003). The change is altering the tempo of the environment within which construction organisations operate, compounded by emerging project delivery arrangements, increasing complexity of projects and client requirements and the temporary multi-organisational context of projects. Construction professionals are facing constantly changing organisational procedures, processes and requirements associated with increasingly demanding and ambiguous objectives of projects (Kűsel et al., 2001). This complex and dynamic situation has been described by Rowlinson and Mcdermott (1999) as one that makes the "control and command paradigm of project management inefficient" and requires resolving the emergent ambiguity through the construction of shared consensus of the project objectives. Complex and dynamic work settings such as in construction project environments have long been viewed as appropriately suited for the empowerment of individuals and teams (c.f. Kanter, 1977, Greasley *et al.*, 2005, Langfred, 2000, Loosemore *et al.*, 2003).

Empowerment has emerged as a popular concept in managerial rhetoric and the focus of numerous scholarly studies. Many of these suggest that empowerment practices are likely to offer substantial impact in many organisational contexts, including enhanced organisational agility and greater employee satisfaction (Chebat & Collias 2000). Nevertheless, despite its popularity, empowerment is still a term that confuses as much as it inspires (Simon, 1990). A review of the literature reveals little shared understanding of the term. Lincoln et al. (2002) describe it as a floating concept which means different things in different organisations, and to different organisational actors. Both management and employees interpret empowerment from their own perspective to suit their own needs and accordingly, have differing expectations.

This seemingly confusing view is compounded by the bolting of empowerment onto other managerial interventions such as total quality management (TQM), reengineering, lean concepts and just-in-time (JIT) aimed at improving the delivery of construction projects for example (Dainty, Bryman & Price, 2002). The pervasive process fragmentation and the mutual interdependence of interfunctional teams within the project delivery process, however, make it difficult to understand how empowerment intertwines with these organisational strategies. The complex and dynamic nature of the project environment therefore presents both opportunities and challenges for the empowerment of individuals and teams. Not least, its own complex nature, taking on multiple forms across people, levels, is contextually embedded and shifts over time (Tuuli and Rowlinson 2010; Foster-Fishman et al, 1998). This paper presents this spatiotemporal perspective on empowerment within the context of the complex, dynamic and uncertain operational realities of projects. It argues that the spatiotemporal nature of empowerment can be better understood through the lens of chaos and complexity theory, a perspective that better illuminates the way in which empowerment is intertwined with other managerial interventions and business strategies for the successful delivery of projects.

THE EMPOWERMENT CONCEPT

The empowerment concept is elastic and so it is not always clear what it means in different organisations (Dainty et al., 2002). It is also a contested concept whose meaning shifts

according to the interests and goals of those who use it. The concern however, is that, much of the literature on empowerment is both generalised and unitarised in orientation without cognisance to its multiplicity and dynamism (Foster-Fishman et al., 1998). McIntyre (1986) notes that, the way in which empowerment is conceptualised will influence the way in which strategies are developed for structural changes. This is because, different understandings of empowerment will shape the way in which we construct models of empowerment. Thus, actions considered empowering by an employee, may be experienced by management as stifling and vice versa (Pease, 2002). Solas (1996) has argued that some of the key assumptions, goals and practices of empowerment can actually perpetuate hierarchical power relation between employees and senior management. Those on top of the hierarchy are viewed as the ones who have the power to be given to employees below the organisational ladder.

Whether an empowerment strategy is successful or not is dependent on the organisational context and the mode of its implementation (Conger and Kanungo, 1988). Most of the management literature refers to empowerment from two distinct perspectives; the psychological perspective and the structural phenomenon (Spreitzer 1995; Thomas & Velthouse 1990). The former focuses on a psychological state encompassing the individual job incumbent‟ perception of a) meaningfulness, b) competence, c) self-determination, and d) impact (Conger & Kanongo, 1988; Spreitzer 1995). The structural perspective refers to empowerment as managerial initiated phenomenon. This perspective focuses on a set of organisational policies and practices initiated by management with a goal of addressing conditions that foster powerlessness and cascading decision-making authority down the organisational hierarchy (Conger & Kanongo, 1988; Eylon & Bamberger 2000).

An incomplete picture of the empowerment journey is presented when psychological and structural perspectives are considered as separate constructs, a perspective that ignores their complementarity as a case for integration (Tuuli and Rowlinson 2007). The empowerment process is therefore better conceived as an interactional process in which the perception of empowerment (psychological empowerment) is shaped through interaction with environmental factors (structural perspective), producing behavioural outcomes. Thus changes within the work environment perceived as empowering should influence and reinforce the cognitive state of employees and eventually affect outcomes and provide justification for continual reinforcement of organisational practices (Tuuli and Rowlinson 2007). However, there is a paradox that lies beneath the implementation processes. The very existence of circumstances that place the organisation or more precisely senior management in a position to provide another group with discretion to do their jobs well, through structural/managerial interventions implies that empowerment is a finite commodity controlled by a sub-set within the organisation (e.g., Eylon, 1998)

Examining empowerment from the psychological and structural perspectives alone, however, belies the complex and multiple forms empowerment manifests across people, levels, its contextual embeddedness and its shifting forms over time (Tuuli and Rowlinson 2010; Foster-Fishman et al, 1998). In the sections that follow we examine this spatiotemporal nature of empowerment with reference to the project context and allude to the paradoxical tendencies in empowerment implementation.

SPACIOTEMPORAL NATURE OF EMPOWERMENT IN PROJECTS

An important feature of projects is that each exhibits a unique lifecycle that defines its complexity and dynamic characteristics. These could relate to its site-specific nature, design and custom-built to unique specification, constant refinement of project outcome to meet emerging clients‟ needs. This dynamism is compounded by the use of specialised teams (Cherns & Bryant, 1984) that are usually geographically distant and functionally disparate (Murray, et al., 1999, Eccles, 1981) who convene as a temporary multi-organisation to complete the project (Cherns & Bryant, 1984). As each project organisation is temporary, there is no innate drive to build long-term relationships. Winch (2000) posits that the multi-organisation nature of projects creates an organisational dynamism, which can easily generate conflict rather than cooperation within the project coalition. The transient nature of construction projects and the temporary requirement of the project team make it difficult to develop the trust and the cohesiveness required for effective teamwork. Such dynamism significantly impacts employee‟s empowerment experiences. In project context therefore, the preeminent question that arises is: How does empowerment manifests across co-located or geographically/physically spaced individuals on the same or different projects/teams across the same organisation and throughout the project phases?

Contextual Dynamics of Empowerment

As a contextually determined construct, empowerment is particularly prone to fluctuations over time within the project environment (Foster-Fishman, 1998). Individuals‟ perception of their changing environment and shifting organisational demands highlight the elements of the contextual dynamism that are most salient to their empowerment experience. Koberg *et al.* (1999) posit that perceived empowerment is a process that expands an individual‟s power as opposed to merely a state of being and as such, it takes place in varying degrees throughout an organisation, with individuals experiencing different feelings of empowerment at different times. Hence, feelings of empowerment are not fixed. Depending on the organization and leadership‟s continued support, trust and value systems, empowerment levels will change. This dynamism may diminish significantly the efficacy of an intervention created from an understanding of the context and its members that is based on one point in time (Moos, 1996). Thus intervention plans should include ongoing measurement of the context, in order to assure a continuing alignment between contextual influences, participant needs, and intervention goals (Foster-Fishman et a., 1998). Understanding the dynamism of empowerment in project settings demands a theoretical position which illuminates the complex and interwoven set of perspectives and decisions which characterise the project environment.

Within a given project team, empowerment will take on multiple forms dependent on individual‟s sociocultural and political context and the internal climate of the project environment (Foster-Fishman et al., 1998). Empowerment has different meanings and different factors influence the employee empowerment experiences. Within a given project team, individual members will have unique personal histories, assume different roles and often come from different social background (Martin, 1992). It has been argued that these social and historical characteristics shape individual desire for empowerment (Zimmerman, 1995). Collins (1986) also emphasised that individuals with different racial, gender, ethnic, class, and social backgrounds will desire different forms of empowerment. Culture also

influences one‟s desire for empowerment. Every culture has a consistent core set of rules that influences people to act similarly in ways that help them understand each other. Family emphasis, individual preferences and other factors influence how deeply embedded one is in one‟s culture (King, 1994). If the internal climate of the project team is not in alignment with the individual‟s cultural influence and belief system, his behaviour and attitude towards his work will be impacted. Factors emanating from the individual, team, organisation and project contexts have therefore been found to exert significant influences on the empowerment experiences of individuals and teams (Tuuli, 2009). Without a supportive structure and an enabling context, any attempt to reinforce empowerment will be blocked, either by structural reasons or lack of support at both inter and intra personal levels. Thus, to overcome the empowerment paradox, that is, to achieve genuine empowerment, the organisation must constantly seek and be adaptive to contextual influences different levels.

Empowerment at Different Levels

Empowerment is relevant at the individual, team, and strategic levels. The capacity to organise and mobilise ideas to solve problems is a critical team level capability. The norms and network that enable collective action drives the project forward. There is a reciprocal relationship between individual capabilities and the capability to act collectively as a team (PREM World Bank, 2002). In a strategic context, organisational policies and culture shape the actions of all other actors within the organisation. There has been interest in the development of a conceptual framework, which explores the relationships among different levels of empowerment; how participation in organisations or communities concern can enhance individual empowerment and vice versa (Gutierrez, 1988). Different conceptualisations of empowerment have ranged from empowerment at the individual level as an increased sense of control, power, or personal life events (Schulz, et al 1993), to individual and teamwork performance behaviours (Tuuli & Rowlinson 2009), or multiple levels of interactions as individuals, organisations and communities act to create social change (Wallerstein, 1992). Examination of the empowerment process, which incorporates individuals, project, and strategic levels of analysis, will represent a more holistic picture of how empowerment manifests.

Perceived control at the individual level has been explored in research on self-efficacy (Bandura, 1982), and the ability to take action or improve interaction skills (Pinderhughes, 1985). Bandura‟s (1982) conception of self-efficacy involves beliefs about one‟s ability to produce and regulate events in life. Perceptions of influence or efficacy are explicitly linked with participation in organisational or team change efforts and the concurrent development of analytical and practical skills (Zimmerman, 1990). At the team level, empowerment involves the shared experience, analysis and influence of group on their own effort (Presby, et al 1990). Linkages between empowerment at the individual level and at team and strategic levels are made by linking development of personal power and ability to act to opportunities for support and development of interpersonal and required skills (Kieffer, 1984). At the strategic level, empowerment revolves around the utilisation of resources and strategies to enhance organisational control (Labonte, 1989).

Empowerment manifests at the strategic level when organisations provide opportunities for individual growth and access to decision-making process (Schulz, et al 1993). However, a levels perspective of empowerment raises the question of how organisations can empower employees at different levels and still be able to achieve goal congruence across the organisation. Empowering organisations are cooperatively controlled by their members and

work toward goals defined by those members within the parameters of external opportunities and constraints (Crowfoot, 1981). Individuals may develop skills and a sense of personal effectiveness through participation and leadership opportunities within the organisation (Schulz, et al 1993). The conception of strategic empowerment helps to link the individual and the project levels of empowerment. Individuals work within cooperatively managed organisations and become empowered through the development of skills and the opportunities to participate in process of decision making and goal setting with other team members. In turn, the individuals empower the organisation to effectively work toward the project goals within the context of the strategic organisational environment and external influences. Thus, perceived influence at the strategic and team levels both shapes and is shaped by perceptions of individual control.

THE EMPOWERMENT PARADOX

At the core of the empowerment paradox however, is the belief that there is some clear demarcation between management and employees - between those who have and those who do not have power (Eylon, 1998). The contention here is that, whatever the good intentions of those who seek to empower others through the levels as discussed previously, those intentions will be translated into concrete practical initiatives which set limits and boundaries within which the empowered operates (Potter, 1994). This notion was emphasised by Simons (1995) when he contended that „management must exercise levers of control in a climate of empowerment to harness employees‟ creativity. Empowerment thus becomes senior management controlled initiatives. Yet, the use of such barriers restricts the supposed freedom which empowerment is meant to offer employees. This is consistence to Argris (1998) assertion that empowerment process only appears to give employees greater control, but in reality, it remains dominated and restricted by management. He therefore views empowerment as still mostly an illusion. It is the practical objective limits set by management that raises tensions between the perceptions and needs of management and are likely to be set against the perceptions and needs of the empowered (Conger & Kanungo, 1988). This is consistent with circumstances where empowerment represents a “moral hazard dilemma” for managers, as the success or failure of empowerment then depends on the ability of managers to reconcile the inherent loss of control that empowerment brings with the fundamental organisational need for goal congruence (Mills and Ungson, 2003).

In addition to the need of resolving this paradox, as long as some organisational members do not have full access to information, autonomy, or the trust to plan and carry out improvement, then the need for empowerment will perpetuate the organisational process. Empowerment requires the belief that all have the right to be active and interactive participants of the organisation. It is only when all view each other equally that true empowerment will occur. Only under these circumstances can individuals truly unveil their unique experiences and abilities to the organisation (Eylon, 1998). Not subscribing to this notion will result in limiting the sphere within which empowerment is pursued, thus creating a condition which defeats the empowerment process. The paradox surrounding empowerment contributes in making the construct more complex than often realised. As Conger & Kanungo (1988) and subsequently, Lincoln et al (2002) note, „the management literature on empowerment often lacks clarity, is overly simplistic and is riddled with ambiguity‟ as the concept is difficult to grapple with in practice. The spatiotemporal perspective on empowerment coupled with the paradox surrounding its implementation emphasis it‟s complex and dynamic characteristics

and in particular how its manifestations shift over time, across space and levels in projects. Such a perspective is better understood through a theoretical lens that affords explicit consideration of the multiplicity, complex and dynamic characteristics of empowerment. In the section that follow, the principles of chaos and complexity theory are introduced and portrayed as representing such a theoretical lens. The key elements of chaos and complexity theory are seen as providing an interpretive framework for understanding the nature of empowerment in projects as it enables us to explore the context that governs project dealings and interactions among project participants, and enables us to address those aspects of the complex nature of projects that cannot be captured by project management processes for planning, prediction and control.

CHAOS AND COMPLEXITY THEORY

Chaos and complexity theory first rose to prominence through Lorenz‟s work on weather patterns and spread to other physical systems (Gleick, 1987). Complexity theory on the other hand, advanced through its application in biology where the search for an explanation to the apparently escalating evolutionary complexity of living organisms has been sought (Smith, 2004). Another stimulus to the advancement of complexity theory has been through work on systems theory in organisation science. General systems theory proposes that the universe should be recognised as a vast, interconnected, and interdependent whole (Kielhofner, 1995), where a system refers to "any complex of elements which interact and together constitute a logical whole with a purpose or function" (Kielhofner, 1995, p. 9). Open systems allow the dynamic, self-organisation that is exhibited during interaction with the environment (Allport, 1968). An extension of this, dynamical systems theory, assumes that when sufficient energy is channeled into systems of complexity, new states of organisation can emerge spontaneously, arising from chaotic states (Haken, 1987). The common thread in chaos and complexity thinking revolves around the idea of interaction of elements in a system.

Chaos theory deals with simple, deterministic, nonlinear, dynamic systems, that are sensitive to initial conditions resulting in an unpredictable chaotic response to any minute initial differences or perturbation, whereas complexity theory focuses on complex, nonlinear systems. Complex systems respond to perturbation by self-organising into emergent forms that cannot be predicted from an understanding of its parts (Reitsma, 2001). The focus of chaos theory is on the manner in which simple systems give rise to very complicated unpredictable behaviour, while complexity theory focuses on how systems consisting of many elements can lead to well-organised and predictable behaviour (Bloom, 2000). Smith (2004) argues that chaos and complexity need to be considered in unison from an organisational perspective. They are perhaps best viewed as complementary notions, at least from a managerial perspective, because they both encourage thinking differently about the way systems and organisations operate (Smith 2004). The two terms represent the ends of the same conceptual continuum. From complex systems comes simple behaviours and from simple systems comes chaotic behaviours. The appeal of such a theoretical lens for understanding organisation concepts emerges from the ability to illuminate how order, structure, pattern, and novelty arise from extremely sophisticated, apparently chaotic systems and conversely, how complex behaviour and structure emerges from simple underlying rules (Cook-Davies et al., 2007).

Although the conceptual basis of complexity theory arose from work undertaken in physical systems science, and subsequently from systems theories that have developed from organisation science, it is typically assumed that its popularity amongst managers has improved as a consequence of uncertainty in the future of organisations (Smith 2004). Similarly, Tetenbaum (1998) contend that complexity theory is gaining momentum as management practice as the new world is full of unintended consequences and counterintuitive outcomes where the map to the future cannot be drawn in advance as we cannot know enough to set forth a meaningful vision or to plan productivity. Complexity theory provides a way to understand the unknowns and uncertainties associated with complex systems. The management of projects transpire in a complex environment (Bertelsen, 2004) thus the application of complexity theory to the understanding of empowerment in projects may enable the systematic considerations of the conditions that give rise to such complexity (Antoniadis et al., 2009). Understanding the nature of empowerment in projects will enable management to respond with a design of more efficient project delivery systems to improve the setting up, management style and decision making processes for the delivery of projects.

Generally, project management practice understands the project as an ordered, linear and therefore predictable phenomenon which can be organised, planned, and managed top down. The project is therefore often divided into constituent parts such as contracts, activities, work packages, etc and assembled more or less interdependently to achieve the whole without considering the dynamics of the surrounding (Wood and Ashton, 2009). The frequent failures to complete projects on time, on budget and on quality (Bertelsen, 2004) give rise to the thinking that the process may not be as predictable as it may look. Complexity theory advocates perceive projects in a different light to that of the mainstream views. Through the perspective of chaos and complexity theory, a project is a nonlinear, complex and dynamic process which has within itself the capacity to interact with its environment resulting in a whole that cannot be understood by analysing it constituent parts (Cook-Davies et al., 2007). This perspective therefore requires that project team members should not be encased in a machine-like working mode which emphasises control, order and predictability but rather be more engaged with the environment and processes to encourage learning, creativity and flexibility.

Complexity theory advocates challenge two main assumptions of mainstream project management researchers and practitioners. First, they question the image of a project, and its human practitioners, as a predictable system or machine, that is predictable by understanding its functioning parts. Secondly, they resist the notion that the project manager is an objective, or impartial, agent of understanding and control (Sage, Dainty & Brookes, 2011); Masterpasqua & Perna, 1997). Sage et al (2011) have outlined manifold reasons for challenging machanistic views. They point out that it encourages hopeful long-term planning over continuous reflection and group communication, it does not address and value the dynamic and unpredictable emergence of social interactions through which project decisions are made, this influences project outcomes, goals, ethics and politics, it assumes stability and predictability is the ideal state for organisation, which prevents project organisations from understanding and bringing about the required change. It also reduces people to predictable parts in a machine hence it impedes learning and flexibility (Sage et al 2011; Cook-Davies et al., 2007). We contend here that these bottlenecks similarly inhibit a better understanding of the multiple, dynamic and complex manifestation of empowerment in projects and that a chaos and complexity perspective provides a more profound alternative view.

UNDERSTANDING THE SPATIOTEMPORAL NATURE OF EMPOWERMENT THROUGH CHAOS AND COMPLEXITY THEORY

Scholars of organisational studies have often used metaphors and models to help describe and explain the complex social phenomena observed in organisations (Lamberg & Parvinen, 2003). The metaphors applied to understanding behaviours and organisational change have included those derived from complex sciences, including chaos complexity theory (Olson & Eoyongi, 2001). Given that the impact of empowerment affects behaviour in ways that may not be entirely predictable (Wilkinson, 1998), it is reasonable to suggest that metaphors and models applied to organizations may transfer to the study of empowerment in projects. Complexity theory is negotiated and open to varied interpretation, which presents a wide range of possibilities in exploring its implications on social phenomena such as the project environment. Empowerment is seen here as a complex and iterative process, which can change, grow or diminish based on unfolding events; individuals and projects historical/social contexts, and organisational processes. It is not controlled or predictable in its outcomes. Eylon (1998) posits that empowerment is an ongoing development and will have lasting repercussion for organisational structure. Her argument suggests that organisational structure will need to evolve as empowerment initiatives are implemented. Organisational interventions are by their nature complex, dynamic and comprehensive. Interventions, which comprise simultaneously many target populations at various levels (individual, team and strategic), are complex to evaluate and comprehend. Chaos and complexity theory may provide a lens for understanding the complex and dynamic nature of empowerment in projects.

Empowerment in projects is dynamic as a consequence of the dynamic nature of project environments; a shift in internal and external factors impact on organisational processes and outcomes. People‟s perception of their work environment changes inline with the dynamic state of the organisation and external influences. Chaos and complexity theory recognises this dynamism and can help explain why empowerment feelings can be on a constant shift based on unfolding events as opposed to a state of being. Such a view is also consistent with the post-modern self perspective, whose basis can be found in chaos and complexity theory (Bloom 2000). In contrast to the modern man who could objectively discover the machine-like workings of the universe, the post-modern self is an open system, dependent on context, always in a state of becoming, actively integrating new information and exchanging that information with a changing environment (Masterpasqua & Perna, 1997). According to Smith (2004) the need for non-reductionist ways of approaching management problems has set the scene for complexity theory to be considered as management tool. The mechanistic approach of reducing all systems to their constituent parts is inadequate to allow managers to deal with the changing environment (Keene 2000). To keep with the flow, workers are required to adapt to environmental changes. Thus, empowerment interventions become processes for aligning individual needs with current environmental and organisational conditions. The output of empowerment initiatives can therefore not be controlled or predicted. In chaos, this can be likened to “sensitive dependence on initial condition”, expressing an understanding that even minute differences in input can quickly manifest as an overwhelming difference in output (Bloom, 2000). The implication for project organisation is that providing teams with necessary skills and training or the adoption of seemingly minor technology or software that could enhance job performance can have a substantial impact on project outcomes. Murphy (1996) suggests that this principle defines the very nature of nonlinearity in that, minute change in some system‟s initial conditions may actually amplify exponentially as their effects unfold so the end result bears little resemblance to the beginning.

There is a reciprocal relationship between empowerment at different levels (individual level, team level and strategic level). Chaos theorists hold the view that the proper role for organisations is to be a safe container for the chaos of individuals‟ experience, alternating between provoking enough anxiety to propel the person or team into the vortex of change while soothing anxiety that is threatening to overwhelm the system forcing it into regressive solutions (Bloom 2000). An organisation that encourages such type of empowering process is referred to in chaos theory as fractal organisation, one that trusts in natural organisational phenomena to order itself. McClure (1998), postulates that there is a process of chaotic transformation that can occur in a team if there is effective group leadership that does not seek to control and limit the group transit through the period of conflict and chaos. He sees groups that become regressive and even disruptive as those that have been unable to evolve and develop, to self organise out of the chaotic transition in a healthy way. Change is encouraged when organisational design is there only to gently direct informal behaviour toward goals. From a chaos and complexity perspective therefore, the development or implementation of empowerment accounts for the dynamic interaction and influence of empowerment at the individual, team and strategic levels.

At the strategic level, empowerment revolves around the provision of organisational resources and opportunities for individual and team support and growth. At the team level, empowerment manifests when those supports enable the teams to achieve the assigned projects goals within the context of organisational and external influences. By allowing members of the team within the organisation autonomy, this encourages the team to organise itself into emergent state, enacting multiple iterations of its own functioning until the various pieces of the team members can work together most effectively. Emergence is a characteristic of a complex system arising through the innovation and learning that occurs as the internal structures of systems evolves and changes (Mason, 2001). Under the right circumstances these emergent behaviours can lead to unpredictable innovations (Stacey, 2003). The emergent order represents a „bottom up‟ process arising when the collective behaviour of interactive individuals results in a system or part of a system adapting and creating new ordered state (Stacey, 2003). The implication is that the key strategic empowerment level will shift from maintaining control to supporting the emergence of new order where emergent innovations can react to market changes.

Individual perception of empowerment experience could take multiple forms dependent on demographic characteristics and social opportunities. Cultural values may highlight the fluctuation in the meaning of empowerment dimensions across peoples. Empowerment strategies that work well in the western world may not be valid in other cultures. Project teams could be bound by common objectives but difficult to capture the wholeness of the external influences that play on an individual‟s cognitive motive. Chaos theory holds the view that, systems operate in highly complex and instable manner, but a „strange attractor‟ which is an element of a complex system creates an order within chaos; it bounds the behaviour of the system (Thietart and Forgues, 1995). Strategic planning can thus be focused on a limited number of scenarios defined by the system‟s attractors (Levy, 1994). This encourages organisations to concentrate on the significant issues within the project team, which need to be handled in the short-term, and ensure that the debate about their long-term consequences is lively and engaged. Thietart & Forgues (1995) describe strange attractors within organisations as „organisational configurations which demonstrate regularities in their macro-characteristics even though they may reveal large differences in their internal process. Strange attractors are not steady state, but temporary patterns of behaviour that may be changed at any time (McBride, 2005). This therefore informs us that empowerment

interventions may be defined to acknowledge the contexts that impinge upon the short-term projects goals but not to focus on the entirety of the environmental influences. This will ensure more pragmatic balance between present concerns and future potentialities (Stacey, 1996). Empowerment decisions and factors both internally and externally may shift the project team focus out of stability and move the behaviour to a new strange attractor within a new outcome basin, the state to which a complex system is attracted after interactive process has taken place amongst the actors in the system (c.f. Young, 1997). Interpretive use of chaos theory as metaphor for exploring the multiple dimension of empowerment in project will involve recognising general patterns and looking for shifts between semi-stable attractors and exploring reasons for those shifts. Strange attractors enshrine „temporary stabilities in a sea of change" (Chia, 1998). The focus here is on this sea of change and the shifts that occur between strange attractors and its impact on the project.

The transition of complexity theory from the natural world to the world of management is still comparatively nascent and, although comparatively slow to gain widespread acceptance as a valid management perspective, it has increasingly attracted a number of followers despite remaining clouded in misunderstanding (Stacey, 1996). For converts, it is lauded as the next radical management paradigm for business developments (Lynch & Kordis, 1988). For others however, the popularity of complexity theory as an organisational tool is guarded at best (Merry, 1995). They argue that few examples exist of organisations, which have directly benefited from a practical form of the theory. This ongoing discourse seeks to take a more critical perspective toward chaos and complexity theory. An attempt has been made here to explain the philosophy, unveil the common metaphors employed by chaos and complexity writers, assess its unique application or new contribution to the understanding of project environment and ultimately enable a more critical assessment of the spaciotemporal manifestation of empowerment in projects. It will seem from the review of the literature that, chaos and complexity theory does offer the potential to better understanding the intertwine nature of empowerment in relation to managerial strategies. Mobilising such a perspective may help advance the study of the complex and dynamic manifestation of empowerment in projects.

CONCLUSION

Empowerment is an elastic concept that takes on multiple forms across people, levels, is contextually embedded and shifts over time. The construction process is also more complex than project management often envisage as the perceived ordered, linear view of project behaviour, reflected in the underlying project planning, management and delivery processes can be misleading. From the examination of the behaviour of complex systems, this is not the way the world operates. For example, even small uncertainties in the prerequisites add up to a significant uncertainty on the project"s workflow as a whole. Yet, as Olsson (2006) found, rather paradoxically, while flexibility is frequently needed in projects it is rarely prepared for.

Empowerment with its own complexity and dynamism however provides an opportunity to introduce flexibility and adaptive functionality that can enable individuals, teams and organisations to be more responsive to the complex and dynamic project environment. However, too often empowerment initiatives are smothered by organisational practices which discouraged collective participation. The tendency to think in terms of dichotomies, such as leaders and followers, superiors and subordinates or a rigid preoccupation with hierarchy

rather than function inhibit the recognition, development and utilisation of full human potential within the project organisation. When boundaries to involvement are defined by management, empowerment then appears merely as rhetoric and the centralisation of power and control as the reality (Sewell & Wilkinson, 1992). Thus, the removal of structural impediments to the full participation of the employees is at the core of resolving the empowerment paradox. Organisations which stop short of inviting full and equal interaction are not truly empowering.

As Eylon (1998) notes, „if an empowerment programme is executed without all those affected being included in its development, there is little chance that it will be successful". Understanding the nature of the interaction among empowered project actors in the context of chaos and complexity theory is illuminating as it affords sense making of how different actors respond to, and cope with, the complex nature and dynamic character of project settings. This opens up several avenues for new ideas on how to improve project management. For example, based on the way projects are organised, planned, managed and delivered, the discussion here will suggest that the understanding of the dynamics of project settings is still incomplete. Future research may therefore benefit from a much more critical perspective from the viewpoint of chaos and complexity theory of organisational interventions such as empowerment as a way of getting a deeper insight into the world of project organisations.

'EXEMPLARY URBAN PRACTITIONERS'. PROFESSIONALS WHO MAKE THE DIFFERENCE IN URBAN RENEWAL

TON VAN DER PENNEN

Abstract
In our research, a joint project with Tilburg University and commissioned by NICIS, a scientific knowledge centre for the Dutch cities, our aim was to investigate the qualities of selected practitioners in their working context, namely deprived urban districts.
Our research will connect both in method (observation, interview and text analysis) as in chosen perspective (daily and intersubjective interactions in institutional settings) to two current and lively debates in mainly British and American research on urban policy.
The first one deals with the emergence of new forms of institutional arrangements (governance) and neo-liberal strategies of urban policy. The second debate is on the use of a social constructionist paradigm in 'housing studies'. In this debate urban renewal is not seen as a neutral and value-free domain, but as an expression and result of political influence and power strategies. Professionals and residents working in community organizations (proto-professionals) try to find ways to express their personal ambitions and qualities and to shape the space around them.
In our paper we give a theoretical description of this 'new (proto-) professional' and illustrate this practice with empirical case studies of 3 of these (proto-) professionals working in deprived districts in The Hague, The Netherlands. What they have in common is their attention to everyday life (in deprived urban districts) and a holistic problem orientation. They take part in relevant governance processes of policy making, but are not detained by the systematic and logic of their organization or by bureaucratic rationality. In the actual policy of neighborhood renewal this 'exemplary urban practitioner' gets/takes a new, integrated task to solve complex problems bottom up, and finds challenges in the everyday life in urban communities.

Introduction

In urban disadvantaged neighborhoods, it is not always the standard procedure that gets things done. In the Netherlands decades of urban renewal in its various forms have not solved problems permanently. This does not mean that success is never attained. What seems to have helped in some cases is the presence of a type of practitioner who goes beyond standard procedure. These are people who do not to give up and who are able to succeed where others have failed. Most likely these are experienced practitioners who learned how to cope. Most likely these are actors who inspire others. In the Public Administration literature and the literature of related disciplines we find examples of such exemplary urban practitioners (Van Hulst, et al, 2009). In this research we are looking for people who seem to be successful in pursuing the social goals they set

together with their partners[1]. What we ask is how these practitioners in urban districts do their job in controversial, politically sensitive policy processes that might develop in unintended and surprising ways. In other words we ask as a central question: *'Through what ways of working and relating do exemplary urban practitioner (try to) get things done?'*
The (proto-) professionals we call *exemplary* are not always taking the common routes to realize their goals. They will not automatic follow the routines of problem solving and because of that they can make a difference. They are critical about 'main stream' practices and try to find solutions starting from the perspectives of citizens. When we talk about *'ways of working and relating'* we refer to the qualities these professionals put to use in the planning and decision making processes of urban renewal. It has to do with personal qualities like attitude and experience, but also with strategic skills such as networking with policy partners. '*Getting things done'* will mean solving problems or better stated exploiting opportunities. More broadly is their aim to transform what is called 'urban problem districts' into 'livable neighborhoods'.

Opening the black box of urban renewal

The context of practice is the Dutch urban renewal in deprived neighborhoods; the working place of the exemplary urban practitioners. Urban renewal is no longer merely large-scale demolition and new construction. In policy circles urban renewal is seen as a profound form of comprehensive social, physical and economic renewal. This broad-based policy intervention includes both physical interventions in the housing stock and living environment as well as measures and activities to improve the social, cultural and economic conditions in deprived areas. Vulnerable situations should be adjusted in such a way that residents have more opportunities for social integration or even social mobility. This means that professionals who are involved in urban renewal come from several areas: local government, housing corporations, residents, police, education, health, welfare, art and media. It has long seemed self-evident to see urban renewal as a process of rational planning led by one dominant and controlling party, the (local) government. Urban renewal is then seen as a linear development process in successive stages over time, or viewed at the least as an attempt in this direction, in order to reduce structural uncertainties (knowledge, organizational and institutional) (See: Van der Pennen, 2005). But these uncertainties are also the reasons why urban renewal is termed complex, calling for a more flexible and context sensitive approach. If we regard the current developments in planning practices in the Netherlands, we can see that this leads to a more important role for citizens in decision making processes and that especially the social conditions of the citizens living in deprived districts, become increasingly central. So it can be stated that the relationships between practitioners and residents become crucial in urban renewal (Van der Pennen, 2010).

[1] The exemplary practitioners we studied are part of a research pool of 45 practitioners spread over 5 cities, which we observed in their daily routine and interviewed afterwards. For the selection a so called 'scouting' procedure was started in which an independent researcher tried to find 'exemplary' practitioners. Through recommendations and snowballing he found in each city a group of practitioners that were named by many for doing inspiring and exemplary work in urban renewal.

The exemplary urban practitioners seem to have a 'good' impact on complex policy problems, by working more bottom-up, bringing in social and citizen-focused orientations and experiences.

The exemplary urban practitioners are not driven by the logic of the institutional world, logic of rational planning in the time, to get a grip on the unexpected and uncertainties. They are driven by the logic of 'the everyday world', that is the notion that urbanity is a dynamic process that does not stop with planning urban space, with designing and realizing a building, a street, a square. Once realized there are the citizens who give their signature to the urban space, their expressions of their ways of life (Reijndorp & Reinders, 2010).

Research context

The theoretical origin of researching practitioners in public services can be found in the work of Michael Lipsky. Since the end of the 1960s Lipsky has researched the collective acts of public service agencies, resulting in his well-known book on street-level bureaucracy (Lipsky, 1980). Lipsky's focus was on the professional practice of street-level bureaucrats – e.g., police officers, teachers, social workers and judges- and on the way they (personally) experience their work. In general, street-level bureaucrats are motivated to serve the common good. Inspired by and in his line of thinking, other researchers came with new types of practitioners. Hulst, et al (2009) did a literature scan and distinguished characters like the Reflective Practitioner (Schön, 1983); the Deliberative Practitioner (Forester, 1999); the Everyday Maker (Bang & Sorensen, 1999; Bang, 2005) and the Everyday fixer (Hendriks & Tops, 2002; 2005).

The research question is connected to an assumption that is more and more heard in policy administration and in policy scientific debates. Effective neighborhood interventions would need a certain kind of professional. Several researchers have demonstrated the importance of such professionals as a result of increasing social and administrative complexity (Schön, 1983; Healey, 1992, Forester, 1999; Bosch & Van der Pennen, 2009). Like these other researchers, we are interested in their way of looking at the world around them, their problem definitions and aims, their qualities, the methods and strategies these 'new' professionals use in their practices / projects.

Talking of exemplary urban practitioners we think of individuals in various formal or informal positions (cf. Kingdon1984/1995:179).They might be working for the local government as a public manager, a policy maker or as a front-line worker. They might be working for a housing association, a community center or welfare organization. They might also be an active citizen working as volunteer. We think that the label of *exemplary urban practitioners* fits this category of individuals. We do not think that these practitioners do their work all by themselves. Nor do we believe in fairy tales of strong leaders who single-handedly dominate the discourse and fix problems once and for all. We think these practitioners are part of and work together with groups, teams and organizations. Moreover, the socio-political work of forming what has been called 'vital coalitions' (Hendriks & Tops, 2005) – that is, coalitions of people who are able to get things done and keep things going in and around urban districts - might be a central part of their practice. At the same time, we also believe that individual actors through their deliberative, reflective and/or credible acting can make important contributions to the way the collective tries

to deal with its problems. In sum, we believe that some individuals, alone or in collaboration with their partners, are able to positively influence the course of processes.

Qualities

What have these persons in common? If we add what we know about (working in) disadvantaged neighborhoods to what researchers like Schön (1983), Bang & Sørensen (1999), Forester (1993), Hendriks & Tops (2005) tell us, a first crucial conclusion is that practitioners working in this field are confronted with uncertainty and ambiguity. Reality does not fit the rules. These conditions are also the conditions in which many practitioners can make the difference. In other words, these situations potentially offer the possibility for 'making a difference'. Whether practitioners do exemplary work, however, depends on their (inter)personal qualities. Moreover, practitioners need a keen understanding of what is needed, taking into account that they will have to find out the specificities of problems and solutions every time they come into contact with new people, issues and situations. In other words, local knowledge (Yanow, 204) is needed to be able to connect the generic solution strategies of policy practices to problems experienced by residents in their everyday life world. Furthermore, we expect that in order to create these connections the practitioners have entrepreneurial ways of working; they have to start creating new solutions. This necessitates networking and management skills as well as a willingness to take initiatives. Lastly, these practitioners are no rookies. They are experienced practitioners. They have learned a craft and developed a 'repertoire' (Schön, 1983). On the other hand, even if experience has led practitioners to develop a repertoire, they maintain a receptive and involved attitude toward the changing life worlds of the people they work with and to which they respond. A particular part of practice where all these elements seem to come together is the way in which problems are approached. Problems are regarded as challenges, solving them is always on the mind of the practitioner. If that is not a simple short term opportunity, strategies are deployed that work on the long term.

Three examples of exemplary urban practitioners

Ahmed. A Coaching Resident

Ahmed, a resident of the neighborhood Transvaal in The Hague working as a tram driver, started eight years ago to organize activities to create a cleaner, more attractive street, with a group of local youngsters and mothers. In the beginning they mainly joined others' street activities, but in the time an active, independent organization "Jongeren4You(th)' had come into being. Today activities are organized by and for youngsters living in the neighborhood, who are mostly Moroccan. This old working class neighborhood has nowadays a relatively high share of young people (10 % more than is average in The Hague) and a large share non-western immigrant (80%). Ahmed wants to help and activate the youngsters, since boredom and lack of scope to develop one's talents are major problems for them. Activities range from sweeping the streets together, homework support, building a website, discussion groups for adolescents, supporting youths with their family problems, school internships and work, and celebrating new years' eve together on the streets. Many of these activities aim to connect the life worlds of Jongeren4You(th)'s members and that of other resident groups in the neighborhood. Ahmed shows young residents that it isn't strange or hard to make an effort for your neighborhood and

to take part in the world outside your social circle. Moreover, in his view, the neighborhoods' problems and the individual problems of the youths living here are connected. *"If things go wrong in this kind of neighborhood, a 'ghetto' atmosphere arises."* In this ghetto 'atmosphere' youngsters loose perspective on how they can take their lives in their own hands. On the other hand, loitering youngsters who misbehave in public space can be quite detrimental to public life in the neighborhood. He therefore strives to help the youngsters in many areas of their lives, and also work with them to improve the neighborhood. For this he cooperates with many organizations in and around the neighborhood.

Ahmed regards education as very important and sees a clear role for him to stimulate the youngsters. This can be very basic. Ahmed says that boys in the neighborhood often do not know what to do and where to go for certain things. *"They don't get a side job, they don't know the social procedures involved either. Shaking someone's hand, introducing yourself and things like that."* Part of his daily routines is walking the streets of the neighborhood. While visiting the streets and squares he has shorter and longer chats with older residents, but mainly with youngsters. Subjects can be anything, from fashion to the weather, but almost always education is a topic. Ahmed casually asks youngsters how they are doing in school. If there is a problem he listens and gives a word of advice. Interestingly, we overheard members of Jongeren4You(th) share educational success stories with each other. Also, youngsters use their educational assets for the club: one built a website, another uses his law degree to help Ahmed in his struggles with the municipality, a student of engineering gives homework support classes.

Even if youngsters help out with their capacities, Ahmed's qualities are still very much called upon. Ahmed guides and takes part in many activities and as the clubs president he is the contact person for other organizations in the neighborhood. Based on his acts we perceive a strong empathic attitude towards the youngsters. Besides his job as a tram driver, he spends a lot of time doing voluntary work to help and accompany youngsters. Listening and giving attention is crucial according to Ahmed. He told us: *"The power in our organization is attention. You have to have quite a bit of patience and an attentive ear. Listening to many stories."* At the same moment we see him practice this statement. He goes to Abdel who is in the office of their organization and wants to talk about his exams of that morning. But Ahmed is not only a listener, he is also very much a doer.

His walking around in the neighborhood is not a passive happening because he gives a helping hand to several events in the public domain. Anonymous public spots in Transvaal become familiar through his performance in the public domain. His encounters are short and fleeting with passersby and other residents but they are trustful in its kind (See: Sztompka, 1999). The comparison can be made with the theoretical concept of the public familiarity. (Milligram, 1977; Fisher, 1982; Soenen, 2006; Blokland, 2009;). Public familiarity stems from the repeated encounters of the same people in the public space through which we can more easily assess who we can trust and who not, which in turn can be related Jane Jacobs statement: " The trust for a city street is formed over time from many, many little public sidewalk contacts." Familiar places can also be meeting points for people with a common history. Places where they recognize a personalized treatment and feel them at ease and at home. Common trusted places make a sense of kinship between people possible. Based on this power of repetition is the quality of life and the social environment of an area served by various trusted sites for various mixes of user groups

across the area so the streets and squares, vibrant public spaces can be. (See: Van der Zwaard, 2010).

During a day of observation we saw Ahmed participating in a football tournament with the youngsters and a school class, climbing on the roof of the club house to catch a dog, walking the streets to see the neighborhoods' youngsters, and sitting in a square to hear from other parents what is going on in the neighborhood and watch the safety of the kids in the playground at the same time. His strategies are for the most part everyday actions together with others in the neighborhood. Many of them are solution oriented. During the activities with the youngsters he shows management skills. Ahmed, who knows how to take someone else's perspective, seems to enjoy it as well when his own efforts and the clubs successes are recognized. He enjoys praise and knows how to mobilize attention for the club. Apart from benefiting society, doing volunteering work can create its own rewards for the volunteer. It is nice to have a framework for your own talents and interests, which creates also respect for your efforts and ideas. As you will see tangible results of those efforts and ideas, the project can be a rewarding task and a vehicle for self-realization (Bosch, 2010). The role of 'active citizen' requires according to Wijdeven & Oude Vrielink (2008) a significant degree of organizational skills, perseverance, communication skills, bureaucratic skills and a personal network. Residents (groups) in whom these skills are well developed, are limited in problem areas. Since Ahmed, our practitioner, is operating in Transvaal, he is in any case for this aspect exemplary. Nevertheless, Ahmed does encounter problems with obtaining subsidies from local government, that sees the value of his organization but cannot make structural payments to volunteers because of its internal rules. Ahmed would like to see a more transparent discussion about how subsidies are distributed over the volunteering organization of the neighborhood but this is hard to achieve.

Hans. A Casting Cop

Hans is a police officer working in Escamp, more or less the southern quarter of The Hague. This part of the city was mainly built in the early post-war period. The now problematized walk-up apartment buildings where at that time part of a utopian vision on urban design. They were seen as the opportunity to create light, air and space in the living environment of every household; it was the expression of a new perspective of a post war generation. Today the residents of Escamp have on average a moderate income. Half of the population is of non-western descent; largest groups among these are Moroccans and Turks.
Escamp today is an environment that offers its residents possibilities for social mobility on the one hand, and social tensions on the other. The yearly bonfires around New Years' Eve are the public symbol of these social tensions. Ever since the nineteen fifties residents have organized bonfires, by setting fire to thrown out Christmas trees and other inflammables like cars and furniture they have collected in the streets. These bonfires are often moments of an urban conflict through fights among youths or between youths and the police. The escalations have earned political attention, and were explained through the decades by discussions that were part of the public debate at that time. In the eighties anti-social group behavior was the main explanation, in the nineties the focus was on the trend of individualization. In the last decade the ethnic diversity of the neighborhood is mirrored in the composition of the groups of youth having the bonfires, and today the New Years' Eve situation is connected to the debate on cultural integration. Following Leary (2004) the bonfire conflicts can be seen as 'critical moments' in which the

relations between groups are redefined. At critical moments an appropriate interventionist approach is of great importance.
Hans has developed the 'role models' project to address problems with youths in public space. According to him youths 'cooperate with professional partners to contribute their part to keeping the neighborhood clean, safe and free of vandalism. They are not police officers but stand together with police and youth workers on risk locations and speak to other youths if they misbehave. In this way they correct and direct the youths in the street so that little or no damage or nuisance will occur'. It is part of his strategy to go to youths that are threatening public order. *'This means that sometimes you have to drop by them, talk informally with them 'over a cup of coffee' etcetera. Also at night. They live at night'.* Hans' role models come from the mosque, the Morroccan cultural club, the football club, organizations that are formed along ethnic lines, but according to Hans they are people 'of flesh and blood', by saying this he means to put their ethnic background in perspective.
The disruption of public order in Escamp centers on youths. Hans sees results with his project: *'We have not had as much damage with New Years' Eve as other years. We almost had no car fires'.*
The youths in Hans' area do not only ask for attention around New Years' Eve. On several sites in the neighborhood there is trouble: they commit burglary, theft, muggings, arson, mischief, violence, drug dealing, intimidation, noise nuisance, fights, urinating in public etc.
Typical for the strategy is that the police call upon active citizens. Police and residents are put into action to correct known nuisance givers and to offer them alternatives for their behavior. In this way Hans also tries to attain a larger role for community police officers within the The Hague police force. With more and better community police officers citizens will get to know their police officer again, Hans claims. He characterizes his neighborhood based police work in this way: *"The police can act, but it always acts in ways of arresting people, fining people, or whatever is at hand (…) the only way in which it will work in the neighborhood is by doing it together. Let the police do its job, but in cooperation with you"*. 'You' is the neighborhood residents, which he addresses to make an effort for the neighborhood during a kick off meeting - we attended - for the role model project. *"Everyone is talking about that things are going wrong in this or that neighborhood. But the only one, who can change that, is you. That has to be understood. You are the one who will have a better neighborhood or will have a miserable neighborhood. The neighborhoods we now have are not miserable, but good. And that is because there are a lot of people living here that want it to be good."*
The way of intervening Hans promotes is known as the community police officer model. In this model the police are present in the neighborhood on a daily basis and keeps close contacts with the residents, entrepreneurs, shopkeepers, and teachers. It is not generic policy making, but 'fine tuning'; measures are taken at places and times when that is needed according to perception. This strategy to maintain safety in public space is not characterized by hiding behind shields, but by meeting potential threats openly, by listening and entering into conversation. *"No circumlocutions, but go straight to the matter. Just go and listen to what is the problem for once."*

Hans is given the freedom to do it in another way because of his personal qualities. He is an 'every day fixer' because of his focus on action in practice, his solution-oriented approach to occurring problems. But he also has the strategic ability to form appropriate working coalitions, which is typical for the figure of the 'deliberative practitioner' as known from scientific

literature. His project was not always understood and appreciated by his colleagues. He had to battle to get it through. But like a social entrepreneur Hans managed to put together his role model project. It is a 'police project' but it does not bear the dominant culture of that organization. Hans talks in this respect about three types of police professionals: "Managers, people who work with the police and cops'. He counts himself as someone from the last category, which is people with a certain professional passion, which means among other things that he cannot work 'nine to five'. He says about the other categories: *"They talk about the everyday reality of the street in abstract, in terms of rules and policy. They are remote from the people and speak a completely different language."* His role model project furthermore transfers an approach known in social work – where it has proved to be effective- to the domain of the police. This gives it a different angle. Hans is trespassing domain boundaries. Among many youths seeing the police as an institution of repression, the distrust is broken down. In trust, through confidants, these youths are approached.

Gerben. A Liaison Officer.

After working as a researcher of urban renewal for many years, Gerben took a job with housing corporation HaagWonen as a 'manager of social projects' for the Schilderswijk in The Hague. The corporation owns many of the dwellings in this large, deprived and dense central district (about 33.000 residents). Gerben is coordinator of the many social projects the housing corporation undertakes and / or is (co-) financer. In addition he is a member of the "Krachtwijkteam Schilderswijk', a project organization for realizing national policy goals in deprived urban districts. His activities centre on liveability issues and the emancipation of the residents and their participation in (the wider) society. Gerben stresses that it is important not to expand the great number of independent social projects even further; the problem of the so called 'merry-go-round of projects'. Many organizations take good intentioned initiatives, but are mostly realizing their own aims and don't know about the others. Knowing this, Gerben searches for connections and opportunities for cooperation between existing initiatives and organizations. This boils down to matching interests, needs and persons on many different levels. A clear example is his activities to support new resident participation processes. Here a large group of organizations works together to create more contemporary forms of resident participation consisting of more creative forms and more active involvement of residents. The Schilderswijk Communication bureau is an important project for him: it connects and strengthens existing forms of communication about what is going on in the district, made for and by its residents.

Gerben grounds his problem definition on the one hand in existing documents (the policy document 'The treaty of Schilderswijk' from 2007, which is the basis for the national governments' interventions in this district), as well as a independent study that investigated the possibilities for resident participation in Schilderswijk. This study is based on stakeholder interviews and ethnographic fieldwork in (semi-)public space, and concludes that the neighborhood is characterized by mono-ethnic communities living alongside but not with each other. Another conclusion is that Schilderswijk has a great number of resident (self)help- and participation initiatives, which show overlap, inefficiency and a lack of continuity.
The second starting point for Gerben's problem definition are his 'treks through the neighborhood'. Gerben: *"By listening well to the residents and professionals who put their shoulder to the wheel. In other words, by using the eyes and ears of concierges and people*

working in maintenance and mediation in the neighborhood. In this way you can connect to the needs and the possibilities and impossibilities of the neighborhood and its residents'.
The way Gerben formulated his problem definition seems to catch up with The front-line worker. A selection of quotes: "Implementation cannot be prepared in advance and from a distance" (…) "One has to be able to 'read' the situation" (…) "Every situation is different" (…) "One has to act in accordance with what the situation demands." (Tops & Hartman, 2003).

Gerben characterizes himself as a 'liaison officer'. In a more theoretical sense he can be typed as a boundary spanner (Steadman, 1992; Richter, et al, 2006). It's all about creating meaningful connections and this is the challenge and aim for a boundary spanner. Gerben explains that in many researches, advices and projects not enough connection is made between content and process. *"We know what we need to do and we write in memoranda that we will work demand-driven, area-based and integrated, but at the end of the day we go back to working in our old traditions and ways of working and thinking.* (…) *So in our thinking we should not so much start from a sector or organization, but start from the neighborhood and its residents."* In other words: connect to the life world of the neighborhood. Stop thinking activity-oriented and start thinking goal-oriented. For Schilderswijk this means to his opinion for instance that you have to deal with the Dutch culture of organizing official meetings in another way. Sending a letter to invite residents to a meeting will not yield many reactions in this neighborhood with a high rate of analphabetism. *"That seems logical, but nevertheless there are still a lot of organizations that offer their products in this way. (…) It also means looking for gains of working together, in stead of all working by ourselves. It is this mindset that has to change. That is a lot more difficult than just setting up a few new projects overnight."*

Gerbens strategy to connect organizations and people is, in his words, to seduce them. The descriptions he gives of his seductions make clear that it involves approaching other parties as equal to the corporation, and asking them to think and create ideas together, instead of forcing them into a structure. Gerben uses the words "looking together', 'thinking together', 'talking with our legs on the table', 'sticking post-its'. By giving other parties space, he tries to generate enthusiasm and corporation to eventually produce better, more efficient plans.

The Schilderswijk Communication Office which Gerben initiated is located in the neighborhood. *"That is more easily accessible for residents than city hall or the Haag Wonen office",* Gerben says. The office acts as a hub that connects small-scale but potentially very interesting resident initiatives about communication into a coherent whole that is usable for the whole district. There were already initiatives when the office started, but these needed a professional impulse and support. For example: *"(…) there was a paper called 'The Little Bridge', that wrote about a certain part of the neighborhood. These people wanted to grow bigger and they were interested in professionalizing. There also was a website HaagWonen had offered to residents but nobody was updating it. And then we said, ok, let's try and professionalize and expand that, together with the residents that are already involved. So use that existing power. Without doing new things, try to connect."* The office tries to reach all (ethnic) audiences in Schilderswijk through different media (text, sound, image, word of mouth). Additionally, these channels serve the many organization working in the neighborhood well. The office has many advantages, according to Gerben. First of all it works with the (initiatives of the) residents: In this way, from the start there is coherence in and support for the communication. It is close to home for the audience, it speaks

their language, it is reliable. Because for the main part they made it themselves. In addition the media reinforce one another, since they are made in the same place and are compatible. This creates synergy, effectiveness and efficiency. Lastly the communication office offers a future: it draws people out of their isolation and if needed educates them" according to Gerben. *"The office is close to our central thought: residents participate instead of consume. We give space to talent development and we strive for structural improvement and the structuring the jungle of existing projects."* This seems a thought that is not core-business to a housing corporation. Gerbens insistence on practicing cooperative and sector exceeding urban renewal, underlines his boundary spanning activities.

Conclusions

In this paper we have introduced the concept of the exemplary urban professional. They get their freedom in the policy network. They pick it up to realize their aims. Doing this by using their exemplary qualities. They are respected and seen by their governmental actors/colleagues and scientists analysts as a constructive and positive 'impulse' to get things done. In a literature scan we recognized qualities of these exemplary practitioners, we added to these and illustrated the practices of exemplary practitioners with three cases. Three projects in well known Dutch urban problem districts, in which they where involved and acted as such.

In the line of the literature scan we distinguished some relevant qualities for exemplary urban practitioners such as the solution oriented stance of the everyday fixers (Hendriks & Tops, 2005) and the aptitude for reflection of the deliberative practitioners (Forester, 1999). The three practitioners described here reflect on the role of the police (Hans), of the housing corporation and media (Gerben) and of volunteering organizations (Ahmed). However, they also have the entrepreneurial ways of working that involve looking for new opportunities and making connections a variety of people within and beyond the boundaries of the area in which they work. Often, we noticed, they have initiated their own projects. However, they are not entrepreneurs in managerial sense (Lowndes & Sullivan 2008). Being effective is just a part of what they are after. These practitioners are more likely driven by a wish to move society in a certain direction (Ahmed wants to prevent a ghetto atmosphere, Gerben wishes to connect citizens and stop the merry go round of projects, Hans wants to cooperate with residents to make the neighborhood as livable as the residents want it to be than by their professional standards or institutional rules of some sort. Their interest is not in keeping the system intact, they want to bend the system if needed. This is because they acknowledge that reality – the every day reality of citizens - does not perfectly fit the rules and policy traditions of problem solving. Our exemplary practitioners in the case see it as a challenge to make the difference and connect policy and interventions to the life worlds of citizens. Gerben in this vein stretches the professional domain of the housing cooperation, Hans tries to create more space for community police officers in his organization, Ahmed asks for transparency and professionalization in his own organization and in its relation with the local government. Furthermore, these exemplary professionals are more engaged with the life world of residents in need than most other practitioners. Their way of relating to the world is characterized by empathy, and frequent (everyday) social interactions with other professionals and residents are important to them. They 'talk over a cup of coffee' with youngsters creating nuisance in the neighborhood (Hans), visit them in the street on a daily basis (Ahmed) or talk to them 'with the legs on the table' in order to

find out about their interests and capacities (Gerben). It is mainly through these interactions that they gain local knowledge, which is essential to their work. Local knowledge is 'the very mundane, yet expert understanding of and practical reasoning about local conditions derived from lived experience' (Yanow, 2004: 12). The contact these practitioners have with people in and around the areas in which they work give them access to local knowledge and help them to develop their own local knowledge.
This translates in trying to understand the problems of the residents 'inside out', e.g. when investigating the challenge at hand they make an effort to take on the perspective of the residents they work with. In doing so they find out about the different problems a person has and the ways in which they are related, but also about this person's motivations and capacities. In the 'system' world of public help provision help is parceled over different professions and trajectories. In the 'life world' of residents problems and people are complex. By actively looking at the 'whole' problem owner, the (proto-) professionals are often brought to new, more integrated help strategies. We use the term holistic problem orientation to indicate practitioners' receptivity to the full extent of residents' problems and opportunities, and the willingness to bend the systematic of public services in such a way that they match these problems and opportunities. As a result, not only the exemplary (proto-) professionals problem orientation but also his or her interventionist actions can be seen as generalistic rather than specialized, they go outside of their domain and take on a variety of tasks ranging from watching over a kindergarten to creating a media centre. So, in order to deal with both uncertainty and complexity, our practitioners become creative. This creativity can involve matching rules with situations, but sometimes practitioners even need to cross institutional or professional rules and borders. In this sense, exemplary (proto-) professionals act as boundary spanners.

To sum up:

1. Their reality (problem definition and aims) does not fit the rules and regulations.
2. They move society in a certain direction than by professional standards or institutional rules of some sort.
3. They have a strong engagement with the life world of residents (empathic).
4. They gain local knowledge, which is essential to their work.
5. They have entrepreneurial ways of working.
6. Their context / orientation of handling can be labeled as 'every day urban world' versus the planned / institutional 'system' world.
7. In the 'system' world of public help provision help is parceled over different professions and trajectories. In the 'life world' of residents problems and people are complex. By actively looking at the 'whole' problem owner, the (proto-) professionals are often brought to new, more integrated help strategies.
8. They are generalists.
9. Their creativity can involve matching rules with situations, but sometimes practitioners even need to cross institutional or professional rules and borders. In this sense, exemplary (proto-) professionals act as boundary spanners.

Our list, however, is not intended as a full profile of an exemplary urban practitioner. Context of acting and qualities are different. Every situation, each district requires its own approach and therefore specific properties. "Good practice can never be bottled and applied somewhere else

like an ointment. There are no one-size-fits-all, magic solutions to complex social problems. The public sector is highly heterogeneous: entrepreneurial solutions will vary for different organizations, with different histories, cultures, users and political leadership" (Leadbeater & Goss, 1998: 22).

Abstract
Construction project planning and control are core processes for building project management. In practice project time management is achieved by computer based techniques like Precedence Diagramming Method (PDM). Many researchers and practitioners claims that Networking techniques as such do not provide a suitable model for construction process, especially in repetitive projects. Construction process modeling, for repetitive projects in particular, should incorporate for specific features of resource flows through project activities. With the aim of improving resource scheduling with PDM, a heuristic algorithm for repetitive activity scheduling process is presented (REPNET), based on a precedence network plotted on a resource–space chart. The heuristics of REPNET are used to carry out resource timing in two phases: in the first phase as soon as possible project schedule is performed; in the second phase the REPNET algorithm search for resource scheduling optimization by minimization of resource idle time in repetitive activity performance. The work continuity constraint is relaxed in order to maintain the PDM minimum project duration. Optimized project schedule of case study is compared with original schedule and discussed.

Keywords: activity network, Precedence Diagramming Method, resource scheduling, repetitive construction, location based scheduling.

INTRODUCTION

Construction project planning, scheduling and control are core processes for building project management. The plan of a construction process should be a forecast of the best way to construct the building and to control the process itself. Thus a major objective of planning should be a tool by which to control the actual process (Birrel, 1980) to give feedback information in relation to the plan for the process. This can be done in an effective way mainly developing a realistic model of the construction process.
In practice project time management is achieved by computer based techniques like Precedence Diagramming Method (PDM). PDM is a network-based planning instrument where building processes are represented topologically by means of an activity network. Activity network is a time oriented building process model where resources are simply loaded to corresponding activities as an attribute or a label.

Networking techniques represent the state of the art of construction project planning and scheduling in most real life projects, but many researchers and practitioners claims that these techniques do not provide a suitable model for construction process, especially in repetitive projects. This is mainly because activity network is discrete while construction process is basically a continuous flow of working operation performed by specialized resources.
Many scheduling methods have been proposed in literature in order to improve repetitive construction project efficiency.

Literature overview

Building construction projects often include consirerable amount of repetitive activities that are carried out in a cyclic manner (start-operations-close) from one space unit to another one. Such efforts are called repetitive projects. In repetitive projects like high – rise building, housing, highway projects and pipeline constructions, resources are required to perform the work on similar activities in the various locations of the project. As a matter of fact construction crews move from one space unit (i.e. storey of the building) to another one in a sequence. This is manly because the building of a construction item performed by trade crews (i.e. floor concrete slab) can be divided into specific activities associated with particular units (i.e. floor concrete slab at each floor of a multi-storey building).
Repetitive construction projects can be classified according to the direction of sequence of work from one space unit to another one (Vanhoucke M. 2006). In horizontal repetitive projects the activities are performed horizontally e.g. highway or pipeline projects. These projects are also classified as continuous repetitive projects or linear projects due to the linear nature of the end product of the construction process. In vertical repetitive projects the repetitive activities are performed vertically e.g. multi-storey building or high – rise building. Discrete repetitive projects consists of a repetition of a unit network through the project, like floors of high – rise building, factory buildings of an industrial plant, housing projects. In continuous repetitive projects space is not discrete, like highways or pipeline networks (Yang and Ioannou 2001). Kang, Park and Lee (2001) argue that construction projects can consist of both horizontal and vertical repetitive processes among several multi-storey structures and classify this projects as multiple repetitive projects.
Basic instrument suggested by researchers and practitioners for the planning and scheduling of a repetitive projects are time / space diagrams, in which activities performed by resources are plotted as line or other geometrical shape on a time/space chart.
Researchers have proposed many scheduling methods, that can be classified as Line of Balance for Projects with discrete space units, and Linear Scheduling Method for continuous space projects. El-Rayes and Mosehli (1998) suggested that resource – driven scheduling accounts directly for crew work continuity and facilitate effective resource utilization. They suggested that resource – driven scheduling of repetitive activities requires the satisfaction of three constraint: precedence relationship, crew availability and crew work continuity. Basic concept of resource – driven scheduling of a repetitive project is to account for: a) numbers of crews to work simultaneously on different space units of repetitive activities; b) interruption of crew work continuity. Harris and Ioannou (1998) created the scheduling repetitive model that ensures continuous resource utilization with a flow view and a PDM view of the model. Arditi, Tokdemir and Suh (2001, 2002) integrated non – linear and discrete activities into LOB calculations and defined time and space interdependencies among activities as a base concept for repetitive project scheduling.
Kang (2001) observed that in a multiple repetitive construction project construction cost and duration are dependent on: number of work areas, proper crew grouping, size of work areas, frequency of repetition of each activity, and provided an heuristic approach to allow optimal

construction planning. Kenley and Seppänen (2009, 2010) observed that locations are important in construction because building can be seen as a discrete repetitive construction process, a series of physical locations in which work of variable type and quantity must be completed. They also observed that the location based methodology does not exclude Critical Path Method (CPM), in fact dependencies between activities in the various locations and between tasks that are made up of activities of the same work item are realized with CPM logic links. In general repetitive scheduling methods are more concerned with movement of resources through locations or places than with repetition of activities, so they introduced the Location-Based Management System (LBMS) which shifts the focus from individual discrete activities to managing the progress of repetitive activities as performed by crews moving through a building and completing all their work location by location.

Location Based Scheduling

A repetitive project is a multi–unit project where resources move through the various similar location of the project (e.g. multi – storey building, housing projects, highway projects), while a non-repetitive project is a building project that has a complex location breakdown structure and is mostly a set of one-off activities.

Construction process modeling, for repetitive projects in particular, needs a more detailed model regarding resource flows through project activities. Location Based Scheduling is a resource oriented construction process model. Location Based Scheduling produces schedule that achieve a continuous workflow by considering the relationship between the work to be done and the location of the work (Firat et al, 2010). In a repetitive construction project locations require the establishment of a hierarchical Location Breakdown Structure (LBS), where a higher level location logically includes all the lower level locations (Kenley and Seppanen, 2010).

In Location Based Scheduling working tasks, set of repetitive activities, are plotted on time / space chart using general principles of the Line of Balance (LOB). The essence of location based resource scheduling is the view of the movement of construction resources through the various project locations as a key to improve project performance.

Location Based Scheduling recognize that networking techniques like Precedence Diagramming Method does not well match the character of construction projects, which consists of large amounts of one site fabrication involving continuous or repetitive work. The character of a repetitive construction project can be defined as (Kenley and Seppanen, 2010):

- multiple working places;
- one site and continuous assembly of components;
- repetitive activities performed in different locations, but in which the amount or context changes;
- equally parallel and sequential paths;
- resource management is a flow-optimization problem, designed to achieve smooth flow and continuity in the use of resources.

So at least three basic item of construction project scheduling with precedence diagramming method must be implemented for repetitive project scheduling: resource – driven scheduling, work area or space definition and resource flow tracking. In the resource driven scheduling process resources must be committed on a specific range of time for one job, assuring maximum efficiency of committed resources. In fact any task or activity requires a specific work space, termed “Space demand” for its execution. This space demand is based on the space requirements of each resource allocated to the activity. If the required space becomes limited or unavailable, the activity or task can not be executed or performed with the required

productivity rate. Often critical path method ignore requirements of activities for work space or work area for specialized resources (Thabet W. Y., Beliveau Y. J. 1994).
Birrell (1980) highlighted that basically construction process is a set of construction operations performed by specialized resources who moves through the various locations of the project. Starting from the building to be done basic concept is to define the sequence of trades on every construction item, and to set the route of the work crews that will be moving through the various project locations or space units. Buffer space or time are needed to prevent crews from interfering. Once the first crew has started, the following crews will be added in the same sequence. This creates a flow of crews or a trade parade (Tommelein, Riley and Howell, 1999) moving through the space units of the project.
In summary, construction site space is an important concept and viewpoint for understanding characteristics of repetitive construction projects. The earlier research has covered already several important methodological characteristics of construction planning and scheduling with the site space on focus. Although not covered explicitly here some research has covered also computerized assistance for the generation of alternative plans and schedules – for example (Kahkonen, 1994; Märki et al, 2007). The research to be presented in the following chapters is also targeting to produce such a solution that would incorporate characteristics of repetitive construction operations and to present this together with computerized assistant that would enable efficient high quality scheduling.

REPETITIVE NETWORKING TECHNIQUE (REPNET): BASIC PRINCIPLES

With the aim of improving resource scheduling in repetitive construction projects with Precedence Diagramming Method, an heuristic algorithm for repetitive activity scheduling process called REPNET is presented, based on a precedence network plotted on a resource–space chart (Bragadin, 2010). In repetitive-unit projects it is important that repetitive activities are planned in such a way as to enable timely movement of crews from one repetitive unit to the next, avoiding crew idle time. This is known as the "work continuity constraint" and its application during project planning can provide an effective resource utilization strategy that can lead to: maximization of the benefits from the learning curve effect for each crew; minimization of idle time of each crew; minimization of the off-on movement of crews on a project once work as begun.

Resource-flow tracking

A Precedence Diagram Network of the repetitive project is plotted on a resource – space chart, with the x-axis representing resources and the y – axis representing space units of the project. So the network node representing the activity is identified by two coordinates: the main resource performing the activity and the work space in which the activity is to be performed. The procedure of plotting the network on a resource – space coordinates has been used by many researchers in the past. In particular Yi, Lee and Choi (2002) presented an heuristic method for network construction and development for repetitive units project, with the aim of minimizing total project duration by reducing idle time of resources and spaces. Actually the heuristic changes the sequence with which crews complete the scope of work encompassed in each repetitive activity. About this procedure Moselhi and Hassanein (2004) observed that this approach and general formulation has been applied in earlier and more accurate models (e.g. El Rayes and Moselhi, 1998) and that the Yi, Lee and Choi method does not guarantee a global optimum solution.

Resources in the x-axis of the chart are generally the work crews or the equipments that perform activities. When the activities are completed the crews are released to the next activities in the successor space units. Resources are grouped by work item i.e. masonry, plastering, floor concrete slab etc. Multiple resources, i.e. crews, are allowed for the same work item in order to perform parallel repetitive activities in different locations for the same task. In this way in every column of the chart activities are grouped by resources.
Space units of the projects are plotted on the y-axis. Space units are the locations where only one crew can perform one activity at a time. The Location Breakdown Structure is represented on the y-axis. The location breakdown structure (LBS) consists of an higher level of locations where it is possible to perform construction process independently of the other locations. The middle level should consists of locations where the flow of work can be planned across middle level locations. The lowest level are the space units of the project (Kenley and Seppanen, 2010). Space Units on the y – axis should be small, only one crew can work in that area and are identified by the k - code.
Activity is defined as the set of construction operation performed by a specialized crew or equipment in a space unit of the construction project. In a repetitive construction project a set of activities, performed by the same crew in more than one space unit is defined repetitive activity. Resources that perform a repetitive activity are identified by a j code. Task is defined as a set of repetitive activities performed by one or more than one crew for a work item, and is identified by the i code. So a resource path is completely identified as a repetitive activity by the ij code and a single activity is identified by the ij-k code (figure 1) where i identifies the work item or task, j identifies the repetitive activity or the single crew (i.e. resource path) and k identifies the space unit where the activity is performed (i.e. space path).
Plotting the PDM network on a Resource – Space chart makes easier resource tracking, in fact columns of the chart identify resource path through the project and the logical relationships between activities of the same task or repetitive activity represent resource flow tracking, while k rows of the chart identify space units of the project and make possible to detect unit path where the relationships between activities performed by different trades represent physical or technological dependencies (figure 1).

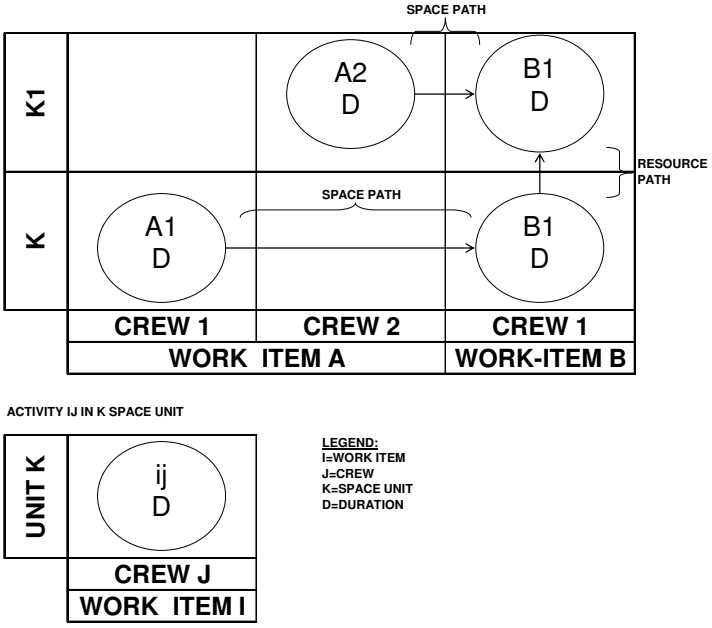

Figure 1: *Network Diagram plotted on a Resource-Space Chart (adapted from Yi, Lee and Choi, 2002).*

Work continuity requirement

After PDM critical path analysis, minimum construction project duration is found and as soon as possible project schedule is detected (ASAP) with Early Start (ES) and Early Finish (EF) of activities. Critical Path is detected and Free Float (FF) and Total Float (TF) for every activity can be found. In general non-zero link lags due to early time position of activities belonging to the same resource path prevent the ASAP schedule from satisfying the work continuity requirement. The proposed method aims at minimizing idle time of crews by activity shifting. Since that the optimization algorithm does not modify total project duration (TPD) as computed by traditional forward pass of Precedence Diagramming and resource flow continuity can be obtained only if made possible by network logic and activity float. If the work continuity requirement is satisfied for every activity of a resource path, the resource path is defined critical (figure 1).

The idle time of crew j on a resource path ij between the k' predecessor space unit and the k successor space unit, is computed as the difference between the early start of the successor ij-k activity and the early finish of the predecessor ij-k' activity:

$$\text{Idle ij } (k',k) = ESij\text{-}k - EFij\text{-}k' \qquad \text{(eq.1)}$$

Work interruption can be detected in the same way between activities of different tasks in the same space unit. If there are not any work interruptions between all the activities of the various task on a space unit, the space unit is defined critical.

The idle time of work on a space unit k, between activities belonging to the ij' predecessor task and the ij successor task is computed as the difference between the early start of the successor activity ij-k and early finish of the predecessor activity ij'-k:

$$\text{Idle k } (ij',ij) = ESij\text{-}k - EFij'\text{-}k \qquad \text{(eq.2)}$$

Rule 1: Critical Resource Path

If, for every k',k couple of space units of a resource path ij the idle time Idle ij (k',k) value is equal to 0, or for every single activity ij-k of the same resource path ij the Total float TFij-k value is equal to 0, the resource path ij is defined critical, although sub-critical.

Rule 2: Critical Space Unit

If, for every ij',ij couple of the resource paths of a space unit k the idle time Idle k (ij',ij) value is equal to 0, or for every single activity ij-k of the same space unit k the Total float TFij-k value is equal to 0, the space unit k is defined critical, although sub-critical.

Time Critical Path

Note that a critical resource path or a critical space unit are not critical path in the original CPM sense, because they are defined by the idle time (eq.1 and 2) which does not mean the absence of Total Float of the activities, but only the absence of a part or the entire Free Float (with the exception of the cases of rule 1 and rule 2, where actually the Total Float TFij-k is equal to 0). In fact the chain of critical tasks or of critical space units can still have float time in the CPM sense.

To highlight this difference the original CPM critical path can be called "Time Critical Path".

Also note that critical tasks are desirable, because of work continuity constraint, while critical space units are not desirable, because of the risk of interference between various tasks in the same space unit.

Contingency Buffer

The resource- space chart enhances Location Based Scheduling. The activities itself are defined as a set of work operations on a single space unit. The focus is on the process performed on a sequence of locations by resources. So the flow of resources must be protected with buffers to allow for variability (Kenley and Seppanen, 2009). Buffer is a time allowance provided to absorb any disturbance between two activities or tasks.

Contingency Buffers (CB) are placed at the end of every sub critical task (i.e. resource path ij) to protect Time Critical Path from overruns, and to maintain the minimum project total duration.

REPETITIVE NETWORKING TECHNIQUE: SCHEDULING PROCESS

The Repetitive Networking Technique (REPNET) is an heuristic solution for resource scheduling for repetitive projects. The proposed method is a PDM based optimization of resource constrained project scheduling. The project solution can be sub-optima, but it is a simple method, easy to perform by researchers and practitioners.

The heuristics of REPNET carry out resource timing in two phases: in the first phase traditional PDM as soon as possible project schedule is performed; in the second phase the REPNET algorithm search for resource scheduling optimization by minimization of resource idle time in repetitive activity performance. The work continuity constraint is relaxed in order to maintain the PDM minimum project duration. In this way, besides the classic time critical path, a resource critical path is detected. Space critical path can be highlighted if useful.

Phase 1 – Resource – Space Chart Network

In the first phase the resource – space chart is plotted. In the x – axis resources are grouped by construction item and work crews are identified. In the y – axis space units are plotted. Then PDM network is drawn on the chart. Activities on the same k row show the work flow in the k space unit (i.e. space path), activities on the same j column show the work flow performed by the same crew j on a work item i (i.e. resource path).

Note that network plotting on the chart is an important phase. In fact by means of ordering PDM network by resources and space units the sequence of work is set.

The traditional forward pass and backward pass are performed and early activity times (ES and EF) and late activity times (LS and LF) are detected. Free Floats and Total Floats for every activity are found. Time Critical Path is found ($TF_{ij\text{-}k} = 0$).

Phase 2 – Schedule optimization

Resource paths ij are analyzed and critical resource paths are found. Then every sub – critical resource path is processed, starting from the last one. A contingency buffer is inserted at the end of resource path. Then, starting from the last activity of the resource path, every predecessor activity with idle time of crew is shifted forward by the shift S. The shift S is equal to the minimum between the Free Float of the activity and the Idle Time of crew. By addition of early times (ES and EF) and shift (S) Planned Start (PS) and Planned Finish (PF)

are found for every activity. The optimization process go on until all the resource path is optimized, then goes to the earlier resource path and it is repeated starting from the last activity. The scheduling process is performed for every sub-critical resource path until all paths are optimized. The flow charts of figure 2 and 3 show this process.

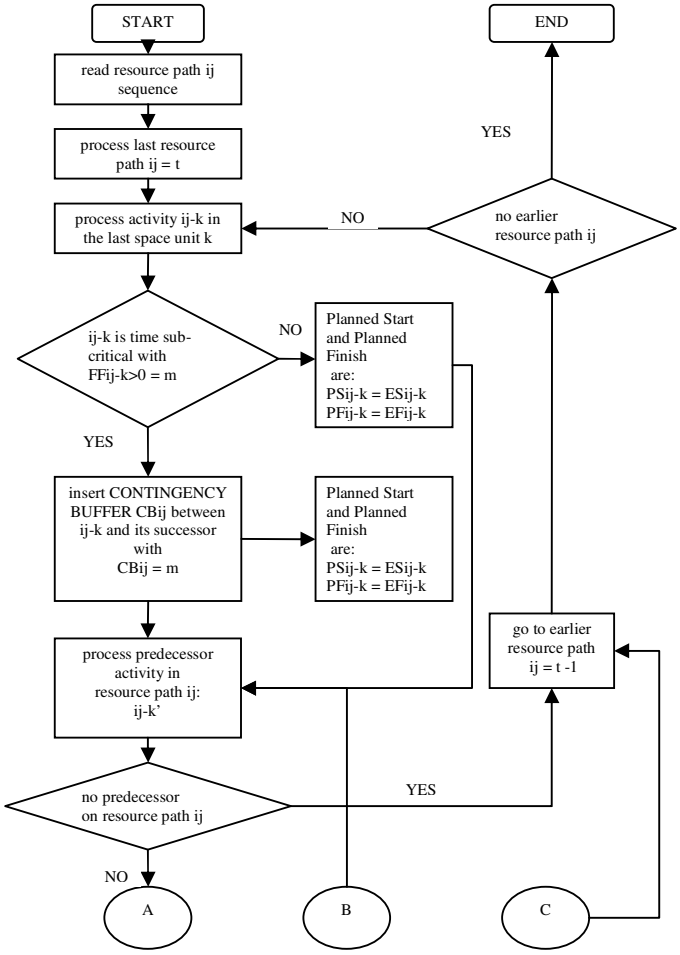

Figure 2: *Flowchart of REPNET – part 1*

CASE STUDY AND DISCUSSION

The REPNET optimization algorithm is tested using a case study from pertinent literature. The case study used for REPNET was presented by El Rayes and Moselhi (1998) and is a construction project which involves the construction of a three-lane highway for a stretch of 15 Km., and consists of five consecutive tasks: "A – cut and chip trees", "B – grub and remove stumps", "C – earthmoving", "D – base" and "E – paving". The space units are 15 segments of 1 Km each. The precedence relationships among these repetitive activities are Finish to Start with no lead time. For every task multiple crews are allowed. In the table of figure 4 activity data are presented. For simplicity activity data has been synthesized in crews allocated for each space unit k and the corresponding activity duration. The scope of the case study is to test the proposed heuristic solution with a simple but feasible project, which involves multiple crews in a multi-unit repetitive project.

The resource space chart with the PDM network is plotted in figure 5. The original ASAP schedule does not assure the work continuity requirement in 6 resource paths out of 13 (B1, B2, C1, E1, E2, E3). The flow line chart or production lines (Selinger, 1980, Kenley and Seppanen 2010) of figure 6 shows activities represented by lines on a time / space chart, where time (days) is plotted on the x-axis and space units are plotted on the y-axis. Activities are the lines starting from the lower left corner (start of location, start of duration) to the upper right corner (end of location, end of duration). In general, since activities are performed by a single crew, the lines represent crews passing through locations. The activities of a same resource path are linked each other by arrows representing the Finish To Start (FTS) relationships. Solid arrows are FTS links with no lag, dashed arrows are FTS links with non-zero lag, i.e. with crew work interruption. The flow line of the ASAP schedule shows work flow discontinuity between predecessor and successor space units in the afore mentioned sub-critical paths. Note that crew idle time, generally speaking, is more common in the last group of resource paths, due to network complexity.

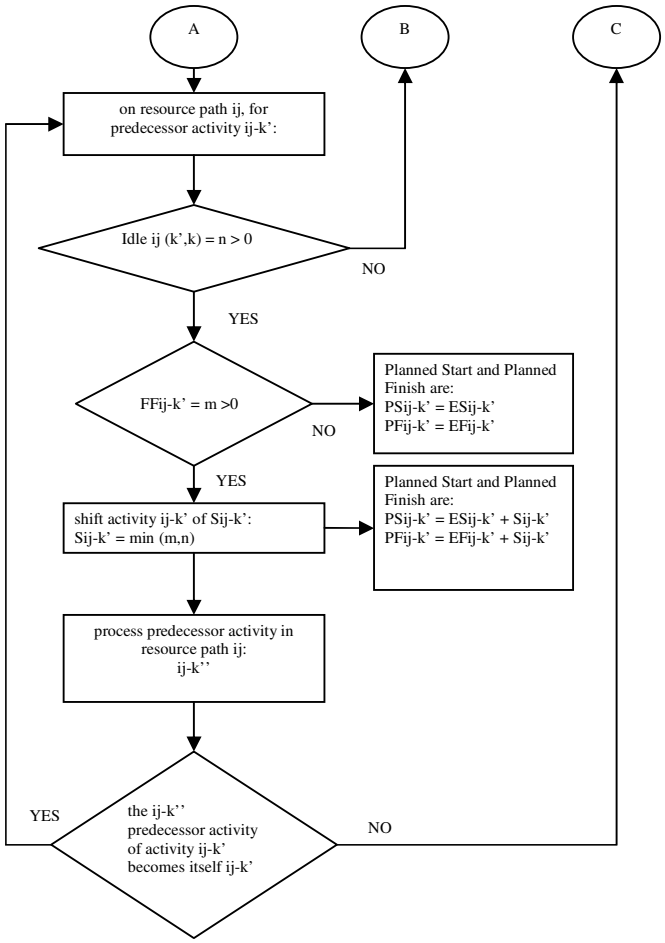

Figure 3: *Flowchart of REPNET – part 2*

The application of the REPNET heuristic solution reduces these non – optimized paths to 3, and the work continuity is not assured only in 3 resource path and in four cases (resource path B1: between unit 1 and 3; resource path B2: between unit 2 and 4; resource path C1: between unit 1 and 3, 3 and 5). Also, in the found solution all resource paths except B2 and C1 are

resource critical. The REPNET optimized schedule flow line of figure 7 shows resource path compression due to activity shifting, and at the same time work continuity requirement satisfaction in most paths.
Further optimization of the REPNET schedule can be made by hand manipulation of the network. Nevertheless the semi/automatic found solution seems ready for building site execution without further in depth study. This could be very helpful in real life project where the time for the scheduling phase itself is often very short.
The REPNET found solution is different from the solution found in the original case of El Rayes and Moselhi, because the objective of the REPNET is to implement a simple semi/automatic optimization that maintains PDM total project duration without changing activity sequencing imposed by the project planner. With this aim the REPNET keeps the PDM project duration of 100 days as a data of the problem, which is the result of the activity duration and sequencing imposed by the planner, and critical path calculation. On the other hand El Rayes and Moselhi found 83 or 87 days respectively with or without the satisfaction of the requirement of crew work continuity in every resource path, but this with semi/automatic activity sequencing. Scope of the REPNET is not to automate crew work sequencing, but to automate work idle time reduction, thinking that crew work sequencing is a strategic objective of site managers due to context, productive and contingency requirements.

Work item i	A		B		C		D		E	
Space Unit	Crew Number	activity duration	Crew Number	activity duration	Crew Number	activity duration	Crew Number	activity duration	Crew Number	activity duration
k	j	D	j	D	j	D	j	D	j	D

CONCLUSION

The REPNET heuristic procedure for resource based construction process preparation is presented. The REPNET is a semi/automatic procedure that can help inexperienced planner in repetitive construction project scheduling. The optimization process carry out resource timing in two phases: resource – space network implementation and schedule optimization. In the first phase a traditional PDM network is plotted on a resource – space chart and the as soon as possible project schedule is performed. In the second phase the REPNET algorithm search for resource scheduling optimization by minimization of resource idle time in every

resource path on repetitive space units. The work continuity constraint is relaxed in order to maintain the PDM minimum project duration. In this way, besides the classic time critical path, a resource critical path is detected. Space critical path can be highlighted if useful.
Some of the critical elements of traditional Network Scheduling for repetitive projects are tackled by implementing Location Based-Scheduling in the proposed method. In particular the resource driven scheduling is implemented by network definition and activity sequencing on the resource paths plotted on the resource – space chart. The work space definition is implemented by location based scheduling due to allocation of activities on specific space units. These two features make possible to implement resource flow tracking, i.e. the movement of resources through the construction project. Thus resource flow can be easily optimized reducing idle time of resources as much as possible. Also the resource - space chart shows the workflow and the use of resources (e.g. crews and equipment) on the same graph, thus providing an easy-to-control schedule, improving the control phase during project execution.

SUSTAINABILITY AND URBAN DENSITY
A DECISION BASED DESIGN APPROACH

PETER PAUL VAN LOON

Abstract
This paper concerns the definition, construction and application of a decision based design model which able the integration of the allocation of a variety of urban land uses with the distribution of different urban densities, in particular of residential urban areas. Urban planning is, among others things about the spatial distribution of human activities and their physical facilities like buildings, roads, green areas etc. in amount, place and time over a well-defined area. Today, sustainable urban development and sustainability in urban areas are important issues in urban planning. The aspects related to these issues have to be taken in account when developing urban areas. One of these aspects is urban density. Nowadays, it is generally assumed (and accepted) that urban density is related to sustainability. New urban planning approaches, loosely based around new urbanism, are successfully reducing environmental impacts by altering the built environment to create and preserve sustainable cities which support sustainable transport. Residents in compact urban neighborhoods drive fewer miles, and have significantly lower environmental impacts across a range of measures, compared with those living in sprawling suburbs.

Keywords: Sustainability, built environment, urban density, urban design and decision making.

URBAN DENSITY

The concept of density in urbanism is frequently used to describe the relationship between an area and the number of certain entities in that area. These entities might be people, dwellings, services, or floor space. However, the simple fact that density is used in, for instance, design requirements, plan descriptions and communication between parties, does not mean that it is used correctly or to its full potential.
One of the problems of defining density in operational terms is the relatively weak relationship between density and building type. The same density can be obtained with radically different building types, and the same type can be used to obtain different densities.
It is important to make a distinction between urban density used to describe a built environment (*descriptive* use); and urban density used as a norm in the process of planning and designing the city (*prescriptive*, or normative, use). Prior to the 20th century, density in cities was merely a result of the complex process of city development. Building techniques, legal constraints, traditions, the requirements for economic profitability, etcetera determined the possible resulting densities. However, no conscious use was made of density. As a matter of fact, density as a concept in urban analysis and planning probably did not exist until the second half of the 19th century. During this period, high densities in industrializing cities

were argued to be one of the major causes of fires, disease and social disorder. Mainly through critical publications in England and Germany, the awareness of the problem grew among legislators and urban planners. As a result, planning controls were developed that prescribed *maximum* allowable densities (M.Berghauser Pont and P. Haupt, 2010).
Urban density can be expressed in many ways. A widely used measurement is the number of dwelling units per unit area (acre, hectare). This measurement gives only information about the number of dwellings, not about their size or the way they are grouped. More general and precise ways of measuring density are measurements based on built area or gross floor area, respectively named ground space index and floor space index.
Using these measurements in urban design processes cannot guarantee a good or bad urban area because they are only measurements about the ratio of built and non-built spaces and give no information about the activities and functions within these spaces, neither about their distribution. Therefore, the outcome of an urban design model based on only density factors (as the amounts of built and non-built areas) gives no information about contents of these spaces. Consequently, these types of models are not applicable in a context of social oriented decision making, as in urban planning.

In this paper we present the integration of an urban function or urban activity based model with an urban density based model.
The first part will give an overview of the definitions, differences and similarities of both function based and density based models, as well as definitions of the combined model.
The second part describes the application of the combined model in a number of tests, including a final conclusion.

THE BASIC MULTI ACTOR URBAN PLANNING MODEL

We begin with an example for which a mathematical urban planning model can be constructed (Van Loon, 1998).

The decision-making problem of a housing association

A housing association wants to build a number of blocks of residential property and facility units (shops, school, social and cultural centre, etc.) on a particular site. The site covers 14,000 m^2. The association hopes to complete the project within 16 months. A block (construction time 2 months) covers 1,000 m^2, while a facility unit (construction time 1 month) covers 2,000 m^2. A residential block costs 8.10^6 Euros, and a facility unit costs 5.10^6 Euros; the overall budget is 80.10^6 Euros. It is not necessary to cover the entire site. A survey has been conducted among the future residents. This has revealed that they value housing blocks and facilities at a ratio of 5:3. The aim is to ensure that the future residents are as pleased with their neighborhood as possible.
This problem can be represented mathematically in a LP model. X_1 is the number of blocks of residential property and X_2 is the number of facility units. Two decision-makers are involved in this problem: the housing association and the future residents. The housing association decides what site area is to be built on, how long the building work will take, how much it will cost and sets out the timetable for the project. The future residents decide on their opinion of the houses and facilities. These give us the decision variables. The input variables are the total budget (80.10^6 Euros maximum) and the land available (14,000 m^2 maximum). These have been determined by the local authority within the constraints of its overall urban plan and the regulations governing its housing budget. The future residents want to see their views taken into account to the greatest possible extent, so $5 X_1 + 3 X_2$ must be maximized. The housing association wants to complete the project within 16 months and

stick to its decisions regarding construction costs, construction time and site area. These are the goals, and they can be represented as follows:

MAX! $5\ X_1 + 3\ X_2$ (appreciation)

Sub:

$1{,}000\ X_1$	$+ 2{,}000\ X_2$	$\leq$	$14{,}000$	(site area)
$2\ X_1$	$+ X_2$	$\leq$	16	(construction time)
$8.10^6\ X_1$	$+ 5.10^6\ X_2$	$\leq$	80.10^6	(budget)
X_1		$\geq$	0	
	X_2	$\geq$	0	

The simplex algorithm (a mathematical procedure which allows an LP model to be solved with 2 or more unknown variables) can be used to find the mathematical solution to this problem. Since the example has only two unknown variables, it can be solved using a simple drawing. This can be explained quite simply and allows the mathematical solution to be presented graphically. The problem facing the housing association is represented in Figure 1

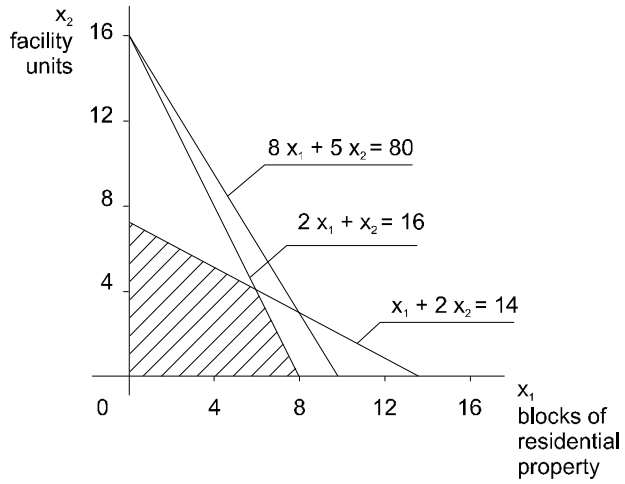

***Figure 1**: The solution space (shaded)*

The maximum value of the linear equation $5X_1 + 3X_2$ (the objective function) must be found within the shaded area. Consider the group of parallel lines $5X_1 + 3X_2 = c$. The highest possible value of c has to be obtained, within the constraints. This can be achieved when $X_1 = 6$ and $X_2 = 4$, because $c = 42$. The best outcome is achieved with 6 housing blocks and 4 facility units (Figure 2).

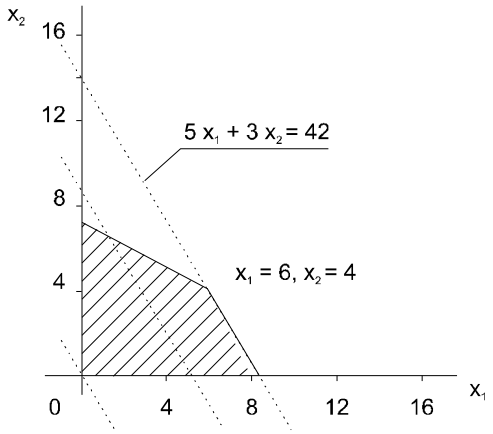

***Figure 2**: The objective function*

This modeling of the decision problem faced by the housing association is represented in diagrammatic form in Figure 3

The housing association and the future residents will undoubtedly continue negotiating their decisions and goals after this 'initial' solution has been found. Such negotiation is useful in order, for instance, to establish whether a change in the construction costs might better suit the preferences of the residents. Other, cheaper building materials could lower the costs, which might lead to a better distribution of houses and facilities.

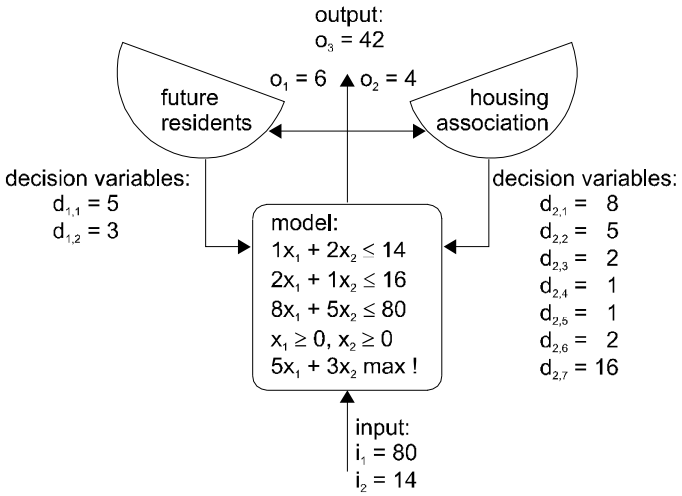

***Figure 3**:The decision model for the problem faced by the housing association*

The general structure of this model is as follows. This model is to select the values for the decision variables $x_1, x_2, \ldots, x_n$ so as to:

Maximize $\quad Z = c_1 x_2 + c_2 x_2 + \ldots + c_n x_n$

Subject to

$$a_{11} x_1 + a_{12} x_2 + \ldots\ldots a_{1n} x_n \leq b_1$$
$$a_{21} x_1 + a_{22} x_2 \ + \ldots a_{2n} x_n \leq b_2 \quad :$$

$$\vdots$$

$$a_{m1}x_1 + a_{m2}x_2 + ...a_{mn}x_n \le b_m,$$

and

$$x_1 \ge 0,\ x_2 \ge 0,...,\ x_n \ge 0.$$

For the sake of brevity, we use Σ notation and write:

Maximise $\quad Z = \sum_{j=1}^{n} c_j x_j$

subject to

$$\sum_{j=1}^{n} a_{ij} x_j \le b_i \qquad \text{for } i = 1, 2, \ldots, m$$

and

$$x_j \ge 0 \qquad \text{for } j = 1, 2, \ldots, n .$$

This is adopted as the *standard form* for the linear programming problem. Any situation whose mathematical formulation fits this model is a linear programming model.
The function Z being maximised, $c_1x_1 + c_2x_2 + \ldots + c_nx_n$, is called *the objective function.* The *decision variables* – the x_j – are sometimes referred to as the *uncontrolled* or *endogenous* variables. The input variables – the a_{ij}, b_i , and c_j – may be referred to as *parameters* of the model or as the *controlled* or *exogenous variables*.
The restrictions are referred to as *constraints*. The first m constraints b_1, b_2 , …, b_m (those with a function $a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n$ representing the total usage of resource i, on the left) are called functional constraints. The $x_j > o$ restrictions are called non-negativity constraints. In this paper the non-negativity constraints of the variables xj and xij will be implicitly assumed.

ALLOCATION OF URBAN ACTIVITIES TO SPACE

First extension of the basic model

In urban planning not only the quantities of and the preferences for the resources (like land to be used, buildings, infrastructure) to be allocated play a role, but also the location of the resources in the urban space. (R. Binnekamp, e.a. 2006). With an extension of the basic multi actor urban planning model – the linear programming model with negotiable constraints – we are able to model the allocation of urban activities to space (urban land use). In urban design and planning, a dominant spatial dimension of resources is the position of resources in two- and three-dimensional space. This position is commonly expressed in floor plans, land use plans, and three dimensional models of buildings and their urban environments. In terms of allocation of resources, a floor plan is a proposal for allocation of architectural spaces to accommodate human activities such as living, shopping, eating, and office work: Which spatial layout of the resources fits the activities to be accommodated best, in accordance with stakeholders' wishes, goals, and constraints, and with the architectural style chosen?

If we define the activities as demand (d) and the resources as supply (s) we can represent this problem (which is called in Operations Research literature the transportation problem or the distribution problem) in an LP model as follows:

Minimise $$Z = \sum_{i=1}^{m} \sum_{j=1}^{n} c_{ij} x_{ij}$$

subject to

$$\sum_{j=1}^{n} x_{ij} \geq d_i \qquad \text{for } i = 1, 2, \ldots, m$$

$$\sum_{i=1}^{m} x_{ij} \leq s_j \qquad \text{for } j = 1, 2, \ldots, n$$

In this model x_{ij} is the representation of an activity i in space j. c_{ij} is the representation of the cost (expressed in money, energy, appreciation, and the like) of the realisation of activity i in space j. This representation can be explained with two aspects of the relationship between activities and spaces as follows: Since in buildings and urban areas human activities are not fixed to one unique space – or in other words activities are spread out over more spaces, like rooms, auditoria, corridors, zones, areas – a design expresses, among a lot of other things, a spatial pattern of different architectural and urban spaces to fit a set of different activities allocated to the designed spaces. In the remainder of this paper the index i refers to an activity, j to a space or zone, k to a lot, m to number of activities, n to number of zones and pj to the number of lot within zone j.

The second aspect concerns the fact that most of the urban spaces are suited for more than one activity, but of course not all. This means that the designer can propose alternative arrangements of the activities required, for a given spatial arrangement of spaces. Also the other way around: for a given spatial arrangement of activities, alternative layouts of urban spaces may be proposed. By changing the input values of c_{ij}, a representation of the design process on both aspects becomes available. With this mechanism, a designer can represent his pattern of possible activities in such a way that he can see how well this pattern fits the activities required.

While urban spaces may be suited for more than one activity, they are not necessarily suited for all activities due to technical constraints such as daylight, noise hindrance, permitted location in the building, or conceptual constraints such as structure of spaces and patterns of connections.

The model for this design problem (the limited distribution problem) can be formulated as follows:

Minimise $$Z = \sum_{i=1}^{m} \sum_{j=1}^{n} c_{ij} x_{ij}$$

subject to

$$\sum_{j=1}^{n} a_{ij} x_{ij} \geq d_i \qquad \text{for } i = 1, 2, \ldots, m$$

$$\sum_{i=1}^{m} a_{ij} x_{ij} \leq s_j \qquad \text{for } j = 1, 2, \ldots, n$$

and

$$a_{ij} = \{0,1\} \qquad \text{for } i = 1, 2, \ldots, m \quad \text{for } j = 1, 2, \ldots, n .$$

Due to the LP problem solving algorithm, x_{ij} will be zero if $a_{ij} = 0$, and x_{ij} will get a value greater than or equal to zero if $a_{ij} = 1$. This means that if the designer decides that space s_j is not suited or otherwise not appropriate for activity i, he sets $a_{ij} = 0$ and automatically x_{ij} becomes 0. In other words, using the zero and one value of a_{ij}, the designer uses the model to calculate the best allocation of activities to the designed pattern of spaces.
In the representation of the space allocation described above, it is assumed that the total demanded space for activities equals the total supplied space for the activities. In the beginning of a design process this is often not the case. In architectural design and urban planning, demand and supply are independent of each other. They are not fixed at the start of a design process. Designers propose spatial arrangements of spaces based on their ideas, style, and concepts. Of course, these proposals are not that far from the required spaces, but they are not equal. So, a design can give ideas for activities one was not thinking of. Similarly, a designer can discover that he does not yet have space for an activity which certainly should be in the building. The designers have to find the best fit. With two extensions to the above model, it is possible to cope with this design question.

Minimise $$Z = \sum_{i=1}^{m} \sum_{j=1}^{n} c_{ij} x_{ij}$$

subject to

$$\sum_{i=1}^{m} a_{ij} x_{ij} - S_j = 0 \qquad \text{for } j = 1, 2, \ldots, n$$

$$\sum_{j=1}^{n} a_{ij} x_{ij} - D_i = 0 \qquad \text{for } i = 1, 2, \ldots, m$$

$$D_i \geq d_min_i \qquad \text{for } i = 1, 2, \ldots, m$$

$$D_i \leq d_max_i \qquad \text{for } i = 1, 2, \ldots, m$$

$$S_j \geq s_min_j \qquad \text{for } j = 1, 2, \ldots, n$$

$$S_j \leq s_max_j \qquad \text{for } j = 1, 2, \ldots, n$$

and

$$D_i \geq 0 \qquad \text{for } i = 1, 2, \ldots, m$$

$$S_j \geq 0 \qquad \text{for } j = 1, 2, \ldots, n$$

$$a_{ij} = \{0,1\} \qquad \text{for } i = 1, 2, \ldots, m \quad \text{for } j = 1, 2, \ldots, n .$$

where

S_j	Allocated space in zone *j*.
D_j	Allocated space for activity
s_min_j	Minimum available space in zone *j*.
s_max_j	Maximum available space in zone *j*
d_min_i	Minimum demand for activity *i*.
d_max_i	Maximum demand for activity *i*.

GROUND SPACE VERSUS FLOOR SPACE

Second extension of the basic urban planning model

The above described model deals with the distribution of a number of activities (demand) to a number of available urban areas (supply) both expressed as surfaces. Within an urban context the available space is commonly assumed to be ground space. Consequently, the demand of space is also assumed to be ground space. However, in many cases the supply of as well the demand for (urban) space is expressed as floor space, for instance the supply of space for schools is expressed in floor space, which can be distributed to one or more stories.
In order to facilitate this floor space in the described model, a new object is introduced, called a *lot*. A lot can be considered as a universal object for describing all built.
Related to this model, the most important spatial properties of a lot are:

- the base area of the lot (ground space),
- the area of the lot to be built also called the footprint of the building (a footprint is the amount of space on a surface that something needs),
- the floor area, which can be distributed to several stories.

Between these properties a number of relations can be defined, expressed as ratios, called the Ground Space Index and Footprint Ratio.
The values of these ratios can be defined within a margin between a given minimum and maximum value.

Ground Space Index

The Ground Space Index defines the relation between the built and non-built area of the lot, expressed as a ratio.

$$A_BLT \geq p_min_a_blt \cdot A_LOT$$
$$A_BLT \leq p_max_a_blt \cdot A_LOT$$

where

A_LOT	Total area of the lot.
A_BLT	Total amount of built area of the lot (at ground level).
p_min_a_blt	Minimum percentage of built area of the lot.
p_max_a_blt	Maximum percentage of built area of the lot.

Footprint Ratio

The Footprint Ratio defines the relation between the area of the footprint built and total floor area, expressed as a ratio. Or, the percentage of the floor area at ground level.

$$A_BLT \geq p_min_a_ftp \cdot A_GFA$$
$$A_BLT \leq p_max_a_ftp \cdot A_GFA$$

where

A_BLT	Total amount of built area of the lot (at ground level).
A_GFA	Total amount of floor area.

p_min_a_ftp	Minimum percentage of floor area at ground level.
p_max_a_ftp	Maximum percentage of floor area at ground level.

The basic planning model can now be extended using these two constraints, first on the supply site, second on the demand site.

Supply of urban space
In order to be able to allocate the activities in several buildings, one or more lots are added to each resource or space (called zone), each lot having its own properties.

$$S_j = S_TOT_LOT_j \qquad \text{for } j = 1, \ldots, n$$

$$S_TOT_LOT_j = \sum_k S_LOT_{jk} \qquad \text{for } j = 1, \ldots, n$$

$$S_TOT_BLT_j = \sum_k S_BLT_{jk} \qquad \text{for } j = 1, \ldots, n$$

$$S_TOT_GFA_j = \sum_k S_GFA_{jk} \qquad \text{for } j = 1, \ldots, n$$

$$S_LOT_{jk} \geq p_min_s_lot_{jk} \cdot S_j \qquad \text{for } j = 1, \ldots, n \;\; k = 1, \ldots, p_j$$

$$S_LOT_{jk} \leq p_max_s_lot_{jk} \cdot S_j \qquad \text{for } j = 1, \ldots, n \;\; k = 1, \ldots, p_j$$

$$S_BLT_{jk} \geq p_min_s_blt_{jk} \cdot S_LOT_{jk} \qquad \text{for } j = 1, \ldots, n \;\; k = 1, \ldots, p_j$$

$$S_BLT_{jk} \leq p_max_s_blt_{jk} \cdot S_LOT_{jk} \qquad \text{for } j = 1, \ldots, n \;\; k = 1, \ldots, p_j$$

$$S_BLT_{jk} \geq p_min_s_ftp_{jk} \cdot S_GFA_{jk} \qquad \text{for } j = 1, \ldots, n \;\; k = 1, \ldots, p_j$$

$$S_BLT_{jk} \leq p_max_s_ftp_{jk} \cdot S_GFA_j \qquad \text{for } j = 1, \ldots, n \;\; k = 1, \ldots, p_j$$

where

S_j	Total available area in zone *j*.
$S_TOT_LOT_j$	Total available lot area in zone *j*.
$S_TOT_BLT_j$	Total built area within all lots in zone *j*.
$S_TOT_GFA_j$	Total floor area within all lots in zone *j*.

S_LOT_{jk}	Total available lot area of lot *k* in zone *j*.
S_BLT_{jk}	Total built area within lot *k* in zone *j*.
S_GFA_{jk}	Total floor area within lot *k* in zone *j*.

n	Total number of zones
j	Index of a zone

p_j Number of lots within zone j.
k Index of a lot within a zone
$p_min_s_lot_j$ Minimum percentage of lot area in zone j.
$p_max_s_lot_j$ Maximum percentage of lot area in zone j.
$p_min_s_blt_{jk}$ Minimum percentage of built area related to lot area within lot k in zone j.
$p_max_s_blt_{jk}$ Maximum percentage of built area related to lot area within lot k in zone zone j.
$p_min_s_ftp_{jk}$ Minimum percentage of flootprint area related to floor area within lot k in zone j.
$p_max_s_ftp_{jk}$ Maximum percentage of flootprint area related to floor area within lot k in zone j.

Demand of urban space
The demand for space for activities is now expressed in floor area instead of ground space.

$$D_GFA_i \geq d_min_gfa_i \qquad \text{for } i = 1, \ldots, m$$
$$D_GFA_i \leq d_max_gfa_i \qquad \text{for } i = 1, \ldots, m$$

where

D_GFA_i Total allocated floor area of activity i.
$d_min_gfa_i$ Minimum demand for floor area activity i.
$d_max_gfa_i$ Maximum demand for floor area activity i.

Allocation of demand to supply
The allocation in this extended model concerns the distribution of floor space for activities to the lots of each zone.

$$\sum_{i=1}^{m} a_{ijk}\, x_gfa_{ijk} - S_GFA_{jk} = 0 \qquad \text{for } j = 1, \ldots, n \;\; k = 1, \ldots, p_j$$
$$\sum_{j=1}^{n} a_{ijk}\, x_gfa_{ijk} - D_GFA_i = 0 \qquad \text{for } i = 1, \ldots, m \;\; k = 1, \ldots, p_j$$
$$a_{ijk} = \{0,1\} \qquad \text{for } i = 1, 2, \ldots, m \;\; j = 1, 2, \ldots, n \quad k = 1, \ldots, p_j$$

where

S_GFA_{jk} Total supply of floor area within lot k in zone j.
D_GFA_i Total allocated floor area of activity i.
a_{ijk} Indication whether activity i may be allocated to lot k of zone j.
x_gfa_{ijk} Allocated floor area for activity i in lot k of zone j.
i, j, k, m, n, p_j As above

The described model only allocates activities to floor areas within lots and does not provide in the allocation of "non-built" activities, like pavement or parks. This can be solved by considering one lot as being open space. Its floor area is considered as non-built space and the values of both its Ground Space Index and Footprint Index are fixed to one. Also, the floor areas of the activities which will be allocated to these non-built lots are considered to be open space.

URBAN DENSITY AND MULTI ACTOR DECISION MAKING

Third extension of the basic planning model

The third extension of the basic planning model is urban density. As stated in the introduction, the concept of density in urbanism is frequently used to describe the relationship between an area and the number of certain entities in that area, for instance people, dwellings or floor space. This means that density is a feature of a set of objects, in case the urban system. And features are always expressions of relations between objects.
In order to be widely applicable urban entities are chosen that do not depend on the specific urban use of space, like dwellings, offices, shops. Therefore, entities based on built space and non-built space are used as entities of densities.

Building Intensity (FSI)
FSI reflects the building intensity of a base land area independently of the programmatic composition and is calculated as follows:

$$FSI = \frac{A_GFA}{A_BAS}$$

where
A_GFA Total gross floor area.
A_BAS Total base land area.

Coverage (GSI)
GSI, or coverage, demonstrates the relationship between built and non-built space of a base land area and is calculated as follows:

$$GSI = \frac{A_BLT}{A_BAS}$$

where
A_BLT Total built area (footprint).
A_BAS Total base land area.

The formula for *GSI* can be rewritten as.

$$A_BLT = GSI \cdot A_BAS$$

In this form it can be added to the LP-model if the value of *GSI* is fixed and known in advance. Both A_BLT and A_BAS are assumed to be endogenous variables. Unfortunately, in case the variable *GSI* is introduced as an endogenous variable the LP-model becomes non-linear because of the multiplication of two endogenous variables within this constraint. However, in case *GSI* is *only* used in this constraint *and* is bounded between a known minimum value gsi_{min} and kown maximum value gsi_{max} the variable *GSI* can be eliminated from the LP-model without violating the boundary constraints by replacing the constraint by two other ones.

$$A_BLT \geq gsi_{min} \cdot A_BAS$$
$$A_BLT \leq gsi_{max} \cdot A_BAS$$

The endogenous variable *GSI* has now been eliminated from the LP-model. Its actual value can be calculated afterwards, i.e. after (successfully) solving the LP-model.
In a similar way the endogenous variable *FSI* can be eliminated from the LP-model and be replaced by two constraints defining a minimum value fsi_{min} and maximum value fsi_{max}.

$$A_GFA \geq fsi_{min} \cdot A_BAS$$
$$A_GFA \leq fsi_{max} \cdot A_BAS$$

These basic constraints can easily be applied to both the supply and demand variables in the LP-model. For instance, the overall *FSI* and overall *GSI* of a particular zone *j* can be defined as follows (the first lot having index 1 is considerd to be a non-built lot):

$$\sum_{k=2}^{p_j} S_BLT_{jk} \geq gsi_min_j \cdot S_TOT_LOT_j$$
$$\sum_{k=2}^{p_j} S_BLT_{jk} \leq gsi_max_j \cdot S_TOT_LOT_j$$

$$\sum_{k=2}^{p_j} S_GFA_{jk} \geq fsi_min_j \cdot S_TOT_LOT_j$$
$$\sum_{k=2}^{p_j} S_GFA_{jk} \leq fsi_max_j \cdot S_TOT_LOT_j$$

EXAMPLE.

The described model is tested in a case: the development of a residential area of 100 hectares including space for green areas, pavement and basic facilities like schools, shops, medical and cultural centres.

The municipality of the city to which this area belongs, wants to achieve a dwelling density between 45 and 70 dwellings per hectare. The dwellings to be built are divided into twelve possible dwelling types. For each dwelling type (average) values are given for the size of its parcel, the size of the footprint (built area of the parcel), the dwelling size and the number of dwellings per parcel.
In order to create a variety of dwellings for each dwelling type mimimum and maximum percentages are given according to the housing needs.

Three different models have been applied. In all models the total number of dwellings has been maximised. As an output, the GSI and FSI of the area for only housing are calculated. The area for housing comprises the area of the lots, the space needed to access these houses, green area nearby the housing blocks, small parks (e.g. childrens playground) at a short distance of the housing blocks and parking lots for the inhabitants and their visitors.

Area needed for other facilities like schools, shops, large parks, water are not included in this calculation.

First, the municipality wanted to determine the maximum number of dwellings that can be built without dividing the area into subareas. The result is 6,219 dwellings. The GSI of the whole area for housing is about 0.62; the floor space index is about 1.1.
Table 1 outlines the results of the dwelling distribution of each model as well as the dwelling density, the total GSI and total FSI of the area for housing.

Table 1: Distribution of the dwellings in the three models

	Basic (no zoning)		**Zoning without density constraints**		**Zoning with Density constraints**	
Dwelling type	**Number**	**%**	**Number**	**%**	**Number**	**%**
Terrace houses	622	10%	536	10%	468	10%
Apartments youngsters	933	15%	803	15%	702	15%
Apartments elderly	933	15%	640	12%	702	15%
Terrace houses small	311	5%	268	5%	357	8%
Terrace houses	311	5%	431	8%	468	10%
Semi-detached medium	0	0%	0	0%	0	0%
Semi-detached family	311	5%	268	5%	265	6%
Apartments seniors	933	15%	803	15%	702	15%
Semi-detached family	311	5%	268	5%	234	5%
Apartments	933	15%	803	15%	0	0%
Large Apartments	311	5%	268	5%	547	12%
Villas	311	5%	268	5%	234	5%
Total	**6219**		**5356**		**4678**	
Density (Calculated)						
GSI	0.6265		0.6277		0.6639	
FSI	1.1136		1.1257		1.0495	
Dwellings per hectare	62		54		47	

In order to achieve a more the whole area has been divided into six subareas called zones. For each zone, one can define which dwelling types *may* be built in that zone. The two central zones, numbered 4 and 5, are reserved for other activities (education, leisure, shopping) primarily meant for the inhabitants of this area. Table 2 shows to which zone a dwelling type may be allocated.

Table 2: Possible allocation of dwelling types to a zone

Possible allocation of dwellingtypes						
Dwelling type	**Zone 1**	**Zone 2**	**Zone 3**	**Zone 4**	**Zone 5**	**Zone 6**
Terrace houses	*					
Apartments youngsters	*					*
Apartments elderly	*					*
Terrace houses small	*					*
Terrace houses medium	*					
Semi-detached medium	*					
Semi-detached family	*					

Apartments seniors	*		*			
Semi-detached family		*				
Apartments			*			
Large Apartments		*				
Villas		*				

Taking in account these allocation constraints, the total number of dwellings that can be built, reduces to 5356 (See table 3). In comparison with the first model, both the FSI and GSI (for housing) of the whole area do not change, but there are significant differences between the zones. The GSI varies between 0.55 and 0.73, the FSI between 0.90 and 2.12.

Table 3: Allocation of dwellings to zones without density constraints

Allocation without Density constraints							
Dwelling type	**Zone 1**	**Zone 2**	**Zone 3**	**Zone 4**	**Zone 5**	**Zone 6**	**Total**
Terrace houses	536						**536**
Apartments youngsters						803	**803**
Apartments elderly						640	**640**
Terrace houses small						268	**268**
Terrace houses medium	431						**431**
Semi-detached medium							
Semi-detached family	268						**268**
Apartments seniors	413		390				**803**
Semi-detached family		268					**268**
Apartments			803				**803**
Large Apartments		268					**268**
Villas		268					**268**
Total	**1648**	**803**	**1194**			**1711**	**5356**
Density (Calculated)							
GSI	0.6413	0.5526	0.6654			0.7348	0.6277
FSI	1.0175	0.9002	2.1287			1.2133	1.1257
Dwellings per hectare	55	32	92			101	54

The municipality does not want the FSI to exceed 2.0, except the one of zone 6. This zone is considered as an extension of the neighbouring residential area. Therefore, its GSI and FSI must correspond to the ones of this neighbouring residential area. Consequently, the built area of zone 6 is set to at least 70% and its FSI is set to a maximum value of 1.0.
For similar reasons, the GSI in zone 1 may not be less than 0.67.

These extra requirements cause the total number of dwellings that can be built decreases to 4678 (see table 4). Because the FSI in zone 3 may not exceed 2.0, it is not possible to built dwellings in this zone (in favour of other facilities).
In order to agree the additional constraints more large dwellings will be realised in this new residential area.

Table 4: Allocation of dwellings to zones with density constraints

Allocation with Density constraints							
Dwelling type	**Zone 1**	**Zone 2**	**Zone 3**	**Zone 4**	**Zone 5**	**Zone 6**	**Total**

CONCLUSIONS

In spite of the practical advantages of the concept of urban density in urban planning, critics have argued – especially since the revolt in the 1970s against the quantitative methods of modernist planning – that the use of density for anything but statistical purposes is questionable, as it is perceived as a too elastic concept that poorly reflects the spatial properties of an urban area. Professionals, as well as researchers, hold the opinion that measured density and other physical properties are independent of each other: Very different physical layouts can have similar measured densities. (M. Berghauser Pont and P. Haupt, 2010)
Often people confuse density with building type and assume, for example, that detached houses are lower density than attached housing types. While this is generally true it is not always the case.

Besides the argued lack of relationship between density and form, density is also considered with suspicion because of the confusion regarding the definition of plan boundaries and the scale at which these are measured. Although it is common to distinguish between net and gross density, the definitions vary from place to place parcel density, net-net density, net and gross residential density, general density and community density are some of the units of measure used.

Since the urban planning model we described, represent building types as well as density parameters it is possible s to decide on both aspect of urban areas in one

Abstract
Recently available figures for South Wales' university's and college's intake indicate a ratio of 83 male to 17 female students on undergraduate built environment courses. It could be contended that any increase in the numbers of females attending such courses should reflect more females at the 'coal face' but what of the experiences, perceptions and expectations while on those courses? The female respondents were questioned utilising semi-structured, digitally recorded discussions in relation to education, employment and how and why they arrived at their careers determining the influences in choosing that career path. Issues arose including poor careers advice, inappropriate work experience, lack of peer support, a general lack of knowledge of the industry and the perception of outmoded male attitudes. The aim is to ultimately gain a longitudinal view of female experiences over the 'life' of their courses and concurrent employment, to ascertain over time if the respondent's views have changed and original expectations met. It is suggested a better understanding of women's experiences through a longitudinal study may support the sector to improve the number of successful female built environment technicians.

Keywords: Women, built environment, careers, education, longitudinal study

INTRODUCTION

The imbalanced ratio of female to male construction workers in the built environment sector is well documented (Chwarae Teg 2009; Kirkup et al. 2010) and that gender imbalance is reflected in the ratio of female to male built environment undergraduates in the South Wales education sector (Unistats 2009). Anecdotal and documentary evidence has been provided various reasons for the low uptake of women into the industry; outmoded sexist attitudes and discrimination; negative stereotyping of construction; lack of peer support and work-life balance (Loosemore *et al* 2003; Gurjao 2006; Clarke and Gribling 2008; Watts 2010) to list but a few. With an aim to counter the industry image debate organisations such as CITB-ConstructionSkills have presented promotional campaigns in order to attract more females into the sector; campaigns such as "*Positive Image*" (2007) and "*Girls Allowed*" (2010); ConstructionSkills reporting favourable results following the *Positive Image* publicity.

Construction industry labour shortages are reported in times of high industry output as opposed to the economic nadir we currently find ourselves in. Indeed, McDermott (2011) of KPMG reported in *Construction Manager*, construction firms are "*...pricing below break-even levels*" but it can be argued that 'good times' always follow 'bad' and the call for more professionals will increase again. Greed (1991) suggested "*At at a time of 'man' power shortages, we must do all we can to enable, and not deter, women to participate fully...*" indicating a benefit it "*...actually saves money...*" through the "*...efficient use of...*" human resource management, reducing the "*...cost factor at all stages of the development process*". A factor reiterated as a benefit of diversity by David (2010) restating McEnrue (1993). Of particular concern is Fulcher's (2010) report indicating "*...practising female architects has dropped an alarming five per cent since 2008...*" although contradictory to that "*...statistics suggest an increase in women registering...*". The contention '*man*' power shortages will continue to be reported, particularly at high periods of construction output, will prevail unless real positive actions are taken to entice more professional women and possibly alleviating both the HRM issues and gender imbalance. It is also contended that until female pre-school leavers and women of working age are made aware of the full range of disciplines available; both the 'clean' and 'dirty' jobs; continuing evidence of the gender imbalance on built environment courses will remain. In providing clear information and continual positive promotion of the industry, a change of more women's attitudes will be witnessed as far as industry stereotyping is concerned and highlight the positive aspects and not only the negative characteristics of the sector. Industry stakeholders must ensure is women realise construction is not merely *muck and bullets*! (Murphy and Ren 2010).

This paper aims to provide a preliminary perspective of female experiences at the early stages of their built environment courses primarily through open question interviews. The questions purposely focussed on previous school, current education and their concurrent employment experience. This paper contains some of the responses provided by the interviewees and an analysis of the discussions followed by my conclusions from the analysis. It is envisaged to follow on with consequent research over the 'life' of their programmes through yearly staged interviews, the overall aim of ascertaining a long-term portrayal of those experiences will hopefully provide a clearer picture of the issues that arise. Also, their perceptions over time and a measure of their original expectations are to be considered. It is suggested a better understanding of women's experiences through a longitudinal study may support the sector to improve the number of successful female built environment technicians.

LITERATURE REVIEW

Industry Awareness and Image

A number of organisations and institutions have researched and advised on the causes for the lack of females in construction occupations and are consequently attempting to reverse the trend; an example in Wales is the *Women in Construction* initiative. Others such as Salford University's *Construction & Women* (2009) project and the National Association of Women in Construction (NAWIC 2009); NAWIC attempting to improve the opinion of women toward the industry, provide support in their chosen professions and ultimately elevate the image of female professionals. Similarly, the Women in Project Management (WiPM 2010) Specific Interest Group (SIG); an arm of The Association of Project Management (APM) (2010); aim to provide information for those interested in working in the discipline, declaring a focus on *"…school leavers, graduates and returners to work"*. Crucially, the focus on diversity and not separation or segregation is professed to promote good working practices

amongst both sexes. Watts (2010), chief executive of the Construction Industry Council (CIC) reported and enforced the issue of the image problem but also added on a positive note the role of the Royal Town Planning Institute (RTPI) in faring better than most institutions questioned on diversity employment practices. Examples provided construction organisations who have *broken the mould*, Mott Macdonald and Mace specifically named as two firms demonstrating good practice. Watts' argument is the industry will always have image problems and competitive disadvantages if it continues in the same vein, notwithstanding the slow growth in female employees.

Influences

Amaratunga et al. (2008) provides an encouraging image through the *Construction & Women* project with vignettes of women with a professional involvement who generally speak positively of their experiences. In contrast the project also refers to the fact "*…women tend to lack access to informal networks…and wide range of developmental experiences...that build the credibility to advance..."* Positive images are also provided by ConstructionSkills (Northern Ireland) (2008) with case studies of young women working in civil engineering, quantity surveying and health and safety. Good and bad points of their job roles are given but two replies reflect previous assertions being stereotypes and lack of women, although the advice is *"…not to be put off by stereotypes"*. Powell et al. (2006) reported issues of women within engineering, responses similar to previous researcher's findings; particularly women being amongst the minority. Reasons proffered include, poor careers advice, lack of family support, lack of supporting professional engineers as *role models* and quoting Dryburgh (1999) similar *cultural and occupational barriers* experienced in construction; mirroring those discussed in depth by Dainty et al. (2000) considering the broader aspects of female underachievement. As an antidote, Shanmugam et al. (2006) suggested "*…raise awareness…*" by "*…women working on construction committees…*" utilising them as "*…role models*"; the concept discussed by Lu and Sexton (2010), highlighted by McCarthy (2010). Lu et al. (2008) confirm in the managerial context, the need for role models to encourage and champion female employees, developing burgeoning careers. Clarke and Gribling (2008) argued the industry's structure and intrinsically created barriers influenced employment also reaffirming promoting the industry and better utilising schools as breeding grounds.

Education and Training

The drive by organisations including SSCs and Chwarae Teg in Wales to improve the uptake of women arguably should be making inroads on the professional female presence. This drive primarily concentrated on trade aspects; carpenters, decorators and the like but what of the boost for technical and managerial? SummitSkills (2010) highlighted the need for lines of learning and professional routes to be made clearer in schools as opposed to current practice, stating they *"…are guilty of not supporting females in their career choices if they are seeking non-traditional employment…"*

Table 1 **Male to Female Ratio of South Wales Built Environment Students**

	Ratio		Numbers	
Total Students	Male	Female	Male	Female
1570	83	17	1180	390

Historical statistics available to the CIB (1996) from the University and College Admission Service (UCAS), indicated an average 12% of the student cohort on built environment courses as female; similar to contemporary figures (11.6%) provided by bConstructive

(2009). The currently available figures for South Wales' universities' intake (*Table 1*) indicate a ratio of 83 male to 17 female students (Unistats 2009). It could be contended any improvement in numbers of females attending courses should indicate more females at the 'coal face'; is a student increase of 5% in 13 years acceptable? On the contrary the Royal Institute of British Architects (RIBA) (2009) provided information to *The Panel on Fair Access to the Professions* comparing male to female entrants on RIBA validated courses. According to their figures, 42% of *Part 1* entrants were women compared to 35% on the *Part 2* course, an increase between the two years. What are the experiences of female students while in education and employment? Powell et al. (2009) discussed a number of issues ranging from tutor positive discrimination to feeling they were only there in an attempt to improve numbers in the gender divide. Fulcher (2010) provides concern stating "*Universities have achieved close to 40 per cent female participation on architecture courses, indicating that the profession is still failing to make use of the pool of qualified labour*".

RESEARCH METHOD

Naoum (2007) stated unstructured interviews tend to be *very general* and used mainly when the researcher wants to see where the respondent will lead the interview. Merton and Kendal (1946) are quoted by Naoum in discussing the semi-structured approach and reiterate the characteristics; interviewees are known to be or have been involved in the situation under review. The semi-structured approach was preferred alluding to the above; the aim to research the respondent's experiences following the processing of an interview guide. As Caven (2008) argued referring to Jones (1983) and Evetts (1996), the interview method of information gathering is appropriate, the views of participants subjective and broadly career based. The internal validity of the findings, discussion and conclusions were tested by seeking feedback from the respondents as Burns and Grove (2005) attest, to ensure the results of the study truly reflect the views of the respondents.

Prior to the discussions/interviews commencing, participants were assured confidentiality of information proffered; consent for digital recording also requested. Enquiries sought the influences in choosing their careers and who were party to that influence. Much has been discussed regarding the quality of careers advice provided by advisors and schools; similarly of work experience so associated information was sought. Questions were included to discover how information relating to the built environment was provided, their experiences in employment and views on the role of training agencies in engaging females into the industry. Opportunities to provide further comments or observations allowed participants to add personally considered comments.

INTERVIEW RESPONSES

Career Choice

Of the respondents, four chose their current career; otherwise the careers "*chose them*" through progression or as some stated "*by luck*". Of those four, one always wanted to be a surveyor, following her father into the industry, an 'engineer', "*I used to occasionally go to work with my father to jobs*"; another showed interest "*...before I was ten*" in engineering. The other had some idea of what she wanted to do (architectural technician), received careers advice and thought "*...that sounds good...*" the career followed. While another worked in a

social housing organisation, a post "*...that sounded interesting...*" was advertised in another department and successfully gained the position.

Family Influences

Family influences varied including "*…they didn't mind as long as I went into something sensible*"; another's parents "*…advised from their own experiences…of the education system.*" A respondent's father arranged for her to speak to a local authority surveyor regarding built environment routes but "*…was focussed on what I wanted to do anyway...*". Another was influenced by her uncle, a QS; another, her family from a farming background, stated "*...my parents talked to me and asked what I wanted to do and tried to push me in the right direction. They said they would support me…*" whatever she decided. Fathers and brothers in the industry initially had no influence "*...my brother is civil engineer and my father a mechanical engineer...*"; "*...my father is a QS but I became a teacher…and hated it! I* (then) *decided to go into construction*". Others were influenced on their parent's careers and attitudes towards career advancement, some working in the industry not discussing the option including one father who "*…tried to put me off construction…I was too young and shy!*".

Another used to draught jewellery as a profession "*...and was good at it...*" in some respects an architectural profession "*...naturally followed...*" applying the design aspect. Others enjoyed buildings generally, "*I was always interested in buildings…pubs not houses*" (for aesthetic reasons!) found it interesting. Another established, she built up her curiosity as her "*...mother used to do a lot of decorating*". A non-British student was influenced by her uncle a QS who "*...taught her about building*". Family support differed "*…I used to go home crying from work…*" but was told by her family "*…keep with it, it would be fine"*, aged 16 working in a smoke-filled builder's office. A small number of respondents did not talk of careers at all with family.

Career Paths

The original careers of respondents varied significantly, including stable hand, teaching, travel agent, medical researcher, nanny, accountancy, administration and shoe factory worker. Some changed employment reasoning boredom, needing a career change and in one case, repetitive strain injury. Most worked their way "*up the ladder*" or between departments into their current positions. The majority received careers advice at some time, the perceived standard of advice varying; most did not know what they wanted to do while in school. Advice provided was generally perceived the "*...usual suggestions...*" of nursing, chemist, child-carer or teacher, not having mapped out a career path advice considered inappropriate or poor. Typical responses were "*...advice may have been useful if I had taken more notice*"; "*...had little bit of advice after O levels but in retrospect it was poor*"; "*...not much advice… only girl's jobs*".

School and Teacher's Advice

Whether teachers advised on construction depended mainly on the age of respondent, the youngest of them receiving some information, as one confirmed "*...they were happy to talk if you had any questions, but only knew a great deal about their own subjects*" another confirmed they (teachers) "*...knew the job titles but did not know what went on in the jobs…could not say what a QS or structural engineer did*". One declared she attended woodwork and metalwork classes and "*...enjoyed it...*" If advice was offered by teachers it was more in the vein of becoming teachers, working in travel and tourism or taking science at university. When questioned if the built environment had been discussed as a career option,

not one replied positively, information aimed at the boys and not girls. One individual declared "…*teachers seemed surprised when I said I was applying to do architecture*".

Work Experience

Work experience is arguably an important stage toward a working life for schoolchildren nearing school-leaving age. Almost half of participants did not receive work experience. Those that did, experienced working in hotels; two in equine centres; one being "*...bored at an accountancy office*"; two in pharmacies, one just "*...sweeping up at the end of the day*". Another described "*...sweeping up cockroaches*" at a stadium and at a swimming baths "*...waiting for someone to drown*"! Only three declared work experience worthwhile and relevant to construction.

Recruitment, Training and Work

Participant's experiences during recruitment and/or training provided a variety of responses; both positive and negative. An assistant QS confessed her recruitment "*...was easy*…" and now "…*if any help was needed I could ask anyone*"; even though they are all male "*...I am the only female who goes to site*". A similar response was "…*the boss took me out onto sites during my initial training…I now go on my own but if I have a problem my boss will help me*". Others had worked in sectors such as the fire service, "…*a male dominated environment…so it does not faze me…*" and have "…*never felt discriminated…wherever I have worked has always been positive*". Another recounted the informality of her interview process, "…*I took in a portfolio of my work and was told I had the job...*" as an architectural technologist.

A concerned participant stated "*... I wanted to be a trainee…it took me three 'shots' to be where I am now...there is an element of 'old school'...*" A piece of advice she provided when applying for jobs was "…*not to indicate you're a woman to get to the interview stage…it happened in a few places where I have been invited to interview…when attending the interviews, there were a few 'raised eyebrows'...*".

A negative experience in work placement "…*in a private practice, I often felt subject to sexual discrimination. There would always be comments from one of the directors and after 6 months I got moved into a room with him by myself. This made me feel very uncomfortable on a daily basis and the comments continued…even always assumed I would make his tea!*" Now working for another employer "…*it is completely the opposite…encouraged to progress and I feel as if I am part of a team…I know I have a lot to learn I feel like they want me to be here and want me to learn…not sure if this is the difference between private practice and local government?*"

One confessed she came into construction *late* and considers construction a "…*negative environment to be in for a woman. It may sound harsh and may not be an intentional thing; a lot of men I work with and around tend to see you as the little girl in the office…does not matter how bright you are, it is very hard for them to see past that barrier…it has been hard for my boss to accept what I can do…as I become more confident and realise what I know and my value* (is to the company)*…I find it hard to step out of the role I did before…"* Ironically, she admitted "*...the foremen and tradesmen are more accepting in the change in my role…more difficult for the manager…the policies are in place, it's just the acceptance of them*".

Some advice proffered to women was "*...be confident and give commitment, it seems as if commitment is one of the big issues…childcare...and young parents having to finish at 3.30…if you're a QS or an architect it's a long day, you have to be there for the full days and full weeks*".

Further Thoughts

Respondents opinions for the gender imbalance included "*...industry image*"; "*…confidence to get into the industry*"; "*...traditionally a male dominated environment, women probably worry that prejudice will occur*"; "*...not many women are aware of the various options within the construction industry from school age*". One suggestion was "*…more a fact that women don't choose to come into the industry….needs more advertising…I grew up in that environment* (father a QS) *but if not in it, it can be daunting but it's not bad actually…things have changed a lot*". Another suggested to "*Look at recruitment as a whole…careers have changed…advice needs to change…lot more information to* (school) *children*". One concern was "*No media coverage…* (her) *daughter would not be given advice at all about construction at school*".

Almost half mentioned SSCs targeting schools offering advice to potential candidates; comments such as "*Go back into schools more often…improve image…still think of 'girls jobs' and 'boys jobs'*; and "*…more hands on experiences and experiments from primary school age…imagination needs to be stimulated early*". Another confirmed "*More promotion within schools, the younger schools, primary schools. The last year of primary school is where you really think, when you are going up to comprehensive…target the younger years…not just year 9 or 10 where they have to make a decision*". She added, *"Knowing what I know now I would have done design technology* (in school) *but nobody told me*" of the options available.

Some enforced the need for change. "*People in industry* (training) *need to get used to women being in the industry…marketing…showing women*"; and "*...introduce girls early through work experience…vet placements early on for suitability*". A criticism railed at an SSC was they "*...are only good for chasing bills at the end of the year…don't support the employer to support apprentices…no idea of taking on females*".

ANALYSIS OF DISCUSSIONS

Careers advice for school leavers remains effectively under-utilised, not providing the full range of employment opportunities, significantly construction (SummitSkills 2010). If school teachers cannot provide the information, more thorough careers advice must be provided to include visits by suitably vetted built environment employers, considering Clarke and Gribling's (2008) assertion, to attract the required calibre of prospective candidate at an early age whether male or female. Successful women may help to improve diversity (Gurjao 2006, Lloyd 2009) in targeting schools more effectively, schools otherwise tending to guide towards the stereotypical male/female careers. The choice of subjects including woodwork, the 'male' fields of study, must be encouraged improving the reported stereotypical nature of learning in school.

Generally, any initial careers advice provided was either inappropriate or poor, on the whole directing the recipients towards the aforementioned stereotypical occupations; only those with a career in mind used the service effectively. Some admitted they did not listen to advice

and could not comment on the usefulness of the process. Subsequent advice prior to or during career changes from services such as Careers Wales was deemed to be more appropriate but used by only a small number of the women.

Issues were encountered during work experience (if provided); participants expected to generally work at 'conventional' female workplaces, three arranging their placements at built environment related organisations. Work experience was in the main unsatisfactory, participants utilised as 'cheap' labour by the hosts. A more rigid system of work placement is necessary, hosts vetted for suitability. By utilising an effective process with worthwhile realistic training for the incumbents, arguably more candidates of the calibre required for the industry will progress. It must be ensured both sexes are provided with equal opportunities and offered the chance of attaining qualifications outside the stereotypical job roles. Most of the interviewees did not initially choose to be involved in construction, those that did, influenced by parents or close relatives in the industry. Bearing in mind Lu and Sexton (2010), even parents in the industry may dissuade their daughters from taking construction careers but some will have a positive effect if only by osmosis. Those that end up in construction tended to 'fall' into the positions than arrive there with a clear career path, begging the question if clearer career paths are mapped out with pre-school leavers, would more females take on the technical roles in the built environment? Many participants did not remain with their original professions but eventually moved to their current positions by a chain of events and by chance.

A concern is the poor image of the built environment amongst the general public, until that issue is thoroughly addressed it will continue to pervade public psyche. To counter that, as a contractor referred, there are fantastic landmark buildings to be proud of so stakeholders must promote that it can be a very rewarding industry to be employed in. There are not many sectors where its incumbents can stand back and proudly say "*I was involved in part of that*".

The significant gender imbalance can in part be connected to the lack of effective media coverage, as one interviewee stated "*…women don't choose to come into the industry…*". A problem of the general lack of awareness of the possibilities is; everyone is a "*builder*" in the negative sense. To counteract O'Donnell's (2008) ineffective promotion assertion, a broader spread of parents and prospective school leavers may be targeted to effectively highlight the range of careers on offer.

The apparent lack of knowledge of industry networks requires addressing to offset McCarthy's (2010) view of the lack of provision of a supportive network. Used effectively the networks can provide further support to complement *ambassadors* as discussed by Murphy and Ren (2010). The use of peers providing support and advice to individuals (Lu et al. 2008; Lu and Sexton 2010) is not a new phenomenon but the call from most interviewees for more of this form of encouragement provides added weight for a clear structure of peer support and networks. The ConstructionSkills model of 'ambassadors' should be utilised thoroughly and from evidence provided, employed to encourage not only females already working in the industry but those considering a construction career whether school leavers or those considering changing vocation.

The ConstructionSkills-Wales (2010) document "*Be part of tomorrow*" enthuses careers opportunities available in construction. It would be interesting to follow up how effective such publications are in terms of attracting youngsters into the industry, particularly girls, as it includes two case studies of successful women. It is apparent, reiterating O'Donnell (2008)

there is a lack of sustainable and thorough promotional campaigns and ongoing review to deduce the effectiveness of those campaigns. Campaigns are seemingly initiated in waves pertaining to contemporary issues and themes at the time. Comments made by a number of respondents were they had seen little or no publicity for opportunities in the built environment, if it was there; it was not reaching those that mattered.

To test the internal validity of my interpretation of the discussions, the participants were requested to provide feedback on my analysis, from that a number of similar replies were returned. Responses ranged from simple confirmation or agreement of the accuracy of the reported results or as in one particular case a further affirmation of the issues already discussed. H, a female trainee QS employed by an SME, confirmed the need for better promotion of successful women in the industry, the success of that arguably increasing female uptake, "*...if they are aware of the roles and possibilities that are within the industry for them*". She continued, "*Career's advice needs to be much broader...with the acceptance of women doing 'men's work' such as roles within construction and men doing 'women's work' such as nursing. Career advice should not be aimed at the stereotypical roles for the different sexes, but should give everyone a broad range of advice*.

H did not differentiate between the sexes and confirmed, "*Specialist career days should be set up where each sex can find out about the roles without discrimination*". The issue of poor built environment advice provided in schools was also touched upon continuing on the *Career Days* theme, stating, "*These should be made compulsory within school so that girls would attend instead of thinking they didn't need to go as it was for the boys. Without the knowledge of the roles, then many women will not find construction as an attractive industry to work*". H summed up her response declaring, "*With knowledge and acceptance, it will be a big help to allow females into the industry*".

CONCLUSION

Considering the Eaton and Morton's (2008) scenario and employing that method with role models as Lu et al. (2008) and McCarthy (2010) discuss, opportunities will arise to provide for realistic and effective work experience for both sexes, the objective being to attract more females into the industry. It could be considered a 'token' gesture towards women but Lawrance's (2009) argument counters that with the "*…massive under representation … undermines…a sense of social justice*…" albeit relating to an engineering context. Similarly, as Keith Clarke of Atkins was reported by Swiszczowski (2007) "*Diversity and differences enrich organisations and are the opposite of tokenism…achieving diversity is not convenient but is a right*".

The inclusion of the built environment (reflecting the CIB's (1996) emphasis) as part of the school curriculum in the 14-16 provision and in the process of being "rolled out" in Wales as a 'pilot' is the Principal Learning qualification. Already used in England, it may be arguably provided at the moment, only to 'disaffected' schoolchildren. Included in the qualification is a wide range of learning criteria connected to the industry with a provision for work experience. By utilising effective placements with worthwhile realistic training for the students, hopefully more candidates of the calibre required for the industry will come forward as a result of the process. An assurance and willingness from all educational establishments must be provided that both sexes are presented with the equal opportunity of attaining the qualification, not guiding the girls into stereotypical job roles as reported. Whether male or

female, it is recognised that a "sense of humour" is required for what can be a very demanding and challenging industry to work in regardless of occupation or profession. The case of "*getting used*" to old industry attitudes is another matter and is unacceptable, the industry needs to move on and accept modern values to become a modern, unbiased industry.

Finally, the question posed by Dainty et al. (2005) why should women (and ethnic minority and disabled people, not discussed here) be attracted to an industry where evidence of negativity apparently remains? Do women need to 'undo' (Powell et al. 2009) their gender to cope with the industry? What changes are needed to make the industry not only attractive but also a viable option for others other than men to build a career in it?

RETROFITTING COMMERCIAL OFFICE BUILDINGS FOR SUSTAINABILITY: TENANTS' EXPECTATIONS AND EXPERIENCES

l.buys@qut.edu.au

ABSTRACT

Introduction
Buildings, which account for approximately half of all annual energy and greenhouse gas emissions, are an important target area for any strategy addressing climate change. Whilst new commercial buildings increasingly address sustainability considerations, incorporating sustainability technologies in the refurbishment process of older buildings is technically, financially and socially challenging. This research explores the expectations and experiences of commercial office building tenants, whose building was under-going sustainability retrofitting.

Methodology
Semi-structured in-depth interviews with seven residents and neighbours of a large case-study building under-going sustainability refurbishment in Melbourne, Australia. Built in 1979, the 7,008m² 'B' grade building consists of 11 upper levels of office accommodation, ground floor retail, and a basement area leased as a licensed restaurant. After refurbishment, which included the installation of chilled water pumps, solar water heating, waterless urinals, insulation, disabled toilets, and automatic dimming lights, it was expected that the environmental performance of the building would move from a non-existent zero ABGR (Australian Building Greenhouse Rating) star rating to 3.5 stars, with a 40% reduction in water consumption and 20% reduction in energy consumption. Interviews were transcribed, with responses analysed using a thematic approach, identifying categories, themes and patterns.

Results
Commercial property tenants are on a journey to sustainability - they are interested and willing to engage in discussions about sustainability initiatives, but the process, costs and benefits need to be clear. Critically, whilst sustainability was an essential and non-negotiable criterion in building selection for government and larger corporate tenants, sustainability was not yet a core business value for smaller organisations – whilst they could see it as an emerging issue, they wanted detailed cost-benefit analyses, pay-back calculations of proposed technologies and, ideally, wished they could trial the technology first-hand in some way. Although extremely interested in learning more, most participants reported relatively minimal knowledge of specific sustainability features, designs or products. In discussions about different sustainable technologies (e.g., waterless urinals, sustainable carpets), participants frequently commented that they knew little about the technology, had not heard of it or were not sure exactly how it worked. Whilst participants viewed sustainable commercial buildings as the future, they had varied expectations about the fate of existing older buildings – most

felt that they would have to be retrofitted at some point to meet market expectations and predicted the emergence of a 'non-sustainability discount' for residing in a building without sustainable features.

Discussion

This research offers a beginning point for understanding the difficulty of integrating sustainable technologies in older commercial buildings. Tenants currently have limited understandings of technology and potential building performance outcomes, which ultimately could impede the implementation of sustainable initiatives in older buildings. Whilst the commercial property market is interested in learning about sustainability in the built environment, the findings highlight the importance of developing a strong business case, communication and transition plan for implementing sustainability retrofits in existing commercial buildings.

Keywords*:* commercial buildings, retrofitting for sustainability, qualitative research

As buildings are responsible for nearly half of all global energy and greenhouse gas emissions, there is increasing pressure for the design, construction and maintenance of the built environment to be environmentally sustainable (Brown *et al.*, 2005; Commission for Architecture and the Built Environment, 2007). Indeed, internationally, many government agencies and private organisations are mandating the integration of environmentally sustainable development (ESD) principles in commercial buildings and enforcing sustainability benchmarks for buildings (Madew, 2006). Yet, whilst it is relatively easy to incorporate sustainability technologies and initiatives into new buildings, retrofitting existing buildings for sustainability is much more difficult Thus, to better understand the challenges, this paper explores the experience of residents and neighbours of a large case-study building under-going sustainability refurbishment in Melbourne, Australia.

Sustainable commercial buildings

There is a wide diversity of definitions for a 'sustainable' building, but the Green Building Council of Australia (Madew, 2003, p.15) defines it as one that "incorporates design, construction and operational practices that significantly reduce or eliminate the negative impact of development on the environment and occupants with strategies for addressing: energy efficiency; greenhouse gas emission abatement; water conservation; waste avoidance, reuse and recycling; pollution prevention - noise, water, air, soil & light; enhanced biodiversity; reduced natural resource consumption; productive & healthier environments; flexible & adaptable spaces". Similarly, Lucuik (2005) argues that the essential difference between a sustainable and conventional building is that sustainable buildings offer healthier interior spaces and include measures which reduce a building's ecological footprint. Critically, there has been significant market transformation towards sustainable buildings due to their environmental, social and economic benefits. As well as reducing environmental impact through energy and water efficiency, research suggests that sustainable buildings are cost-effective and enhance occupant wellbeing and productivity (Madew, 2003). Yet, whilst it is relatively easy to integrate standard sustainable features and products into new buildings, a key challenge is the retrofitting and refurbishment of existing buildings.

Retrofitting commercial buildings for sustainability

Existing buildings, designed without sustainability as a key consideration, are much less energy and resource efficient then most new buildings. Retrofitting existing buildings for sustainability is much more challenging, however, than designing a new sustainable building from scratch. Retrofitting for sustainability is typically viewed as expensive and disruptive, with building owners wary of the design challenges and costs and building users resistance to change and the disruptive process (The Royal Institution of Chartered Surveyors, 2007). Fortunately, there is increasing international pressure for action; for example, in May 2007, under the banner of the Clinton Climate Initiative (CCI, 2010), former President Bill Clinton announced the creation of a global Energy Efficiency Building Retrofit Program. In an attempt to reduce energy consumption in existing buildings, the program brings together energy service companies, banks, and fifteen of the world's largest cities, including Melbourne in Australia. The participating city councils will retrofit buildings and develop incentives to encourage private owners to audit and retrofit buildings, with the energy service companies conducting audits to identify energy efficient opportunities and the banks financing these retrofits at no net cost (paybacks for the loans plus interest will come from future energy savings). Initiatives such as these are designed to foster the implementation and uptake of sustainable interventions into existing commercial buildings.

In Australia, the reality is that older existing buildings comprise the bulk of commercial office accommodation: according to the Property Council of Australia's (PCA) Major Office Market Report (2005, cited in Madew, 2006), existing B and C grade (i.e., non sustainable) buildings comprise over half (53%) of the existing office building stock. Thus, like many developed economies, making the transition to a sustainable built environment will require significant investment from developers and property owners. And despite the environmental benefits of retrofitting for sustainability, there remain significant economic and social barriers. First, from an economic perspective, although several studies have demonstrated that sustainability initiatives are, in the long-term, cost-neutral and often significantly reduce expenses deriving from water and energy consumption (see Davies 2005; Lucuik, 2005), the reality is that an initial financial outlay is necessary to install sustainability features in existing commercial buildings. Second, from a social perspective, there needs to be a demand for supply – for substantial change to occur, citizens (especially tenants) need to place a value on sustainability and demand that existing buildings adopt sustainable initiatives and practices.

The reality is that, regardless of the ability of designers and constructors to create high quality sustainable built environments, the cost involved with incorporating sustainable features in either new or existing assets means that it will only become mainstream when tenants demand it. This is particularly problematic given the almost inevitable degree of disruption associated with any building renovation – as Pivo (2010) explains through eight examples from the United States, Europe, and Australia, whilst improving existing commercial buildings is better than demolishment, it is often more difficult because there must be cooperation between owners and tenants. Indeed, even the development and construction of a new sustainable building can be very challenging, as Brown and Vergragt (2008) documented via a recent case study and interviews with six project management team

members (architects, developer, urban planner, energy analyst) involved with a new zero-energy residential building in Chicago. Focussing on problem definition, learning style and processes, Brown and Vergragt (2008) found that ensuring key stakeholders share the same vision, and are open to sharing ideas and learning together was critical to the success of the project. Rohracher and Ornetzeder (2002) explored the impacts of living in green buildings on occupants and found that only owners of apartments, who participated in planning, design and construction decisions accepted and incorporated new sustainable energy-saving technologies into their daily lives. Apartment tenants, who did not participate in the decision-making process, were much less positive. Such findings raise interesting questions about how tenants of existing non-sustainable commercial buildings might experience and react to decisions to retrofit for sustainability, especially when the retrofitting process is disruptive and owner-driven.

To date, very little is known about how commercial building occupants view and experience retrofitting for sustainability. Thus, to begin to fill this knowledge gap, our exploratory qualitative research explores the experience of residents and neighbours of a large case-study building under-going sustainability refurbishment in Melbourne, Australia. Three research questions drove this study: (a) do commercial building tenants perceive sustainability as a key criterion in building selection; (b) what is the existing knowledge base and relative importance of sustainability for commercial building tenants and (c) what is the actual experience of undergoing sustainability refurbishment.

Method

Participants and procedure

Five residents (50% of the current tenants) and two neighbours (a state government representative and a leasing agent) of the case-study building in the central business district of Melbourne, Victoria were interviewed. Whilst only a relatively small number of participants were interviewed (n=7) in this exploratory study, it is important to remember that in qualitative research: "the success of a study is *not* in the least dependent on sample size, it is *not* the case that a larger sample necessarily indicates a more painstaking or worthwhile piece of research. Indeed, more interviews can simply add to the labour involved without adding anything to the analysis" (Potter & Wetherell, 1987, p. 161). Potential interviewees were contacted via email and phone and invited to participate in an in-depth interview exploring sustainability issues in commercial buildings. Participants received an information packet and consent form which provided details of the project. The interviews, which lasted between 45 minutes and 2 hours, were conducted in a convenient location chosen by the participant. A semi-structured discussion format was utilised to explore perceptions of sustainable features and services in existing commercial buildings, focussing on the interviewees' experiences and understandings. The following areas were broadly covered: key factors influencing commercial building selection, experience in case-study building (including refurbishment process), knowledge of sustainable initiatives, designs and technologies, and the relative appeal of sustainability from personal and corporate decision-making perspectives.

Case Study Building and Locality

At the time of interviews (late 2007), the large case-study building was under-going refurbishment for sustainability. Built in 1979, the 7,008m² 'B' grade building consists of 11 upper levels of office accommodation, ground floor retail, and a basement area leased as a licensed restaurant. After refurbishment, which included the installation of chilled water pumps, solar water heating, waterless urinals, insulation, disabled toilets, and automatic dimming lights, it was expected that the environmental performance of the building would move from a non-existent zero ABGR (Australian Building Greenhouse Rating) star rating to 3.5 stars, with a 40% reduction in water consumption and 20% reduction in energy consumption. This building was located in the central business district of Melbourne, the state capital of Victoria in Australia. Whilst sustainability considerations are increasingly important in all of Australia, Victoria in particular has made sustainability in the built environment a top priority and views itself as a world leader in this area. This is demonstrated by Melbourne's participation (one of only 15 cities worldwide) in the Clinton Climate Initiative's Efficiency Building Retrofit Program (CCI, 2010).

Analysis

Transcripts and responses were analysed using a thematic approach, identifying key categories, themes and patterns. The process of identifying, categorising and coding data, described by Punch (1998) as "putting tags, names or labels against pieces of the data" (p204), helps reduce and simplify the vast amount of data and identify dominant themes. A key focus was to identify the extent of convergence or divergence in views on the relative importance of sustainability in existing commercial buildings.

Results

All participants felt there had been a significant growth in demand for sustainable buildings, as people have become more aware of the importance of conserving the natural environment and the impact buildings have. As the quote below illustrates, making commercial buildings sustainable was seen as the responsible and '*right thing to do'*. In particular, tenants described how staff and clients expected their business to be sustainable, and the younger generation in particular were increasingly expecting to "*help save the environment at home and work*". Having a sustainable office was increasingly viewed as a factor in recruiting staff, with several participants indicating that potential staff (primarily Generation Y) had asked in interviews what the organisation did to promote sustainability.

> Residing in a sustainable building is very important – it reduces my outgoings which means I make more money. It creates a better work environment which means my staff will want to come to work because the place is attractive, pleasant and comfortable. And I think consciously or subconsciously they feel that they are making a contribution because they are working in a work environment that is in a sustainable building and the other things is that I can say to my clients this is part of my commitment.
>
> To me it would be ridiculous to be looking after the staff's wellbeing without having environmental policies in place. I occasionally get asked about our environmental policy. They want to know what we do – if we have a social conscience. They want to know what we do for the environment, whether we give to charity and what charities we give to.

Making older buildings 'sustainable'

With sustainable commercial buildings viewed as the future, participants had varied expectations about the fate of existing older buildings. Although most felt that there would

always be a place for older non-sustainable buildings, there was an expectation that most would have to be retrofitted at some point to meet market expectations.

> I think there are people out there looking for that competitive edge. Not only in terms of being able to brag about the fact that they have 5 star [sustainability] rating, but also increasingly with the cost of overheads

> Owners who don't take this [sustainability] approach now or in the near future will basically rule themselves out of obtaining about 70% of the marketplace. If you don't address this, you are going to be left behind the eight ball and you will find it will eventually hit your hip pocket because you haven't done it.. so you are better off spending the dollars now, meeting the tenants needs.. where the market is going now.

There was a view that older commercial buildings could not be brought up to the ideal sustainability standard and thus should be either demolished or turned into residential apartments. Others suggested that as sustainable buildings become mainstream, there may be a 'non-sustainability discount' for residing in a building without sustainable features. The argument was that as operating costs (i.e., water & energy) would be lower in a sustainable building, there should be a rental subsidy in non-sustainable buildings to compensate for this.

Sustainable technologies: aware, but not knowledgeable

For many, sustainability in commercial buildings was currently a relatively abstract concept. Participants frequently described themselves as '*aware, but not knowledgeable*' about sustainable technologies. In addition, although generally supportive of sustainable technologies, occasionally there were questions about whether there was the same standard of quality in services (particularly among the potentially less well tested and developing technologies) and demand for specific cost-benefit analyses. In discussions about different sustainable technologies (e.g., waterless urinals, sustainable carpets etc), participants frequently commented that they knew little about the technology, had not heard of it or were not sure exactly how it worked. Comments such as the following, in response to a question about waterless urinals, were common: *"I've heard of them but I don't know a great deal about it. If they do the work as well as the ones with the water in them and they are still as clean and sanitary then I think it is great"*. Many current tenants of the case-study building also wanted to be convinced of the financial value of sustainable initiatives. They wanted tangible evidence through exposure to case-study buildings, detailed cost-benefit analyses, examples, and the ability to trial and 'see it in action'. The cost was critical, with sustainability "*not a big factor, not overtly prioritised….need to convince him [management] why this would be good for 'me' – I think it is always for 'me' first then the environmental benefit because it is really all about me – in the society we are living in and the business definitely it is always at the bottom dollar"*.

Role of organisational size in commitment to sustainability

Interestingly, the relative importance and experience of sustainability in commercial buildings differed considerably as a function of organisation size. For smaller organisations, sustainability was not yet a core business value. The greatest barrier to sustainability raised by smaller organisations was cost, with participants expressing a desire to see detailed cost-benefit analyses and pay-back calculations of proposed technologies and, ideally, wished they could trial the technology first-hand in some way. Notably, although current tenants did not

want to pay more rent, most were open to discussions about the implementation of sustainable initiatives, particularly those associated with reducing energy (i.e., lighting and air-conditioning). In general, smaller organisations were relatively unaware and uninterested in cost-sharing arrangements and partnerships, such as 'green' leases, which were perceived to be too complicated. For government and larger corporate tenants, however, sustainability was a critical factor and they *expected* to reside in sustainable and green star rated buildings. Sustainability was the norm and residing in non-sustainable buildings was *not an option*. Essentially, sustainability was a non-negotiable criterion in building selection for government and larger private organisations. To capture this market, some participants recommended that owners and landlords seize opportunities (i.e., vacancies) to integrate sustainable features and 'future-proof' buildings or they would be ruled out of the majority of the market in the future.

Experience of refurbishment in case study building

In terms of the case-study building, tenants were clear about their likes and dislikes. Participants were extremely satisfied with the natural light and views offered by the building, emphasising the benefits of the layout and location. On the other hand, the lifts and general 'oldness' of the building were negatives. The refurbishment process was described as never-ending, with some noting that if the installation of sustainable initiatives took as long and was as disruptive they would have to think 'long and hard' about the cost-benefit balance.

> One thing we have noticed here is how disruptive the work is progress are – we've had constant clients come in and there is noise. And if someone said to us for the next five years to upgrade to set to a certain standard there would be noise all the time there would be some kind of consideration about leaving the building and obviously that wouldn't be so great for us... but ultimately that building would be up to scratch eventually

Case-study building tenants emphasised the importance of retrofitting in a manner which is cost-effective (i.e., immediately obvious initiatives, such as smart/low-energy lighting and air-conditioning) and socially-acceptable (i.e., minimal impact on existing tenants). However, on the other hand, one tenant encouraged the owners and management to be innovative and 'think outside the box' in terms of retrofitting the building, possibly via the development of a roof-top garden and communal space.

Discussion

This research offers a beginning point for understanding the difficulty of integrating sustainable technology in older commercial buildings. Tenants currently have limited understandings of technology and potential building performance outcomes, which ultimately could impede the implementation of sustainable initiatives in older buildings. Whilst the commercial property market is interested in learning about sustainability in the built environment, the findings highlight the importance of developing a strong business case, clear communication about the benefits and a transition plan for implementing sustainability retrofits in existing commercial buildings. Whilst conducted in Australia, we believe these findings are applicable to commercial building sustainability retrofitting and refurbishment programs in most Western contexts and provide some valuable lessons for those wishing to implement such initiatives.

Overall, there is little doubt that participants were supportive of sustainability as a general principle and the idea of residing in a sustainable commercial building. They felt that residing in a sustainable building is a relatively easy way through which organisations can

demonstrate their commitment to the TBL philosophy, integrating economic, social and environmental considerations. This research suggests that the tenants of the case-study building are interested and willing to engage in discussions about sustainability initiatives, but that the process, costs and benefits needed to be clearly delineated. In light of these findings, there are three key recommendations.

First, with participants unanimously expecting sustainability in commercial offices to become standard in the next decade or so, it is clear that making the transition to sustainability should be a priority. Larger and government tenants will not consider non-sustainable commercial office buildings, with smaller tenants anticipating the emergence of a 'non-sustainability discount' for residing in a building without sustainable features that would cost them more in terms of utility outgoings (e.g., electricity, water). This is consistent with two recent Jones Lang La Salle reports (Hilderson, 2004; Wallbank 2006), which have highlighted the possibility of market-driven non-sustainability discount, which is essentially the opposite notion of a 'green' lease. Specifically, the reports raise the possibility that while "*tenants currently may not be willing to pay a premium rental for buildings with sustainability features, some tenants will very soon come to expect a discount to occupy buildings that do not have these features*" (Wallbank, 2006, p6). Thus, although change is not easy, given trends in the marketplace indicating 'sustainability' is good for asset value and may soon be non-negotiable, building owners need to consider building a sustainability retrofitting program into their planning.

Second, whilst generally accepting of the main environmental, financial and social benefits of sustainability, smaller organisations needed to see tangible proof and detailed cost/benefit analyses of specific sustainability features. Thus, occupant education regarding these issues (and particularly the cost benefit of them) needs to clearly quantify the financial and non-financial costs and benefits of each feature. Of concern is the finding that most participants reported relatively minimal knowledge of specific sustainability features, designs or products. Such limited knowledge highlights the importance of generic industry and consumer awareness-raising activities, illustrating that researchers need to work harder to ensure that the business case for sustainability is clear and convincing. Third, unlike new buildings, existing buildings need to be retrofitted, which inevitability involves some disruption for existing tenants. With case-study building tenants currently experiencing significant disruption due to ongoing refurbishment, they felt that the benefits of further retrofitting would have to be very clear; thus, we recommend the development of a clear transition plan, outlining the timeline, information and cost benefits of each sustainable feature or new technology essential.

Finally, we must acknowledge the limitations of our exploratory qualitative research, which is based on in-depth interviews with seven commercial building tenants in Melbourne, Australia. Obviously, we cannot draw generic conclusions from one small case study and our hope is that these findings will inspire other researchers to explore the experience of sustainability refurbishment and retrofitting. We would argue that although the attitudes and experiences described are not that dissimilar to those highlighted in other economies, future international and quantitative research is clearly needed to further explore these issues. Critically, whilst our study is obviously small scale, it has considerable depth: the building is

quite typical of much of the stock in central business districts across Australian cities and the profile of their tenant base. Our findings provide a unique insight into the challenges of retrofitting existing commercial buildings for sustainability and the expectations and experiences of tenants.

Abstract

Architectural design can be considered as a process influenced by many stakeholders, each of which has different decision power. Each stakeholder might have his/her own criteria and weightings depending on his/her own perspective and role. Hence design can be seen as a multi-criteria decision making (MCDM) process.

Considering architectural design, its evaluation and quality assessment within a context of MCDM is not regularly performed within building processes. The aim of the paper is to find/adapt proper methodologies of MCDM, used in other domains for assessment of design quality, adapt them to the construction domain and test their applicability.

Current tools (for instance DQI, DEEP, AEDET, HQI, LEED, BREEAM, BQA) for quality assessment will be reviewed and compared with several MCDM methods (ie. AHP, ANP, PROMETHEE, SAW AND TOPSIS). Advantages and disadvantages of gathered outcomes from comparisons for assessment and applicability within architectural design will be discussed. Finally reflections on the outcomes will be provided.

Keywords: Architectural Design Quality, Analytic Hierarchy Process (AHP), Design Quality Assessment Tools, Multi Criteria Decision Making (MCDM)

INTRODUCTION

Dickson (2004) stated that, the overall design and procurement process can be seen as a series of decisions that lead progressively towards the built reality. Analysing a design process, as the sum of decisions made by each stakeholder with decisive power, is not the most often used way of approaching design (quality) within architecture. Considering design as a multi-stakeholder decision making process, it seems reasonable to apply multi criteria decision making (MCDM) techniques to asses design quality. MCDM can be defined as the evaluation of the alternatives for the purpose of selection or ranking, using a number of qualitative and/or quantitative criteria that have different measurement units (Özcan et al., 2011). Remarkably the most often used tools nowadays are based on evaluation of chosen criteria via Likert/rated scoring systems. The aim of the paper is to find out the potentials of MCDM methods for development of architectural design quality tools. For that reason existing quality tools will be analysed to bring out their strong and weak points. Methods used in other domains for decision making will be analysed to find possible potentials of them to cope with the weaknesses of current tools used in architectural design.

"Since solid theoretical foundation and best practices are rare in architecture and construction, it is recommended to learn from state-of-the-art in other relevant domains, i.e. social and organizational psychology, organizational management and behaviour, and other industries" (Sebastian, 2003, 2007). Built on this statement, this study aims to improve existing quality assessment tools used in architectural design, by using MCDM methods which are used in other domains for decision making. Quality assessments of multi-stakeholders might be useful in terms of providing designers with input for improving their design according to stakeholder preferences. Besides, their attitude is beneficial for taking decisions at design team meetings at stage boundaries, for selection between different design alternatives in case of disputes or design contests, or for post occupancy evaluations. The strategy within this research is to evaluate the most often used current tools more specific on the applicability seen from a multi stakeholder perspective, and to review existing MCDM methods as regularly used within other domains comparing them on their applicability within building processes.

The first part of the paper will cover a review of current tools used for assessment. After this, a discussion will follow to review their strengths and weaknesses, from a multi stakeholder decision making perspective. In the second part, MCDM methodologies will be analysed with the to what extend they might cope with the specific weaknesses which are defined in the first part of the paper as being characteristic for the existing tools most often used in practice. Also comparative analysis of Likert/rated scale to pair wise comparison will be revealed. Finally the outcomes will be discussed to reveal potentials of MCDM methods to use for architectural design quality assessment.

RELEVANCE AND BACKGROUNDS OF THE RESEARCH

Each architectural design most often typically can be seen as a one off production. The design process is complex, considering its content, context, stakeholders, ill-defined problems and moreover multifaceted interactions of them to each other. Design is obviously not a linear-running but an iterative process which is analysing through synthesizing (Sebastian, 2003, 2007). Each design process has special characteristics which cannot be standardized easily. Since buildings are so diverse, serving many different types of occupancies or functions, any attempt to develop a single system to define and rate performance of these buildings will not

be perfect and will even be unsatisfactory for many potential users (MacDonald, 2000). This might be the reason so many different assessment tools are developed for building processes.

As stated, within this research architectural design is considered to be a decision making process. Within the process, decisions are taken by the evaluation of criteria and sub-criteria from the perspectives of stakeholders related to various limitations, so called multi-criteria decision making (MCDM) processes. This might be seen as a valid approach as even in the simplest cases today at least architects in design processes have to cope with their clients or/and users, specialist engineering advisors, governmental bodies and the contractors. This approach is especially valid in case of, complex buildings for instance designs for the Health Care sector, in which projects (depending to a certain extend to their organization and national context) have a multi-facetted client situation (the diverse specialist and health groups and a wide variety of users) whose expert knowledge is an absolute necessity in terms of the future usability of the building and of which many have decisive power within the design and construction process.

In complex circumstances, our practice based experiences, interviews held and literature survey executed are shown that easy-to-use tools may provide unsatisfactory outcomes while intending to use efficiently and repetitively.

ARCHITECTURAL DESIGN QUALITY

Literature was reviewed for a common understanding of architectural design quality. In the history, one of the first written definitions date backs to 20's BC. Utilitas, Firmitas and Venustas – commonly translated as Commodity, Firmness and Delight- was one of the first defined frameworks for criteria used to asses architectural design quality as developed by the Roman architect Marcus Vitruvius. This Vitruvian framework has been an essential base for forthcoming architectural theory later on. The framework up till today is also the most addressed trilogy to define excellence. (Vitruvius, 1993; Volker et al., 2008; Prins, 2009)

Related to Nelson (2006), quality is the degree to which a set of inherent characteristics fulfils stated, implied or obligatory needs or expectations. Nelson (2006) defines quality for domain of architecture as improving the degree to which design fulfils needs and expectations. In the building environment, Volker et al. (2008) outlines that architectural quality embraces all the aspects by which a building is judged while in the construction industry, quality is associated with competency and proficiency levels as a route to customer satisfaction. (Thomson et al., 2003)

Throughout the history of architecture, definitions of criteria and their sub-criteria differ according to era, technology, culture and the society. Quality is a subjective matter meaning different things to different people depending on perceived priorities. (Choy and Burke, 2006) That is to say, quality is in the eye of the beholder. Within this paper, it is intended not only to explore methodologies but also to explore the criteria which may be effective about getting the ideas of stakeholders involved to the quality, rather than trying to create or contribute to the existing series of holistic attempts to define architectural quality.

RESEARCH METHODOLOGY

This paper aims to structure the conceptual framework of an assessment tool for architectural design quality based on MCDM methods. The research is based on an explorative analysis using an inductive approach according to the steps listed below:

- Current design tools –DQI, DEEP, AEDET, BREEAM, LEED and BQA-will be introduced and reviewed. (Tools are selected due to their reputation in academic papers and use in practice)
- Outcomes will be discussed to reveal strengths and weaknesses of the current tools from a multi stakeholder decision making perspective.
- MCDM methods, as widely used in other domains will be introduced and reviewed on applicability for architectural design and construction and compared with the earlier mentioned tools most often used today within the domain.
- The specific potential of MCDM methods will be discussed, more in special compared to the weaknesses of the current tools used in architectural design and construction.

Research questions related with the steps are:

- How are the tools linked to architectural design quality assessment?
- What are the criteria and sub-criteria of the currently used tools for architectural design quality assessment?
- Are the tools flexible/adaptable enough to change the criteria for different types of buildings and for different project teams?
- What are the assessment methodologies?
- What is the difference between Likert/Rated scale and pair wise comparison? Which one should be used for design quality assessment?
- What are the strengths and weaknesses of the current tools?
- Can MCDM methods be used for assessment of quality?
- Can MCDM methods cope with the weaknesses of the current tools, more in special as discussed in an MCDM perspective and for the different usages mentioned?

CRITICAL REVIEW OF ARCHITECTURAL DESIGN QUALITY ASSESSMENT TOOLS

What cannot be numerically measured is deemed not to exist (Prasad, 2004)

Design quality is a complex phenomenon. Everybody has an opinion about buildings and quality, but consensus and scientific explanations are difficult. (Dewulf and van Meel, 2004). Nevertheless to cope with the problem of evaluation, several tools have been developed which have different approaches for assessment. DQI, AEDET Evolution, DEEP, HQI, LEED, BREEAM and BQA are the tools chosen for analysis within this paper. They are selected due to their reputation in academic publications and their usage frequency in practice depending on literature review. (Dewulf and van Meel, 2004 - Gann et al., 2003 - van der Voordt, 2009, 2005 - Volker et al., 2008 – Volker , 2010 - Giddings et al., 2010 - MacMillan, 2004 CABE, 2011) Following brief explanations about the tools, they will be reviewed especially for their criteria selection, methodology, scope of assessment possible usage phases in building process and their efficiency and applicability.

DQI (Design Quality Indicator)

The Design Quality Indicator (DQI), maybe the best known tool amongst the others, was developed based on a "rational-adaptive approach" (Volker, 2010) as an extension of the "*Rethinking Construction Agenda*" for targeting, mapping, measuring and managing performance improvement in construction. (Gann et al., 2003) There is a general DQI for all building types and a specific one for school buildings; together with two subsets, AEDET which focuses on hospitals and DEEP, which is exclusively for military housing (Giddings et al., 2010). The tool is based on a method that integrates measures of 'hard' physical attributes and 'soft' perceptual viewpoints about the performance of buildings in relation to design decisions. The former are typically found in areas such as build quality and function. (Whyte, j. et al., 2004) More detailed information can be found, in Gann et al (2004).

AEDET Evolution (Achieving Excellence Design Evaluation Toolkit)

The AEDET Evolution (Achieving Excellence Design Evaluation) Toolkit -the latest version of AEDET- is a subset modification of DQI, aims to be used in case of healthcare facilities to evaluate architectural design quality. It delivers a profile that indicates the strengths and weaknesses of a design or an existing building. AEDET is a tool specifically directed towards achieving 'excellence in design' rather than ensuring compliance with legislation, regulation and guidance (Aedet web page). It can be used from initial proposals through to post project evaluation. It is also being used as a benchmarking tool. The toolkit comprises a series of key questions supported by lists of related issues that need to be considered (AEDET webpage) (van der voordt, 2009, 2005). A detailed review can be found in Gesler et al. (2004).

DEEP (Design Excellence Evaluation Process)

The DEEP (Design Excellence Evaluation Process) Toolkit is also a subset modification of DQI to be used in buildings of the United Kingdom Ministry Of Defense to evaluate architectural design quality at the key stages in the project life cycle. DEEP determines both the required design standard (usually expressed as a percentage) and compliance with required minimum standards. DEEP provides the technical assurance that a military construction project is both compliant with Government construction policies and of a sufficient design quality to ensure fitness for purpose and value for money over the whole life of the facility. (DEEP web page)

HQI (Housing Quality Indicator)

Housing Quality Indicator (HQI) measures the quality of housing schemes funded through the United Kingdom National Affordable Housing Programme (NAHP)(HQI web page). It was developed with ease of use in mind. The HQI system allows an assessment of quality of the key features of a housing project in relation to location, design and performance. The system was developed such that quality is evaluated from many different aspects (Wheeler, p., 2004). According to Giddings et al. (2010), design quality assessment using this tool, is limited to standards and measurement. More can be found at Giddings et al. (2010) Wheeler,P. (2004) and Franklin (2001)

BREEAM (Building Research Establishment Environmental Assessment Method)

BREEAM (Building Research Establishment Environmental Assessment Method) is one of the oldest building assessment systems. Developed in 1988 by the Building Research Establishment (BRE), the national building research organization of the UK, it was initially created to help transform the construction of office buildings to high performance standards (Ulukavak Harputlugil and Hensen, 2006). BREEAM which covers a range of building types, including offices; industrial premises; retail outlets; schools, etc has been an inspiring tool which

further developed tools have adapted as a reference model, and also is widely used in other countries (Lee and Burnett, 2008). BREEAM nowadays developed into one of the leading and most widely used environmental assessment methods for buildings. It sets the standard for best practice in sustainable design, describing a building's environmental performance. (BREEAM web site)

LEED (Leadership in Energy & Environmental Design)
LEED is an internationally recognized green building certification system. It provides third-party verification that a building or community was designed and built using strategies aimed at improving performance across all the metrics that matter most in this respect: energy savings, water efficiency, CO2 emissions reduction, improved indoor environmental quality, and stewardship of resources and sensitivity to their impacts. (LEED website)

BQA (Building Quality Assessment)
BQA is a tool for scoring the performance of a building, relating actual performance to identified requirements for user groups in that type of building. The quality of a building is defined in BQA as the degree to which the design and specification meets the requirements for that building (Clift, 1996). The BQA system divides the building into nine categories that establish a broad classification of user requirements. The performance and quality of a number of office buildings can be compared at all levels – the overall BQA total, the category and/or section totals and down to the individual factor levels. Individual clients using BQA can choose their own weightings if they wish to emphasize a particular characteristic.

SYSTEMATIC REVIEW OF MOST COMMONLY USED QUALITY ASSESSMENT TOOLS

There are several tools to assess, evaluate and define architectural design quality, some of the most important of them described above. Developing such tools in a wide variety, for different types of buildings system represents the struggle to improve the quality of buildings and the build environment in general (Wheeler, 2004). The quality assessment tools discussed above were reviewed to bring out strengths and weaknesses depending their usage for certain building types, methodology, scope of assessment, their use in the building process, organization and finally their criteria and sub-criteria selection. (Table 2)

	DQI	AEDET	DEEP	HQI	LEED	BREEAM	BQA
1)Building Type	Educational Buildings Specific. (Can also be used on wide variety of buildings)	Hospitals (Health Care facilities)	Military Housing	Housing (schemes)	All types of buildings (residential to commercial)	Housing Eco-homes Office Schools Industrial build. Courts Healthcare Prison Retail education (Other types of buildings)	Office buildings
	DQI, LEED and BREEAM can be used for a wide variety of buildings, while the rest is more or less related with a specific building type.						
2)Aim of Use	-Architectural design quality (ADQ) assessment	-ADQ Assessment -Benchmarking	-ADQ Assessment -Generic Checklist	-Measurement and assessment of potential and existing house schemes based ADQ	-Green building certification system	-Sets the standard for best practice for sustainability	-Performance assessment
	DQI, AEDET, DEEP and HQI aim to assess architectural design quality. LEED and BREEAM try to set the standards for certification of green buildings, while BQA aims to assess the performance of office buildings.						

3)Main Criteria **Sub-Criteria**	**-Functionality** Use Access Space **-Build Quality** Performance Engineering sys. Construction **-Impact** Character &Innovation Urban&social Integration Staff Environment	**-Functionality** Use Access Space **-Build Quality** Performance Engineering sys Construction **-Impact** Character &Innovation Urban &social Integration Staff& Patient Environment	**-Functionality** Client Operation Single Living Accommodation Innovation **-Build Quality** Performance Engineering sys Building Fabric Innovation **-Impact** Context&estate Planning Form&appearance Internal Environment Conversation of buildings Sustainability	**-Location** **-Site** Visual Impact Open space Routes &movement **-Unit** Size Layout Noise,light, services and adaptability Accessibility Sustainability **-External environment** Size	**-Sustainable Sites** **-Water Efficiency** **-Energy and Atmosphere** **-Materials and Resources** **-Indoor Environmental Quality** **-Location& linkages** **-Awareness &education** **-Innovation in design** **-Regional Priority.**	**-Management** Life cycle cost Site investigation **-Health and well Being** Lighting Water Noise control **-Energy** Co2 emissions Energy use Noise control **-Transport** Public Transport Cyclist Deliveries **-Water** Recycling Irrigation sys. **-Materials** Re-use Insulation **-Landuse &Ecology** Re-use Ecological value Bio diversity **-Pollution** Water sources Refrigerant leaks **-Innovation**	**-Presentation** **-Space functionality** **-Access and circulation** **-Business services** **-Amenities** **-Working and environment** **-Health and safety** **-Structural considerations** **-manageability**
	The tools use adapted Vitruvian frameworks which can be defined as functionality, build quality and impact, extended with ecological approaches like sustainability, health, wellbeing and preserving resources for assessment of architectural design quality. For assessment, design quality is seen as a degree of excellence within the intersection of the main criteria with their sub-criteria.						
4)Adaptability /Flexibility	General adaptation (Not case specific)	General adaptation (Not case specific)	General adaptation (Not case specific)	General adaptation (Not case specific)	General adaptation (Not case specific)	Adaptability for each building type	No adaptability
	No flexibility to change or adapt the criteria for different tasks. General modifications or updates on the system take time to get in action in further versions, which makes it hard to adapt the tools case based specific						
5)Methodology	Structured workshop, online form and questionnaires	Stand alone forms, Workshops	Stand Alone Forms Workshops (in some cases)	Stand alone forms	Online certification	Stand alone form	Software based survey
	The tools make assessment via standalone forms or in some cases with web based online surveys/questionnaires to reflect stakeholders' priorities. DQI, AEDET and DEEP also use workshops to get individual priorities. LEED, BREEAM, BQA use threshold levels for assessment of quality.						
6)Scope of Assessment	Achieve the best building possible based quality.	Evaluate the quality of design in healthcare buildings.	Identify and minimize risk in the design of projects (MOD Building)	Measurement and assessment of potential and existing house schemes based quality	Accelerate the adoption of green building practices	Energy and sustainability	Assessment of Performance of a building
	DQI, DEEP,AEDET, HQI assess the design quality. LEED and BREAM certificates buildings related to energy usage and sustainability, while BQA assesses performance of a building						
7)Phase of Building Process	All stages of building process including all design stages.	All stages of building process including all design stages.	All stages of building process including all design stages.	Design and in use	All stages of building process including all design stages.	Design and in use	Post occupancy evaluation (can be carried out to design stages)
	All tools claim that they can be used within the all stages of building process from briefing to in use. Although the tools are introduced as they can be used in any stages of the building process, they can be used effectively in post occupancy evaluation (POE).						

8)Organization (stakeholders)	Internal and external stakeholders (Especially users)	Internal and external stakeholders	Internal and external stakeholders	Internal and external stakeholders	Commercial building project stakeholders or project team members	Internal and external stakeholders	Internal and external stakeholders
	The intention behind the tools on design quality is to get ideas for the stakeholders, especially from users, for the assessment of architectural design quality. Getting stakeholders ideas is a big plus to achieve success for integrated design teams, however transferring ideas to design process as knowledge for design teams can be underlined as missing part of the tools. Tools generally aim to score a building in general, rather than transferring knowledge to design teams.						
9)Weighting System	Likert/Rating Scale	Likert/Rating Scale	Likert/Rating Scale	Likert/Rating Scale, Yes/No Questions	Likert/Rating Scale	Likert/Rating Scale	Likert/Rating Scale
	All of the tools use adapted Likert/rating scale system for assessment. Some of them are using verbal scales while others use point scaling system. HQI also asks Yes/No questions.						

Table 1: *Design quality assessment tools review.*

Strengths

- Tools tend to be used for assessment of design quality in a wide variety of buildings, although there are still limitations.
- Criteria selection mostly are based on a Vitruvian like framework and sustainable principles often after extended discussions and many iterations before these terms were agreed upon.(Gann et al., 2003)
- Dewulf and van Meel (2004) stress that the recognized importance of the built environment makes it absolutely necessary to discuss design quality with laymen, architects, government and other stakeholders. Proving the statement, there is a growing intention of the tools to get stakeholders ideas, especially users, for assessment of architectural design quality. Reflecting stakeholders' priorities in building processes is a big plus to achieve success for integrated design teams.

Weaknesses

- Although the tools can be used for different types of buildings and for different phases of building processes, it is still a problem to adapt the underlying system of the pre-defined sets of criteria (something all above mentioned tools have in common) for making a case base specific design evaluation.
- The tools have problems to contribute to design stages since they are not succeeded to make comparative assessment of design alternatives.
- Most often the tools must be used with expert facilitators, or are at least assumed to, which make assessment process tough considering total numbers of stakeholders and time needed.
- A big concern for all the tools reviewed is their weighting systems and their methodologies which they use for assessment. All the tools reviewed use a Likert/rating scale system, some of which use verbal judgments while the others use point system for scaling(HQI also uses Yes/No questions). Outcomes of the surveys related to assessment contain heterogeneous data since using this methodology it is not clearly known what the relative importance is of the each criteria and sub-criteria to each other.
- Another problem is the lack of consistency measurement. Consistency cannot be checked until a certain amount of participants exist. As the tools intend to get also non-expert stakeholders' ideas, consistency should be considered and inconsistent surveys should be avoided.

Considering the above mentioned weak sides of the currently used tools, multi criteria decision making methodologies will be introduced and evaluated on their ability to cope with them. After the review of methodologies, a comparative chart of the most used methodologies will be introduced to cope with the weak sides of the current tools for further developments.

PROBLEMS OF LIKERT/RATED SCALE

It is hard to find a holistic way of an assessment approach of architectural design quality. Architectural design quality consists of tangible and intangible criteria which may be evaluated from different perspectives of the stakeholders. Who is going to assess the quality? For who are they going to do this and how are the solid questions to be answered? To point out problems of Likert/rated scaling which is used by most of the current tools related to assessment of design quality; rather than stating problems in theoretical ways, it should be better to make a short illustration to analyze problems in practice. Since architectural design is a one off attempt, keeping in mind that criteria may vary for each design problem, let us consider 20 criteria consisting of both tangible and intangible factors for assessment of architectural design quality for an existing building. (Table 2)

Criteria
C1, C2, C3, C4, C5, C6, C7, C8, C9, C10, C11, C12, C13, C14, C15, C16, C17, C18, C19, C20

Table 2: *Criteria List*

Having defined the criteria, in the second step, tangible and intangible criteria are grouped separately. (table 3)

Criteria	
Tangible	C1, C3, C5, C7, C9, C10,C11, C12, C15, C18,C19,C20
Intangible	C2,C4, C6, C8,C13,C14,C16,C17

Table 3: *Criteria List*

Based on Likert/rated scale, for the third step, criteria are listed for quality assessment. The respondents are asked to assign weighting to the importance of each feature; on a scale of Excellent/5/Strongly Agree to Poor/1/Strongly Disagree called "Likert /Rated Scaling" which most of the current tools use as a methodology for design quality assessment.

Criteria	**Excellent (5) Strongly agree**	**Very Good (4) Agree**	**Good (3) Undecided**	**Fair (2) Disagree**	**Poor (1) Strongly Disagree**	**No idea (0)**
C1	+					
C2		+				
C3						+
C4		+				
……						
…..						
C20			+			

AVERAGE	Average of the building is good/3/undecided

Table 4: *Likert/rated scale based assessment methodology*

During the evaluation problems may be stated as:

1) Although tangible criteria may be evaluated with numeric values, according to Saaty(2008) intangible criteria cannot be evaluated numerically.
2) Since there is no hierarchic formation, every criterion is evaluated at the same level.
3) The relative importance of the criteria each other is not clear.
4) The consistency of the evaluation cannot be measured until a certain amount of participants exist.

For the next step, to cope with these problems stated above a hierarchic formation can be made. And also using weighting factors for evaluation may be added.

Weighting Factor	**Main Criteria**	**Sub-Criteria**	**Excellent (5) Strongly agree**	**Very Good (4) Agree**	**Good (3) Undecided**	**Fair (2) Disagree**	**Poor (1) Strongly Disagree**	**No idea(0)**
3	C1		+					
2		C5				+		
3	C2							+
2		C4		+				
1		C6						
…..	……	……						
4	C3				+			
2		C20			+			
AVERAGE		Average of the building is good/3/undecided						

Table 5: *Likert/rated scale based assessment methodology-Hierarchy and weighting factors added*

Although Hierarchy is formed, weighting factors are defined, there are still problems which may be stated as:

1) Still tangible and intangible criteria are evaluated with numeric values.
2) The relative importance of the criteria although they are hierarchically formed is still not known.
3) To assign weighting factors for the importance of each criterion is problematic since humans can only evaluate 5-9 factors in one task depending on Miller's (1956) famous theorem.
4) The consistency of the evaluation cannot be measured until a certain amount of participants exist

Pair wise compared MCDM based methodology will be introduced to cope with the problems stated above in further chapters of this paper.

MULTI-CRITERIA DECISION MAKING

Multi-criteria decision making (MCDM) methods deal with the process of making decisions in the presence of multiple criteria. Decision-makers are required to choose among quantifiable or non-quantifiable and multiple criteria. The objectives are usually conflicting and therefore, the solution is highly dependent on the preferences of the decision-maker and must be a compromise (Pohekar and Ramachandran, 2004). Priority based, outranking, distance based and mixed methods are also applied to various problems. Each method has its own characteristics and the methods can also be classified as deterministic, stochastic and fuzzy. There may be combinations of the above methods. Depending upon the number of decision makers, the methods can be classified as single or group decision making methods. Most used MCDM methods are AHP, ANP, PROMETHEE SAW and TOPSIS. (Pohekar and Ramachandran, 2004) (Triantaphyllou et al., 1998) (Özcan et al., 2011)

Considering its internal and external stakeholders, architectural design can be defined as an affective decision making process which is dynamic: a complex search for information, full of detours, enriched by feedback from casting about in all directions, gathering and discarding information, fuelled by fluctuating uncertainty, indistinct and conflicting concepts (Zeleny, 1982). Although methodology of current quality assessment tools shall be notified as MCDM to some degree, MCDM methods will be reviewed to cope with their ability to assess architectural design quality while keeping in mind the weaknesses of current tools as stated above.

Analytic Hierarchy Process (AHP)

The analytic hierarchy process (AHP) (Saaty, 1980, 1990) is based on decomposing a complex MCDM problem into a system of hierarchies. The pairwise comparison matrix is constructed by using the relative importance of the alternatives in terms of each criterion. The vector (ai1, ai2, ai3, ..., aiN) for each i is the principal eigenvector of an N×N reciprocal matrix which is determined by pairwise comparisons of the impact of the M alternatives on the i-th criterion (Triantaphyllou et al..,1998). AHP is based on three main principles a) Forming Hierarchy b) Determining supremacies c) Numeric and logical consistency (Topçu, 1999). AHP is an effective method of dealing with complex problems.

Analytic Network Process (ANP)

The ANP, also introduced by Saaty, is a generalization of the AHP (Saaty, 1996). While the AHP represents a framework with a uni-directional hierarchical relationship, the ANP allows complex interrelationships among decision levels and attributes. Related to Yuksel and Dağdeviren (2007), Maede and Sarkis (1998) define that the ANP feedback approach replaces hierarchies with networks in which the relationships between levels are not easily represented as higher or lower, dominant or subordinate, direct or indirect. For instance, not only does the importance of the criteria determine the importance of the alternatives, as in a hierarchy, but the importance of the alternatives may also have an impact on the importance of the criteria. (Yüksel and Dağdeviren, 2007)

Preference Ranking Organization METHod for Enrichment Evaluation (PROMETHEE)

PROMETHEE, proposed by Brans and Vincke (1985), builds outranking relations among alternative pairs. An outranking relation is defined in the set of alternatives such that alternative *a* outranks alternative *b* if there are enough arguments to decide that *a* is at least as good as *b*, while there is no essential reason to refute that statement. There are two extensions

of the method: PROMETHEE I yields partial rankings (incomparability is allowed), on the other hand PROMETHEE II yields complete rankings.

Simple Additive Weighting (SAW)
SAW method calculates a global (total) score for each alternative by adding contributions of alternative with respect to each attribute (Yoon & Hwang, 1995; Vincke, 1992). A common numerical scaling system such as normalization (instead of single dimensional value functions) is required to permit addition among attributed values. Then alternatives are ranked by using their global scores.

Technique for Order Preference by Similarity to Ideal Solution (TOPSIS)
TOPSIS method evaluates alternatives according to their distance to positive and negative ideal solutions (Yoon & Hwang, 1995; Hwang & Ming, 1987). An alternative that would be recommended to the decision maker(s) should have the shortest distance from the positive ideal solution and the longest distance from the negative ideal solution. Positive and negative ideal solutions are imaginary alternatives. A positive ideal alternative has the best performance value for each attribute while a negative ideal alternative has the worst.

ANALYSIS OF MCDM METHODS FOR POTENTIALS OF DESIGN QUALITY

	AHP	ANP	PROMETHEE	SAW	TOPSIS
Decision Making	Individual and group	Individual and Group	Individual and Group	Individual and Group	Individual and Group
Methodology	Creating hierarchical structure and pairwise comparison matrices	Creating network structure and pairwise comparison matrices	Creating matrix structure and comparing pairs of alternatives to form an outranking relation	Creating matrix structure and calculating a global (total) score for each alternative by adding contributions of alternative with respect to each attribute	Creating matrix structure and calculating distance to positive and negative ideal point
Areas of Usage	To support decision making for complexity	To support decision making for complexity	To support decision making for complexity	To support decision making for complexity	To support decision making for complexity
Adaptability/Flexibility	+ easy to adapt case specific	+ easy to adapt case specific	- not easy to adapt	- not easy to adapt	- not easy to adapt
Consistency Measurement	+	+	No need	No need	No need
Weighting System	Pair Wise comparison	Pair Wise comparisons	No specific method.	No specific method.	No specific method. Linear or vector normalization
Criteria Evaluation	Tangible and intangible criteria	Tangible and intangible criteria	Tangible criteria	Tangible criteria	Tangible criteria

Pros	Can give consistent results for every decision making process	Easy to implement, expressive power of modeling	Low level of interaction with decision maker (It may be defined as a negative issue for integrated design teams for assessment of design quality)	Low level of interaction with decision maker (It may be defined as a negative issue for integrated design teams for assessment of design quality)	Low level of interaction with decision maker (It may be defined as a negative issue for integrated design teams for assessment of design quality)
Cons	Linear evaluation	Several pairwise comparison questions. Complex survey process for non-expert participants	Identifying thresholds, incomparable results	Very easy, can give unreliable results	Easy, can give unreliable results

Table 6: *Multi Criteria Decision Making Methods(MCDM) comparison*

MCDM tools as described above are not used for imposing solutions to the decision makers. They aid decision makers to make decisions under the consideration of evaluation criteria. Their methodologies vary in their ability to cope with problems of design quality assessment in case of multi stakeholder decision making. Related to review above it might be stated that MCDM methodologies, especially the ones using pair wise comparisons, have the potentials to cope with most weaknesses of the current tools stated in the previous chapters.

Design and architecture may be listed amongst the wide variety of domains which MCDM methods are used. Some of the researches and studies (Binnekamp, 2010; Loon and Wilms,2006; Heurkens, 2006, leeuwen and timmermans-editors-, 2006) may be notified as instances/models for usage of MCDM methods in the design domain related to urbanism and architecture. Although several approaches of usage of MCDM for design and design processes are reported, there is no architectural design quality assessment tool in the literature found which is widely used and broadly accepted using MCDM methods based on pairwise comparisons.

PAIRWISE COMPARISON

Saaty (2008) states that "Numerical measurement must be interpreted for meaning and usefulness according to its priority to serve our values in a particular decision. It does not have the same priority for all problems. Its importance is relative". To cope with the complexity of assessment of architectural design quality, a systematic approach based on Simon's idea may be formed. Simon(1969) in his famous book- Sciences of Artificial - defines the shape of design as a hierarchy. He believes that to design a complex structure, one powerful technique is to discover viable ways of decomposing it into semi-independent components corresponding to its many functional parts. Considering his statement as a base, to cope the complexity of assessment of architectural design quality, decomposing the quality in criteria and sub-criteria hierarchically may be a fruitful approach. Using pair wise

comparison based approaches instead of Likert/rated scale which as used by all the current tools discussed, may provide better results to cope with many of the weaknesses listed above.

Underlying factors to use pair-wise comparison rather than Likert/rated scale can be endorsed by Saaty's notifications as follows: "Long before measurement scales were invented, people had no direct way to measure because they had no scales and had to compare things with each other or against a standard to determine their relative order. People still have that ability, and it is still critically necessary to be able to make comparisons much of the time, especially when they cannot measure things. One reason may be that people do not have the instrument or scale to do it. Another reason is that they may believe that the outcome of comparisons using their judgment would be calibrated better to their values than using a scale of measurement that was not devised particularly for the use they are putting it to. A third reason may be that there is no way known to measure something like: political effectiveness, happiness, aesthetic appeal. Ancient people used their judgment to order things. The way they did it was to compare two things at a time to determine which was the larger or more preferred. By repeating the process they obtained a total ordering of the objects without assigning them numerical values. After being ordered they could rank them: first, second, and so on". (Saaty, 2008)

20 criteria set illustration which was implemented for Likert/rated scale in previous chapter of the paper can be adapted to pair wise comparison matrix. (table 8) Main criteria (c1,c2,c3) and sub-criteria (c4, c5, ….,c20) can be ordered hierarchically. Hierarchically structured criteria and sub-criteria regardless of whether they are tangible or intangible can be pair wise compared. If it is needed, it is also possible to evaluate the alternatives. By using MCDM methods, for instance AHP or ANP, consistency can also be measured.

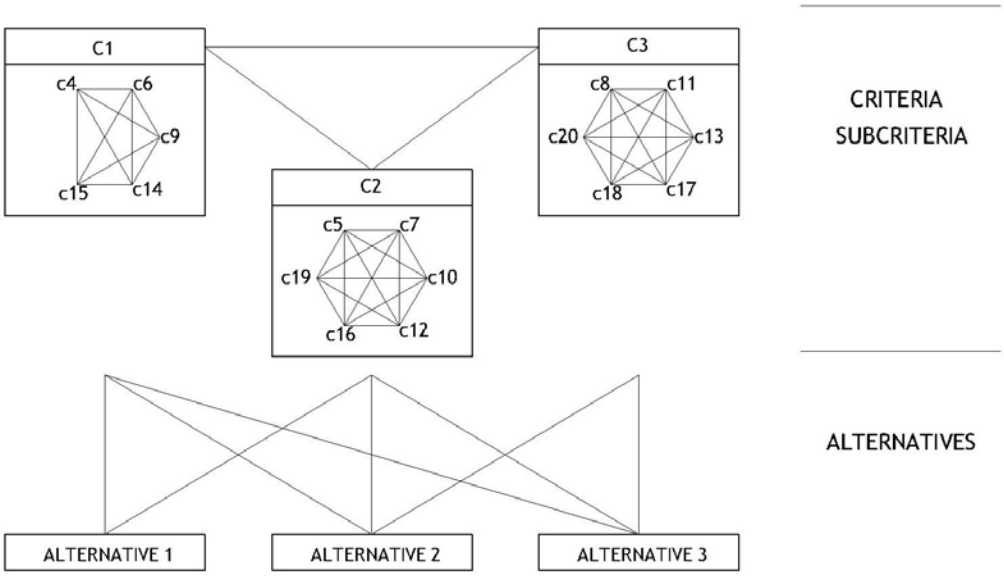

Table 7: *Pair wise comparison*

By using pair wise comparisons method:

- Criteria and sub-criteria can be grouped hierarchically. So related ones can be compared.
- Tangible and intangible criteria can be evaluated. (Saaty, 1980, 1990, 2008)
- Relative importance of the each criteria and sub-criteria to each other can be defined.

- If it is wished design alternatives can be evaluated.
- It is possible to add decision makers with weighting factors which makes group decision making available.
- Consistency levels of priorities of non-expert stakeholders can be measured with limited amount of participants.

MCDM methods, especially the ones using pair wise comparisons, may bring out relative importance of the criteria of preferences of stakeholders related to architectural design quality. They may be adapted easily for each step of building process mostly to design stages to evaluate alternatives within the design process.

CONCLUSION

This paper has begun by noticing significant problems of quality assessment tools in building processes mostly about architectural design quality assessment. Having remarked weaknesses of current assessment tools and major problems for their methodologies, outcomes to be used further about quality assessment can be listed as below:

- As there is not a universal definition for quality, tools to be created for architectural design quality assessment should consider a flexible/adaptable system for criteria selection. Criteria must be adapted for different building types, for the different phases of the building process and for different project teams.

- Reflection of the ideas of stakeholders to building processes is a big plus for integration. Tools to be designed for design quality should consider adapting stakeholders' preferences accurately into the building design process.

- As design is a complex decision making process, MCDM methods, especially the ones using pair wise comparisons, can be used/adapted for architectural design quality assessment to overcome the some of the weaknesses all current tools seems to have in common. To help designers to get stakeholders ideas into the design process, rather than using Likert/rated scaling system, pair wise comparisons can be used instead to evaluate criteria and sub-criteria. Otherwise the score of assessment will contain heterogeneous data which cannot be transferred to knowledge for design teams. Also consistency should be considered in case of data gathering.

- Assessment tools must put out not only assessment scores but must also provide methodologies about transferring the data to be used as knowledge within the design process by design teams.

LIVING BUILDINGS AND THE ASSOCIATED R&D BASED MANUFACTURERS - *The Revolution towards Evolutionary Construction*

Hennes DE RIDDER
Delft Technical University
Delft, the Netherlands
H.A.J.deRidder@tudelft.nl

Abstract
The construction industry is not sustainable. Expressed in percentages of the totals in the Netherlands and when calculated over the total lifecycle, from the early start to the processing of waste after demolition, energy consumption is more than 50%, CO2 emission is more than 50%, waste production is 35 %, road transport is 25 %, failure costs is more than 15 %, average profits of construction companies are less than 2% of the turnover. The contribution of the construction industry to the GNP is 11%. The global figures will probably be worse as cooling requires disproportional more energy than heating. Obviously, the construction industry should be changed fundamentally. In this paper a great design of a sustainable construction industry is presented. Using ”attribute listing” as method, the contours of a future Construction Industry are described in 50 typical characteristics and attributes each of them in full contrast to the current situation. The result can be considered as Evolutionary Construction with Living Buildings, which are able to survive in a faster and faster changing world. These sustainable buildings are created by variation, selection and reproduction. Like car producers, building producers will develop new buildings from existing buildings. All properties, attributes and features with respect to architecture, quality, quantity and costs of these buildings should be described in a Parametric Knowledge Model which is continuously fed by each realization. Hence, each new or adapted building will contain the experience and knowledge accumulated during a long series of already realized buildings. A main condition is that each building of the family of buildings should have the same structure, which is the set of architectural, structural, mechanical and physical relations between the elements. But at the same time each building is unique by a large variation of elements. These buildings are fully (de) mountable and composed of standardized industrial elements in order to cope with changing environmental circumstances. As the lifetime of most elements and components are longer than the expected lifetime of buildings as a whole, a major part of buildings can thus be reused after dismantling. This Darwinism for construction industry manifests itself in adaptability not only over generations of buildings but also in each building that should survive in its own lifetime. In result, the Big Picture of the future culture and structure of the construction sector can give us some hypothetical benefits. An estimate: The value of buildings will be at least twice as much, the prices at least 50 % lower and the delivery time at least 50 % shorter. Moreover the energy consumption and CO2 emissions will be halved. In this paper the basic principles and thoughts, which have been used for this design work and the 10 most important changes out of 50 are presented. In 2012 a book will be published on Evolutionary Construction.

Keywords: Living Buildings, Sustainable IFD Buildings, R&D based Buildings, Parametric Design, Integrated Supply Chain

INTRODUCTION

Practitioners and scientists all over the world agree that the construction industry shows systemic failings resulting in disappointing production, effectiveness and efficiency. The first movements aimed at substantial changes date from the early nineties of the last century and was initiated in the UK by the Latham commission (Latham,1994), followed by Rethinking Construction (Egan ,1998). After Australia and Finland also in Holland started an initiative after the big fraud affair (Tweede Kamer, 2002 and PSIB,2004). Measures were mainly aimed at change of the adversarial culture of the construction industry which manifest itself in lack of respect of its employees and uncapability of delivering for its custumers. During the last decades improvements were achieved by creating more openness, cooperation, trust, honesty, commitment and teamwork in projects (Egan,2002).

In the late nineties of the last century, the notion of sustainability emerged in the world when facing the climate problems. Here, the construction sector plays a critical role, as its contribution is rather bad (Dubois &Gaddle,2002; Nam & Tatum, 1988). Expressed in percentages of the totals in the Netherlands the energy consumption during the utilization phase is 35 %, the CO2 emission during the utilization phase is also 35 %, the consumption of energy and the CO2 emission due to the production of materials is 35 %, the waste production is 35 %, road transport is 25 %, failure costs is more than 15 %, which is about 10 billion Euros per year. Moreover the average profits of construction companies are less than 2% of the turnover. These figures are rather bad when compared with the 11% contribution of the construction industry to the GNP (Lichtenberg, 2006). The global figures will probably be worse because cooling requires more energy than heating.

The reason behind this bad performance is that every building is treated as a unique product. The world is covered with billions of unique buildings and unique structures. Each of them is not only the result of a unique project, but it is also developed by a unique combination of people, built under unique circumstances, delivered to a unique client, to be used by unique users, erected at a unique location, surrounded by a unique environment and constructed for a unique long lifetime. For each building the wheel is invented again and again (London & Kenley, 1999). For buildings as a whole neither learning curves, nor repetition effects can be observed throughout the supply chain (Vrijhoef & Koskela; Woudhuysen & Abley; Lansley,1994; Koskela,2003). In all, buildings and structures have an artisan character and show suboptimal performance).

With the current credit crunch, the coming energy crisis and the booming construction activities in Asia, it is perhaps time for the international community in and around the construction industry to make a very fundamental change of the whole system with its associated cultural and structural aspects. In this paper a Big Picture of a sustainable construction sector is presented.

METHODOLOGY

The method used in this paper is called ”Attribute Listing” and developed in design theory for innovation. Attribute listing, as used and adapted for this special purpose (the change of a complex and complicated system), contains 8 subsequent steps:

Step 1: Take for granted that the construction industry is not a good system. Based on the figures as presented in the introduction, this starting point can easily be defended.

Step 2: Make a list of typical characteristics and attributes associated with the present construction industry. This is rather difficult because this step requires a generalization of the construction industry. It is generally accepted that ”the construction industry” as a whole does not exist. Therefore this step is quite debatable and can only be based on general reports of governments (see paragraph 2). Nevertheless this step suffers to personal interpretation.

Step 3: Provide each characteristic with theoretical and practical objections. These comments are essential for the directing the possible changes. These objections can be found in the general reports (see step1)

Step 4: Develop, using the objections of step 3, an idea about a new system, that is not only understandable for everyone but also imaginable for everyone. Obviously the first idea used is the normal industrial market for consumer products. It fulfills the two requirements and it is far more sustainable than construction industry. A problem is that buildings should be tailor made and should also have a large lifetime. Therefore a second idea was added. That is the analogy of the termitarium. All information of the termitarium is contained in the combination building/builder. It is stored in the DNA of the termites. Each building is slightly different in shape but totally similar in structure. The structure is the most important factor, where the final shape depends on local environmental circumstances. It seems to be that termites have the disposal of build-in learning curves and build-in repetition effects. That is exactly what lacks in the construction industry.

Step 5: Change the characteristics and attributes of the old system as much as possible towards associated characteristics and attributes of the newly to developed system. This is a difficult step because the construction industry has some specific characterics that are totally different frojm the normal consumer’s articles. For instance, buildings are fixed on the ground, have low value per kg material and a long lifetime.

Step 6: Cluster the characteristics and attributes on mutual relations. The reason behind is that the relations imply a combined approach for change

Step 7: Try to arrange the clusters of step 7 in a causal order. This is important because some changes have to be started first before other changes make a chance.

Step 8: Provide the characteristics and attributes of the new system with individual examples that show those characteristics and attributes already or in a certain rate. This is an important step, because people only want to change a system when they clearly see not only advantages and benefits but also working examples (not presented in this paper).

The main 10 changes

The basic topic of the construction industry is to develop a building frictionless in its environment (Alexander, 1961). The fit between building and environment is given in al large set of conflicting variables like capacity, costs, safety, reliability, etc. This is sketched in figure 0, that is the main reference of the description of the present construction industry at one side and the prescription of a future construction industry at the other side.

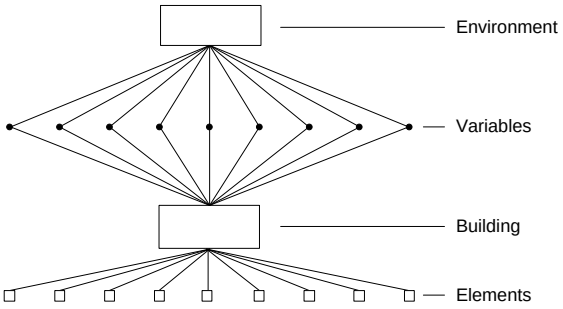

Figure 0: *Fit between building and environment*

1. The present practice to fix all variables in a set of output specifications for the building should be changed into the creation of a solution space (see figure 1).

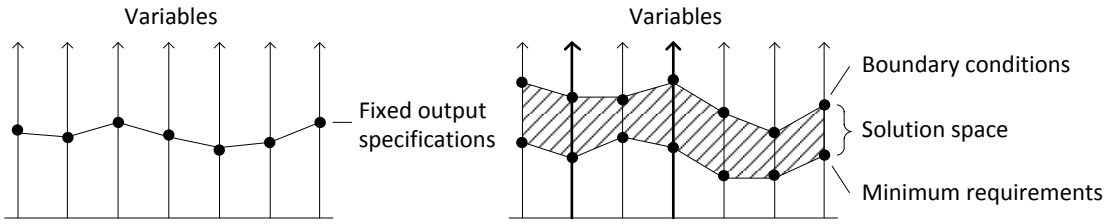

Figure 1: *Change in specification*

All variables are wishes (as much/less/large as possible), provides with weighting factors, minimum requirements (internal) and boundary conditions (external). This was applied for the €400 million Storm Surge Barrier in Rotterdam in The Netherlands (de Ridder,1994).

2. The present price competition should be changed into a competition on value price ratio (see figure 2).

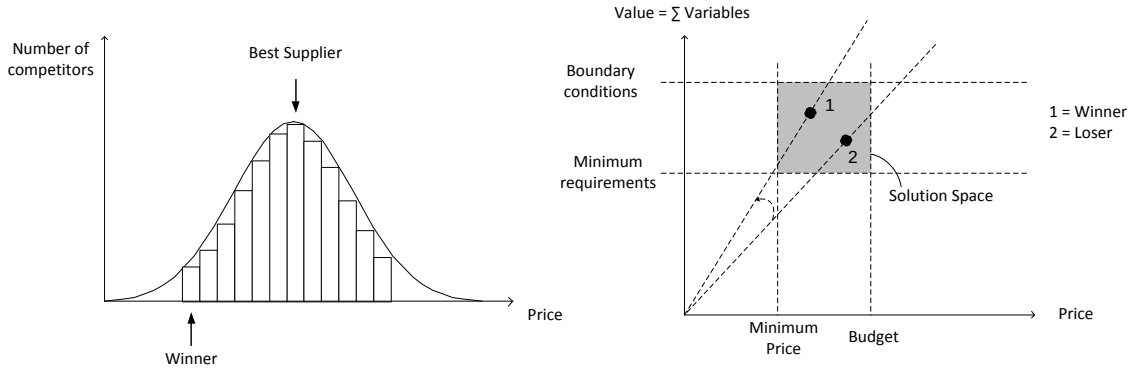

Figure 2: *Change in competition*

The lowest price bidder is in most cases not the best builder. When considering the weighted scores on the variables and checking whether the bids are inside the solution space (specific validation) , it is easy to select the bidder with best value price ratio. This was applied for the Storm Surge Barrier in Rotterdam.

3. The present focus on the building of all players in the supply chain should be changed in a focus on the solution space (context) at the demand side and the building at the supply side (see figure 3).

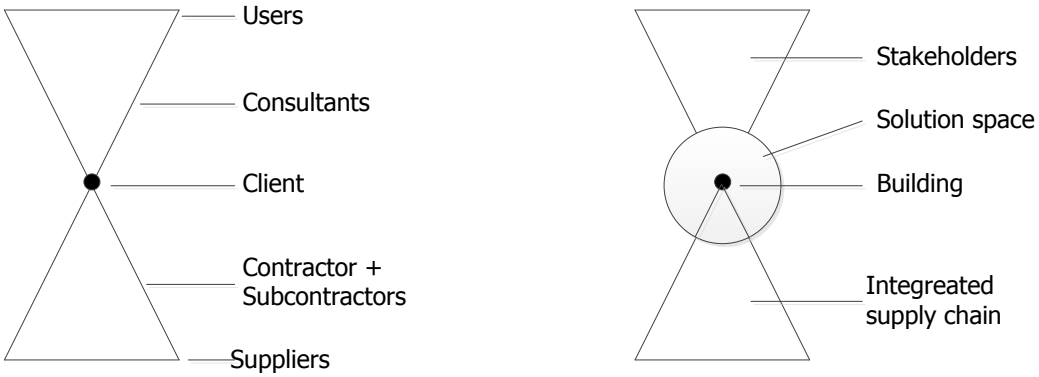

Figure 3: *Change in supply chain*

The main consequence is that the demand side and the supply side have their own responsibility. In result building companies are able to develop their own specific buildings and will be specialized. It also allows for creation of learning curves and repetition effects.

4. The present practice of the client to ask a series of consultants to make a complex design with associated output specifications should be changed into a situation in which the client asks consultants to define the complicated solution space (see figure 4).

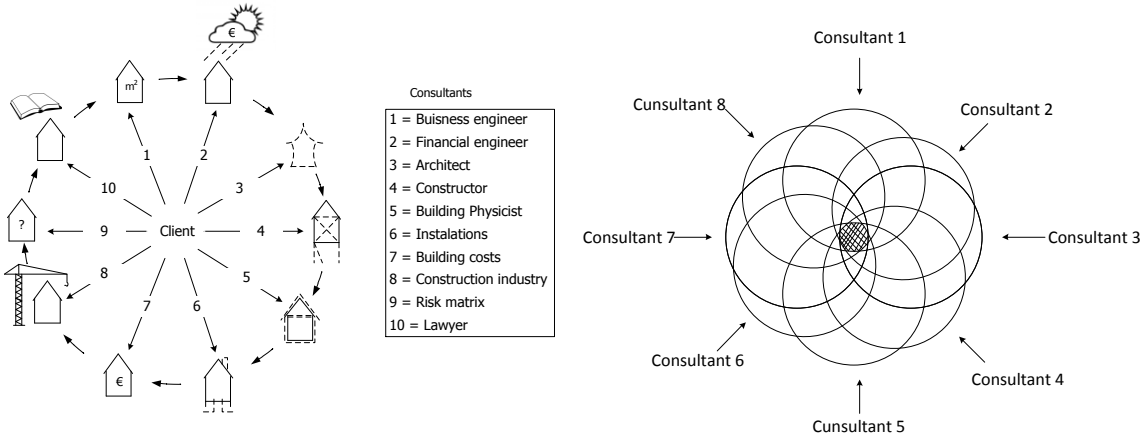

Figure 4: *Change in consultants' work*

Because complexity can't be decomposed the serial design work of consultants without obligations for the final result is not advisable. The building will not be specified correctly. It is better for the client to stay out design work because it attracts responsibility. This was applied for the demand specification for a Living Building Concept hospital in Den Helder in The Netherlands (Gemini).

5. The present practice to focus design work on disciplinary interfaces, clenched in between fixed requirements and fixed industrial elements, should be changed into a focus on fixed relations between all variables (see figure 5)

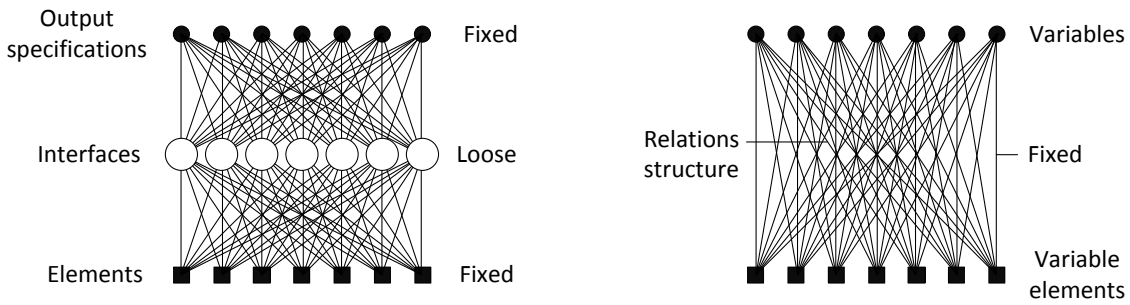

Figure 5: *Change in system approach*

When fixing the relations, the designer fixes the internal structure of the building. Design work then becomes adaption. Design work becomes research and development. This is applied by Burggraaff in Leeuwarden,The Netherlands (Burggraaff).

6. The present practice to fit the building in between the fixed demand (output specifications) and the fixed elements from suppliers, should be changed into tuning the demand with its complicated context and the supply with its complex building (see figure 6)

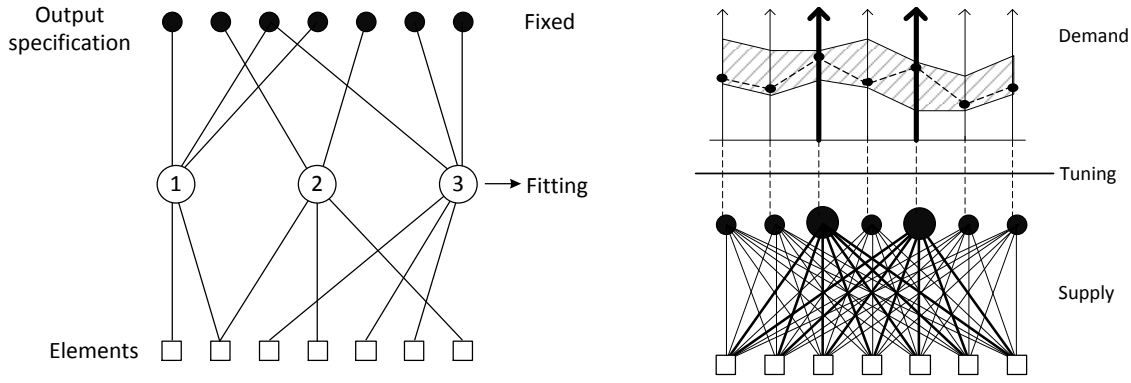

Figure 6: *Change in design work*

As can be seen in figure 6, the supplier can easy choose a magnitude for a variable in order to get a good score. Because the internal structure is fixed, the consequences for all elements are known. The tuning operation is in fact playing with elements. Due to the fast changing demand in relation to the long lifetime of buildings this leads automatically to industrialized flexible (de)mountable (IFD) buildings. The range however is limited. Exotic one shot realizations, which require specific internal structures, can't be offered. No examples in the construction industry yet.

7. The present organization of the supply chain based on outsourcing should be changed into a supply chain based on collaboration (see figure 7)

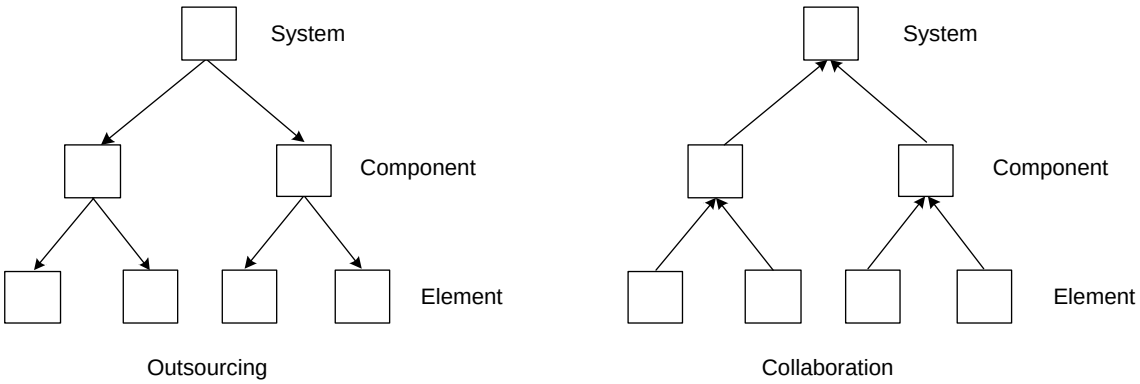

Figure 7: *Change in supply chain organization*

The major change is from an ad hoc project based supply chain towards a project independent supply chain. Outsourcing is top down specification and neglecting relations between parts. Collaboration is bottom up and making the whole more than the sum of the parts. No examples in the construction industry yet.

8. The present practice to produce and build on site should be changed into prefabrication in factories and assembly on site (see figure 8)

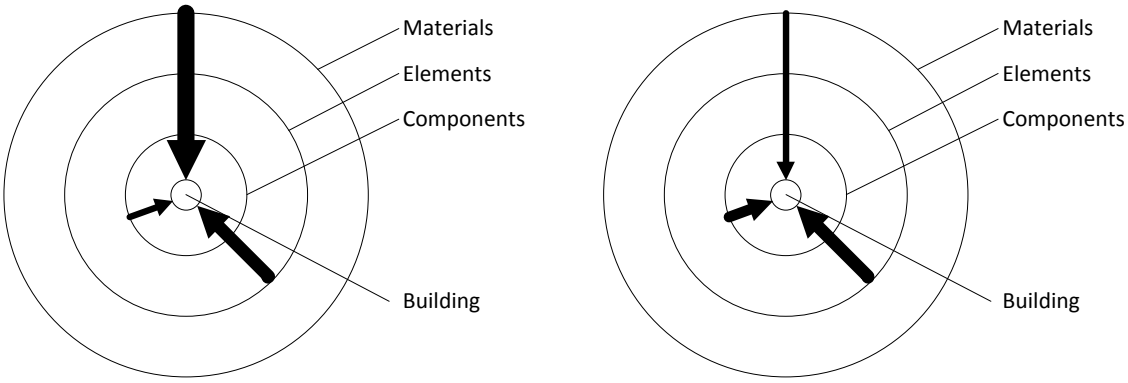

Figure 8: *Change in logistics*

The change into prefabrication is not only beneficial for the quality of buildings, but also for the speed in construction and mainly for the transport efforts in time, money, resources and emissions. This was applied for the 100 meter height Millenium Tower in Amsterdam without construction yard (Wessels Zeist) .

9. The present practice to downcycle all elements and components of a building after dismantling should be changed into a practice where elements and components with longer lifetime than the building itself will be reused (see figure 9). No examples yet.

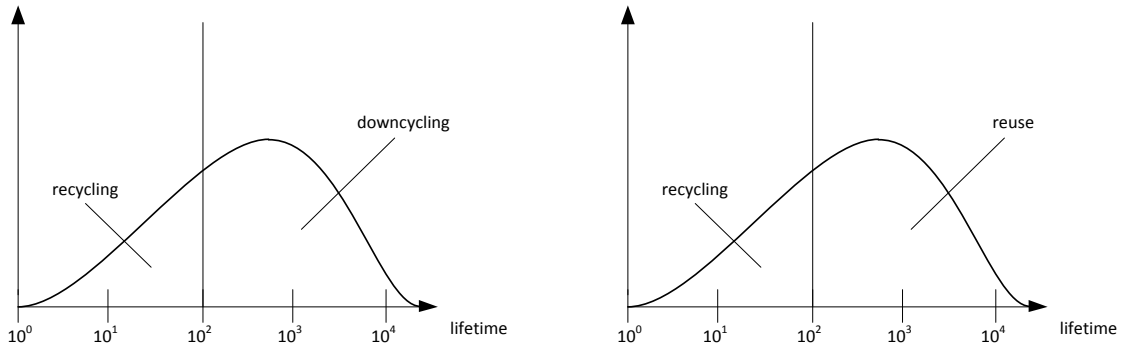

Figure 9: *Change in recylcing*

10. The present Design & Construct practice should be changed into a Research & Development practice (see figure 10)

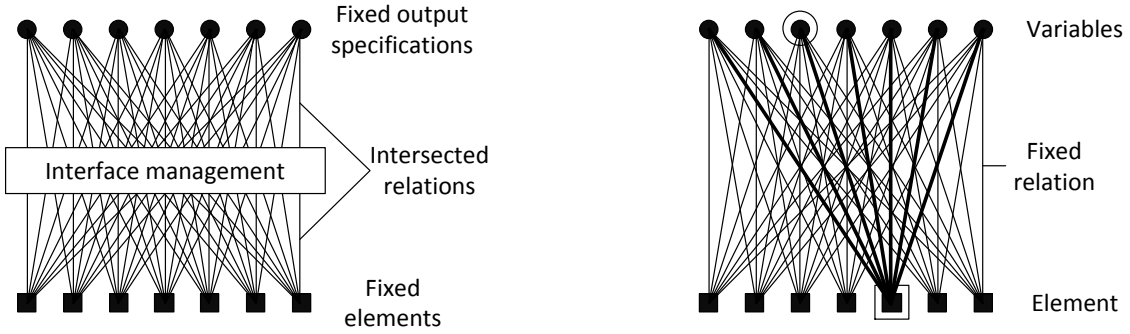

Figure 10: *Change in knowledge*

Inventing the wheel again and again with Design & construct of one shot, unique realizations should be replaced by a sound R&D supported with a Parametric Knowledge Model of Supplier specific Buildings. New buildings can easily be developed from existing buildings by researching the consequence for the elements when changing a variable or, reversely, researching the consequence for the variables when changing an element. This is applied with Burggraaff (Burggraaff).

CONCLUSIONS

When the construction industry is able to change itself in the description of the right sides of the columns, then producers and buildings together form living buildings. They belong to the set of living man-made systems. These buildings will be developed from a long series of already realized buildings. The buildings obey to Darwin's principle of the survival of the fittest. Producers experiment with variations on existing buildings and select the best variations for multiplication. A crucial condition is that producers fill their Parametric Knowledge Models of their buildings with each delivery, inducing continuous improvement. Each building has more or less the same structure but the final form is totally different as result of the interaction with the environment. The buildings are flexible and adaptable, keeping them up to date en fit for changing purposes provided with state of the art technology. This is very important as the world inside and outside buildings changes faster then the buildings itself. Living buildings and

structures are sustainable in any imaginable respect and at least doubles the lifecycle value, halves the lifecycle cost, doubles the profit of construction companies and halves the energy consumption and emissions. This will be achieved by increasing effectiveness by learning curves and increasing efficiency by repetitiveness. It is comparable with automotive and computer R&D. Each newly developed type contains all experience and knowledge of a long series of earlier types.

Abstract
Several research studies have identified critical success factors and their impact on project success. Central to both success and failure is the issue of selection criteria, and the importance of incorporating qualitative factors when contracting for complex design and construction projects. Empirical findings suggest that price is still commonly used criterion for selecting a winner, even though tendering documents indicate that quality factors are part of the evaluation. In this paper we argue that tender competitions with high focus on price in complex design and construction projects deteriorate both incentives for collaboration and project outcome in terms of cost and quality. Thus, the lowest bid may paradoxically result in the most expensive project from both an investment and a life cycle cost perspective. We offer an alternative approach to evaluating tenders, based on the Equivalent Tender Price Model (ETPM). The aim is to increase the probability of avoiding project failure related to cost overrun, poor quality and lack of functionality, in addition to ensure more transparency in the tender evaluation process. Simulation tests of the model demonstrate that evaluation of tenders through an Equivalent Tender Price model makes selection criteria more transparent and quantifiable and therefore less at risk of manipulation.

Keywords: Equivalent Tender Price, selection criteria, evaluation models, LCC, PDCS

INTRODUCTION

Several research studies have identified critical success factors and their impact on project success (see e.g. Belassi and Tukel, 1996; Fortune and White, 2006; Park, 2009; Pinto and Slevin, 1988; Zwikael and Globerson, 2006). Central to success is the factor of quality, operationalized as e.g. availability of required technology and expertise, technical background of contractor's personnel, and communication skills. Empirical research also identifies central determinants of project failure (Meland, 2000). These *failure factors* include the use of price competition on complex design services, poor communication and information logistics, as well as lack of competence. Common to both failure and success

factors in construction projects is the importance of quality-based selection criteria when contracting for complex design and construction projects. The problem is that tender competitions with high focus on price in complex design and construction projects deteriorate both incentives for collaboration and project outcome in terms of cost and quality. Thus, the lowest bid may paradoxically result in the most expensive project from both an investment and a life cycle perspective. An increasing focus on environmental sustainability and life cycle costs in construction projects necessitates a new form of competence in the planning and management of construction projects, which in turn needs to be reflected and incorporated into the selection model. Recent practices of project management, however, emphasize qualitative aspects in the selection of contractors such as key personnel, past project performance, company standing (reputation), and technical expertise (Watt, Kayis and Willey, 2010). But the emphasis on soft factors increases the complexity of evaluation due to subjectivity and lack of transparency in the selection process.

Despite numerous efforts to establish a universal set of selection criteria, the issue continues to plague both theory and practice (Holt, 2010; Watt et al., 2009). The failure to develop such universal methods and criteria can be attributed to the complex circumstances of project contracting; the combination of soft and hard objectives, coupled with a large doze of uncertainty and risk. Even though mainstream literature is turning focus in criteria selection from "lowest price" to "value enhancement", anecdotal evidence suggest that price is still a commonly used criterion for selecting the winner. The gap between theoretical ideal and industry practice on criteria selection places a "credit crunch" (Holt, 2010, p. 305) on the "value literature". We offer an alternative approach to evaluating tenders, based on the Equivalent Tender Price Model (ETPM). The aim is to increase value enhancement for the client, by increasing the probability of avoiding project failure related to cost overrun, poor quality and lack of functionality, in addition to ensure more transparency in the tender evaluation process. In this paper we present and test the ETP model through simulation and compare the results to traditional selection models. The results demonstrate that evaluation of tenders through an Equivalent Tender Price model yields a result less at risk of manipulation in the selection process, because the selection criteria are transparent and quantifiable. The Equivalent Tender Price model is able to absorb and reflect the market price for qualitative elements such as competence and experience of key personnel, and should thus enable clients to make more correct decisions regarding price and quality in tender competitions.

CRITERIA FOR SELECTION

For any given project, it is essential to establish objectives and assess them according to how they influence the choice of project delivery and contract strategy (PDCS). This may include cost and schedule restrictions, as well as quality and business requirements (CII 2003; Lædre 2006). It is a crucial phase of the project process and encourages the client to focus on the critical success and failure factors for the project under consideration. Another central part of the PDCS is the selection of compensation forms, qualification criteria, selection criteria and the selection model itself. All these elements should represent choices that increase the probability of "best-value" for the client. Best-value contracting strategy aims at combining the use of price and qualitative factors in the qualification and selection process to enhance the long-term performance of the project. Among these are the criteria of reasonable whole life costing principles (WLC/LCC) and sustainability.

The importance of tender evaluation and selection criteria is well established in the project management and purchasing literature (Holt, 2010; Watt et al., 2010). Selection criteria and processes are directly related to project success and achievement of project objectives (Alsugair, 1999; Holt, Olomolaiye and Harris, 1994; Lopes and Flavell, 1998; Meland, 2000).

The success factors commonly focus on objectives such as availability of required technology, key personnel, expertise, technical background, and communication skills (Belassi and Tukel, 1996; Fortune and White, 2006; Park, 2009; Pinto and Slevin, 1988; Zwikael and Globerson, 2006). These are all indicators of "competence". Furthermore is past project performance, financial and technical capabilities, as well as tender price elements that are normally taken into the selection model. However, critical determinants in selection models have varied over time. Previous research point to price and cost as critical determinants of selection criteria (Hatush and Skitmore, 1997; Holt et al., 1994; Proverbs, Holt and Olomolaiye, 1997), whereas recent reviews contradict the findings from a decade earlier (see e.g. Holt, 2010). One study concludes that amongst 16 categories of selection criteria, price was found as the third lowest reported occurrence (Watt et al., 2009), even though anecdotal evidence and actual practice may point in a different direction. The increased value focus in tendering may partly be explained by the tendency of focusing more on life cycle cost and environmental sustainability, which in itself require a selection model that assess long term value rather than just the investments costs. Furthermore, the use of partnering models as well as collaborative contracting, necessitate more qualitative elements in the evaluation of tenders in order to reflect the participating parties' ability and incentives to cooperate, and to avoid sub-optimalization processes during the project.

Some of the traditional factors in tender evaluation should be taken care of outside the selection model itself, partly because they should not be exposed to competition, and partly because they are not acceptable criteria according to EU directives on public procurement (2004/18/EC 2004). The latter is a much debated issue within public procurement, because public clients commonly confuse qualification criteria with selection criteria. Even though they are closely related, there is a distinction between company capabilities in general and a company's bidding of specific personnel for a specific project. In the evaluation process it is therefore important to distinguish between qualitative factors that directly reflect value for a specific project, and qualitative factors that are merely an expression of the company's technological and financial capability.

Previous research on tendering competition of design services reveals two factors that should be avoided to circumvent project failure (Meland, 2000):

- too short time available for an adequate design process
- price competition on design services

To contest on time schedule in tender competition for design services jeopardizes the quality aspect of the design process itself, because a competition on the number of man hours and time factor in the design process represents a high risk for poor quality and costly changes in the construction phase. Unless time is an extremely important success criterion, it should be set up by the client as part of the project strategy aims and objectives. Due to economic incentives and EU procurement regulations, there should however be an element of price competition for design services. But in order to avoid the risk of inadequate design, these contracts should be reimbursable, and the tender price should focus on man-hour rates, which then is included in the selection model (Meland, 2000).

As previously pointed out competence is commonly viewed as a success factor for construction projects, and should therefore be an important criterion in any selection model for complex design and construction projects. Competence, however, is a typical proxy measure of quality which includes several indicators such as technical expertise and capability of key personnel. In the construction industry the problem with 'value enhancement' criteria is often that the qualitative elements either become too "costly" during

the decision process, or they are not properly appreciated by the client, because the selection model can not absorb the quality differences between tenders. Suppliers of construction projects, who offer higher quality at the cost of higher price, run the risk of being discriminated *and* loose the bid, because the client is unable to assess the market price of quality in the selection model. The market price for competence is reflected in the average salaries for various levels of formal education and years of experience. Salary data may thus be used to estimate the price differences between different qualifications. Hence, in order to increase the markets' offering of higher competence levels in tenders, the client must be willing to pay for it. The suppliers must also be ensured that offering increased quality, through higher levels of competence, will be appreciated in terms of fair comparison of tenders. Finally, the "equivalent price" of each tender, on which comparisons are made, must reflect the value of quality in transparent and objective ways.
To establish incentives for offering increased quality at the cost of higher price, two factors must be attended:

1) The value of quality must be reflected and valued in the selection model
2) The selection model must have capacity to absorb differences in quality in a consistent way

The above factors are central elements in the ETP model as will be demonstrated in the following sections.

THE ETP MODEL VERSUS TRADITIONAL SELECTION MODELS

From an economic point of view, the theoretical problem in all selection models is the potential for adverse selection. This is especially a problem when the tender process involves qualitative elements, such as for instance supplier capability and competence. If hidden information exists about the suppliers' competence and no information is available for the client, price will be the only decision criteria. The risk of low price and low quality will be significant, and the client risks a suboptimal procurement situation. The issue of selection processes is to reveal relevant and trustworthy information about the supplier's and competencies. There may be two ways of acquiring such information. One is obviously to do the necessary research and gather relevant information about the different suppliers. But this may be both costly and possibly not very reliable data. The other way is through screening, by using relevant market information. Suppliers pay a market price for the staff employed. The price, as reflected in average market salaries, is based upon different employee characteristics. The salary can be interpreted as a hedonistic price function, because it is decomposed as a sum of values for the different characteristics; for instance formal education and years of relevant experience. By using the values for the different employee characteristics, observations can be made on how the market values these characteristics. This market information is valuable to reduce the risk of adverse selection and increase the probability of selecting the supplier offering the best combination of price and quality. In the following section we will illustrate this point by using the "equivalent tender price" (ETP) model. For comparison, we will first illustrate how a traditional selection model fails on three important issues. First of all a traditional model is usually linear, which delimits the model's mathematical capacity to absorb the variety of tender scores on selection criteria. Second, a linear model does not "act" in the interest of the client, and thirdly it does not reflect the marked pricing of competence. These weaknesses are illustrated in the sections below.

Selection criteria and corresponding measures

Common selection criteria for construction projects include a price element and one or more qualitative elements. Normally the client assigns weights to each element to reflect the client's emphasis on the different criteria in the model. Each tender receives a score per criterion, based on the client's evaluation of each tender. The final value for each bid in a linear selection model will be a sum of the weighted scores per criterion, where the winner has highest sum.

For illustration purposes, we first simulate results of a tender competition with a linear selection model. We then use the same simulation data in the ETP model and compare the results. The following selection criteria are used throughout the testing of the two models:

- Price
- Competence
- Other (project related criteria of importance)

In the model simulation our specific focus is on the price and competence criteria. However, we have included a third criterion, "Other", to illustrate the model's rest capacity to include other criteria in addition to price and competence. Each criterion is assigned an individual weight summarized to 1,0 (100 %). The weights are labeled as follows:

- V_1 = Price
- V_2 = Competence
- V_3 = Other

Each criterion can be divided into several indexes that are relevant and measurable. In this simulation we limit the use of indexes to the competence criterion, which is measured by following:

- V_{21}= Level of formal education (master, bachelor etc)
- V_{22}= Relevance of education compared to the actual project position and project
- V_{23}= Time of experience
- V_{24}= Relevance of experience compared to the actual project position and project

An individual score per tender will be assigned to each of the four indexes. The individual scores will range between 0,0 and 5,0 and is labeled as follows:

- m_{21} = Score on formal education, where Master of Science =5,0,
  Bachelor of Science =4,0, No formal education beyond high school=2,0.
  Scale interpolation is used for additional studies/courses etc.
- m_{22} = Score on relevance of education, where for instance a degree in architectural science yields top score (5,0) while a computer science degree yields a low score (1,0) in an architectural design competition
- m_{23} = Score on experience, where > 30 years of experience =5,0 and
  no experience = 0. Values are to be interpolated linearly between 0 and 5.
- m_{24} = Score on relevance of experience, where 3 relevant projects in the CV =5,0 and less relevancy is to be linearly interpolated towards 0.

Each candidate offered in the individual tender is rated according to the above indexes, and a weighted average score is calculated to reflect each tender's total score on V_2 Competence.
Normally the market price for competence can be measured by the average salaries according to employee characteristics such as level of education and relevant experience. The

association of chartered engineers in Norway (RIF) yearly presents statistics of salaries, invoicing level, different cost elements etc for their members. We use RIF statistics (2009/2010) to compare the marked value of three competence indicators:

- Formal education (V_{21}),
- Time of experience (V_{23}),
- Relevance of education and experience (V_{22} and V_{24} summarized).

Based on statistics from RIF (2010), table 1 presents simulated examples of yearly salaries for engineers. The other items included in the table are various costs and parameters associated with the corresponding salary level for engineers in Norway. From table 1 we find that an average salary for a Master of Science in engineering is priced to €85625 per year, and a Bachelor of Science degree is priced to €72875, which gives a difference of €12750. When controlling for all other parameters but formal degree, the equivalent market price of a Master of Science candidate is €111 per man-hour (mhr), whereas the man-hour rate for a Bachelor of Science candidate is €98. The difference in a company's bid price for these two candidates is €13 which represents the difference in marked price between the score 4,0 and 5,0 for the factor formal education (V_{21}) in our model.

			MSc candidate		BSc candidate		
Yearly salary	100 000	87 500	**85 625**	75 000	**72 875**	62 500	56 125
Manhour salary	57	50	49	43	42	36	32
Social costs (25%)	14	12	12	11	10	9	8
Company's salary cost	71	62	61	53	52	44	40
Invoicing level	73 %	73 %	73 %	73 %	73 %	73 %	73 %
Company's real cost	98	86	84	73	71	61	55
Overhead per manhour	18	18	18	18	18	18	18
Profit	9 %	9 %	9 %	9 %	9 %	9 %	9 %
Company's bid price	126	113	**111**	100	**98**	86	80

Table 1: *Salary and cost statistics for employment of different engineering candidates. All figures in € (based on statistics from RIF, 2010)*

According to the RIF statistics (2010) a yearly salary for a Master of Science degree varies on average from €59625 for a non-experienced master candidate, to €124125 for an employee with 30 years experience on top of her master degree. Corresponding figures for Bachelor degrees are €53375 and €81625, respectively. Thus on average for both categories this indicates that the marked price of one additional year of experience for an average engineer is close to €1,25 per man-hour. The scale interval for V_{23} (time of experience) represents 7,5 years. This corresponds to a market price difference of €9,12 per interval, which, all else equal, indicates the price difference between a candidate with 30 years and a candidate 22,5 years of experience. Finally, according to RIF, the salary gap between the group of highest paid engineers (measured as 90 % percentile) and the lowest paid engineers (measured as 25 % percentile, since 10 % not available), is on average for both masters and bachelors €18,75. This figure represents the full range of the scale for V_{24} and V_{22}, with a marginal change value of €4,75.

The salary data for Norwegian technical personnel is reliable for the characteristics V_{21} (Level of education) and V_{23} (Years of experience). There is, however, no salary information available for criteria V_{22} and V_{24}, which both relates to work-specific relevance of education

and experience. As an approximation we have used a measure of the variation in salaries for these criteria. We assume that salary variation for engineers across all education and experience levels is partly explained by differences in relevant skills. This assumption is, however, highly debatable. The variation may also reflect different scarcities in different marked segments for technical personnel.

In the following illustrations he figures above are assumed to be the market price for the value of formal education (V_{21}), time of experience (V_{23}), relevance of education and experience (V_{22} and V_{24}). In the next section we test the general linear model and the ETP model, using estimated market values to demonstrate the difference in capacity and transparency between the two models.

Testing selection criteria in a linear model

A traditional way of calculating for the price score for a tender is to give the score 2,5 for the average priced bid, 0 for the highest bid and the score 5,0 for the lowest bid (score scale 0-5). The other bids' score are calculated linearly. Five bids with the illustrated man-hour rates and tender price in table 2 should then be given the following price scores:

Bids	A	B	C	D	F
Manhour rate and tender price (€)	100	106	113	119	125
Price score (m_1)	5,00	3,75	2,50	1,25	0,00

Table 2: *Five illustrated bids with linear score on price*

As illustrated in table 1, the marked price for an average master candidate is €111 and €98 for a bachelor candidate. All other factors equal, tenders based on these man-hour rates should be given equal score in any selection model, given that market value of competence is of importance for the client. We add these two "bids" to the 5 other bids in table 3 and start the selection process based on a linear selection model. Price is given the weight 25 % of total.

	BSc candidate			MSc candidate			
Manhour rate and tender price (€)	**98**	100	106	**111**	113	119	125
v_1 Price	0,25	0,25	0,25	0,25	0,25	0,25	0,25
m_1 Price score	5	4,57	3,43	2,54	2,29	1,38	0,00
v_{21} Formal degree	**0,62**	0,62	0,62	**0,62**	0,62	0,62	0,62
m_2 Degree score	**4**	4	4	**5**	5	5	5
v_3 Other criterion	0,13	0,13	0,13	0,13	0,13	0,13	0,13
m_3 Score other	5	5	5	5	5	5	5
Score total	**4,38**	4,27	3,99	**4,38**	4,32	4,09	3,75

Table 3: *Traditional linear selection model (Score= v1* m1 + v2* m2 + v3* m3)*

Table 3 demonstrates that by weighting the formal degree (V_{21}) criteria 0,62, the two candidates (master and bachelor) obtain the same total score (4,38) as they should, according to the pricing of formal degree. All the other tenders are overpriced relative to the type of candidate offered. Their price score in combination with formal degree score is causing their tender loss. As shown, price (V_1) and formal degree (V_{21}) constitute a total of 87 % (0,62+0,25) out of the total model capacity. Thus the model is inadequate to absorb the full value competence as V_{22}, V_{23} and V_{24} are not included. Hence the linear model does not "act"

in the interest of the client, because it does not reflect the marked pricing of competence in its full scope, but reflects competence only through formal degree. Capacity constraints is one of the major weaknesses in traditional, linear selection models, and it jeopardizes possibilities for a more thorough and objective differentiation of qualitative aspects in bids.
We also observe another capacity weakness of the traditional model. By comparing table 2 and 3, we observe that the price score (m_1) given for the original five bids have changed as a consequence of adding the two new "bids". This indicates that the model is neither predictable nor robust. Linear selection models usually assign the price weight to be between 40 to 80 % of total criteria. This means that in practice the competition is almost solely based on price, even though the client may indicate otherwise in the tender documents. Furthermore, it is commonly observed that the full scale range for price is fully used (e.g. 0-5), but the scale range for other criteria is often used between 2 and 4. The real evaluation is thus even more price focused than exemplified above.

We have demonstrated that a linear selection model is very sensitive to the tender evaluation structure and in fact also to the numbers of tenders. This affects the model's robustness in an undesirable way. We suggest a solution to the problem by constructing a more robust and universal applicable model.

Testing selection criteria in the ETP Model
A main purpose in the ETP-model is to establish a useful and operational balance between the consideration of price and qualitative elements in selection models. Formally this is done by choosing one single parameter, k, in the ETP-model. The model is constructed in such a way that the value of k influences the client's choice of focus; from pure price competition to hardly any weight on price at all. A very large value of k represents pure price competition, whereas when k is reduced towards zero, more and more emphasis is placed on qualitative elements.
As the intention is to use market price information, the model has to be aligned to the observable market prices (salaries). We will demonstrate one way of doing this, and at the same time discuss various design of the model. We have argued that a linear selection model for projects where quality elements play a critical role is more or less useless. Instead we propose a quadratic model, and demonstrates its usefulness by simulate different values of the parameters for scores and weights. In these simulations we will be using market information for the salaries for technical skilled personnel in Norway (RIF, 2010).

The general formula for the ETP model we are going to use is (note its quadratic form):

$$ETP = P\frac{M^2 + k}{(\sum_i v_i m_i)^2 + k}$$

where:

ETP = Equivalent tender price
P = Estimated price inclusive of the suppliers profit
M = Maximum score on a selected scale (e.g. 5)
k = A selected constant as a number $[0,\infty)$
v_i = Weight of the quality factor i ($\sum v_i = 1$)
m_i = Score of the quality factor i (e.g. [1,5])

The sensitivity of ETP with respect to the choice of k, may be illustrated as the derivative of ETP with respect to k:

$$\frac{\partial ETP}{\partial k} = P\frac{\left(\left(\sum_i v_i m_i\right)^2 + k\right) - \left(M^2 + k\right)}{\left(\sum_i v_i m_i\right)^2 + k\right)^2} \leq 0$$

If k is increased the ETP is reduced, so a higher k means less weight on the quality factors described by $\sum_i v_i m_i$. Furthermore as $k \to \infty$ $\frac{\partial ETP}{\partial k} \to 0$, which means that ETP is an asymptotic downward sloping function towards P. A simulation of ETP with different levels of scores on $\sum_i v_i m_i$ is shown in figure 1. In the figure, k varies between 0 and 100, and the maximum score is 5 so $M^2 = 25$. The figure illustrates the ETP when the estimated price =1 for suppliers scoring a $\left(\sum_i v_i m_i\right)^2$ of 5, 10, 15, 20 or 25.

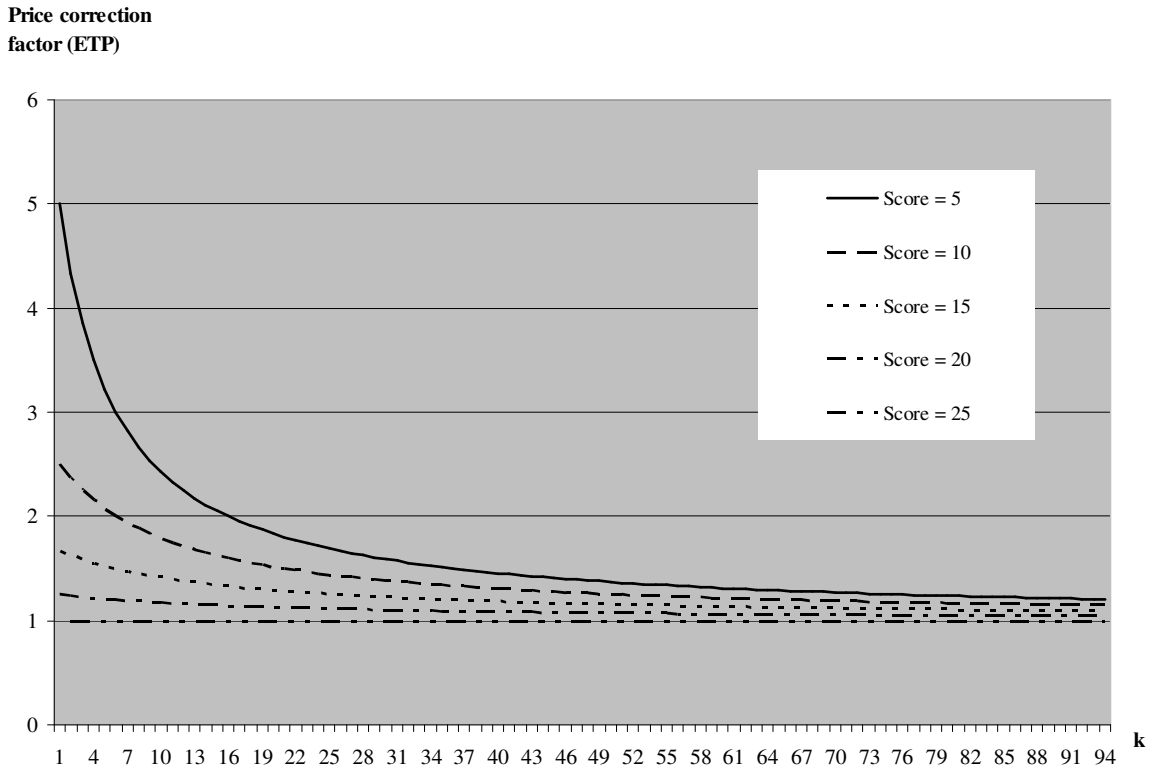

Figure 1: *Price correction factor (ETP) for different values of k*

Figure 1 shows the importance of selecting a low k if quality is the dominant selection parameter of a tender. Furthermore if there is a variety of selection parameters, a low k must be chosen to "make room" for aligning the model to market information, as will be demonstrated in the simulations in the next section. The quadratic model has the potential to discriminate between different suppliers more efficiently than a linear model as one can reduce k towards zero to exponentially increase the weight on quality. This will also be illustrated in the simulations in table 3 and 4. Figure 1 also demonstrates that by choosing a

low k one harshly punishes law quality tenders as the difference between the ETPs increases progressively when the scores on $(\sum_i v_i m_i)^2$ declines.

The model incorporates both a price element and qualitative elements, as the aim is to give high score (yielding a low ETP) to tenders offering factors that increases the probability of avoiding project failure related to cost overrun, pure quality and lack of functionality. We aim for a model with few and simple quality factors, but with build-in capacity to open for use of supplementing factors. Furthermore, the ETP selection model will be able to incorporate relevant success-factors at their marked price, and balance price and qualitative elements in a way that reveals the best tender. Finally the ETP model allows the individual bids score to be independent of each other so every criterion in the model – even price – can be evaluated in a transparent way. Of course, to ensure transparency, the score scale and the individual weight for the selection criterions must be clearly defined in the tender papers and meticulously used in the evaluation process.

In the following we present a numerical example of using a non-linear ETP model. As demonstrated in table 4, the model is capable of absorbing 34 % of the total weighting for other criterion than competence (V_3) by using k=0.

Offered tender candidates	MSc candidate	BSc candidate	BSc candidate, w/less experience	BSc candidate, w/less experience and low relevance

Table 4: *Examples of tenders evaluated by the ETP model with k=0*

In table 4 we present four tenders with different man-hour rates and different competencies of the candidates offered. A fully experienced (30 years or more) MSc candidate with relevant project experience (3 or more) has a tender price of €111. A fully experienced BSc candidate with relevant project experience is offered at €98. However, a BSc candidate with only 22,5 years of experience, but with full relevant project experience is offered at €88. Finally a BSc with 22,5 years of experience, and less relevant project experience is priced to €84. All these tenders should be evaluated equally valuable for the client, given equal score on parameter V_3 (other criterion). They are all priced according to marked value for the individual competence factors $V_{21} – V_{24}$. Thus the equivalent tender price illustrates how a high priced tender with a

fully experienced and qualified master is valued equal to a low priced tender offering a bachelor candidate with 22,5 years of experience and less relevant project experience.

In table 5 we present the same tenders as in table 4, but k=5 is used instead of k=0. As illustrated in the table, the model capacity is reduced by increasing the value of k. There is only about 20% left for other criteria than competence. This demonstrates that for tenders of design and design build contracts, where competence is an important economic factor, k should be set low in order to fully take advantage of what the market can offer.

Offered tender candidates	MSc candidate	BSc candidate	BSc candidate, w/less experience	BSc candidate, w/less experience and low relevance
Manhour rate and tender price (€)	111	98	88	84

Equivalent Tender Price (ETP)	**111**	**111**	**111**	**111**

Table 5: *Examples of tenders evaluated by the ETP model with k=5*

We recommend k=0 for tenders of complex to middle complex design services. More simulations, however, are needed in order to qualify for recommendations in pure construction contracts.

CONCLUSION

The ETP-model has, with different values of the *k* factor, been used in proximately 20 tender competitions in Norway. For every competition the score scale and the individual weights of the chosen selection criteria have been defined in details and strongly adhered to in the evaluation process. The evaluation of competence has thus been fairly simple and transparent. The use of other criteria, such as process understanding, project manning plans, and team management with client and users etc., have been given a wide range of scores, which is an indication of measurement problems and low predictability.

Commonly used models and criteria for selection of tenders are still highly focused on price, even though literature indicates a turn of focus from lowest cost to value enhancement in complex construction projects. The important issue, however, is how traditional selection

models are capable of including the value of qualitative elements, of for instance competence, as reflected by the market price.
We have demonstrated that traditional linear selection models do not have the capacity to absorb the market's pricing of competence in tender competition for consultancy services and complex construction projects. We therefore offer an alternative approach to evaluating tenders, based on the Equivalent Tender Price Model (ETPM). The aim is to increase the probability of avoiding project failure related to cost overrun, poor quality and lack of functionality, in addition to ensure more transparency in the tender evaluation process. Simulation tests of the model demonstrate that evaluation of tenders through an Equivalent Tender Price model makes selection criteria more transparent and quantifiable, and therefore less at risk of manipulation. Furthermore the ETP model demonstrates more robustness with respect to adding more qualitative elements into the model. The model is also capable of reflecting marked prices for services irrespective of other tenders, as well as encountering new bids without having to alter the pre-assigned weights.
Our simulations of the ETP model conclude that competence should be given a weight of 66 – 81 % of total weighing in the model, depending on the value of k (0-5). How competence should be weighted for pure construction contracts is dependent upon the specific contract strategy, further studies of the market's pricing of the competence profile in construction companies, and the fact that engineers are representing approximately 10-20 % of total construction costs. A tender competition for a design-built contract should yield higher competence weighting than a pure built (design-bid-built) contract, and the uncertainty and complexity should be taken into consideration. The choice of the constant k in the ETP model will balance these considerations.

LIMITATIONS AND FURTHER RESEARCH

We have argued that the ETP-model is more robust and universal applicable than e.g. a linear selection model. This does not however mean that the weights and scores used in our example are applicable in every situation. For different purposes and especially for different countries, it may be useful to align the scores and weights according to for example the country specific conditions. For the competence criterion, different countries may have different educational systems which may justify other grades of the scores.
Future research should seek to remedy these limitations by providing greater empirical evidence of the robustness of the model.

PARADOXES OF INNOVATION AND ARCHITECTURAL DESIGN: A MODEL OF DESIGN KNOWLEDGE GENERATION IN ARCHITECTURAL PRACTICES

PETER RAISBECK
The University of Melbourne
raisbeck@unimelb.edu.au

Abstract

What are the organisational paradoxes that beset the design process in architectural firms? As innovative knowledge workers and system integrators architects are often called upon to produce innovative and custom designed buildings. Architects can be characterized as knowledge intensive professionals who help to lead innovation. However, most of the research conducted in design innovation and organisational paradoxes has had a product portfolio focus. For example, it has been claimed that product innovation relies on two seemingly contradictory and paradoxical processes in product development organisations: the exploitative and the exploratory. How might these concepts be related to architectural firms and design teams? Using the above concepts an initial model was developed and then tested in order to understand the paradoxical processes that architects employ when designing. How might design processes in service firms differ from either linear or dichotomous models of innovation with their origins in product development? An initial model is proposed which is then tested and refined. These questions are tested in a broader survey of 73 Australian architectural practices. The survey aimed to identify the links between exploitative and exploratory design processes in the firms and the organisational paradoxes which surround these. A survey framework was developed which defined and highlighted to what degree architects instigate Radical or Incremental design changes in projects. The survey identified the extent to which Australian architects generate new design solutions after a particular design has been mandated. It concludes that these architects deliberately sought to foster highly paradoxical processes within their firms in the early stages of a project in order to create new design knowledge. Highly paradoxical processes, which oppose exploitative and exploratory design activities, tend to diminish as the project proceeds. Further research is needed to clarify if design processes with a high degree of paradox are where project innovation occurs. The paper concludes by outlining a model of exploitative and exploratory innovation and organisational paradox in knowledge intensive design firms.

Keywords: Architecture, Design, Organizational Paradoxes, Innovation.

INTRODUCTION

Design architects are often accused of changing their minds once decisions have been made during the project development and delivery process. Design changes are often seen as being unwelcome and at odds with sequential project development milestones. Some have argued that this contributes to rework during the construction process and adds to project risks. On the other hand creative and generative design is seen to foster innovation. This paper explores the paradoxes evident within the architectural design process. For the purposes of this paper a paradox is defined as "the simultaneous presence of contradictory even mutually exclusive elements" (Cameron and Quinn 1988:2 in Clegg, Cunha and Cunha et al 2010). In

construction management very little is known about how organizational paradoxes might play themselves out within design teams. This may be because design is an activity which 'poses difficult managerial problems' which requires interdependent decision-making. (Tzortzopolous and Cooper 2007, 17). The need to understand the interdependencies and paradoxes between an initial design concept and its implementation and delivery as a constructed project is important. One way to understand these interdependencies is to investigate the paradoxical modes of design that architects appear to employ.

The paper proposes and then tests a theoretical model of how design oriented organisational paradoxes are created and resolved within architectural practices. Tushman and Benner's concepts of exploitative and exploratory innovation are adapted to the architectural design context (Benner and Tushman 2003). It will be seen to what extent these different modes exist simultaneously when creating design knowledge and that this process should not be characterised as being either strictly binary or linear. The model developed in this paper suggests that Architects might blur sequential distinctions between exploitative and exploratory design by pursuing both at the same time. Specifically, the model suggests that both types of design take place simultaneously and that the pathway to an innovative project outcome is not linear. The model suggests that during the design process exploitative innovations are purposefully destroyed in order to create exploratory outcomes; and conversely, exploratory outcomes are destroyed in order to create exploitative innovations. Moreover, it will be suggested that design paradoxes are resolved through processes of improvisation.

Design Knowledge Creation and Organisational Paradox

Linear and binary descriptions of the design process abound in design literature. However, these concepts have not often been developed as paradoxical concepts. For example, Winch theorises that designing can either be characterized as a conjectural model or a linear model (Winch, 2008). He claims that the linear model is a problem solving approach which involves analysis, synthesis and evaluation. He argues that the conjectural model, a model which is arguably linked to design, is 'much closer to scientific method' and more discontinuous or disruptive. This model is not unlike Tushman's concept of exploratory innovation. Winch argues that in a conjectural design approach, an initial hunch or conjecture is formulated and following this the process then proceeds through a number of iterations. It is through these paradoxical iterations that design knowledge is created; in each iteration conjectures are proposed and then abandoned. Lawson argues that architectural design processes are complex and need to be distinguished from engineering definitions of optimised design. He argues that many of the maps or descriptions of the design process tend to be overly theoretical or prescriptive and that these tend to place a value on those linear descriptions of the design process sometimes ignoring the iterative design process that takes place within a particular design exercise. (Lawson, 1980, 29).

Architects have also been seen as Systems Integrators who are able to create innovations. However, System Integration has not been developed further or conceptualized in terms of organizational paradoxes. Obviously, the systems integration concept could easily be seen as the means by which paradoxes, for example, related to different innovation pathways or requirements, might be reconciled. In a study of 10 architectural firms Renier, Volker and Wamelink test Winch's idea that architects are System Integrators (Renier et al 2010). They conclude that architects are indeed System Integrators who will strive to attain a particular level of innovation in order to maintain the firm's competitive advantage. Referring to

Winch's two-moment model of innovation they assert architects have two primary modes of idea generation: The first is based on problem solving dynamics centered on the project, often as the result of the need to develop new solutions. The second dynamic is the generation of new ideas as a result of changes in broader market conditions. In this model Winch contextualizes innovation with reference to the way in which a firm and a project are linked to its broader environments: "new ideas can either be adopted by firms and implemented on projects, or result from problem-solving on projects or be learned by firms" (Renier et al. 2010). This model is based on a binary top down and bottom up model. But it does not explore or suggest how these two different modes of innovation might generate paradoxes either in the organization or within the project.

Another more complex model that has been advanced is the idea that architectural designers can be characterised as Knowledge Intensive Professionals Firms who 'have a pivotal role of the knowledge worker in leading the co-production of innovation with clients' (Lu and Sexton, 2006). Despite the fact that architects and clients are often in conflict this model does not see co-production as having a paradoxical potential. Shu-Ling and Sexton have adapted and developed Nonaka and Takeuchi's spiral model of Knowledge Capital creation in order to explain how knowledge is created in, what they call, KIPFCS. Interestingly, this is a model which does not describe the role of paradoxical processes in the creation of design knowledge. It is an interaction model which posits that knowledge - for example, design knowledge - is created via individuals in project organizations. This knowledge then becomes more explicit, rather than tacit, through collaborative interaction between individuals, teams and organizations. The model presumes that knowledge is created in a continuous or linear fashion in which knowledge capital is increased as these interactions increase. The model is linear, despite its spiraling nature, because it does not allow for the paradoxical processes that might take place in the interactions between individuals, teams and organisations.

In attempting to adapt ideas of organizational paradox to construction Price and Newson argue that strategic management in organizations has been portrayed as a linear process, that is, a process which privileges notions of rationality and logic over those of creativity and the imagination. Price and Newson adopt a top down strategic management approach to describe paradoxes in relation to strategy formulation in construction organizations. They argue that construction organisations should pursue an optimal balance between organizational paradoxes when planning long term strategies. They conceive of, from a construction viewpoint, a taxonomy of paradoxes, which they categorise in binary terms as: Logical (rational) versus creative (generative) strategies; Intended (deliberate) versus realized (emergent) strategies; Revolutionary versus Transformational strategies; Strategic fit versus strategic stretch; and Strategy versus organizational effectiveness (Price and Newsom 2003).

Of the paradoxes identified by Price and Newsom the terms Logical and Creative are characterized as signifying a paradox between "structured decision-making" that leads to incremental change and a "more creative approach" that may lead to greater innovation and "Radical step changes." This distinction echoes the work of Tushman and Benner who have made the distinction between exploitative and exploratory innovation. Exploitative actions utilize existing organizational resources in order to generate short term competitive advantage. Exploratory innovation employs new organizational resources in order to generate "sustainable long term competitive advantage. Clegg, Cunha and Cunha suggest that some of the above binary dichotomies and distinction can be reconciled using a bilateral relational model of organizational paradoxes. In this model they employ the concept of improvisation and claim that this is the process by which organizations resolve paradoxes. They highlight

the paradoxes that exist between exploration and exploitation in organizations. They state that "exploration and exploitation enter a mutually supportive relationship when existing resources are used to look for and take advantage of new opportunities." (Clegg, Cunha and Cunha et al 2010).

Each of the above models or concepts is conceived to explain a different aspect of organisations' approach to innovation. All of the above models are built on a range of expressions that signify binary oppositions: external and internal, top down and bottom up, logical versus creative, rational versus generative, linear versus iterative and exploitative and exploratory. Remarkably, these terms seem to exist in isolation. Very little discussion is noted about the process by which these paradoxes are held apart, consciously encouraged or resolved. If these concepts are regarded as paradoxes then it is possible that more dynamic models may emerge that better relate design processes to construction innovation. Improvisation by way of generative problem solving or designing is not conceptualised in the above models. Seeing architects as systems integrators suggest that they can easily reconcile conflicting and contradictory elements within different project contexts. But this says little about how this is done.

Methodology

The above concepts were examined in a way that attempted to illuminate the paradoxes between rational and exploitative design process and generative design. Underlying the approach in this context is the idea that organizational paradoxes should be examined at the level of project and team business processes and not exclusively from a top down strategic management approach. As suggested above, this survey presumes that generative or exploratory actions are a key driver of innovation. This research aims to understand if simultaneous occurrence of design paradoxes in a project organization may be related to

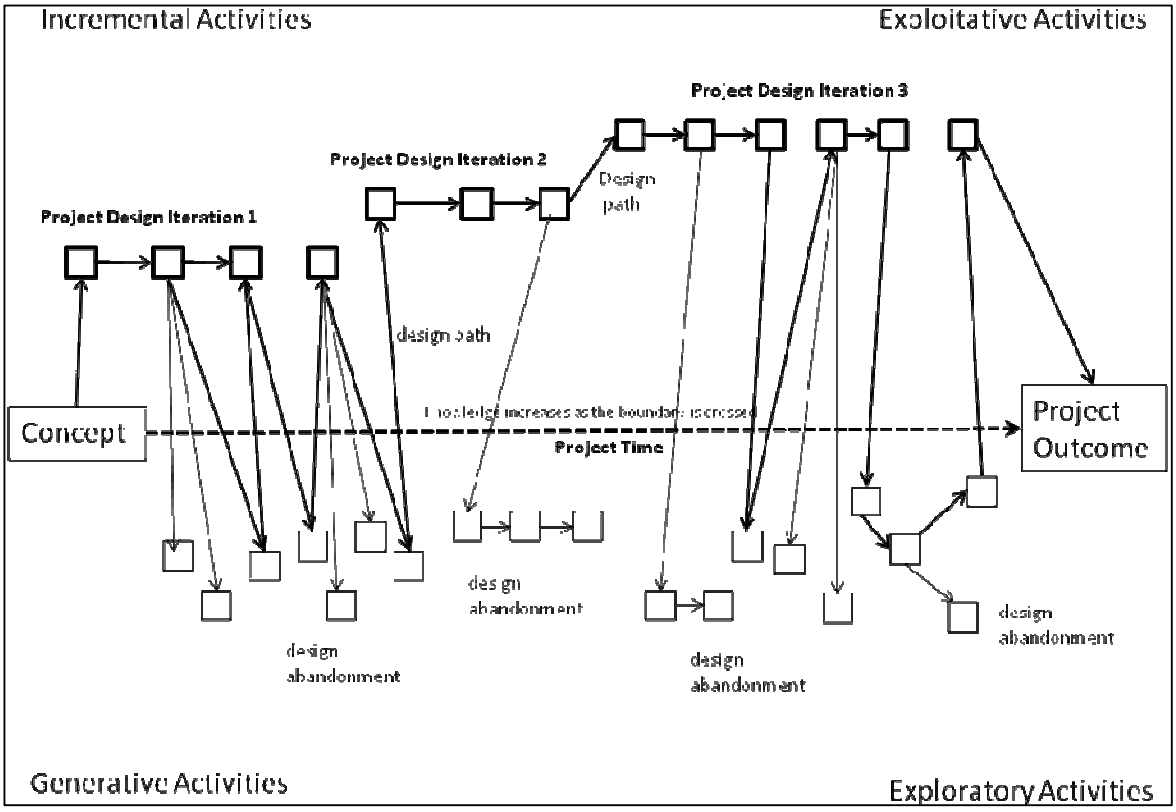

Fig 1: *Design Paradox Systems Integration Model*

innovative outcomes. This research is a first step in approaching this aim. An initial model of how Incremental and Exploitative activities might take place during the design process is set out in Figure. 1. A paradox occurs when generative or exploratory activities occur at the same time as Incremental or Exploitative activities. The survey was designed to ascertain to what degree architects paradoxically pursue both Radical or Incremental design solutions in a given project context. The term Incremental is a signifier for exploitative, logical, and rational design versus Radical which signifies exploratory, generative and creative design. In the survey in order to begin to define these terms, Radical and Incremental were also equated with the kinds of design changes that might take place in a project context. The survey respondents were also asked to define how they themselves defined these terms in a project context.

Using the above definitions the hypothesis employed was the proposition that architects deliberately seek to foster highly paradoxical processes within their firms in order to create new design knowledge. To achieve this the research questions of this paper are aimed to discover to what degree architects are *continuing to simultaneously generate both radical and incremental design solutions throughout the design process.* In order to test this hypothesis a survey was developed that would begin to investigate how architects approached concepts of incremental and radical design during the sketch design, design development and construction stages of the project process. In other words as the design proceeds, to what degree do architects continually question and reconsider design knowledge that has already been created? To what degree will architects consider making radical design changes after a particular design stage has been decided upon? It is important to also understand if architects pursue both Radical and Incremental design solutions at the same time.

In the survey the underlying structure is that exploratory actions are designated as Radical design solutions. These are generative and conjectural in nature. Likewise, incremental design solutions are translated from the concept of exploitative actions. These are linear and incremental in nature. The survey was sent to 1145 architects around Australia all of whom were members of the Australian Institute of Architects. There were 63 responses.

Survey Questions

Given that most architectural practices are SMEs and work on a range of projects in size and financial value it was decided to develop the survey by identifying each practice's largest project, the number of staff in the practice and the type of work they did. The survey also identifies the predominant project type in the firm as well as the monetary value of this project in order to ascertain the complexity of the project. Alongside this project context the number of staff in the practice was identified together with the role, experience and involvement of survey respondent.

Having asked questions about the architectural firm the survey then included questions about how the firm might define Radical and Incremental design changes. Respondents were then asked why such changes take place during the project delivery process. Following this a number of questions were asked about the extent to which Design teams or designers within the practice have the freedom to continue to generate Radical design solutions even if a design or design stage has been agreed on. Finally, the respondents were asked to respond to

a number of statements which gauged to what degree they felt Radical or Incremental design solutions coexisted within a particular project context or design process.

Results

There were 73 responses to the survey out of 1145 invitations. 95% of respondents were architectural directors and 70% of these had over twenty years experience. Most practices were small with 43% having between 2 and 5 staff and 18% having up to 10 staff. 8% of respondents came from practices that were larger than 50 staff. 48% of respondents stated that the largest project in their office was between $AUD1M and $AUD5M. Notably, 78% of respondents stated that they spent at least 25% of their time managing design and design teams.

The respondents strongly agreed that Radical design changes were most related to: the functionality of the project as a result of briefing changes 69%, the overall floor area or building heights 59%, the projects siting or orientation 54%. Radical design changes were seen to encompass a wide range of activites such as: "the inclusion or removal of significant functions", "significant change in the floor area", "changes in leadership within the briefing team", "planning or design changes required due to significant program or delivery timing parameters/budget amount/funding source/ legislative changes." Many respondents were less specific in their definitions and stated that Radical design changes were design changes that: "lead to fundamental rethinking of elements of the project", "affect the form or conceptual origin", "change the design concept" or "A change that affects the fundamental design - so great that the concept must be re-assessed or thrown out."

In response to the question of why Architect initiated Radical design changes are instigated, the respondents agreed that such changes were neccesary in order to: respond to a cost cutting or value management exercise 82%, better co-ordinate services and systems within the project 55%, improve the quality of the projects aesthetic or spatial qualities 50%. Finally, 58% of respondents agreed or strongly agreed that such changes were often made to deliberately explore innovative aesthetic and spatial solutions.

Once a Conceptual or Sketch Design has been signed off, to what extent will the designer and project team be allowed to:					
Number %	Greatly Discouraged	Discouraged	Neither Discouraged or Encouraged	Encouraged	greatly Encouraged
Continue to test the Conceptual Design or Sketch Design solutions by creating alternatives to it.	5 7%	17 23%	24 33%	25 34%	2 3%
Pursue new design solutions at the risk of creating a new Conceptual or Sketch Design.	8 11%	30 42%	23 32%	11 15%	0 0%

Play with the design in order to see what new concepts or solutions may emerge.	6 8%	25 34%	25 34%	15 21%	2 3%
Use the Conceptual Design or Sketch Design as a basis for generating new subsidiary design solutions in order to advance the design to the next stage.	2 3%	10 14%	11 15%	41 56%	9 12%
Advance the design to the next stage using the practice's processes and resources.	1 1%	5 7%	8 11%	45 62%	14 19%

Table 1: *% of firms that continue to generate creative design solutions after sketch and concept design stage.*

The responses seemed to indicate that most exploratory or generative design activities take place in the early stages of the project design process. At this stage, as can be seen in table 1, even though a sketch design or concept design had been mandated, 38% of firms either encouraged or greatly encouraged a generative design process in order to create alternative solutions to the mandated design. Most firms or directors encouraged their teams to use the Conceptual Design or Sketch Design as a basis for generating new subsidiary design solutions in order to advance the design to the next stage. However, a significant percentage actively pursued and encouraged new design solutions or explored the design in order to seek new concepts and solutions. However, it can be seen in tables two and three that once the sketch design stage has passed, architects are reluctant to pursue alternative design solutions.

Once a project has been signed off at Design Development stage to what degree will the designer and project team be allowed to:					
Number %	Greatly Discouraged	Discouraged	Neither Discouraged or Encouraged	Encouraged	Greatly Encouraged
Continue to test the Design Development solution by creating alternatives to it.	13 18%	27 38%	23 32%	7 10%	2 3%
Pursue new design solutions at the risk of creating a new Design Development solution.	19 27%	27 38%	19 27%	5 7%	1 1%

Play with the design in order to see what new concepts or solutions may emerge.	21 29%	24 33%	18 25%	9 12%	0 0%
Use the Design Development stage as a basis for generating new subsidiary design solutions in order to advance the design to the next stage.	13 18%	12 17%	23 32%	23 32%	1 1%
Advance the design to the next stage using the practice's processes and resources.	7 10%	6 8%	11 15%	39 54%	9 12%

Table 2: *% of firms that continue to generate creative design solutions after design development stage.*

It can be seen in Table 2 above and Table 3 below that once the sketch design stage has passed that architects are reluctant to pursue alternative design solutions for their own sake. They will, however, pursue any design solution that will advance the design to the next stage. Obviously in some circumstances, if there is a change of brief of example, this would mean employing Radical design soultions to do this. However, the results suggest that architects are more likely to pursue incremental or exploitative changes at these stages through the generation of subsidiary design solutions and the exploitation of the firm's normative processes and resources.

Once a project has been signed off after Tender stage and is in Construction to what degree will the designer and project team simultaneously:					
Number %	Greatly Discouraged	Discouraged	Neither Discouraged or Encouraged	Encouraged	Greatly Encouraged
Continue to test the Sketch, Design Development and Documentation solutions by creating alternatives.	49 67%	16 22%	7 10%	1 1%	0 0%
Pursue new design solutions at the risk of creating a new conceptual or Sketch Design.	51 71%	16 22%	5 7%	0 0%	0 0%

Play with the Design in order to see what new concepts or solutions may emerge.	48 67%	16 22%	5 7%	3 4%	0 0%
Use the Construction stage as a basis for generating new subsidiary design solutions in order to improve the design.	30 41%	16 22%	13 18%	11 15%	3 4%

Table 3: % of firms that continue to generate creative design solutions after design development stage.

Table 3 above indicates that architects are very reluctant to pursue alternative design solutions once a project is under construction. No firms indicated a willingness to pursue new design solutions at the risk of creating a new sketch or conceptual design. A very few respondents did appear to encourage playing with the design in order to see what new concepts would emerge. However, 19% of respondents did see the construction phase as an opportunity for generating new subsidiary design solutions in order to improve the design as it neared completion.

To what extent do you agree or disagree with the following statment	
Pursing Radical design changes is a part of the practice's normal design process.	28%
In our practice any project the principal designer, designer teams and design architects have the time to pursue new design solutions throughout the project.	29%
Design teams or designers within the practice have the freedom to continue to generate Radical design solutions even if a design has been agreed on.	17%
Continuing to generate both Incremental and Radical design solutions throughout the process helps to identify and highlight new design issues and problems as the design progresses.	42%
Continuing to generate both Radical and Incremental design solutions throughout the process outweighs impacts on project delivery time or cost.	21%
Implementing Radical design solutions throughout the process outweighs impacts on project delivery time or cost.	21%
Sometimes it is necessary to discard a design solution or sketch design and start the design process again in order to achieve a better project outcome.	72%
It is difficult to manage designers and design teams who pursue both radical and incremental design changes in a project simultaneously.	57%
Creating and then culling both Radical and Incremental successive design solutions in a given project helps to achieve high quality and innovative design.	65%

Table 4: % of firms that agree or strongly agree with the question.

Discussion

The survey appears to indicate that a significant proportion of architects foster paradoxical design processes in their firms. The initial model proposed here posited that architectural designers and design teams will undertake exploratory and exploitative activities simultaneously. The hypothesis tested was the proposition: that many architects deliberately seek to foster highly paradoxical processes within their firms in order to create new design knowledge. It would appear that this is the case even though an initial sketch design has been mandated. In the early design stages of a project 37% of architects will continue to pursue alternative design solutions and 15% of architect respondents will continue to test a design solution at the risk of creating a new design solution. Architects will continue to play with the design solution in order to see what new concepts emerge through sketch design, 24%; design development 12% and even into the construction phase 4%.

The results indicate that architects continue to*, simultaneously generate radical and incremental solutions throughout the design process;* this only holds true for the early stages of the project prior to design development. It would appear that the sketch design stage is the stage that appears to be the most paradoxical. This is because it is the primary stage where both exploratory and exploitative activities take place during the project. This is described in Figure 2 which is a revision of the initial model as set out in figure 1. This model, which would be tested by further future research, indicates that in the early stages of a project architects freely generate design solutions which create design paradoxes with other project elements and systems. Some of these solutions are abandoned, or destroyed, and others are then integrated into the project and developed in an exploitative fashion. As the project advances fewer paradoxes are created. This is because fewer generative design solutions are created and the focus in the project is on developing subsidiary solutions and systems integration as the project approaches construction delivery. Those paradoxes that are created

One limitation of this research has been the initial necessity to establish the definitions of what architects regard as radical and incremental design changes. In the survey Radical and Incremental were also equated with the kinds of design changes as well as the solutions that might take place in a project context. These changes are regarded as Radical if they require a substantial change to the brief or a significant change to the original design concept or strategy. Future research would better align definitions of what architects regard as Radical design changes with what they regard as Radical design solutions. Future research could also look at the design processes within a small range of architectural practices, or projects, over time in longitudinal detail. This might require a close observation of architectural design processes particularly in the early design stages. A key aim of future research would be to establish to what degree construction or design innovation is achieved in the early design stages of a project. Creating both exploratory and exploitative design solutions simultaneously may not necessarily lead to innovation.

It would appear that once a design concept is produced Architects deliberately pursue generative solutions which tend to create paradoxes with other more rational project constraints. But this appears to take place primarily in the early stages of a project where architects have more freedom to explore and are not as constrained by time and cost

Deadlines. Through a process of systems integration these solutions are developed and advanced though exploitative means. In the later stages of a project, as can be seen from the results generative, a lesser number of generative, or exploratory, solutions are pursued at the

same time that earlier generative solutions are being integrated, by exploitative means into the project process. On the basis of thesis results it could be argued that for architects the creation of design paradoxes, using generative and exploratory means, diminish as the project proceeds. Nevertheless, the model suggests how architects act as systems integrators and that both types of design take place simultaneously and that the pathway to an innovative project outcome is not linear.

Theories of organisational paradox should allow for the fact that paradoxes are often nested. One paradox may appear one reside within another Paradox. Examining one paradox may often reveal another paradox at a different level or scale. For example For example, 57% of respondents cited the difficulty of managing design teams that pursue both incremental and radical design changes simultaneously. However, they still agreed that creating and destroying both Radical and Incremental design solutions was at least one way to achieve design innovation. If any overarching paradox exists within construction project processes it is that many project systems favour sequential linearity, in other words exploitative processes, alongside actual project processes which are never linear and often complex and chaotic.

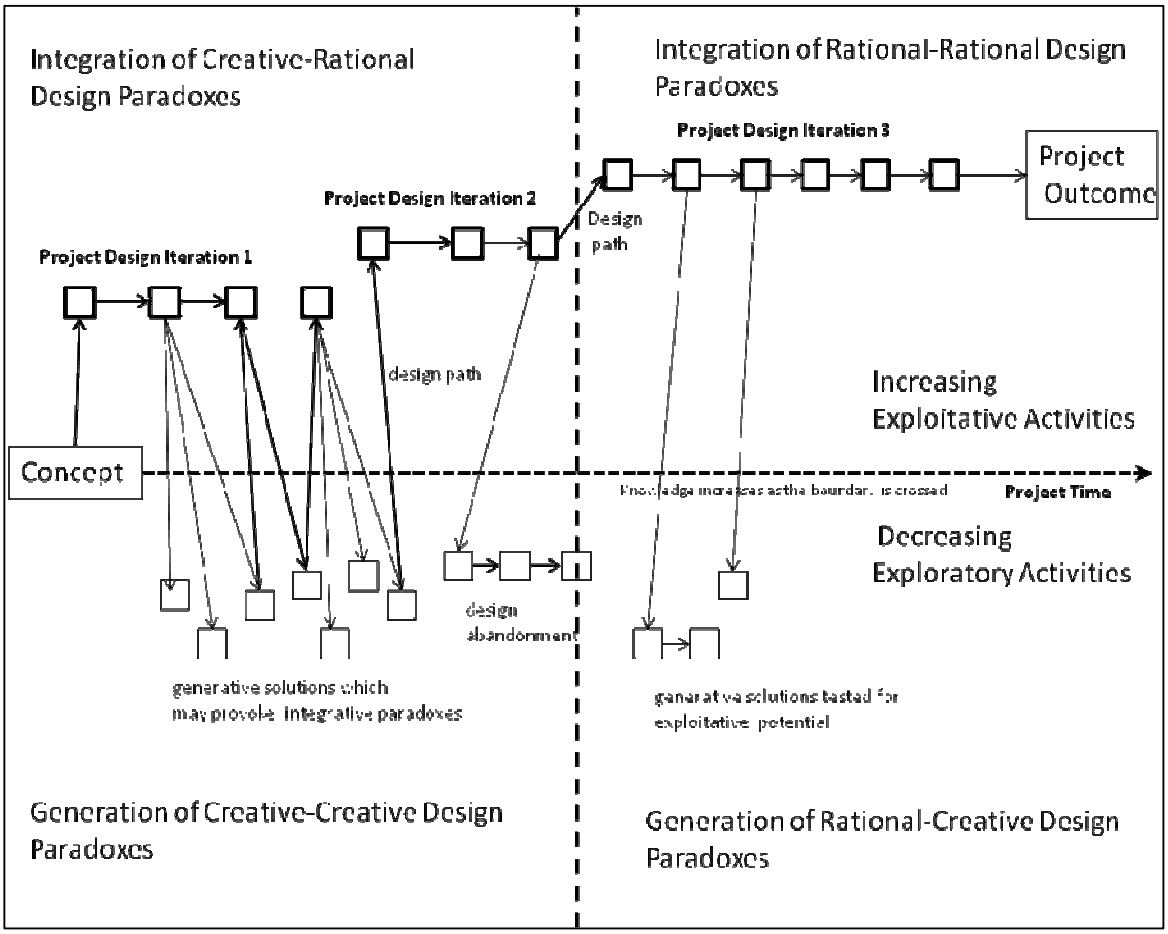

Figure 2: *Revised Paradox Systems Integration Model*

Conclusion

Future research would also examine in detail those firms that continued to engender design paradoxes by pursuing exploratory design solutions throughout the entire process. Whilst only a very small minority of firms were willing to do this after the tender or bid stage it would be interesting to know more about the characteristics of these firms. Are they firms with a good reputation for design? More importantly do paradoxical processes create high quality design knowledge that drives innovation? Much of the literature suggests that in theory so called creative, non linear and conjectural processes create innovation. However, these assertions need to be tested in project organisations and teams. Organisational paradoxes should not be seen as existing only in the domain of high level strategic management. Paradoxically, this research itself raises a number of paradoxes that should be the focus of future research.

Abstract
The building industry is responsible for a large part of the world's environmental degradation as buildings converge in themselves major indexes of energy and water consumption, raw material employment and usage of land. Thus, green buildings, which are defined as resource-efficient and ecosystem-conscious structures designed with a holistic understanding of social and environmental responsibility, have become the flagship of sustainable development. Today, in several countries, there is a well developed green building practice that is used to improve and assess diverse aspects of a building such as site selection, energy, water, material consumption, waste production and pollution. Ongoing development of the sustainability phenomenon, as well as some pioneer green projects in Turkey, has brought on awareness and discussions regarding the green building practice in the Turkish architectural, engineering and construction (AEC) industry recently. In this paper, current green building practice, legislative framework and policies regarding green buildings have been analyzed and deficiencies in policies and statutory regulation in Turkey are determined to bring forward suggestions towards a more institutionalized development of green building practice. On the other hand, Singapore's Green Building Masterplan and its key aspects have been overviewed as a best practice in terms of a planned and holistic approach in the quest for constituting a model for countries looking for a widespread adoption of green building practice in the near future like Turkey.

Keywords: green buildings, building assessment, sustainable design and construction, Turkey.

INTRODUCTION

The debate about sustainability of buildings is becoming more and more intense with the increasing awareness of the impact that buildings have on the environment both in terms of their construction and use. The building industry, indeed, is responsible for a large part of the world's environmental degradation as buildings converge in themselves major indexes of energy and water consumption, raw material employment and usage of land (Melchert, 2007). Buildings account for nearly 40% of energy consumption, 70% of electricity consumption, 40% of carbon dioxide emissions, 12% of water and 40% of raw material use in the developed countries (Retzlaff, 2008). Thus, also variously designated as "ecological", "environment-friendly" or "sustainable" buildings, the green buildings have become one of the most important elements in the issue of sustainability, an issue inevitably highlighted by climate change and depletion of natural resources. Green buildings are defined by the

Turkish Green Building Association (2009) as resource-efficient and ecosystem-conscious structures designed with a holistic understanding of social and environmental responsibility, harmonious with local conditions, built with proper materials and systems so as to minimize energy consumption, where renewable energy sources are given priority and waste production held under control.

This paradigm shift also generated the need to develop norms and regulations for sustainable building design and construction. Today there is a well developed green building practice and a diverse array of regulations and policies regarding green buildings and sustainability in several countries. However, the results of research by Akbiyikli et al. (2009) show that the current level of sustainability understanding and hence its implementation is still unstructured, piecemeal and insufficient in the Turkish AEC industry.

Since the preparation of relevant legislation and adoption of appropriate and resolute policies constitute an indispensable part of the development of the green building practice, current deficiencies in green building legislation and policies in Turkey are determined and Singapore's Green Building Masterplan is analysed as a best practice in this paper in the quest for constituting a model and putting forward suggestions for countries looking for a widespread adoption of green building practice in the near future like Turkey.

GREEN BUILDING PRACTICE IN TURKEY

Green Building Certification Systems

Green Building Certification is the core and most tangible part of the green building practice for the stakeholders of the AEC industry. Today, in several countries, there is a well developed green building certification practice that is used to assess diverse aspects of a building such as site selection, energy, water, material consumption, waste production and pollution. Despite the debate and efforts, there is a consensus that a global standardization (and certification) of green buildings seems not possible due to the regional differences in climate, supply of energy, water, raw materials and land, availability of "green" materials (EMS certified materials etc), environmental conditions, economic conditions, legal framework, culture and way of conducting business in the AEC industry. On the contrary, recently more and more national certification systems are being developed or global systems are being adapted to local conditions. Leadership in Energy and Environmental Design of the US (LEED), Building Research Establishment Environmental Assessment Method (BREEAM) of the UK, Sustainable Building Tool (SBTool) of Canada, German Sustainable Building Certificate (DGNB), Comprehensive Assessment System for Building Environmental Efficiency (CASBEE) of Japan, GreenStar of Australia and BCA Green Mark of Singapore are some of the green building certification systems that are widely adopted around the world.

The concepts of green buildings and sustainable design have gained recognition in the AEC industry within the past decade in Turkey. However, green building practice is still entirely voluntary and generally limited to foreign investment projects, buildings designed for global corporations, new residential developments and educational buildings. BREEAM and LEED are the two certification systems used and supported institutionally by the Turkish Green Building Association (TGBA). However, TGBA is recently working on an adaptation of BREEAM to develop "BREEAM Turkey". BREEAM was chosen over LEED for adaptation since most of the UK's and Turkey's regulations and standards are common or compatible due to Turkey's adoption of the acquis communitaire within the accession process to the EU.

Despite these recent efforts, green building practice is very limited and piecemeal and the total number of projects certified is still very low. This can be explained with the "context" the green building practice is operating in, namely the *legislation* regarding green building issues and green building *policies* adopted by the central or local administrations. These two are analysed in detail below and suggestions are brought forward for a wider adoption and a more institutionalized development of green building practice in Turkey.

Green Building Legislation

Turkey is one of the few countries which included environmental protection in its Constitution. According to the Constitution, "everyone has the right to live in a healthy, balanced environment and it is the duty of the state and citizens to improve the natural environment and to prevent environmental pollution". Despite this provision, no specific legislation exists in Turkey currently on the green buildings. Therefore, in this section, current legal situation is analyzed under common themes relevant to green buildings such as energy, water, building materials, land use and waste.

Legal regulation has recently been made in Turkey with the purpose of stimulating energy conservation in buildings, rendering some practices compulsory and enabling inspection of obtained results. These legal measures are assembled in Regulation on Energy Performance of Buildings (BEP-Y) dated December 5th. This regulation covers the computational rules for the assessment of all energy uses in a building, and its classification with respect to primary energy use and carbon dioxide emission, the specification of minimum energy performance requirements for new or substantially renovated buildings, guidelines for the evaluation of the practicability of renewable energy sources, inspection of heating and cooling systems, abatement of greenhouse gas emissions, and the performance criteria and the implementation guidelines that apply to the buildings. This regulation is promulgated on the EC Directive on the Energy Performance of Buildings, which lays down requirements as regards the general framework for a methodology of calculation of the integrated energy performance of buildings, the application of minimum requirements on the energy performance of new buildings and large existing buildings that are subject to major renovation as well as the energy certification and regular inspection of buildings and its systems. Regulation on Energy Performance of Buildings requires the evaluation of the energy performance of buildings including determination of energy consumption, CO_2 emission, benchmarking these values to a reference building and classification of the building according to the benchmark results. Building Energy Performance Calculation Methodology (BEP-HY) defines the assumptions and methods used in the calculation of energy consumption of heating, cooling, ventilation, lighting and hot-water systems in a building. BEP-HY can be used for comparing the energy performance of alternatives in the design phase, comparing the cases of using and not using energy efficiency measures, developing foresights for the need of energy in future by calculating typical buildings that can represent the building stock in an area and developing a national database of energy performance of various building elements and materials (Ministry of Public Works and Settlement, 2009).

Although one of the most serious problems that Turkey may face in parallel with global warming is water shortage, currently no legislation exists in Turkey regarding water efficiency in buildings. Use of efficient water equipment, rainwater harvesting systems, surface water harvesting systems, efficient irrigation systems, plant types that consume less water in landscaping, recycling of the treated effluent for appropriate reuse in buildings and water efficiency awareness-building programs for the public could be addressed by such a legislation. Building materials, on the other hand, are regulated by Regulation on Building

Material, which requires the materials used in buildings to be mechanically resistant, non-toxic, safe to use, energy efficient and have a CE or G marking. This regulation could be amended to include limits and/or incentives regarding the environmental impact of the production process of materials in order to render the buildings "greener" in Turkey. Furthermore, additional legislation could be prepared to encourage the use of "green materials" in buildings such as recycled, recyclable, local and renewable material. Such legislation might be supported with training of designers and professionals dealing with material selection in construction projects (Ilter, 2011).

Development plans are the main source of restrictive regulations in land use for buildings. Planning areas are divided into zones such as residential, commercial, industrial etc and some development restrictions such as the maximum number of floors and the usable area to land area ratio are included in these development plans. Ercoskun (2005) argues that current development plans do not consider urban identity and ecological values such as climate, spaces between buildings, direction, natural lighting, and air circulation etc resulting in the Turkish cities to be unsustainable. Furthermore, the reality of illegal settlements and brutal development interests has a damaging effect on both natural and built environment in big cities. However limited to big scale projects, a key piece of legislation regarding environmental concerns in site selection is the Regulation on Environmental Impact Assessment, requiring an independent assessment report evaluating the positive and negative impacts of a project on the environment and appropriateness of the site selected for the project. The scope of this regulation covers energy production and distribution plants, industrial and agricultural buildings, as well as hotels with 100 rooms or more, public and private housing projects with 200 units or more, educational and sports complexes.

As for waste, Regulation on the Control of Excavation, Construction and Demolition Wastes, promulgated on 13 March 2004, sets the rules for the collection, accumulation, recycling and disposal of wastes generated in the excavation, construction and demolition phases. According to the regulation, wastes should be minimized at the source, the persons or organisations who are responsible for the management of the wastes should take the necessary precautions to minimise the harmful impacts of the wastes to the environment, the wastes should be recycled and used as building materials where possible, excavation soil and construction / demolition wastes should be processed separately, wastes should be classified at the source for a healthy recycling process, the producers of the unrecyclable excavation, construction and demolition wastes should pay for the disposal of such wastes. Regarding the recycling of excavation soil, the regulation requires the vegetative soil to be used in parks etc and the rest to be used in filling, as a cover material in solid waste storage areas and as clay in cement industry where the chemical properties of the soil allow. Collection, treatment, disposal and recycling of wastewaters and solid wastes produced during the utilization of buildings, i.e. wastewater and solid waste management are also well established fields covered by separate special legislation and institutional agencies (Ilter, 2011).

Green Building Policies

Apart from the ones supporting the well developed legislation stimulating energy conservation in buildings, holistic policies regarding green buildings or sustainable built environments do not exist and seriously needed in Turkey. There are diverse aspects ranging from macro to micro scales in this approach and thus we need to ensure that we learn from best practise on a global level. Singapore is one of the few countries that introduced a resolute policy regarding green buildings and has tackled the issue of green buildings within a Masterplan prepared with a holistic approach. Therefore, in the next section, "Singapore

Green Building Masterplan" and its key aspects are analyzed in the quest for constituting a model for other countries looking for a widespread adoption of green building practice in the near future, such as Turkey.

A Best Practice: Singapore Green Building Masterplan

According to Building Construction Authority - BCA (2009) and Seng (2011), Singapore Inter-Ministerial Committee on Sustainable Development (IMCSD) has set itself an ambitious target of having "at least 80% of the buildings in Singapore to be greened by 2030", which means 80% of the buildings in Singapore must be certified by Building Construction Authority (BCA)'s Green Mark Scheme by 2030. BCA Green Mark was launched in 2005 as a green building rating system to evaluate buildings in terms of environmental impact and performance in Singapore. The key assessment criteria are energy efficiency, water efficiency, environmental protection, indoor environmental quality and some other green features. There are platinum, gold-plus, and gold certificates available for projects with higher scores and projects that achieve mediocre scores are only "certified" without any further classifications. BCA Green Mark Scheme is only a part of Singapore's Green Building Masterplan which has been designed with a holistic approach and has diverse aspects.

The legislation in Singapore require all new buildings to meet the minimum Green Mark standards, and the public sector demonstrate even stronger commitment by targeting the highest Green Mark certificate (Platinum) award for all new projects and existing buildings undergoing major retrofitting works with an air conditioned floor area larger than 5,000 m2. Other existing government buildings with more than 10,000 m2 air conditioned floor area are required to achieve Green Mark Gold Plus certificate by 2020. On the other hand, higher tier Green Mark standards have been set as land sales condition by the government in new growth areas to ensure that they are truly green. This is expected to result in at least 25% reduction in energy use. This represents an estimated project value of $500 million from the government over the next ten years to upgrade all existing buildings owned by government agencies. When all these are done, Singapore is expected to achieve substantial energy savings of $120 million per year.

As for incentivizing the private sector, 102 projects have been funded with a budget up to S$3 million in cash per project. S$20 million incentive resulted in 26 platinum, 14 gold-plus and 62 gold certified buildings, 56 of which were residential and the rest being commercial projects. On the other hand, to encourage private developers to construct new buildings that attain higher tier Green Mark ratings (i.e. Green Mark Platinum or Green Mark Gold-Plus), BCA and Urban Redevelopment Authority (URA) are introducing the Green Mark Bonus GFA Scheme in the form of additional Gross Floor Area (GFA) for higher-tier Green Mark projects. The Green Mark Bonus GFA incentive is extended to all new private developments, redevelopments and reconstruction developments. The quantum of bonus GFA is up to 1% for Green Mark Gold-Plus and up to 2% for Green Mark Platinum. This is expected to help to accelerate the adoption of environmentally-friendly green building technologies and building design practices to enable the development of green buildings to be even more economically viable in the longer term. To date, 46 applications have been received by BCA and URA, 33 applications were approved and 13 applications were given approval in principle.

As for retrofitting the existing buildings to improve energy efficiency, BCA is introducing a bold S$100 million Green Mark Incentive Scheme for Existing Buildings (GMIS-EB) to jumpstart the 'greening' of existing buildings in the private sector. This will probably be

another successful incentive since financial considerations is one of the key barriers for building owners in upgrading the energy performance of their buildings. This scheme will operate in two parts; first being the cash incentive that co-funds up to 35% of the costs of the energy efficient equipment installed. The second part is the 'health check' scheme; this is an energy audit which determines the efficiency of the air-conditioning plants. BCA will also co-fund 50% of the cost for conducting this Health Check. To date, 13 applications were given approval in principle amounting to S$3 million.

BCA has also raised a S$50 million fund for research in green buildings and supported 48 projects. In this context, a Zero Energy Building (ZEB) has been planned as a show-case to encourage the building industry and show that greening existing buildings to meet the highest Green Mark standards is possible. Apart from being a zero energy retrofitted building, ZEB is also a platform for academicians and researchers to analyse green building technologies and their performances in a real setting so as to bring new knowledge to the technical community and explore areas for further research. It also gives BCA a platform where industry stakeholders, local and foreign government officers, building professionals and students learn about green building technologies by physically seeing them in action.

Beside ZEB, there are many large-scale integrated living labs in Singapore. These offer testing of intelligent energy systems, off-grid energy solutions and applications, sustainable public housing solutions, green business park solutions, trialling of EVs & charging solutions and solar capability building on public housing. There is also innovation and R&D centres, centres of excellence and incubation centres established in Singapore dealing with different aspects of sustainable urbanisation such as urban transport management, connected cars, green ICT, green building and infrastructure, integrated water management systems, smart grid and integrated security management.

BCA also committed to building industry capabilities through training. In this regard, in order to meet the challenging target of greening 80% of all buildings by 2030, BCA has estimated that a total of 18,000 - 20,000 green specialists would be needed over the next 10 years. These specialists include personnel across the entire value chain, covering upstream activities of development and design to the downstream activities of construction and operation & maintenance. With the aim of training these specialists, BCA Academy has been established where a comprehensive suite of green related training courses have been put in place. These include Executive Development Programmes targeting at the senior management of firms, as well as the Academic Programmes, Specialist Certification Programmes and Niche Competency Programme targeting at the professionals. To date, 1563 professionals have been trained as Green Mark Manager, 115 as Green Mark Professional and 133 as Green Mark Facilities Manager. BCA is planning to continue to enable the industry to raise its capability to develop more Green Buildings by providing a comprehensive training and educational framework ranging from Master degree, specialist diploma to certificate courses to ensure adequate supply of green building professionals and sub-professionals to meet the expected strong demand for green buildings.

For international recognition and awareness raising purposes, BCA has established the Singapore Green Building Council with an international panel of experts and BCA was connected to global sustainable building community such as the World Green Building Council through Singapore Green Building Council. After this BCA Green Mark Scheme was adopted by many other countries, such as Malaysia, Vietnam, Thailand, China, India and some Middle Eastern countries.

As a statutory obligation, the Code for Environmental Sustainability of Buildings were incorporated into the building control act as a form of legislation that set out the minimum standard for new buildings to meet the minimum green mark certified level.
Over the years, there has been a steady increase in the number of green buildings. By end of FY2010, it is projected we will have 650 green buildings, occupying 20 million m2 of floor space (Figure 1). This is about 9% of the total GFA in Singapore.

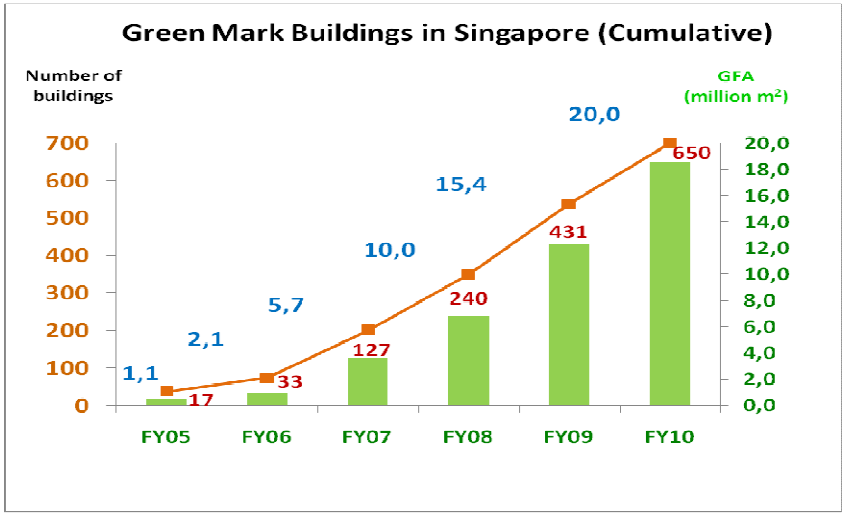

Figure 1: *Green Mark Buildings in Singapore (Seng, 2011).*

BCA Green Mark Scheme was recently revised and Version 4 for new buildings had taken effect from 1st Dec 2010. This new revised rating system placed emphasis on passive design (natural ventilation, day lighting etc), sustainable construction, greenery system as well as enhancement to building energy efficiency standard.

Lessons Learned
Analyzing the best practice of Singapore reveals important lessons for countries aiming a widespread adoption of green building practice in their AEC industry. First of all, as seen in Singapore, government itself has to take the lead and apply green building standards to public buildings (both existing and new) to set a good example for the community. All public sector buildings should meet minimum standards of environmental sustainability. By doing this, government will also be creating a green building industry and business in all levels in terms of production and commerce. On the other hand, government policies for incentivizing the private sector are needed since initial investment is one of the most important barriers to building green in terms of both new developments and retrofits. Resolute policies should be set up ranging from supporting a house owner for retrofitting to tax exemptions for developer companies building green. This can be formulated as direct monetary incentives to developers that achieve a green building rating above a certified level as seen in the Masterplan of Singapore. To further encourage private developers to achieve outstanding design, quality, and sustainability objectives in their projects, policies should set higher standards as land sales conditions for selected new growth areas.

Policies should be formulated to step up developmental and collaborative efforts to build up capabilities and expertise in green building design and technologies. As seen in the Singapore example, this will eventually lead the way to more viable and cost effective applications of

green building designs and technologies. Showcase buildings, laboratories, innovation and excellence centers, incubations hubs are all useful platforms to test bed and showcase new technologies and designs for the built environment. Supporting R&D projects should also be an indispensible part of the policies on furthering the development of green building technologies. Besides supporting the institutions and facilities, human resources should also be created and supported. To meet the increasing demand for green building professionals, it is important to develop the industry's capabilities and ensure an adequate supply of trained professionals. For this purpose, a comprehensive training framework should be prepared to train the specialists in the development, design, construction, operation and maintenance of green buildings. Also, existing personnel will need to be upgraded and new entrants recruited in order to create a highly skilled green collar workforce.

Awareness raising among public and industry stakeholders is an important part of the green building policies. It is important to elevate awareness of green buildings, energy efficiency, and the need for a sustainable built environment within the industry and the community. Green building councils and associations should be supported in this regard for preparing showcase projects, conferences, and workshops etc which are among efficient tools in terms of awareness raising activities.

As for imposing minimum standards on the industry, there certainly is a need for regulations as seen in the Singapore example as well as in Germany, Denmark and the UK. Many countries including Turkey has adopted legislation regulating the energy performance of buildings, however, this should be expanded to include water, raw material efficiency, waste and pollution control etc.

Last but not least, continuous development of the certification systems are needed with different set of measures for new and existing buildings since green building is a relatively new and constantly evolving concept. Serious amount of scientific research and R&D activity is being undertaken and efforts should be made to both support and use the results of these in green building practice in the AEC industry.

CONCLUSIONS

The building industry is responsible for a large part of the world's environmental degradation as buildings converge in themselves major indexes of energy and water consumption, raw material employment and usage of land. Thus, also variously designated as "ecological", "environment-friendly" or "sustainable" buildings, the green buildings have become one of the most important elements in the issue of sustainability, an issue inevitably highlighted by climate change and depletion of natural resources. This paradigm shift also generated the need to develop norms and regulations for sustainable building design and construction. Today there is a well developed green building practice and a diverse array of regulations and policies regarding green buildings and sustainability in several countries. However, the results of research by Akbiyikli et al. (2009) show that the current level of sustainability understanding and hence its implementation is still unstructured, piecemeal and insufficient in the Turkish AEC industry.

Since the preparation of relevant legislation and adoption of appropriate and resolute policies constitute an indispensable part of the development of the green building practice, current deficiencies in green building legislation and policies in Turkey have been determined and Singapore's Green Building Masterplan analysed as a best practice in this paper in the quest

for constituting a model and putting forward suggestions for countries looking for a widespread adoption of green building practice in the near future like Turkey.

Analysis of the current legislation regarding green buildings in Turkey revealed that,

- Energy efficiency is the most advanced theme and there is well established legislation in this area
- Currently no legislation exists in Turkey regarding water efficiency although one of the most serious problems that Turkey may face in parallel with global warming is water shortage
- The Regulation on Building Materials should be amended to include limits and/or incentives regarding the environmental impact of the building materials' production process
- Site selection is the most complex theme requiring regulations and resolute policies on various scales. Besides restoring and implementing development plans with an ecological concern, the problem of illegal settlements in big cities needs to be solved in order to set forth a realistic approach to the issue of sustainable buildings and cities in Turkey
- Regulation on the Control of Excavation, Construction and Demolition Wastes sets the rules for the collection, accumulation, recycling and disposal of wastes generated in the excavation, construction and demolition phases. Collection, treatment, disposal and recycling of wastewaters and solid wastes produced during the utilization of buildings are also well established fields covered by separate special legislation and institutional agencies.

It has been argued in the paper that resolute policies are needed besides the legislative framework for a widespread adoption of green building practice. It has been found that, apart from the ones supporting the well developed legislation stimulating energy conservation in buildings, holistic policies regarding green buildings or sustainable built environments do not exist and seriously needed in Turkey. Analysis of Singapore's Green Building Masterplan as a best practice in this regard constituted a good example for countries looking for a more institutionalized development of green building practice such as Turkey. This analysis revealed that,

- Minimum standards should be imposed in the form of a legislative framework
- Public sector should be taking the lead in terms of greening the public buildings to set up a good example for the community and create a "green building industry"
- Incentive policies should be set up for the private sector in terms of both new developments and retrofitting the existing buildings
- Funds should be raised to support research and technology development projects as well as building up the necessary facilities such as laboratories, innovation and excellence centers, incubations hubs etc.
- Industry capabilities should be improved through training in order to meet the increasing demand for green building professionals
- Awareness raising should be an indispensible part of the policy in order to expand the green building practice to the whole community
- Policies should be set up to provide continuous development of the certification systems to catch up the state of the art in the ever-developing green building technology.

COLLABORATIVE NETWORKS SUPPORT SUSTAINABLE BUSINESS SETTINGS REGARDING INTEGRATION OF DESIGN AND CONSTRUCTION.

JAN WORST
Maastricht School of Management
worst@msm.nl

Abstract
Integration of design, engineering and construction (D-E-C) aligned to collaborative networks (CN's) is about overcoming traditional barriers. Collaborative Network systems are submitted to economic, social and environmental circumstances. D-E-C integration linked to CPFR and submitted to CN's could bridge traditional barriers, when aligned to an agreement and a joint business plan. CPFR contains four levels and eight collaborative tasks and was initiated and co-led as CFAR by Wal-Mart in 1995. CPFR offers entrance to a synchronized process and identified partners submitted to a joint workflow management system. Limits to arrive at D-E-C integration are indicated by defining ontology (a theoretical model) on interdisciplinary activities.

Keywords: collaborative networks, D-E-C integration, CPFR, ontology, identified.

INTRODUCTION
Collaborative networks (CN's) are systems of legally independent partners in industries and services to cooperate on shared economic sense. Partners coordinate and communicate in changed business paradigms that use systems supported by Service Oriented Architecture (SOA) often aligned to web-based services. Collaboration structured through CN's offer the opportunity to enlarge capacity, reinforcement of capabilities and market strength. Due to traditional business settings the barriers are high to enter CN's such as virtual enterprises [Worst, 2009]. According to PwC [2005] firms participating in collaborative networks consider their investments in ERP environments crucial and cherish traditional ICT configurations. Following Sterman [2000] single-loop learning models such as the construction process will use one existing mental model to reach their goal. For instance: The Constructon case [Project Pact, 2004] indicates that unchanged mental models block collaboration. Constructon [2004] was initiated as a pilot project to find a solution on the construction industries' supply chain mismatch. The project was introduced by Constructon to establish virtual enterprises. Constructon initiated a link to ConstrucNed Technologies, which provided web-based services. The main goal was to reinforce integrated co-operation cross the construction supply chain by embedding web-based services. Adoption of e-commerce in combination with business process reengineering (BPR) was addressed as the key to new business settings to arrive at competition on quality instead on price. The key to success was focused on synchronizing business processes within and across project partners to elevate efficiency and effectiveness. The initiative was supported by earlier studies on virtual enterprises of CSTB France [Zarli et al. 2002] and European platforms such as RoadCon, Manubuild, and the OSMOS project [Worst 2004, 2009]. Hosted databases and data warehousing connected to web-based services were introduced in 2006 by ConstrucNed Technologies [2006]. The pilot project ended in 2008 due to lack of support. Although virtual business settings reinforce concurrency in the construction process, it is difficult to arrive at a synchronized process. In particular new roles, functions, and transparency block change of traditional business settings. Integration of design, engineering, and construction requires change of mental models and operational management.

PROBLEM

Considering collaborative networks and D-E-C integration, the following questions are of importance to find a solution:

- How do the construction industry and its adjacent markets cope with collaborative networks to regulate competition and transparency?
- How do partners in a construction project organize collaborative assessment of partners in networks?
- Are collaborative networks adopted by governments, industries, supportive industries, public services and private services? Are they legally supported by current national and international law?

Objective of this paper is:

- To identify ontology of collaborative networks focused on integration of design, engineering, and construction.
- To describe a CPFR model aligned to collaborative networks focused on integration of design, engineering and construction.

Collaborative Networks (CN's): CN's operate legally almost as real firms. CN's represent connected participants opting for one goal. For instance they represent a virtual enterprise, when partners are legally bound, and share economic sense and ideas about economics, environment and social responsibility. Participants are legally independent firms underwriting a contract that settles a code of conduct and rules of engagement. Architects, engineers, contractors, suppliers and subcontractors aligned to a CPFR-model have to accept new roles in the construction process. Do CN's have legal foundation according to domestic law of member states, when looking at the EU? Yes, for instance assets of CN's are e.g. concessions to build, which indicates liability to contracts. Economic, Social and Environmental factors regarding the opportunities CN's offer are currently not an issue of business strategy in the West European construction industry, although the many opportunities CN's offer.

Integration of design and engineering requires a network organization that links investment decisions, marketing, object design, engineering, and execution of processes. CN's submitted to a synchronized process contribute to increase efficiency in mobilization and allocation of design, logistics and engineering. CN's contribute also to reduction of inventory, transportation, and logistic costs. CPFR is a business model to enhance collaboration. To start collaboration, Leeman [2010] indicates CPFR (collaboration, planning, forecasting, and replenishment) as a business solution. It provides guidelines to start up collaboration. The CPFR-model encompasses an opportunity to start up synchronized processes to arrive at design D-E-C integration. It means that investor, marketers, architects, engineers, contractors and suppliers have a legal understanding based on an agreement and a joint business plan.

CPFR began in 1995 [Wikipedia, 2011] as an initiative co-led by Wal-Mart. Originally it started as a model on collaboration, forecasting and replenishment named CFAR-model. CFAR was presented to the Voluntary Interindustry Commerce Standards Committee (VICS). CPFR was [Leeman 2010] developed by the VICS organization since 1998 and is similar to the ideas about the virtual enterprise described by Worst [2009]. In 1998 VICS initiated a roll-out of CFAR as an international standard, which was published in 1998 as CPFR voluntary guidelines and followed by CPFR Technical Specification in 1999. At first CPFR was a 9 data flow process. CPFR was seen by VICS [1999] as a "platform- and vendor independent environment, where multiple parties can operate". "Partners of different sizes

and technical levels can collaborate through accessible technologies, including Internet, and the Web, private Value Added Networks, or transport networks".

Since 2005 VICS describe CPFR as a model that exists of four levels encompassing eight collaborative tasks. CPFR is a licensed tool managed and registered by VICS [Overview May 2004]. Following Prasad [2002] CPFR was initiated to reduce inventory and save on organization of material distribution (time to consumer). However, the projected benefits were not realized due to badly shared information between suppliers and retailers. Induced by lack of visibility replenishment programmes were not realized. CPFR could be disruptive to traditional business paradigms. For instance, collaborative networks such as virtual enterprises [Worst 2009] adopt according to their definition the CPFR-model. Of utmost importance for individual partners is to overcome a cultural lack and ICT time-lag. CPFR is according to Prasad adopted in varying degrees by other industries, although it is assumed best working in consumer good's industries. The following matrix diagram (figure 1) indicates the relation between efficiency and effectiveness when opting to arrive at CPFR level..

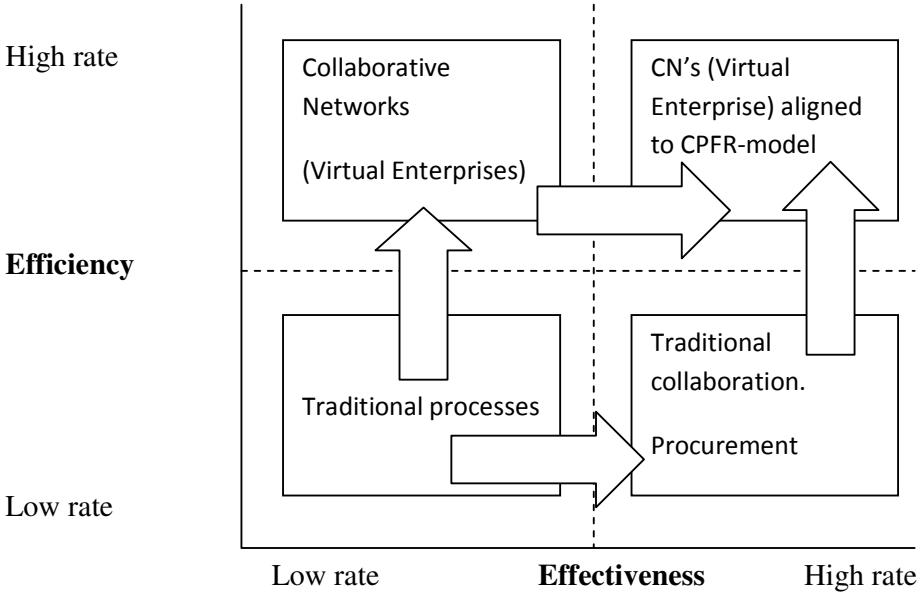

Figure 1: Matrix diagram indicating arrival at CPFR-level.

Arrival at CPFR level is possible by opting for collaborative networks encompassing the CPFR-model, or breaking with traditional procurement policies. Investors, architects, engineers and contracting engineers have an agreement containing: (1) a joint project focused business plan, (2) forecasting objects'exploitation, (3) planning of design, (4) engineering, and construction, (5) delivery plan, (6) guarantee and maintenance, (7) construction monitoring and (8) performance assessment. By developing and implementation of exception management as part of performance management, strengths and weaknesses of the partnership are identified. Following the previous steps, efficiency will be enhanced, because the process is based on transparent and synchronized operations supported by WorkFlowManagementSystems (WFMS). A common catalog eliminates inconsistencies in trading partners and product/service identifiers. CFPR, when aligned to web-based services offers an opportunity to a synchronized process. Effectiveness will increase due to transparency to all trading partners including design and engineering. In fact, it is a meta-

market focused business model, which increase capacity and clear product and service identifiers to all partners. Access to on line procurement of selected and identified partners. Access to a large community of selected and identified partners. Table 1 point at the benefits of CPFR, when D-E-C integration is involved.

Table 1: Benefits, when opting for CPFR to support D-E-C integration

Participant:	**Product demand:**	**Economic:**	**Process:**
Investor/Buyer	Clear point of buying. Clear point for rental.	One price; Fixed DBMOT guarantee.	Synchronized. WFMS.
Architect/Engineer	Clear objective. Approved theme.	Identified products and services.	Synchronized. WFMS
Suppliers	Clear specifications.	Stable work flow. Stable cost-benefit.	Synchronized. WFMS

Looking at the three basic factors [Worst, 2009; pp. 17 to 29] of collaborative networks tables 2, 3 and 4 indicate general strengths and weaknesses. Although the opportunities (including strengths and weaknesses) of the supply chain are known, integration of design, engineering and construction is only possible, when an agreement on collaboration is created and interfaces between all participants are submitted to Service Oriented Architecture (SOA) aligned to web-based services.

Table 2: Economic factors in the context of domestic economic situation.

Economic factors.	Western Europe	Eastern and Mediterranean Europe	USA	BRIC	Developing Countries
Enlargement of capacity on Skilled Labor Force	Domestically diminishing enforced by East European labor force.	Domestically diminishing, because of high payment in Western Europe.	Travelling labor force over the continent.	Training and import from abroad.	Not available. Training programmes are required.
Enlargement of manufacturing capacity on prefabricated elements.	Limited capacity regionally controlled by MNE's.	Limited capacity controlled by domestic suppliers and MNE's.	Limited and controlled by large firms such as MNE's.	Limited and controlled by domestic suppliers.	Small, traditional and domestic.
Doubling of Equipment capacity	Limited and controlled by large suppliers.	Limited and controlled by large suppliers and MNE's.	Limited and controlled by (MNE's)large suppliers.	Limited and controlled by large suppliers.	Import.
Enlargement of Building materials' resources.	Resources controlled by large suppliers.	Resources controlled by large suppliers and MNE's.	Resources controlled by (MNE's)large suppliers.	Resources controlled by domestic suppliers.	Domestic and import.
Double capacity of web-based services.	Partially explored.	Partially explored.	Partially explored.	Partially explored.	Partially explored.

Double D & E capacity.	Export of methods and knowledge.	Domestic plus import.	Architects are often leading consultants.	Domestic plus import of leading consultants.	Import of methods and knowledge.
Double Financial capacity.	PFI and PPP require solvent partners.	PFI and PPP require solvent partners.	PFI in cooperation with private sponsors.	Private, PPP and FDI	FDI
Increased transparency	Tenders on Capacity and Concessions.	Tenders on Capacity and Concessions	Tenders and concessions.	Tenders and concessions.	Tenders and concessions.

Table 3: **Social factors in the context of domestic situation**.

Social factors	Western Europe	Eastern and Mediterranean Europe	USA	BRIC	Developing Countries
PPP and PFI's	Political instruments.	Cutting budgets?	Cutting budgets is necessary	Economic growth offers budget growth	Depend on FDI initiatives
Cross cultures	Industrialized states.	Partly industrialized.	Multi-cultural	Industrializing.	Natural resources.
Responsibility and Accountability	Accept PFI's and PPP's	Proper use of PPP's and PFI's	Private funding	PPP and FDI instrument	UN i.c.w. FDI
Reinforce Equity	Current low profit margin.	Current low profit margin.	Current low profit margin.	Economic growth boosts local margins.	No margin to realize trade-offs.
Social security	Pension plans burden.	Pension plans burden.	Health care insurance.	New regulation required.	No insurance.

Table 4: Environmental aspects in the context of domestic situation.

Environmental factors	Western Europe	Eastern and Mediterranean Europe	USA	BRIC	Developing Countries
Stable Natural resources	Import by MNE's	Import by MNE's	Controlled by MNE's.	Domestically controlled	Controlled through FDI
Pollution	Kyoto	Kyoto	Non Kyoto	Kyoto?	Kyoto?
Ecosystems and sustainability	EU regulation?	EU regulation?	Dispersed regulation?	Dispersed regulation?	Regulation at all?
Collaborative Logistics	Civil law is different between domestic markets.	Civil law is different between domestic markets.	Civil law is different between states.	Civil law is not equal to Western Europe.	Civil law is often absent.

CN's are confronted with legal and cultural constraints. Therefore CN's could be of importance, when investors initiate new projects and are operating on different domestic

markets submitted to different regulation and business culture. The tables 2, 3 and 4 indicate also aspects, that influence not only design, engineering, and construction, but investment, marketing, procurement and financial engineering too.

Crucial in communication between partners is the intention and rationale of architecture. Electronic-concurrent engineering [Mesquita et al. 2002] provides a solution to cope with information sharing to arrive at integration of design, engineering and construction. In line with Love [1997] Mesquita et al. mention the fundamentals of concurrent engineering such as multidisciplinary teams and execution of concurrent product development during different stages of the process. It affects integration of roles of different players during the process. By briefing [Caballero, 2001] of all partners during the design stage, it is possible to initiate a creative learning, which affects interfaces such as: client - architect; client – engineers; architect – engineers; engineers – suppliers; and engineers - contractors. Poor adoption of concurrent engineering by participants of collaborative networks in the construction industry is one reason for low correlation between firms' strategy and operational management (see attachment). Low correlation occurs, because the engineers use communication technology in a unstructured way and without any ranking of data and relationship with workflow management systems (WFMS). To all partners involved in the supply chain adjusting information is crucial (see attachment).

How do you transmit information in the form of single data, meta-data and documents? Not only during the kick-off of a project, but during the whole process. Considering the fragmentation of the industry Caballero et al. [2001] defined an information model, which is similar to portal models supported by web-EDI.

Strategy focused on entrance of CN's is informal, but when aligned to CPFR formally guided. According to Menardi [2010] strategies became relatively formal since the 1960's for two reasons: "(1) The increasing amount of available data on business costs and operational performance; and (2) The uncertainty and anxiety that available data cause. No company could be sure it went on top." Actually, analysis has a retrospective effect and not a pro-active. So the insights of successful strategies are not known. Since the 19-nineties strategy of construction firms [Worst, 2001] was based on acquisition to reinforce construction capacity and being best cost provider.

ICT Strategy focused on replacement of existing system architectures was low. However, according to the Economist (issue dated 18th March 2011) firms have to focus on vertical integration, which means integration of IT hardware, operating systems and applications such as ERP aligned to web-based services aligned to SOA, and applications. In particular computer giants such as Dell and HP are currently competing on the previous mentioned vertical integration due to the overwhelming success of Apple's iPad.

Business strategy, when aligned to collaboration, has no significant correlation with connectivity through the web. Following Worst [2009] the reason is and was that top management considers investments in web-based solutions not in line with the investments in their ERP environment. The pay-off of investment in a virtual environment takes a long time. Currently the effects of the economic crisis and slow economic growth reinforced thinking about the benefits of collaborative networks.

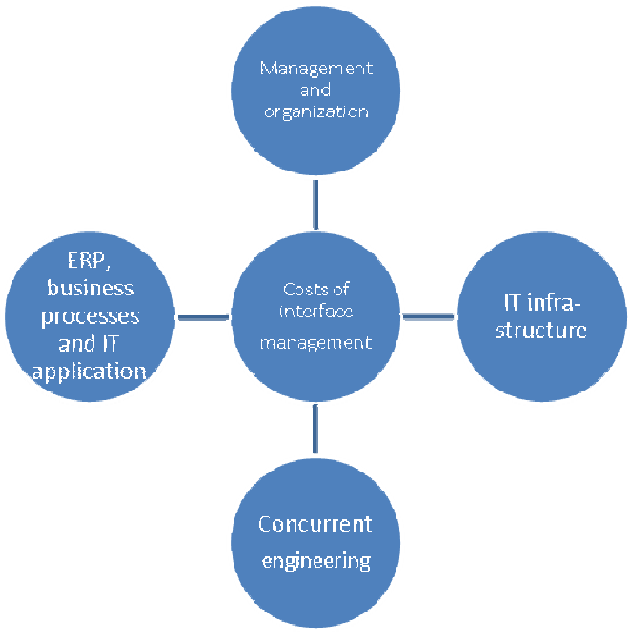

Figure 2: Sustainability and stability considering the cost of controlling interfaces.

Information, communication and integration: Integration of design, engineering and construction will be accelerated, when use of structured exchange of information and communication is organized through use of web-based solutions and SOA. Current development of technology to control interfaces and data exchange, offers support of high quality to systems supporting CN's. It is of utmost importance according to Derksen et al. [2009] to measure the stability of current IT infrastructure, the number of interfaces and the costs of communication and sharing information. Figure 2 indicates costs of interface management given the level of stability between management and organization, business processes, ICT configuration, and acceptance of concurrent engineering. The main question is: What investments need to be made to arrive at a level that firms can fully participate in CPFR driven CN's?

Partners of CN's are considered to be aware of business model stability. So, establishing CN's requires adoption of web-based services aligned to SOA. SOA is also aligned to integration of dispersed installed software such as Planning, CRM, HRCC, Accounting, logistics, and CAD. Firms have to look in the future. In particular to achieve balance (figure 3) between strategy, IT-infrastructure, management and organization and business performance. Partners must be able to respond to CPFR guidelines encompassed in the collaboration agreement next to exception management, which is aligned to performance assessment.

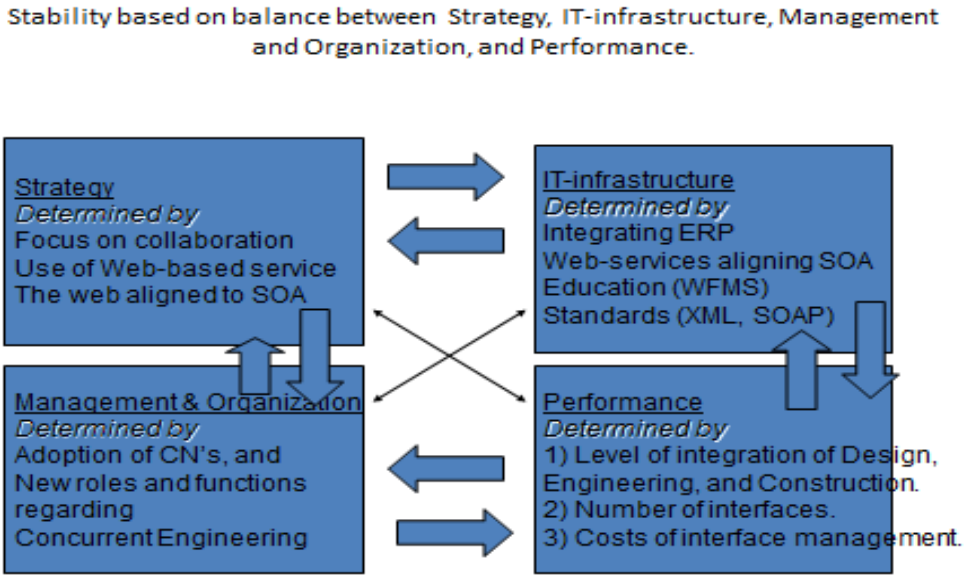

Figure 3: IT Investment focused on balance between strategy, IT-infrastructure, Management & Organization and Performance [source Worst, 2009].

Ontology defining the logical theory of models regarding CN's requires a set of relevant relations. These relations consider aspects of strategy and planning; forecasting; execution; and performance and analysis. Contracts such as BOT; DBOT; DFBOT; DFMBOT and LBC are based on prognosis of project performance and often [Mesquita et al. 2002] subject of incomplete forecasting, because of unbalanced briefing on rationale of design. D-E-C integration of design is subject of research since the 19-sixties. Love et al [1998, 2002] described the barrier between design and construction as an important constraint. Love

suggested cross discipline briefing in the construction industries' supply chain. Not only in the construction vertical (supply chain), but also in the construction horizontal (value chain).

Transparency is required to involve the customer, the user, the investor, contractor, sub-contractors and suppliers in construction supply chain management. To arrive at such point, the following principles are known and set to all partners:

- Synergy due to collocation of economies of scope and economies of scale.
- Openness in sharing information.
- Transparent workflow management systems (WFMS).
- Definition of the layers of communication such as: Chat, telephone call, conference, web-sphere communication, and or web-services?

Using the Internet to reinforce communication between managers requires a stable endogenous business environment when it concerns Web driven Electronic Data Interchange. Exogenous: the quality of the provider, claim of the CN's domain and hosting of web-based service are crucial to arrive at collaboration between client, architect, engineers, suppliers and contractors. As shown in table 5. Structuring collaboration and cooperation starts with alignment of all partners to the intent of design and its rationale. If not, disturbances between partners will occur during the process.

Table 5: Communication and sharing information through use of World Wide Web.

The web	How is openness of entrance to infrastructures and sources?
Provider(s)	Are they offering web-services to support collaborative networks?
Domain	Which domain-owners offer legal solutions to collaborative networks in construction or otherwise?
Hosting	How is hosting organized? By suppliers of web-based services, providers, domain owners?

Ontology: D-E-C integration and the assumption about reduction of cost of failure and low cost of interface management requires a philosophy, or a theoretical model (ontology). In computer science ontology is a technical term for an artifact designed for an objective such as modeling knowledge about a specific business. According to Liu and Özsu [2008] ontology comes from the field of philosophy concerning the study of existence. Their definition is as follows: "ontology defines (specifies) the concepts, relationships, and other distinctions that are relevant for modeling a domain". Osterwalder and Pigneur [2002] base their definition of ontology on four pillars. The first denoted as "product and services", the second as "infrastructure and the network of partners" necessary to create value. The third notation is "relationship capital", which refers to the sustainable contacts with the customer and the fourth refer to "financial aspects" such as cost and revenues. The virtual enterprise is according to its definition [Worst; page 11, 2009] an ontology, which has to fit with all participants' ICT capabilities.

A collaborative network encompassing CPFR aligned to a construction project could be defined as: a legally guided collaboration between legally independent partners in the construction process, to cooperate on shared economic sense, and to coordinate a construction exercise to build a single design, a combination of designs, or a concept using the Internet to

communicate. This definition is broader than the ontology of the virtual enterprise (VE), which was based on coherence between strategies, culture (operational management), information technology and web performance of business models.

Each VE-model has the ability to be adopted by a participant in the construction process. Considering the ideas of Guarino (table 6), conceptualization of CN's has to be seen as a domain of D-E-C integration < I >. Collaboration through guidelines concerning CPFR is related to < P, C >. Given the limits of < P, C > conceptualization of a set of relevant relations affect the current state of affairs encompassing construction industry's fragmentation, and transparency. The engineering artifact is related to the consequences of fragmentation [Caballero, 2001] such as inadequate capture, structuring, prioritization, and implementation of clients' needs. Life-cycle aspects are absent and not subject of collaboration, integration, and coordination. Therefore data about design, engineering, prefabrication and construction of a project are not brought downstream to be readily reused.

Design intent and rationale are according to Caballero et al. [2001] poorly communicated. Such an attitude by all partners involved leads to unwarranted design changes, unnecessary liability claims, and increase of design time and inadequate pre- and post- design specifications. The conclusions about communication flaws during the construction process as shown in the Project Pact report [2004] adjust the conclusion of Caballero et al. Considering the analysis of Guarino [2008] we may in philosophical sense refer to ontology as a particular system accounting for a certain vision on the world. Guarino refers to Gruber [Guarino 2008], who defines ontology as a specification of conceptualization. Table 6 and figure 4 indicate ontology.

Table 6: definition of ontology regarding D-E-C integration (adapted from Guarino 1998)

Category:	Specification:
D-E-C Integration	CN's does not depend on particular relations regarding D-E-C integration.
Artificial Intelligence	Ontology is geared at an engineering artifact. This artifact is constituted by specific CPFR guidelines to describe D-E-C integration.
Relations	Explicit assumptions regarding the intended meaning of the relations, which have the form of a logical theory on managing interfaces.
Intended meaning	Depends on the relations plus the set of assumptions.
CN concepts regarding CPFR driven D-E-C integration.	I is a domain of projects' D-E-C integration C is a set of CPFR guidelines on P D-E-C integration is a concept, which defines domain I structure <P,C>. A domain is collocated with projects (P). Collaboration (C) aligned to integration requires an object and specifications (o); guidelines (g); a synchronized process (s); and a workflow management system (s). So C = {o, g, s, w}.

Ontology [Guarino, 2008] is a logical theory accounting for the intended meaning of a formal CPFR driven relationship, e.g. ontological commitment to D-E-C integration. The intended models of D-E-C integration using CPFR, which are a constraint by its ontological commitment. Ontology indirectly reflects CPFR and the underlying conceptualization by approximating these intended models. In figure 4 the intended models are restricted to formal definition of ontology. O is a prediction within limits of D-E-C integration.

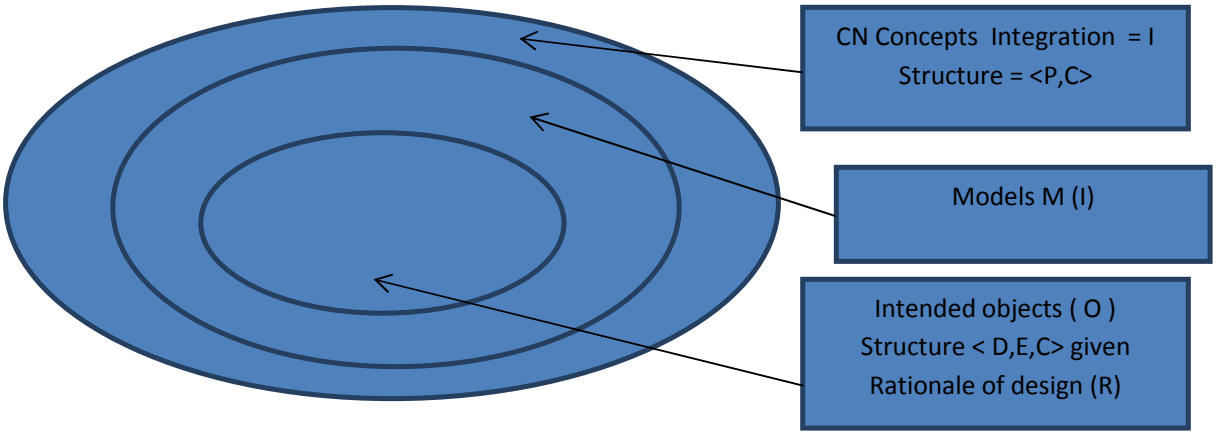

Figure 4 indicates the definition adapted from Guarino [2008]

Regarding business intelligence (BI) there is a lag. According to van Beek [2010] the BI lag increases, because of increasing availability of data and reduction of time to evaluate stages. Decision making is supposed to be done in a very short time. Complexity and dynamics of the business environment increased during the postindustrial era. Liautaud [2004] mentioned that decisions are made by knowledge workers (e.g. architects, technical and financial engineers) and operators (e.g. foreman and craftsmen). However, currently managers (e.g. project managers and construction site managers) are collecting data in a traditional way and neglect the opportunities CN's offer.

Interpreting Guarino [2008] (table 6) the D-E-C integration points at the following: (1) Traditional business settings are no longer accepted. [Love et al. 2000; Caballero et al. 2001]; (2) All partners agree upon intent and rationale of design and engineering [Caballero et al. 2001]; (3) Web-based services related to SOA are open to all participants of a project; (4) Web-based services are required to integrate individual ERP environments (web parts) containing crucial documents [Worst, 2009] Following the language the domain and its admit table extensions can be defined (see figure 4) to D-E-C integration is a concept, which defines domain I structure <P,C>. A domain is collocated with projects (P). Collaboration (C) aligned to integration requires an object and specifications (o); guidelines (g); a synchronized process (s); and a workflow management system (s). So C = {o, g, s, w}.

The D-E-C integration model M is part of I equal to the domain of the integration language. Notation: M is partly a collection of I. The intended models denoted as building Object (O) structured according to <D,E,C> and the architecture's rationale (R) (I) K = <P,C>. Given the DEC integration it is possible to define the models M(I) and the intended models O given the CPFR concept <C,P> and the architecture's intent and rationale (R).

In particular "exception management" and "performance assessment" are crucial parts of CN's CPFR model. CPFR guidelines encompassed in the CN's agreement, assess integration

of different but coherent disciplines. Given the organization of a project, partners are submitted to collaboration guidelines, a joint business plan, forecasting of user's needs, specific construction elements planning; logistics and task fulfillment, exception management and performance assessment. Table 7 indicates the process identifiers, qualifiers, functions and roles of partners and activities involved in the projects' supply chain.

Table 7: CPFR supporting D-E-C integration

Partners:	**Synchronized process:**	**Role in WFMS:**	**Object:**	**Activities:**
Investor/Buyer	Investment and contract partner of CPFR driven collaborative network.	Final approval.	Property investment.	Point of exploitation. Contracting collaborative network.
Leading consultant engineer.	Selection and identification of partners according to investors' and CPFR driven CN's guidelines.	First approval. Knowledge center. Delivery schedule.	One lump sum according to budget.	Planning delivery schedule, mobilization and controlling workflow management.
Architect	Design and identification of design according to investors' specification(s).	Feasibility, design and final design.	Materialization. Detailing design.	Identification of materialization. Identification of details.
Engineer(s)	Identification of design and engineering according to investors' specification(s) and construction method	Calculations. Construction method.	Construction elements split in construction tasks.	Identification and calculation of construction elements split in construction tasks.
Supplier(s)	Allocation of identified services, products and equipment.	Labor. Materials Equipment	Identified and classified products and services.	Allocation and application of labor, materials and services.

To establish a CN such as a virtual enterprise (an almost real business environment) adopting CPFR requires the fulfillment of:

- Ability to support ICT systems supporting collaborative networks (e.g. Web-EDI).
- Quality and solidity of organization, management and staff. Commitment to intentions and rationale of the investor and architect.
- Trust and Organization of Leadership, which means more leaders and less management. Responsibility and accountability are organized at the lowest level of the networks' organization. Commitment to guidelines of the CPFR-model

- Quality of construction capacity, and technical capacity, when looking at construction methods, engineering methods, and equipment.

Table 8: definition of ontology focused on D-E-C integration aligned to the CPFR model

Category:	Specification:
D-E-C Integration	CN's does not depend on particular D-E-C integration. Every partner could enter with own ERP and ICT environment.
Artificial Intelligence	Ontology refers to an engineering artifact. This artifact is constituted by CPFR to describe a certain reality. For instance virtual collaboration.
Relations	Explicit assumptions regarding the intended meaning of CPFR, which have the form of a logical theory. Intensions and rationale of architecture are the main determinants for trust and cooperation.
Intended meaning	Depends on CPFR plus the set of assumptions.
CN concepts regarding D-E-C integration.	I is a domain of projects' D-E-C integration C is a set of CPFR guidelines on P D-E-C integration is a concept, which defines domain I structure <P,C>.
Domain space	I is a set of maximal states of success considering CPFR. I is formulated according to table 7 and aligned to CN's.
Ontology [Guarino, 2008] (CN concepts) regarding integration of design, engineering and construction committed to CPFR, which is aligned to Collaborative Networks such as virtual enterprises.	Ontology is a logical theory accounting for the intended meaning of a formal CN, e.g. its ontological commitment to a particular CN concept. ***For instance a construction project.*** The intended models of collaboration using such a CN concept are constraint by its ontological commitment: ***CPFR guidelines.*** Ontology indirectly reflects this commitment (and the underlying conceptualization) by approximating these intended models. ***CPFR guidelines aligned to CN's.***

Conclusion: Ontology concerning D-E-C integration is crucial to cope with interfaces and CPFR adoption. Especially, when it concerns CN's aligned to a joint business plan and ICT guidelines. According to Guarino and Gruber [2008] this leads to ontology driven information systems. It is not an accidental type casting indicating the result of familiar activities, which are crucial when adopting interdisciplinary activities. In fact, it is an engineering artifact focused on managing interfaces in the context of D-E-C integration and structured by CPFR-model guidelines. An artifact using D-E-C integration to describe CN's given the reality of the construction industry's horizontal (value chain) and the construction industry's vertical (supply chain). The intended model represents the CN aligned to the CPFR principles shown in table 9.

Table 9 The intended CPFR-model determinants for construction projects

1. Strategy and planning focused on D-E-C Integration.	• Collaboration • Joint business plan per project
2. Forecasting	• End user's needs • Specific planning
3. Execution (Planning)	• Planning logistics and construction tasks • Planning construction tasks and segments
4. Performance and Analysis	• Execution Management • Performance Assessment

The construction industry has to deal with specific IT hardware configurations, information systems and development of CPFR aligned to web-based services (Web-EDI). According to Guarino [2008] building ontology's will help to shorten development time and building a CPFR web-based service open for CN's focused on D-E-C integration. Ontology enables reducing the number of interfaces and shorting run time of virtual project analysis. Although ontology is based on theory it will contribute to focused strategy and planning, forecasting, execution (planning) and performance assessment linked to exception management. CN's aligned to CPFR represent promising business paradigms to cope with the current turbulence on markets. Considering D-E-C integration, collaborative networks encompass opportunities like enlargement of capacity, cost effectiveness, avoidance of doubles, and cost reduction on interface management. Collaborative networks (CN's) adopting CPFR and aligned to D-E-C integration indicate total integrated transfers of total spatial solutions identified according to investors' specifications. They provide the best back-up of contracts encompassing offers meeting the "cost of ownership" standard e.g. LBC contracts. CN's aligned to CPFR modeling underpin synergy between "economies of scope" and "economies of scale". Collaboration means cooperation with identified partners. Fully deployed exception management supports performance assessment and contributes to sustainable and competitive collaborative networks.

CPFR indicates working according to strict collaborative guidelines and joint business plans. Supply chain management (SCM) is focused on forecasting "time to market" and "time to volume" set by guidelines to all partners involved in the construction process. In current practice often deployed as Continuous Process Monitoring. Strategy and planning of the CN's containing design, engineering and construction are clearly focused on the investor and user. Logistics and the building process are submitted to fulfillment of the contract.

Participation in CN's provide an opportunity to start a new economic life cycle. The adoption of Internet and alignment to web-based solutions indicate speed in work flow management and exchange of information. Participants such as architects, engineers, contractors, suppliers and subcontractors submitted to CPFR driven D-E-C integration have to accept new roles. In particular when ontology regarding a CN's domain and its interfaces aligned to CPFR guidelines is involved in construction supply chain management.

Model test concerning 125 W-E firms with a strong domestic market and web orientation.
Given the ECVI of 0.630 this model is stable, which indicates a perfect fit.

Table: The covariance relationship matrix of model

Constructs:		**Strategy**	**Culture**	**Technology**	**Performance**
Strategy	Nature of numbers:	1			
Culture	Correlation/Covariance coefficient	0.15	1		
Technology	Correlation/Covariance coefficient	0.07	0.642	1	
Performance	Correlation/Covariance coefficient	0.488	0.631	0.893	1

Strategy is determined by the investments in ICT enabling the adoption of web-based solutions. Strategy is very poorly correlated with Technology and Culture. Culture is based on gaining a strong domestic market position, and adoption of concurrent engineering. The correlation (table) between culture and technology is moderate. Performance is determined by familiarity with web-based solutions and the adoption of e-business. The correlation between performance and strategy is poor, which is moderate for the correlation between performance and culture. Technology is correlated with performance.

Model represents a strong domestic market position and a focus on e-business.

Fit indicators	**Model**	**Values**	**Fit**
N	108	> CN 134.25	Close to fit
Df	14		
Chi-square	23.358	Small	Excellent fit
Chi-square/Df	1,7	- < 2	Excellent fit
P	0.0547	> 0.05	Perfect fit
GFI	0.991	Close to perfect > 0.95	Perfect fit
AGFI	0.978	0.9 – 1	Good fit
PGFI	0.386	0 – 1 Sensitive to model size	Moderate fit
CFI	0.995	0.9 – 1 almost perfect	Perfect fit
NFI	0.988	0.9 – 1	Perfect fit
RMSEA	0.185	Poor > 0.1	Poor fit
RMR	0.124	Close to fit 0.1	Close to fit

Hypotheses testing of Model

Hypotheses	The chi-square indicates excellent fit. The GFI; AGFI; NFI, and PGFI indicate an almost perfect fit.
Hypothesis 1 General Contractors' and project related participants' business strategies are positively related to the e-business setting of virtual enterprises.	The hypothesis is true
Hypothesis 2 General Contractors' and project related participants' business culture is positively related to the e-business setting of virtual enterprises.	The hypothesis is true
Hypothesis 3 Contractors' and project related participants' adoption of ICT is positively related to the e-business setting of virtual enterprises.	The hypothesis is true

Conclusion

There is a gap between ICT strategy and the current options to arrive at entering virtual enterprises. However, there is distance between operational management and ICT management given the moderate correlation between culture and technology. Strategy is not correlated at all with culture and technology. The model indicates, that D-E-C participants do not opt for a strategy primarily focused on business models adopting web-based solutions. In fact, the power of business intelligence to arrive at virtual collaboration is completely ignored. Sharing information to control the interfaces between participants of the construction process to benefit from efficiency is not an issue.

DEVELOPING AND MARKETING SUSTAINABLE CONSTRUCTION SERVICES

ABSTRACT

Increasing calls for action on addressing the negative impact of human activities on the natural environment have lead to the growth of new markets for sustainable solutions. At a more macro level, the role of construction and marketing in economic development has been well established. In striving towards economic growth, a balance between marketing and construction should be considered to achieve sustainability. Engineering consultancies and other businesses have been developing the provision of 'sustainability services' to a diverse range of sectors including construction, energy and transportation, corporate and others. This has also been stimulated by policies enshrined in governmental legislation. Market growth in developed countries such as the UK and Singapore has been fast due to the implementation of more stringent regulations. This paper considers how the principles and practice of marketing may be applied to the promotion of sustainability services offered by engineering and construction consultancies and contractors. It will also consider the constraints and barriers, together with the opportunities for sustainability service markets in developed and developing countries.

Keywords: sustainability, services, marketing, construction, economic development

INTRODUCTION

This paper will set out to define sustainability and the development of markets and services associated with sustainable construction. It will consider the applicability of services

marketing, in particular "green" marketing, to the promotion of sustainability services by consultants and contractors in the built environment sectors.

Awareness of the importance of sustainable development has been growing around the globe for the last few decades. 'Agenda 21', the closing document of the UN 'Earth Summit' in 1992 in Rio de Janerio , the Kyoto protocol for reduction in greenhouse gas emissions, and many other international and national initiatives show the growing concern for protecting the environment for the future generations by introducing sustainable development concepts (Parkin, 2000). Recently, nearly 100 world leaders accepted UN Secretary-General Ban Ki-moon's invitation to participate in an historic Summit on Climate Change to mobilize political will and strengthen momentum for a fair, effective, and ambitious climate deal in Copenhagen in December 2009.

There are many definitions for sustainable development. The World Commission on Environment and Development (WCED) has defined sustainable development as development which meets the needs of the present without compromising the ability of future generation to meet their own needs (Bourdeau, 2000).

The construction industry has a huge contribution to fulfill our quality of life. Construction, building materials and associated professional services together account for some 10% of Gross Domestic Product and provide employment for around 1.5 million people (Raynsford, 2000). Buildings and structures change the nature, function, and appearance of cities, towns and rural areas.

Building has a significant impact on the environment, accounting for one-sixth of the world fresh water, one-quarter of the wood harvest and two-fifth of its material and energy flows (Gottfried, 1996). All the resources are needed to create, operate, and replenish, so to remain competitive and continue to expand and produce profits in the future, the built environment sectors must address the environmental and economic consequences of its actions. Moreover, that recognition is leading to changes in the way the building and building owners/developers approach the design, construction, and operation of the structures which is seen as implementing sustainable construction.

According to Sage (1998), sustainable development refers to fulfill the needs through the improvement of environment, social, economics, culture and technological.

Other researchers define sustainable development, through different perspectives. According to Chaharbaghi and Willis, (1999), every single professional they have their own perspectives of sustainable development such as politicians define as sustainable development a rhetorical device, environmentalists define sustainable development as avoiding a catastrophe, and technologists define sustainable development as a problem they can solve and others.

By referring to Malik et al. (2002), the Department of Environment, Transport and Regions (DETR) argue that sustainable development is all about ensuring a better quality of life for everyone, now and for generation to come through social progress that recognizes the needs of everyone, effective protection of the environment, prudent use of natural resources and maintenance the level of economics and employment.

Sustainable development comprises the three broad themes of social, environmental, and economic accountability. According to Malik et al. (2002) these themes were called 'triple bottom line'. The summary of this themes are outlined in Table 1.

***Table 1**: Themes of Sustainable Development*

Theme	Social	Environmental	Economic
Sub-theme	Equity Community	Global Local and site Internal	Constructions Materials Infrastructure
Issues	Poverty Minorities Inner cities Transport Communications	Climate changes Resources Construction Internal environments Wildlife	Profitability Employment Productivity Transport and Utilities Building stock values

Sustainable is an opportunity to use natural resources efficiently while creating healthier buildings that improve human health, build a better environment and provide cost savings. A green building is a structure that is designed, built, renovated, operated, or reuse in an ecological and resources efficient manner. Green buildings are designed to meet certain objectives such as protecting occupant health, improving employee productivity, using energy, water and other resources more efficiently and reducing the overall impact to the environment (Aysin Sev,2000).

Sustainable Construction

Sustainable construction has different approaches and different priorities in various countries. Some of them identify economic, social and cultural aspects as part of their sustainable construction framework, but it is raised as a major issue only in a few countries (Md Zin Dang Anom, 1998).

According to Charles J. Kibert, sustainable construction could be best defined as the creation and responsible management of a healthy built environment based on resource efficiency and ecological principles (Malik et al., 2002). Sustainable construction is generally used to describe the application of sustainable development to the construction industry. Therefore, sustainable construction also is describe as a subset of sustainable development, which includes design, tendering, site planning, and organization, material selection, recycling, and waste minimization (Langston and Ding, 2001).

There are six main principles for sustainable construction, presented by Charles J. Kibert, University of Florida (Y. Miyatake, 1996). The principles are:

i. Minimization of resource consumption
ii. Maximization of resource reuse

iii. Use renewable and recyclable resources
iv. Protect the natural environment
v. Create a healthy and non-toxic environment

Pursue quality in creating the built environment

APPLYING MARKETING AND "GREEN MARKETING PRINCIPLES

Marketing means different things to different people. Typically, people perceive marketing as advertising, which is only a part of the marketing activities. Marketing is also frequently simplified to selling. Marketing is also adversely associated with such distorted phrases as 'marketing tricks' and 'marketing ploys'. In the field of marketing, however, marketing is seen as a business function, an orientation, and business philosophy.

According to Drucker (1968), the fundamental purpose of business is 'to create customers'. This provides first piece of evidence that marketing is concerned with customer orientation. Furthermore, Drucker (1968) believed that marketing is the basic function of any business. He stated that 'because it is its purpose to create a customer, any business enterprise has two – and only these two – basic functions: marketing and innovation' (Drucker, 1968). Additionally, he maintained that marketing aims to satisfy the needs of today's customers whereas innovation aims to satisfy the needs of tomorrow's customers (citied by Rickards, 1999). This concept of 'marketing as a business function' is important because it demonstrates the importance of marketing in any business environment.

Kotler (2003) has classified his definition of marketing into two categories, as social and managerial definitions. For a social definition, marketing is the societal process by which individuals and groups obtain what their wants through marketing activities. A managerial definition, on the other hand, places the emphasis on marketing as a business function, a concept or business philosophy that governs the direction of any business. The concepts of 'marketing as customer orientation' and 'marketing as business function' are important because they shape the perceptions of academics in interpreting marketing. Recent marketing literature has been focusing on marketing as customer orientation, and some sources offer broader viewpoints by suggesting competitor orientation and interfunctional coordination (Narver and Slater, 1990).

Marketing scholars acknowledge that service is a special kind of offering in business environment. Service is 'intangible' and 'variable' (Baker, 1996; Jobber, 2001; Kotler *et al.* 1999; Kotler, 2003). Such service as consulting has a few tangible elements. Therefore it brings difficulties to service providers to display or demonstrate what kind of service is being offered. At the same time, it is also difficult for customers to measure the standard or quality of the service before buying (Baker, 1996; Jobber, 2001; Kotler *et al.* 1999; Kotler, 2003). On the other hand, because of its variable nature, it is difficult to standardize the quality of service delivery. Because of this, it requires extra care and attention in formulating strategic marketing activities for service industry.

Furthermore, according to Donelly and George (1981), services marketing is marketing based on relationship and value. It may be used to market a service or a product. Marketing a service-base business is different from marketing a goods-base business. There are several major differences, including:

i. The buyer purchases are intangible
ii. The service may be based on the reputation of a single person
iii. It's more difficult to compare the quality of similar services
iv. The buyer cannot return the service

The major difference in the education of services marketing versus regular marketing is that apart from the traditional "4 P's," Product, Price, Place, Promotion, there are three additional "P's" consisting of People, Physical evidence, and Process (Donelly and George, 1981). Service Marketing has been relatively gaining ground in the overall spectrum of educational marketing as developed economies move farther away from industrial importance to service oriented economies.

Green Marketing

Green marketing is defined as"The process of selling products and/or services based on their environmental benefits" (http://sbinfocanada.about.com).

"Green marketing incorporates a broad range of activities, including product modification, changes to the production process, packaging changes, as well as modifying advertising" (Polonsky, 1994).

The American Marketing Association (2010) defined the green marketing as: The marketing of products that are presumed to be environmentally safe. This definition has three key components:

- It is a subset of the overall marketing activity;
- It examines both the positive and negative activities; and
- A narrow range of environmental issues are examined. It ensures that the interests of the organization and all its consumers are protected, as voluntary exchange will not take place unless both the buyer and seller mutually benefit.

As the above definitions illustrate, green marketing encompasses a broad range of activities from product design to writing advertising copy. It is increasingly important because consumers are paying more attention to a product's or service's sustainability features as well as the practices of the provider organization.

Nowadays, a concept of "green marketing" is becoming more and more popular. Li and Cai (2008) mentioned that, it began in Europe in the early 1980s when specific products were identified as being harmful to the earth's atmosphere. Terms like Phosphate Free, Recyclable, Refillable, Ozone Friendly, and environmentally friendly are some of the things consumers most often associate with green marketing. While these terms are green marketing claims, in general green marketing is a much broader concept, one that can be applied to consumer goods, industrial goods and even services. For example, around the world there are resorts that are beginning to promote themselves as "ecotourism" facilities, i.e., facilities that "specialize" in experiencing nature or operating in a fashion that minimizes their environmental impact. Thus green marketing incorporates a broad range of activities, including product modification, changes to the production process, packaging changes, as well as modifying advertising.

Mankind has unlimited wants while limited recourses on the earth. Green marketing looks at how marketing activities utilize these limited resources, while satisfying consumers wants, both of individuals and industry, as well as achieving the selling organization's objectives.

SUSTAINABLE CONSTRUCTION AND MARKETING IN ECONOMIC DEVELOPMENT

The role of construction in economic development has already been well established for many years. The relationship between construction and economic development is especially crucial in the developing countries where infrastructures and buildings play an important role for economic growth. The construction industry is also an important sector in the developed countries even though the rates of growth of the construction industry in the developed countries might be less than those of the developing countries following the formative years of the former (Turin, 1978; Edmonds, 1979; Drewer, 1980; Ofori, 1990; Low and Leong, 1992; Hillebrandt, 2000).

The role of marketing in economic development has likewise been well established for many years. As far back as the 1950s, Drucker (1958) urged that attention should be paid to marketing for countries to achieve economic growth. Marketing inputs at both the domestic and international platforms were seen to contribute to economic development (Dixon, 1981; Cundiff and Hilger, 1982; Etemad, 1984; Kaynak, 1986; Kaynak and Hudanah, 1987). In this context, marketing has been defined as the management function of identifying, anticipating and satisfying client needs at a profit (Kotler, 1967, 1988).

Given that both construction and marketing played their respective role in economic development, it is therefore necessary to ensure that both sectors provide balanced inputs into economic growth plans. Too much of construction inputs at a time when marketing is still lagging behind, can lead to white elephants and under-utilized infrastructural facilities (i.e. over-build). Similarly, when marketing is actively in place, construction must provide adequate infrastructural support to avoid transportation gridlocks and logistical potholes (i.e. under-build). The need to balance both construction and marketing was highlighted by Low (1995) for global economic development.

The macroeconomic views of construction and marketing were presented above. The construction industry has contributed to global climate change because of the massive carbon emissions generated by processes in the industry (Wu and Low, 2010). There is now an urgent need for the construction industry to move towards more sustainable practices. Fundamentally, there are two ways to accomplish this: (a) through cutting-edge technology and (b) better management. Adopting new and appropriate technology (such as renewable building materials and photovoltaic cells in buildings) can be effective but may turn out to be very expensive for the sustainability agenda. Effective management of the building process is seen as a better alternative because it is able to prescribe a less costly solution towards sustainable construction (Low, 2009). In so far as management is concerned, marketing has a significant role to play in that as a business function, marketing helps to identify, anticipate and satisfy client needs at a profit (Kotler, 1967). Hence, just as in the macroeconomic phenomenon described above, there should likewise be a balance approach to matching construction with good sustainable practices through the marketing function.

Sustainability Markets and Development of Services

As the global environmental agenda gathered pace through the 1980s and 1990s, new markets emerged to address the demand for more sustainable solutions. Developed nations in particular experienced a rapid growth in 'sustainability services' aimed primarily at the construction, housing, transportation and corporate sectors. Supported by policies and directives enshrined in governmental legislation, the construction sector has increasingly sought specialist services to ensure acceptable levels of sustainability and achieve governmental standards and targets for performance.

The development of sustainability services in the UK is an example of the rapid growth in this market. The rise of environmental and sustainability discourses during the 1990s and 2000s had a profound and unprecedented impact on the UK construction sector. Whilst ecology and energy related policies have been a part of UK policy for a number of years, this period was characterised by a mushrooming of sustainability policies and increasingly more stringent technical and planning requirements for new developments. National, regional and local planning legislation have placed unprecedented levels of sustainability criteria on all stakeholders involved in construction, covering a variety of issues which include environmental impact of materials, water usage, and on-site waste generation during construction.

To meet these requirements and examine the full spectrum of options for sustainability, property developers working in the construction sector have turned to professional firms to fill the knowledge gap; these include specialist sustainability firms, architects and multi disciplinary engineering companies of various sizes. As a result, the market for sustainability services in the UK has become a competitive and tightly fought arena with companies vying for private and public sector contracts, in the UK as well as overseas (Verdantix, 2010).

The growth of the sustainability market has not been homogenous across the world. Developed countries have tended to enforce more stringent sustainability policies and mechanisms which has stimulated a demand for sustainability services. Specific knowledge and skills of the different technical and non-technical aspects of sustainability performance has become relatively wide spread which, in turn, has supported the growth of the market in these countries. In developing countries however, market growth has been significantly slower in response to a focus on the goals of economic development and less extensive awareness and knowledge in this field. In Malaysia, for example, there is not the national or local legislation in place to support high levels of sustainability in the construction sector and, therefore, sustainability efforts in the design and construction of buildings are currently carried out on a voluntary basis. As a consequence, the sustainability market has not developed at the same pace as a developed country and is unlikely to until there is greater commitment from government in terms of legislation and an appropriate supporting knowledge economy.

Marketing Sustainable Construction Consultancy Services

We live in a marketing-driven, if not marketing-dominated world. Sustainable construction has to be sold along with everything else. Marketing helps a firm develop a platform for telling others about its achievements. The sustainable construction phenomenon is no longer a fad; it's a full-fledged revolution. According to Yudelson (2008) between early 2000 and late 2007, the number of green buildings has grown from a handful to more than 8,000 actively seeking LEED certification. Lots of people already know this, and they want to

know, “How should design and construction firms and professionals profit from this change?”. Marketing sustainable construction is becoming increasingly important and will become a major point of differentiation for all architects, engineers, quantity surveyors and builders. People who take the lessons learned in this sustainability concept and principles seriously will have a major head start on the competition.

There are various ways of developing and marketing sustainable construction, for example:

i. Focus on Capabilities

- Know what the principals and senior level people are doing in the area of sustainable construction and learn what they are hearing about the need and demand for these services among the clients.

ii. Competitors

- Know the strengths and weaknesses of the competition in this area of design and construction, so that we will be prepared.

iii. Differentiate services

- The major focus of sustainable construction marketing has to be some form of service differentiation. Make sure clients know how the firms can approach the project differently from major competitors by showcasing the team design tools and understanding of sustainable construction.

iv. People

- The firm needs to realize that there is a huge commitment required to training and education, as well as to acquire specialized expertise and tools, to compete effectively in the sustainable construction and green building marketplace.

v. Publish results and press

- Tell the story aggressively to as many media outlets as we can. Successful sustainable construction projects are still rare enough in this country. This is one of the main vehicles for new clients to become aware of the firms.

vi. Membership and event activities

- Membership “has its privileges”, to borrow a phrase. The consultant and construction firms in Malaysia can join Green Building Index or Malaysian Green Building Confederation for example, and use their logos on proposals, stationery and brochures. It is probably the best investment a firm can make to establish credibility with clients.

vii. Narrow the focus

- Last but not least, narrow the focus. Not every client is a candidate goes green marketing at this time. Not every client wants to be the "first kid on the block" or to be a technology leader. Therefore, focus most of the marketing efforts on the more adventurous owners, the innovators and the environmentalist clients.

CONCLUSION AND RECOMENDATIONS

As the economic benefits of green and energy-efficient buildings become apparent to more developers and builders, the demand for advice and consulting on technologies and processes is skyrocketing among developers and builders large and small. That is a great business opportunity for entrepreneurs and job seekers with expertise in green architecture, design, and engineering. There will be demand for firms and individuals with expertise in very specific areas, such as the latest window glazing, solar roof system and rainwater harvesting, as well as those skilled in green building project management and accountability. As the sustainability agenda gained momentum through the 1990s, new markets emerged to satisfy the requirement for sustainable solutions in the built environment. However, the growth of sustainability services has been characterised by a distinct global unevenness; relative economic prosperity in the developed world has afforded market and policy expansion whilst developing countries have been unable to prioritise sustainability in the same way.

As demonstrated in the paper and reflective of the global trend more generally, the sustainability market in the built environment sector is experiencing a continuing growth. Based on the evolution of sustainability services, opportunities globally and in particular in developing countries can be identified and include improved policy instruments, capacity building, and public awareness.

Change is inevitable, and should the markets in developing countries follow the trends observed in the developed countries, sustainability in the built environment will become a more mainstream part of the business. Therefore, currently the built environment sector in emerging economies offers a unique opportunity for businesses to invest and develop sustainability services while this part of the marketplace is still at its infancy. Companies focusing on capacity building and development of skills and expertise in sustainability will benefit when policy implementation and enforcement follows the resulting government commitments. The same companies will benefit from a strong Corporate Social Responsibility commitment, enhanced public image and increased recruitment opportunities. By investing in sustainability services now, the construction business has the potential to enjoy the benefits of being a market leader in the future.

The global construction sector would benefit from more detailed recommendations on implementation measures to support the growth of the sustainability service market in the built environment. Research on the specific areas suffering the most from shortages of skills and expertise, could assist in prioritising the capacity building and knowledge transfer exercise. Finally, a comparative assessment of the businesses in the global construction sector on the status of their sustainability services is another area where further research is recommended. Such an analysis within the individual sector groups (such as developers, contractors, consultants, engineering and architectural firms) could provide an interesting insight into the sector, identify gaps and business opportunities.

ABSTRACT

The Malaysian construction industry continues to grow, benefiting the country's economy and providing essential infrastructure. However, this thriving industry is responsible for one of the single largest waste streams in the country. This paper focuses on the current status of waste management in the Malaysian construction sector. It builds on existing research and assesses the level of sustainable practices on construction sites in terms of waste management. It is a reflective paper examining the attitudes and reaction of Malaysian contractors towards a more structured approach to on-site sustainable resource and waste management, the "Site Waste Management Plan". The Site Waste Management Plan, is a framework that has been used in Europe and has successfully reduced on-site construction waste generation. The aim of this study is to gauge the industry's appetite and commitment to sustainable waste management and ultimately guide the future development of a framework for the management of construction wastes in Malaysia. A number of semi-structured interviews were conducted with Malaysian contractors, with no previous experience of Site Waste Management Plans. This exercise allowed the researchers to explore the industry's level of awareness and commitment to sustainable waste management, identify current barriers and suggest future recommendations for an implementation strategy.
Keywords: sustainable development, construction waste management, contractors, Malaysia, environment

INTRODUCTION

The construction industry is one of the main contributors towards the development of nations, providing the necessary infrastructure and physical structures for activities such as commerce, services and utilities. The industry generates employment opportunities and

injects money into a nation's economy by creating foreign and local investment opportunities (M. Agung, 2009). However, despite these contributions, the construction industry has also been linked to global warming, environmental pollution and degradation (Jones & Greenwood, 2009).

Construction waste generation and unsustainable use of depleting natural resources as building materials, are also linked to the adverse environmental impacts of the construction industry. Globally, it is estimated that approximately 10 to 30 per cent of wastes disposed off in landfills originates from construction and demolition activities (Fishbein, 1998). In Malaysia, construction waste is one the single largest waste stream and yet despite a number of government policy initiatives to address this issue,, sustainable resource and waste management on site remains a low priority for the majority of the contractors (Begum, 2009).

This study explores the Malaysian contractors' perspective in relation to sustainable resource and waste management and in particular the application of a more structured management framework, based on the "Site Waste Management Plan" (SWMP) approach. The paper examines what appetite there might be for the adoption of SWMP, to explore the industry's level of awareness and commitment to sustainable waste management, to identify current barriers and suggest future recommendations for an implementation strategy. The paper concludes with recommendations for the formulation of a Malaysian SWMP, based on the empirical findings of this investigation.

SUSTAINABLE WASTE MANAGEMENT AND THE MALAYSIAN CONSTRUCTION SECTOR

Sustainable Development and Waste Management in Malaysia

During the second half of the 20th Century, there were increasing calls for action by scientific, political and civil society groups who raised the need to address the negative impact of human activities on the natural environment. The publication of the Brundtland Report in 1987 followed by the Earth Summit in Rio de Janeiro in 1992 helped to establish the concept of 'sustainable development'; an approach to development now supported by a wide spectrum of governments. The concept rests on the notion of 'development that meets the needs of the present without compromising the ability of future generations to meet their own needs' (Brundtland, 1987).

As a developing country aspiring to achieve developed country status by 2020, Malaysia is faced with the challenge of decoupling economic growth and waste generation (National Economic Advisory Council, 2010). Sustainable growth is a central theme of the 10th Malaysia Plan (Economic Planning Unit, 2010) and demonstrates the Government's commitment to sustainable development. In 2005 the "National Strategic Plan for Solid Waste Management" was adopted forming the basis for solid waste management policy and practice in peninsular Malaysia until 2020 and providing the foundation for the subsequent years (United Nations Development Programme, 2008). The Government's efforts to address this pressing issue include the introduction of the Solid Waste and Public Cleansing Management Act 2007, and the establishment of two new federal institutions aiming to implement the country's solid waste management policy, the National Solid Waste Management Department and the Solid Waste Management and Public Cleansing Corporation, the latter being the operational arm.

Solid waste management has been a concern in Malaysia for some time, due to poor management and handling practices which in turn affect the environment as well as the public. Malaysians produce approximately 25,600 tonnes of waste daily, in response to rapid

development and urbanisation (Fazleena Aziz, 2010). Solid wastes are generated from residential, industrial, commercial, institutional, construction and demolition, municipal services and other human processes (UNESCAP, 2009). Only 76 per cent of solid wastes are successfully collected in Malaysia, and only around 5 per cent is recycled, with 95 per cent of collected wastes disposed at the country's 112 landfills (Alam Flora Sdn. Bhd., 2007). According to the Ministry of Housing and Local Government (MHLG), the majority of landfills are at full capacity and operate to old standards with limited leachate and landfill gas control. This is a far reach from the Government's target for 22 per cent waste minimisation and recycling (Nadzri, 2007), 100 per cent separation at source and closure of all historic, unsanitary dump sites by 2020 (Japan International Cooperation Agency, 2006).

It is clear to see that current practice does not reflect waste management policy in place. Factors such as a lack of implementation, weak enforcement, uncertainty over roles and responsibilities amongst governing authorities and limited stakeholder coordination have all contributed towards this disconnect between policy and practice. Furthermore, despite efforts by the MHLG, public awareness of the environment and, more specifically, waste management is low. However, the Malaysian Government recognises that appropriate waste management is essential in achieving sustainable development as highlighted by the Malaysian Government Model (National Economic Advisory Council, 2010).

In terms of general awareness of sustainability in the Malaysian construction and building sector, the launching of a national initiative called the Green Building Index (GBI) and increasing attention towards international sustainability assessment standards, such as Greenmark, LEAD and BREEAM have served to raise awareness of the broader issues associated with sustainability. However, as long as these initiatives remain voluntary and outside of the remit of government legislation, broad scale uptake of sustainability standards across the sector will remain low.

Status of Construction Waste Management in Malaysia

A study from Mohd Nasir et Al., (1998) reported that 28 per of municipal solid waste originates from industrial and construction waste in the central and southern regions of Malaysia. Waste minimization, reuse and recycling practices are limited in the construction sector and natural resources required as building materials are available at relatively low cost (Begun et al 2009). In addition there is no mandatory requirement for construction companies to practice sustainable resource and waste management and illegal dumping is still an issue for the authorities (Begun et al 2009).

In response, the Government formed an agency called the Construction Industry Development Board (CIDB); one of its aims is to transform the industry by improving its environmental performance. In support to national policy, CIDB has reinforced the industry's commitment to sustainable development and an environmentally responsible industry in the "Construction Industry Master Plan" (Construction Industry Development Board, 2007) and is continuing to educate the industry's key players with series of training courses, workshops and awareness raising events. In addition, the introduction of the GBI is providing a framework to design and construct green sustainable buildings and raises awareness within the sector.

In 2009 the Malaysian construction sector reported a 5 per cent productivity growth (Malaysia Productivity Corporation, 2009). On one hand this figure demonstrates the crucial role the Malaysian construction sector can play in contributing towards the Government's commitment to sustainable development. On the other, it supports predictions that construction waste generation rates will continue rising, putting increasing pressure on the already overstretched waste management infrastructure of the country.

In summary, there are number of policies and voluntary initiatives supporting sustainable resource and waste management in the Malaysian construction sector, however the reality remains challenging. The continuous growth of the sector provides an opportunity for a wider uptake of sustainable waste practices, contributing to the country's aspirations for sustainable development.

Site Waste Management Plans

A Site Waste Management Plan (SWMP) provides a framework which can help contractors or project managers to forecast and record the amount and type of construction waste that is likely to be produced in a project, as well as assist in setting up appropriate management actions that reduce the amount of waste that will be sent to landfill (WRAP, 2007). A construction waste management plan aims to improve materials resource efficiency by implementing reuse, recovery and recycling as well as to minimise issues such as illegal dumping by properly documenting waste removal processes (Defra, 2009).

In number of developed countries such as United States, United Kingdom and Australia, construction waste management plans have been gaining popularity as an important tool to minimise the adverse impacts of the construction industry towards not only the environment but also the nations' economies. The plan requires the cooperation between all parties involved in a construction project, including the client, contractor, designer, engineer, sub-contractors, workers and even the suppliers. It is initiated during the project's pre-planning stage and involves activities throughout the duration of the project up to its completion to ensure the waste management plan's effectiveness and efficiency.

In United States, the framework called Leadership in Energy and Environmental Design (LEED) Green Building Rating System is popularly used, which is a set of standards for environmentally sustainable construction incorporating practices for sound waste management into construction activities (LEED, 2004). Construction projects gain points when they adhere to LEED requirements which subsequently secure a certification. Similar frameworks for sustainable buildings and developments include the Building Research Establishment's Environmental Assessment Method (BREEAM) rating system in the UK, the Green Building Index certification (Real Estate and Housing Property Developers' Association Malaysia, 2010) in Malaysia, Green Mark in Singapore, Green Star in Australia and many more. Sustainable resource and waste management features in all of these frameworks, encouraging the adoption of a form of site waste management plan to guide the process from the design to the decommission of the development.

In most countries SWMPs are voluntary. However, in 2008 SWMPs eventually became compulsory for projects in England exceeding £300,000 (BRE, 2009). This move was supported by developing and offering a SWMP template and other related tools such Netwaste and SMARTwaste for designers, engineers, contractors, developers and other professionals in the constructions industry (WRAP,). Guidance and training courses are freely available to aid the industry achieve waste reduction, re-use and recovery, from the procurement, pre-construction and construction phases of a project.

Typically a SWMP will require the project manager to provide basic information about the type, scale and value of the project, identify the responsible persons involved in the stages of the project (principal contractor, engineer, client, designer, person responsible for waste management on site etc), a proposed timescale and programme of works. The Key Performance Indicators (KPIs) for waste minimisation, recycling, materials recovery or waste generation per area unit, or other relevant targets will be agreed during this initial stage. Figure 1 presents a broad outline of a SWMP.

In the next stage, the series of waste prevention, waste reduction, waste management and recovery actions to be taken during the design, procurement and construction will be agreed and recorded by the project team. Following this, the type, source and quantity of waste arisings anticipated from the project are forecasted with the aid of benchmarks for the various types of development (residential, education, health, infrastructure, commercial, retail etc).
Details of the suitably licensed waste carriers and ultimate waste management destinations of waste arisings are recorded to ensure Duty of Care and prevent illegal dumping or other inappropriate handling of wastes. The actual waste arisings, prevention, recovery, recycling and reuse actions are recorded and compared against the forecasts and KPIs to measure performance, adjust and improve the SWMP as required. Training of staff on site is crucial to the success of a SWMP. Monitoring and reporting continues for the duration of the construction project and informs the final project review and recommendations for future improvements.

***Figure 1**: Proposed Outline of SWMP*

Project Stage	**SWMP Actions**
Project Set Up	• Enter project details
Concept Design	• Record waste prevention actions
Detail Design	• Forecast waste • Record waste reduction actions
Pre Construction	• Specify waste carriers • Plan waste destinations • Record waste management and recovery actions
Construction	• Enter actual waste arisings, reduction, recovery and management activities. • Carry out training, monitoring and recording.
Post Construction	• Compare actual against forecast waste management activities • Assess performance based on KPIs • Suggest improvement for next project

Note: Adapted from WRAP Site Waste Management Plan Template version 2.3

METHODOLOGY

The study included a literature review on sustainable development, the effects of human activities on the environment, the solid waste management systems used in Malaysia and their impact to the nation's development and environment. SWMPs from developed countries were reviewed to identify their main elements and how they affect a project for contractors. An outline SWMP was created by simplifying the elements in the site waste management plans from other countries, extracting the perceived best practices and combining them into one proposed framework to be tested in Malaysia.
Seven semi-structured interviews were conducted as part of this research to determine the uptake of any form of SWMPs by Malaysian contractors, the suitability of existing SWMPs in relation to the local environment, and their impact on the actual project and the environment as a whole. According to the literature review carried out, SWMPs are relatively new in Malaysia and levels of awareness and adoption by contractors are low. Therefore, the target sample chosen were eight (8) contractors located around the Kuala Lumpur and Selangor area who have never implemented SWMPs. The selected contractors were seen as a

representation of the Malaysian construction industry which does not have an official system or guidelines for managing construction wastes on site, yet.

The contractors interviewed, were randomly chosen and are considered a convenience sample. The selected companies had different backgrounds and experiences, and are assumed to be reliable samples by the researchers as they will represent different groups in the construction industry. In this research, seven (7) out of the targeted eight (8) contractors located in the Kuala Lumpur and Selangor area were successfully interviewed using exploratory, semi-structured interviews. All chosen contractors were class G-7 companies with extensive experience in civil, infrastructure works and structures for the commercial, industrial and residential uses, among others. Meanwhile, the respondents interviewed were experienced project managers and engineers with extensive involvement in construction projects.

The interviews were conducted to obtain reviews for the outline SWMP produced by the researchers based on literature review. The selected contractors were asked to review and comment on the proposed framework, in particular the perceived benefits to a project and its effectiveness. Contractors were also asked about their awareness of the campaigns made by the Government and Construction Industry Development Board (CIDB) in encouraging contractors to take up a SWMP, and the incentives that can be awarded by the Government to encourage contractors to adopt SWMPs.

There were limitations to this research which could have inadvertently affected the results. Some of the selected firms were unresponsive and unsupportive, therefore making the data for the research incomplete and possibly biased. There were also time limitations to complete the research, thus fewer interviews were conducted than initially planned for. One the main barriers to this study was the low level of awareness amongst Malaysian contractors regarding sustainable resource and waste management and in particular SWMPs. The lack of knowledge about SWMPs made contractors more reluctant to implement any form of a SWMP. Finally, this study was conducted as a preliminary exploratory exercise to gauge the industry's level of awareness and commitment to sustainable waste management, identify current barriers and suggest future recommendations for an implementation strategy. Further investigations would be required to build on the findings of this study.

FINDINGS AND DISCUSSIONS

Specific Findings

From the target sample of eight contractors, seven were successfully interviewed for the purpose of this research. The questions asked to the interviewees were broadly grouped in the following categories: barriers to SWMPs, awareness of environmental impacts, on site sustainable management practices and recommendations for improvements. The following section details the findings from these specific questions before leading into a broader discussion of the implications for sustainable waste management in Malaysia.

Barriers to SWMPs

The interviewees felt that the main factors preventing contractors from using SWMPs in Malaysia are the lack of promotion and encouragement by the Government and CIDB, and the perception that appropriate solid waste management practices reduce contractors' profits. 57 per cent of contractors stated the perceived cost implications of SWMPs as the main reason why they would not implement one, whereas 43 per cent identified the lack of

available information and guidance, incentives and practical tools about SWMPs as the main barrier.

Level of awareness of environment impact of construction waste generation and current waste practices

The majority of the interviewees (85 per cent) were unaware of the adverse impacts of waste to the environment. 6 out of 7 contractors send all of their wastes to landfill or burn them on site illegally, while 1 contractor admitted to disposing construction wastes on site.

Sustainable resource and waste management practices on site

Despite the low levels of environmental awareness and unsustainable waste management activities, there are some examples of sound waste management practices on site.
According to the contractors that were interviewed some waste segregation at source is practiced with the ultimate aim to recycle materials with some value. Waste materials such as scrap metal are separated and stored on site to be sold on to waste recycling companies, while other wastes are mixed together into one container and either sent to landfill, burned or illegally buried on site.
There are some sustainable practices carried out on site by the contractors, such as recycling and re-using of certain materials or using Industrialised Building System (IBS) which reduces the amount of wastes produced on site. None of the interviewed contractors have targets with regards to waste management on site, which shows that contractors still lack knowledge and awareness on encouraging sustainable practices.

Recommendations for improvement

Six of the contractors felt that the Government should promote SWMPs better, while financial incentives such as tax reduction were perceived the best way to increase uptake. Finally, the interviewed contractors felt that they would support the creation of legislation making SWMPs compulsory as it would ensure the success of their projects and allow them to deal with their wastes more responsibly.

Discussion

Based on the contractor interviews, it can be concluded that there is a greater likelihood of adoption of SWMPs by contractors if there is the correct level of encouragement, incentives, promotion and training. The factors preventing contractors from using SWMPs could be eliminated with suitable training, guidance material and awareness raising. Indeed, the main issue preventing the use of construction waste management plans on site relates to the lack of information on both the contractors and CIDB's part. Before any of these parties can develop construction waste plans for the Malaysian construction industry, they must first equip themselves with the knowledge and understanding of the topic. However, given the limitations in the research as well as the small number of samples taken, more data is needed to confirm this assumption.
The interviews reveal that the Malaysian construction sector relies solely on initiatives led by the government bodies and CIDB and is reluctant to invest time and effort to drive change. The UK experience demonstrates that industry driver initiatives are also required to change the face of the industry. Based on the SWMPs developed in other countries, it is evident that the implementation of construction waste management plans is beneficial to contractors in

terms of the promotion of good management practices, reduction of unnecessary wastes on site, cost and time savings and more. CIDB should also take a step towards increasing promotions for construction waste management as part of the industry's need to deliver sustainable practices for the benefit of the society, economy and the environment.

The study also tested the industry's appetite for regulation on sustainable construction waste management, making SWMPs a mandatory requirement. The industry appeared surprisingly positive and supportive for such a measure appreciating the business benefits it could lead to. This response suggests that a the Malaysian government should consider creating regulation on construction waste management which will address the increasing problems caused by excessive development and environmental degradation and create awareness among contractors to implement SWMPs for their projects. By creating legislation on construction waste management, the efforts in promoting recycling, reducing and re-using activities which the Government has been campaigning in the past years would be fully addressed.

The interviewed sample's response to proposed outline SWMP framework was positive. The contractors felt that the proposed waste guideline was comprehensive and encompassed all stages of a construction project. Most of the activities carried out in the guideline were also seen as achievable and beneficial for contractors if properly carried out. Furthermore, the contractors highlighted the need for waste reduction during the design stage, avoiding unnecessary designs and specifying using durable and reusable building materials.

Finally the inadequate waste management infrastructure of the country and current policy lacking coordination were raised as a concern by the Malaysian contractors. The interviewees were aware that suitable and adequate recycling plants and related infrastructure are crucial to ensuring the success of SWMPs. An example of the disjointed policy is the fact that the Public Works Department's authority has yet to certify and accept the use of recycled materials for construction projects. Therefore, currently the lack of relevant infrastructure, supporting policy, legislation and enabling mechanisms make it difficult to promote sustainable activities like recycling in the Malaysian construction industry and limit the number of options for contractors in the implementation of SWMPs.

CONCLUSION

SWMPs provide a useful framework for the sustainable resource and waste management of construction waste, offering environmental, social and financial benefits. The aim of their implementation on site is to increase the resource efficiency of materials through recycling, reusing or recovering products before they are disposed, and reducing environmental problems, such as illegal dumping and open burning (DTI, 2004). There are many proven benefits of construction waste management plans for contractors, such as cost and time savings, increased productivity on site, good corporate social responsibility and the ability to control the quality and ensure the safety of project sites as a result of a clean site environment.

However, despite these benefits construction waste management remains poorly implemented in construction projects in Malaysia, despite some promotion from the Government and CIDB. It is clear that more efforts are required by CIDB and the Government to promote and develop SWMPs into the local construction industry and contribute to the country's aspirations for sustainable growth. Based on the results of this exploratory exercise guidance, practical tools, regulation and incentives are amongst the priorities highlighted by the Malaysian contractors. Construction waste management guidelines such as the one proposed by this research aims to promote sustainable construction practices by contractors in Malaysia to ensure a comprehensive and integrated management of wastes on site.

In terms of further research, studies exploring the practices that can be adopted by the construction industry to promote sustainable development are recommendation. Currently, there is limited if any research investigating behaviour change in the industry that would lead to improved waste management attitudes and practices. Furthermore, the development of a national standard for SWMPs for Malaysia supported and promoted by CIDB would benefit the sector and improve sustainable resource and wasre management of construction waste in the country.

Abstract
Financial and real estate crises and "new ways of working" reduce the need for office space. As a consequence, office markets become replacement markets without a quantitative need for new office buildings: new buildings drive out bad buildings. In the Netherlands, currently 14% of the office space is vacant, of which 60% is redundant or obsolete. Office users, guided by the government, consider sustainable office space important for their image and status. Besides they want to be accommodated in high quality buildings that fit with their current and future need for space, taking into account expected shrinkage or further development and expansion. Quite often, new office developments were the response to these demands. Public opinion and emerging governmental awareness of sustainability oppose the construction of new office buildings in locations with a high vacancy level, while office users, real estate developers and investors crave for new office developments. Can redesign of existing office buildings answer to the demand for new sustainable office space?
In former research we have revealed that location and building characteristics have a strong influence on office users' preferences and decisions to move to other buildings. Knowledge about these characteristics is important when determining the potential future use of the existing office stock. Based on foregoing research, we propose new use of existing office buildings and delve into the measures that need to be taken in order to adapt existing buildings to new use.

Keywords: offices, vacancy, user preferences, sustainability, re-use

INTRODUCTION

After some booming years for the Dutch office market, this market is now characterised by continuous overproduction and oversupply, resulting in an overall national vacancy rate of 14%. What is even more alarming is that 60% of all vacant office space is vacant for three or more years, pointing towards the obsolescence of this office space. Research by Remøy (2010) showed that obsolescence is a result of the current replacement market. Office users move from existing buildings to new developments, leaving buildings behind that are not taken up by the market, because quantitatively there is no new office demand. Vacancy concentrates in buildings with specific physical characteristics. These are buildings in mono-functional office locations or industrial and distribution areas, typically with few facilities and not well accessible by public

transportation, with poor external appearance, poor flexibility and less parking places than surrounding properties. Residential transformation is a way of coping with obsolete office buildings. Former research (Barlow & Gann, 1993, Beauregard, 2005, Heath, 2001, Remøy, 2010, Remøy & Van der Voordt, 2007) has revealed the possibilities for such (re)developments, including the risks and opportunities for the different parties typically involved. However, though across use adaptation can help solve the problem of vacancy and obsolescence in the office market, continued development of new office buildings will increase the vacancy level and contribute to the persistence of the vacancy problem.

Knowing that the construction industry is responsible for 30% of all energy use, waste production and transportation by road, resulting in a substantial carbon footprint, multinationals and governmental corporations lead the way in an increased demand for sustainable

accommodation. For instance, the Dutch government's building agency demands that all new governmental real estate purchases and leases must be CO2 neutral from 2010 on, and aim at reducing energy use by 25% before 2020 (RGD, 2011). Internationally, cities worldwide like Sydney, Cape Town, Vancouver, Aguascalientes, Nagoya, Copenhagen and Amsterdam aim at becoming climate neutral or CO2 neutral by 2020 or 2030. Building adaptation is a sensible means of reducing the carbon footprint of the construction industry, as the site and a substantial part of the building materials are (re-)used for a longer lifespan. Several studies (**Table 1**) have been conducted that show physical criteria for the adaptation of office buildings. These studies considered both transformations from offices into housing, and within use adaptations of offices. Research by De Jong (2005) and Van den Dobbelsteen (2004) has proved that adaptation of existing buildings has a sustainable advantage compared to demolition and new construction. Though this far adaptation is not taking place on a large scale, building adaptation could be the egg of Columbus! In this paper, we propose new use of existing office buildings as a means for sustainable office development. Can existing office buildings be adapted or redeveloped to cope with the demands of future office users? We will discuss this question, based on literature and results of former research.

NEW WAYS OF WORKING

The quantitative demand for office space is determined roughly by two factors; the number of office employees at work in a specific office market, and the number of square metres used per employee. The number of employees in a market is determined by demographics, macro-economic conditions and the employment market. The number of square metres per employee on the other hand is determined by the way an organisation works. The organisation's view on what kind of work space best supports its activities, its use of new technologies, demand for flexibility, and finally its demand for a specific appearance, are all important factors of an accommodation strategy (Van Meel *et al.*, 2010). The last decade office accommodation goes towards open, flexible, non-territorial office space with desk-sharing and a variety of activity based workspaces, resulting in less square metres per employee than office concepts based on cellular offices (Van der Voordt, 2003).

According to the expectations of real estate agent and advisor DTZ (DTZ, 2011) the demographic trend of an ageing population and less employees together with less square metres used per employee will result in a higher vacancy rate in the years to come. While at the end of 2010 the Dutch office stock in use was 40 million square metres, DTZ expects that by 2030 the office stock in use will be 30-32 million square metres. If this holds true and the stock stays the same, the vacancy will more than double from 7 million in 2010 to 15 million in 2030. That equals one third of the current office stock! A possible trend-break could be that the current oversupply of office space will lead to lower rents in the office market, so that the price of office space will generally become lower. However, research by Keeris and Koppels (2006) has shown a stratification in the office market, where rents in the top segments increase, while only rents in the lowest segments decrease. This layering of rents shows that the preferences of office organisations for high quality office space are not influenced by the availability of cheap office space in other market segments. The vacancy in the low quality segments is expected to increase, while the demand for high quality offices will last.

QUALITY AND OBSOLESCENCE – EXPERT-BASED PROPERTY ASSESSMENT

In property investment, quality is thought to improve investment return and reduce risk (Baum, 1993, Baum & McElhinney, 1997, Bottom *et al.*, 1998, Salway, 1987). Baum refers to obsolescence (categorised as aesthetic, functional, social, legal, economic and environmental obsolescence) as a result of changing quality and as a source of risk for investors. Following Baum, the quality of office buildings could be determined in terms of occupier utility and hence utility for investors. Applied to the currently unbalanced Dutch office market, we expected to discover differences of quality between office buildings functioning well in this market and office buildings with a high level of structural vacancy.

The relationship between quality, obsolescence and investment returns and risks can be studied using so-called expert-based appraisal techniques (Baum, 1993, Bottom *et al.*, 1998, Duffy & Powell, 1997, Salway, 1987). In studies by Duffy and Bottom, (Bottom *et al.*, 1998, Duffy & Powell, 1997) inflexibility was found to be an important indicator of depreciation in commercial buildings, whereas other studies (Healey & Baker, 1987) also included the quality of internal finishes, entrance hall and the external appearance of the building. Baum related depreciation to obsolescence in a series of studies, using both terms to imply low quality (Baum, 1991, Baum, 1993, Baum & McElhinney, 1997). Depreciation may result from tenure-specific or property specific factors. Baum speaks of site value and building depreciation, where building depreciation is a result of physical deterioration and building obsolescence. Building obsolescence, representing a decline in utility of the building, is again one of the major causes of long term vacancy. The investment return and risk are both factors that need to be considered when investing in office buildings. Though hedonic analyses are often used to determine the relationship between the physical characteristics of office buildings and locations and the rent prices of offices as an indicator for the value of office buildings, few studies focused on the risk of vacancy as a threat to the value of investments. However, as the vacancy rate in European cities has been rising the last years, the risk of structural vacancy in office buildings is becoming a more important factor in the equation than it used to be. Obsolete office buildings have reached the end of their functional and or economic lifespan; hence interventions are needed in order to upgrade these buildings for continued or new use. Knowledge about office user preferences is necessary to know which buildings can successfully be upgraded for renewed use.

QUALITY AND OBSOLESCENCE – USER-BASED PROPERTY ASSESSMENT

From studying physical characteristics that contribute to the quality or the obsolescence of a property, the characteristics are known of office buildings that are vacant in the current market. Using a Delphi survey (Remøy *et al.*, 2007), office accommodation advisors stated that office organisations prefer office buildings and locations with certain characteristics (**Table 2**) that enables the organisation to reach their goals. The results from the Delphi survey showed that vacant office buildings can be described by characteristics that are not preferred by office users. However, we did not interview the office organisations or its employees during this study. Bottom et al. (1998), presented an approach combining the former discussed expert-based

appraisal technique with a user-based appraisal technique, best described as a post-occupancy evaluation (POE). The advantages of using POE are recognised in facility and property management (Preiser, 1995, Preiser & Vischer, 2005) because of the possibility of providing feedback information for proactive management. Combining expert-based and user-based property assessments could further help to understand mutations in the office market, revealing which adaptations should be made to enhance the lettability of office buildings.

Table 2 *Physical property characteristics that influence office user preferences*

Building characteristics	**Location characteristics**
1. Car parking	1. Accessibility by car
2. Exterior appearance	2. Status
3. Layout flexibility	3. Accessibility by public transport
4. Space efficiency	4. Facilities
5. Comfort	5. Safety
6. Interior appearance	6. Business cluster
7. Recognisable user	
8. Technical state	
9. Building facilities	
10. Year of construction	
11. Security	
12. Energy performance	
13. Routing	
14. Bike parking	
15. Commodities logistic	

EXAMPLES OF SUCCESSFUL ADAPTATIONS

Studies of the Amsterdam and Melbourne office market (Wilkinson & Remøy, 2011) revealed that adaptations of existing office buildings reduce the risk of obsolescence. The adaptations included in this study all considered larger interventions, registered as building permits. 100 office buildings in Amsterdam were studied and 1500 adaptations of Melbourne office buildings (could be multiple adaptations of the same buildings). A total of 18 building attributes were found to be important drivers for commercial office adaptations in Melbourne and Amsterdam (**Table 3**), of which five were shared (number of storeys, GFA, typical floor area, age and aesthetics). Of the five attributes found important only in the Amsterdam study, namely facade material, long term vacancy, entrance spatiality, provision of sanitary and pantry facilities and the number of elevators in the building, this data was not collected in the Melbourne study and therefore no further comment can be made as to whether this data would have been found to be important; this is an area of possible further research. The final six attributes found to be important only in the Melbourne study were “Property Council of Australia building quality grade”, site boundaries, site access, vertical services location, property location and historic listing, which were not part of the Amsterdam study. One could also make the argument that “Property Council of Australia building grade” (a Melbourne attribute) could be a proxy for the level of amenities provided in a building such as number of elevators and sanitary

accommodation (two of the Amsterdam attributes). The importance in both studies of the number of storeys and total GFA of the building, show that the size of the building is important for the possibility that building adaptation will lead to increased future value of the office building. Typical floor area is an indicator for the flexibility of the layout and is an attribute that is not adaptable; hence its importance is also quite easily comprehended. The level of amenities in the building was found to be important both in the Amsterdam study and in the Melbourne study. Since adaptation of these services easily implies high building costs, the importance of the attributes for adaptations are easily explained.

Table 3 *Criteria for adaptations in Melbourne and Amsterdam. (+) implies that when the value of the attribute increases, adaptation is more likely.*

Important Building Adaptation Attributes	**Melbourne**	**Amsterdam**
Number of storeys (+)	X	X
GFA (+)	X	X
Property Council of Australia building quality grade (-)	X	
Typical floor area (+)	X	X
Site access (+)	X	
Parking places (+)		X
Street frontage (+)	X	
number of elevators/m2 (+)		X
sanitary and pantry facilities/m2 (+)		X
Spatiality of the entrance (+)		X
Historic listing (+)	X	
Age in 2010 (+, old buildings are more likely adapted)	X	X
Long term vacancy (+)		X
Facade material (+)		X
Facade quality / aesthetics (+)	X	X

EXAMPLES OF SUCCESFUL TRANSFORMATIONS

Table 1 showed a list of adaptive reuse criteria for existing buildings. These criteria, all physical characteristics of the property, correspond to both within use adaptation (retrofitting of the office function) and transformation from offices into new functions. Table 4 shows criteria that were found to enhance the transformation potential of office buildings, based on a cross case analysis of 14 completed transformations (Remøy, 2010; Remøy & Van der Voordt, 2007, 2009). The only location characteristic that could be said to be a veto-criterion for residential transformation is noise level on the facade and level of fine dust in the air. If the legal standards are not met, then residential transformation is not feasible. The other location characteristics are less critical, depending on the target group for housing and the combination of characteristics.

Table 4 *Criteria for high transformation potential (from offices into housing) retrieved from case studies (Remøy and Van der Voordt, 2007)*

Attributes	Criteria for transformation
1. Location	No serious health risk (pollution, noise, stench) Noise load on facade < 50 dB, according to Dutch building regulations Functional mix and facilities nearby Zoning plan permitting future modification e.g. with mixed use including housing No serious crime risk (vandalism, burglary, attacks)
2. Building	
Appearance	No "office building look", attractive identity and entrances A high spatial/visual quality
Facade	Replaceable or adaptable, not load-bearing Daylight admittance at least according to building regulations for housing Operable windows Acoustic and thermal insulation according to building regulations for housing
Flexibility / adaptability of the structure	Extendibility, horizontally or vertically Acoustic and thermal insulation according to building regulations for housing A structure that can accommodate floor plans for different target groups Preferably no load-bearing walls, but columns Sufficient escape routes according to housing legislation Free ceiling height > 2.60 m
Installations	No installations integrated in the load-bearing structure Possibility to add service ducts (possibility of cutting holes in floors for shafts)

Few building characteristics make transformation into housing or other functions impossible: A building is more easily manipulated than its location. The characteristics of the structure and the floors are most crucial for the transformation potential. The scale of the structure must allow separations into usable spaces. While older office buildings were not built according to standard measurements, office buildings from the 1980s onwards often have a structure that is a multiple of 1.8 metres, such as 7.2 metres, and is well suited for accommodating housing. The floors of office buildings normally provide enough strength for residential transformation. Problems may occur though when manipulating the floors. A typical floor in an office building is made of pre-stressed hollow core slabs. If the steel in the floors is cut, the floors loose strength. Apartment buildings require a higher density of vertical shafts than office buildings. Penetrating the floors to create shafts for water, electricity and sewer is one of the problems of transforming offices into housing. Though several building characteristics represent potential risks for the legal, functional, technical and cultural feasibility and thus also for the financial feasibility of transformation projects, only one characteristic represents a veto criterion: free floor height >= 2.6 metres. The characteristics of the facade influence the transformation potential of office buildings significantly. Though the facade is often adaptable, all adaptations imply extra building costs, and hence influence the financial feasibility of a transformation. As the requirements for thermal and acoustic insulation are higher for housing than for offices, adaptations of the facade

are needed in most transformation projects. Finally, the image of outdated office buildings does not always trigger positive reactions from potential residents. Except for monuments or renowned buildings that have a specific image or are even able to provide a specific identity to a whole neighbourhood, most office buildings come with 13 in a dozen and have an image too strongly related to office work. In these cases, the facade is often replaced, even if it is technically well maintained and meets the requirements for housing.

The adaptive reuse criteria of within use adaptation to a certain degree correspond to those of transformation. On a location level, the legal requirements for housing are stricter than for offices. On building level, generally the functional adaptation demands more from the technical adaptations. However, many of the same requirements exist for modern offices and housing.

ADAPTATIONS FOR NEW OFFICE USE

While the possibilities for redeveloping and adapting existing office building for the same or new use have been revealed, the question that remains unanswered is: which office buildings and locations could and should be reused for new, sustainable offices that meet future demands and can increase the value of the existing, obsolete office building? Although adaptation of existing offices is a means of reducing the amount of new office developments, not all office buildings can be successfully adapted. If a property is environmentally or locationally obsolete, adapting the building to fit new office user demands will not offer any solace. Additionally, some office buildings have unfavourable measurements or inflexible layouts that cannot accommodate the demands of modern office organisations. In some cases, the existing office building is too small and too technically outdated to be adapted: the costs of interventions that are needed to make the building suitable for new office use will result in a second-best office building that will lose the competition with other buildings and therefore will remain vacant. Moreover, fighting the oversupply in the office market means that some office buildings need to be taken off the market. Departing from the forecasts by DTZ (2011) that if no new office buildings are added to the office stock, 25% of the office supply should be demolished or transformed for other use.

CONCLUSION AND REFLECTION

In an office market with high vacancy rates, remarkably few adaptations have been carried out to enable re-use for office functions. The Dutch office market was mainly driven by expansion, and the development accelerated from the 1980's onwards. The local and national government together with developers and investors viewed the office market expansion as an everlasting gold mine. As the market could not recover from the 2001 crisis before the 2008 crisis hit, the inevitable end of the growth is hard to face. Adaptations of existing buildings have taken place in this expanding market, but the Dutch office market has a lot to learn from other markets, where adaptations are well documented and the goals for future development are clear. Adapting existing office buildings to accommodate modern offices is a possibility of limiting office vacancy by ending the overproduction of new office space. However, if all office buildings are adapted, the quantitative oversupply of office space will persist. Therefore, redevelopment, functional transformations and demolition are inevitable in order to develop a balanced future

office market. Based on former studies, the characteristics of buildings that are best suited for functional transformation can be recognised. Furthermore, the characteristics of office buildings that are best suited for within use adaptation can be described based on the appraisal of the existing building. Following this train of thoughts, buildings that do not expose adaptation potential could better be demolished.

ORGANIZATIONAL AMBIDEXTERITY IN THE CONSTRUCTION INDUSTRY

PER ERIK ERIKSSON
Entrepreneurship and Innovation
Luleå University of Technology
Sweden
pererik.eriksson@ltu.se

Abstract
Organizational ambidexterity refers to an organization's ability to both exploit existing knowledge, assets, and positions for short-term profits and also explore new knowledge, technologies, and markets to enhance long-term development. Ambidexterity research has mostly focused on firm or business unit levels. Studies dealing purely with project or alliance levels in project-based industries are non-existent. The purpose of this conceptual paper is to examine if it is a useful concept for discussing sustainability and competitive advantage in the construction industry, to what degree ambidexterity is present, and how it may be affected by procurement procedures and project governance. Short-term project focus and decentralization inhibits learning from one point in time and space to another, making it more difficult to reap the benefits of exploration than of exploitation. Due to strong path dependence there is an apparent risk that construction industry actors may be trapped in suboptimal stable equilibrium by focusing too heavily on exploitation and too little on exploration. This paper discusses how procurement procedures and project governance can affect the possibilities to achieve ambidexterity in construction projects. Joint specification, partner selection, incentive-based payment, and collaborative tools are important means to affect ambidexterity so that a suitable balance between exploitation and exploration can be obtained in construction projects.

Keywords: ambidexterity, exploration, exploitation, innovation, procurement.

INTRODUCTION

Background
Recently, the focus on trade-off relationships in organizational research has been shifted to paradoxical thinking (Eisenhardt, 2000), which is pinpointed in research about organizational ambidexterity. Although the concept of organizational ambidexterity was first coined by Duncan (1976), most literature on the subject stems from March (1991) and his seminal work on exploration and exploitation in organizational learning. Exploration includes things captured by terms such as search, diversity, adaptability, risk taking, experimentation, flexibility, discovery, innovation, and long-term orientation. Exploitation on the other hand involves refinement, alignment, control, constraints, efficiency, and short-term orientation (March, 1991; Gibson & Birkinshaw, 2004; Andriopoulos & Lewis, 2010). Accordingly, ambidexterity involves the capability to both exploit existing knowledge, assets, and customers/markets for short-term profits and also explore new knowledge, technologies, and customers/markets to enhance long-term development (O´Reilly & Tushman, 2008). Due to exploration's greater uncertainty most organizations focus more on exploitation (Uotila et al., 2009), resulting in short-term success but long-term stagnation and failure (O´Reilly & Tushman, 2008). Achieving an appropriate balance

between exploration and exploitation is therefore critical for sustainable competitive advantage (March, 1991; Gupta et al., 2006).

Earlier ambidexterity research has mostly studied firm level or business unit level (Mom et al., 2007; Raisch & Birkinshaw, 2008). Koza and Levinthal (1998) were first to adopt the exploration/exploitation paradox in an inter-organizational context when investigating strategic alliances. In recent years additional investigations have contributed to this knowledge, suggesting that ambidexterity is a highly relevant concept in external relationships among firms. However, in spite of the emerging interest for ambidexterity in alliances, there is limited understanding of how exploration and exploitation impact alliance performance and how ambidexterity can be facilitated through different organization designs and governance forms (Im & Rai, 2008). Prior investigations that focus on how to achieve ambidexterity at various organizational levels have found that ambidexterity is heavily affected by both formal organizational aspects (e.g hierarchical structures, control mechanisms, formalization, partner selection procedures, forms of payment) (Koza & Lewin, 1998; Jansen et al., 2006; Lavie & Rosenkopf, 2006; Jansen et al., 2008) and informal social aspects (e.g. connectedness, shared vision) (Jansen et al., 2006; Jansen et al., 2008; Tiwana, 2008). However, Tiwana (2008) argues that pure project-level investigations, in which both ambidextrous behaviors and their effects on performance are studied within projects, are very scarce although much of alliances' innovation work is performed within the boundaries of projects. This gap may be due to that ambidexterity studies have not yet investigated project-based industries, such as the construction industry (Eriksson & Westerberg, 2011).

Although sometimes challenged, the conventional view is that the construction industry lacks innovation (Widén & Hansson, 2007), but the suggested improvement agenda fails to address the specificities of innovating within the project-based context (Dubois & Gadde, 2002; Harty, 2008). In prior construction management literature the need to break down barriers to innovation and the need to resolve conflicts between project actors are generally revealed as conclusions rather than starting points (Harty, 2008). Hence, it is vital to develop a more detailed understanding of how a balance between exploration/exploitation can be achieved in inter-organizational projects and how it affects project performance. In construction projects both formal and informal aspects are affected by procurement procedures and project governance, which determine responsibilities and authorities in the entire construction process, affecting the degree of integration and cooperation among project participants (Eriksson & Westerberg, 2011). Formal and informal mechanisms related to procurement procedures and project governance are therefore relevant to investigate in order to increase our understanding of how they may affect the achievement of organizational ambidexterity.

Purpose of the paper

This paper addresses the abovementioned gap in the ambidexterity literature by conceptually investigating ambidexterity in inter-organizational projects in the project-based construction industry. When investigating this subject for the first time in the construction context, it seems pertinent to examine if it is a useful concept for discussing sustainability and competitive advantage in this industry, to what degree ambidexterity is present, and how it may be affected by procurement procedures and project governance.

This paper thereby aims to address and conceptually discuss three research questions:

1) Is organizational ambidexterity a useful concept that can enhance sustainable project performance in the construction industry?
2) To what degree is organizational ambidexterity apparent in construction projects?
3) How can organizational ambidexterity be facilitated through procurement procedures or other related mechanisms?

THEORY

Three types of ambidexterity

In early research, authors have typically viewed ambidexterity in 1) *structural* terms by separating exploitation and exploration activities in different business units (Duncan, 1976; Tushman & O´Reilly, 1996; O´Reilly & Tushman, 2004) or parallel structures involving task partitioning within a single business unit (e.g. project team or quality circle) (Goldstein, 1985; Adler et al., 1999) or 2) *sequential* terms by temporal separation (i.e. punctuated equilibrium) through focusing on first one type of activity and then the other one (Duncan, 1976; Adler et al., 1999; Gupta et al., 2006). True paradoxical thinking is however obtained only when 3) *contextual* ambidexterity is adopted, that is, when there is a capacity to simultaneously and synchronously pursuit exploitation and exploration within a business unit or work group (Gibson & Birkinshaw, 2004; Gupta et al., 2006). Most scholars focus on one or another of these different types of ambidexterity but recent research has found that in reality a combination of different types may be most practical (Raisch et al., 2009; Andriopoulos & Lewis, 2010).

Ambidextrous performance

There is a lack of studies that explicitly address the paradox of ambidextrous performance, including both exploitative results (i.e. alignment with project objectives) and explorative results (i.e. adaptation to changes in the environment) (Tiwana, 2008). Projects are inherently bounded in time and space, making it natural to address and focus on short-term exploitative performance. However, since project objectives can evolve during development in synchrony with new information, unanticipated shifts in underlying technologies, and emerging market requirements, exploration may be equally important (Tiwana, 2008).

In the construction industry, project performance is measured through the short-sighted iron triangle of cost, time, and quality (Chua et al., 1997; Swan & Khalfan, 2007). For industrial actors with concern for sustainability, the exploitation focused “iron triangle” is too limited. Also more long-term and explorative elements, such as lifecycle costs, environmental impact, and innovation, need to be addressed in order to obtain a more sustainable perspective on project performance (Eriksson & Westerberg, 2011). Furthermore, most construction projects are characterized by high complexity (making it hard to estimate an accurate cost of the finished project) and uncertainty (increasing the risk for changes in scope and content) (Palaneeswaran et al., 2003; Eriksson, 2010b), making explorative adaptations required. This paper therefore discusses ambidextrous performance in order to achieve a more sustainable perspective on project performance than the iron triangle obtains.

AMBIDEXTERITY IN DIFFERENT ENVIRONMENTS

Prior research indicates that ambidexterity is applicable in several different environments. 1) Even if empirical findings have identified some differences in how to manage ambidexterity they suggest that ambidexterity is relevant and applicable across different industries in both high-tech (Brown & Eisenhardt, 1997; Beckman, 2006; Lavie & Rosenkopf, 2006; Mom et al., 2007) and low-tech manufacturing industries (He & Wong, 2004; Sidhu et al., 2004). 2) Other empirical investigations concur that exploration is particularly important in a changing environment, whereas it becomes less critical in slow moving environments (Mom et al., 2007; Uotila et al., 2009). Exploitation may thereby be efficient also in a somewhat longer time perspective when slow technological change do not make current knowledge obsolete (Uotila et al., 2009). However, O´Reilly and Tushman (2008) mean that low rates of change do not make ambidexterity pointless; it merely makes it possible to divide exploration and exploitation into different sequences instead of performing them simultaneously. Another study have investigated the uncertainty dimension of dynamic environments and found that ambidexterity is especially vital in contexts with high environmental uncertainty, in terms of fluctuating revenues (i.e. volatile net sales) due to economic booms and downturns (Lin et al., 2007). 3) Another environmental aspect is the degree of competition, reflected in the number of competitors and the number of areas in which there are competition. Through a large scale survey Jansen et al. (2006) found that exploitative innovations improve financial performance in highly competitive environments. In order to tackle tough price competition, exploitation then serves to improve existing products and increase cost efficiency without the substantial risks and costs associated with exploratory innovations (Jansen et al., 2006).

Due to the broad applicability of the ambidexterity concept it is difficult to see why it should not be relevant in the construction industry. 1) Although construction often is labeled as a low-tech industry this notion is not theoretically grounded and is increasingly questioned as new and advanced tools and technologies are utilized to a growing extent (Harty, 2008). 2) In terms of change rate, the construction industry is often said to be characterized by a slow technological change, but Gann and Salter (2000) mean that construction firms operate within a dynamic environment in which rapid economical and societal changes create demands for new types of buildings and infrastructures. In addition, the construction industry is very sensitive to economic booms and downturns, thereby facing an economically volatile and uncertain situation that supports the argument for ambidexterity. 3) In the construction industry the degree of competition is varying in different countries, in different types of projects and at different points of time. In a quantitative study performed by Reichstein et al. (2005) it was found that the competitive forces requiring construction firms to innovate were weak in the UK. In Sweden, there are only a few large contractor firms that compete for major infrastructure contracts, whereas the number of competitors is significantly higher for smaller projects, especially in housing. The competitive environment also fluctuates heavily with economic booms and downturns. In economic downturns there are many companies that compete with low prices to win a project to keep their staff busy. In addition, competitive tendering based on lowest price is the most common way to select a partner (Eriksson, 2008b), indicating tough price competition. All in all, there are some inherent characteristics that suggest that exploitative behaviors may be somewhat more beneficial than exploration but a pure focus on exploitation or exploration is probably not as beneficial as a mix, indicating that ambidexterity is suitable.

Proposition 1: Ambidextrous behaviors among project actors enhance ambidextrous construction project performance.

DEGREE OF AMBIDEXTERITY IN CONSTRUCTION PROJECTS

Divorce of design and construction

For subsystems (e.g. business units or projects) with scarce resources sequential ambidexterity is more practical than structural solutions (Beckman, 2006; Gupta et al., 2006). Sequential ambidexterity is also more suitable in slowly changing environments, whereas exploration and exploitation must be performed simultaneously by structural ambidexterity in fast changing environments (O´Reilly & Tushman, 2008). Sequential ambidexterity can be achieved by focusing more on exploration in the early stages of a project and on exploitation in the end of the project during production/implementation (Raisch et al., 2009; Andriopoulos & Lewis, 2010). Prior ambidexterity research has found that formalization, which acts as a frame of reference that reduces variance and deviation from existing knowledge, is an important factor that enhances exploitative innovation (Jansen et al., 2006). A related finding was made by Mom et al. (2007) in a quantitative investigation of 104 managers in a US company. They found that top-down communication and knowledge inflow enhance a manager's exploitation activities (Mom et al., 2007).

As construction projects are often characterized by scarce resources and a slow or moderate technological change, sequential ambidexterity may be viable. However, ambidexterity is often achieved through a combination of structural and sequential strategies by letting consultants/architects first explore different types of technical solutions during the design phase and then letting contractors exploit their existing knowledge to efficiently build the specified product. The traditional way of procuring construction contractors based on detailed and fixed design specification entails formalization and top-down knowledge inflow from the contractors' perspective. This structural and sequential divorce between design and construction results in a prolonged project duration (Pietroforte, 1997) and poor buildability (Eriksson, 2010a). The divorce also hampers innovation and implementation of explorative solutions during the construction stage due to lack of joint problem-solving (Korczynski, 1996). Hence, the traditional sequential and structural approach enhances more exploitation than exploration and is not reaping the benefits of ambidexterity.

Partner selection based on competitive tendering

Prior research has found that purposeful staffing of subunits and groups is important for ambidexterity (O´Reilly & Tushman, 2008). Diversity is important for creativity and ground-breaking advancement, while cohesiveness nurture mutual understanding and smooth group work and thereby efficiency (Beckman, 2006; Andriopoulos & Lewis, 2010). When partners are familiar with each other, they can rely on prior experience and existing arrangements to enhance the predictability and reliability of the collaboration (Lavie & Rosenkopf, 2006). Exploitation is thereby facilitated by establishing teams of members who have previously worked together, whereas exploration is enhanced by heterogeneous teams in which individuals have different prior experiences and affiliations (Beckman, 2006; Lavie & Rosenkopf, 2006; Andriopoulos &

Lewis, 2010). In addition, Koza and Lewin (1998) argue that output control is most suitable in exploitative alliances. Output control, defined as the degree to which the focal firm monitors the results or outcomes produced by the partner (Aulakh et al., 1996), is closely related to the price mechanism (Hennart, 1993). In line with this reasoning, rigid client constraints (e.g. financial and technical) have been found to turn the focus to exploitation and inhibit exploration (Andriopoulos & Lewis, 2010), whereas slack in human and monetary resources enhance exploration, as they condition information search, experimentation and risk-taking (Sidhu et al., 2004).

These related aspects are relevant in a construction industry context. In a survey study, Eriksson (2008b) found that the most important factor influencing construction clients' choices of governance forms and procurement procedures was the client's project constraints, in terms of budget and time schedule. As a consequence, the most dominant partner selection routine involves competitive tendering with multiple bidders evaluated chiefly on lowest price, entailing a focus on output control (Eriksson & Laan, 2007). Although the open bid procedure enhance the establishment of a heterogeneous team, the short-term focus on time and money in every single construction project results in scarce resources, indicating a propensity for exploitation rather than exploration.

Fixed price payment

A payment system rewarding the supplier for his output (e.g. a fixed price for a product delivered) indicates output control (Gencturk & Aulakh, 1995), which is appropriate in exploitative alliances (Koza & Lewin, 1998). When uncertainty is high, output control through fixed prices may lead to inflexibility since the supplier may resist adapting to changed circumstances (Aulakh & Gencturk, 2000).

In the construction industry fixed price payment is most common although it may generate many problems (Eriksson & Laan, 2007). It shifts all the risk to the contractor who will therefore focus on short-term efficiency and the use of known technological solutions. Since uncertainties in construction are high and derived from many different sources, the design is often changed because of changes in the client's preferences (Kadefors, 2004). The traditional output-based payment that enhances exploitation may therefore be inappropriate.

Exploitation focus

Firms may get stuck in suboptimal stable equilibrium for a long time since path dependence in terms of earlier experiences affects managers' choices more than the suitability of the various alternatives (March, 1991; Lavie & Rosenkopf, 2006). Indication of such path dependence hindering ambidexterity was found in a large cross-industry survey, finding that 67% of the studied firms relied on a single organizational structure (cross-functional teams) for all their development processes, although the results showed that firms tailoring the structure to fit the purpose (incremental vs radical new product development) were more successful (de Visser et al., 2010).

In the construction industry, path dependence seems to heavily influence clients' decisions related to project governance and procurement (Laedre et al., 2006). In fact, the third most important factor influencing construction clients' choices of governance forms and procurement

procedures is the client's earlier experience of the procedure (Eriksson, 2008b). Furthermore, studies of barriers to change in the construction industry have found that the conservative construction industry culture is the single most important barrier to change (Vennström & Eriksson, 2010). To conclude this discussion, it seems that there is an apparent risk that construction industry actors may be trapped in suboptimal stable equilibrium by focusing too heavily on exploitation and too little on exploration.

Proposition 2: Construction project actors rely much more on exploitative behaviors than on explorative behaviors.

HOW TO ACHIEVE AMBIDEXTERITY IN CONSTRUCTION PROJECTS

A viable option for subsystems with scarce resources is contextual ambidexterity (Beckman, 2006), which is less expensive than structural ambidexterity because the costs of coordinating, controlling, and supervising employees are much reduced (Gibson & Birkinshaw, 2004). Contextual ambidexterity is achieved by building a set of processes or systems that enable, encourage and reward individuals or sub-systems to make their own judgments about how to divide their time between conflicting demands for exploration and exploitation (Gibson & Birkinshaw, 2004). The balance between exploration and exploitation is thereby affected by the ways in which targets are set and changed, by recruitment and selection, by incentive systems, by organizational culture, and by risk preferences (March, 1991; Gibson & Birkinshaw, 2004; O´Reilly & Tushman, 2004). Since structural and sequential solutions alone may not be suitable in the construction industry, it seems pertinent to investigate how procurement procedures and governance forms can affect the achievement of contextual ambidexterity in construction projects.

Joint specification

Previous research has found that diverse and complementary assets and knowledge, along with integration and knowledge transfer are important mechanisms for enhancing ambidexterity (Beckman, 2006; O´Reilly & Tushman, 2008; Andriopoulos & Lewis, 2010). A related finding was made by Mom et al. (2007), who found that horizontal and bottom-up communication and knowledge inflow enhance a manager's exploration activities. Furthermore, high levels of uncertainty trigger substantial task interdependence among the involved project members, making participative coordination structures such as cross-functional teams necessary (de Visser et al., 2010). In line with these arguments the involvement of suppliers in design activities has successfully enhanced ambidexterity in the Toyota Production System (Adler et al., 1999).

Construction projects are mostly characterized by high uncertainty (Palaneeswaran et al., 2003; Eriksson, 2010b), due to lack of information concerning ground conditions, weather forecasts, and client requirements. This results in difficulties to forecast all future contingencies and outcomes, making integration among project actors an important means to enhance flexibility and coordination. As such, the integration of design and construction actors may be a viable alternative to the aforementioned combination of structural and sequential arrangements that

results in a divorce between design and construction. Early involvement of contractors and integrated design and construction (i.e. concurrent engineering) has shown to facilitate cost saving and shortened project duration (i.e. exploitation) due to increased buildability (Rahman & Kumaraswamy, 2004; Song et al., 2009) but also innovation (Ling, 2003) due to joint problem-solving and knowledge transfer among design and construction actors. Hence, such joint specification may be a suitable strategy to enhance contextual ambidexterity.

Partner selection based on multiple criteria

In order to enhance a balance between utilization of earlier experience and knowledge of related technologies and generation of fresh ideas and inputs, new product development teams should be constituted by both new and old members (Brown & Eisenhardt, 1997). Furthermore, ambidexterity research has found that during selection and hiring of staff it is important to assess both passion related attributes (exploration) and discipline related attributes (exploitation) in order to find people with ambidextrous identity (Andriopoulos & Lewis, 2010). Koza and Lewin (1998) argue that process (behavior) control is best suited for explorative alliances. Process control, referring to the focal firm's monitoring of the partners' behaviour or the input used to achieve the desired ends (Aulakh et al., 1996), can be accomplished during partner selection when inputs in terms of resources and capabilities are assessed.

When selecting partners for construction projects, process control entails bid evaluation based on multiple criteria (Eriksson & Laan, 2007). In order to enhance ambidexterity, it seems plausible to achieve a balance between direct negotiations with a long-term partner (enhancing exploitation) and more open bid invitations (enhancing exploration) by inviting a few new and old contractors/suppliers to bid and select the most suitable partner based on multiple criteria.

Incentive-based payment

Payment systems that reimburse the supplier for the time worked and the costs of input material (reimbursement payment) entails process control (Gencturk & Aulakh, 1995), which is most appropriate in explorative alliances (Koza & Lewin, 1998). Other studies have however shown that it is important to implement management systems that encourage and reward individuals and/or sub-systems to find a suitable balance between exploration and exploitation (Gibson & Birkinshaw, 2004). Ambidexterity is therefore enhanced by incentive-based payment (contingency rewards) that motivates actors to avoid sub-optimizations and to focus on the overall performance (O´Reilly & Tushman, 2004; Jansen et al., 2008; O´Reilly & Tushman, 2008).

In the construction industry, fixed price payment is common practice, while cost reimbursement and incentive-based payment are not very common (Eriksson, 2008b). Cost reimbursement means that the contractor gets paid for all costs that arise for which reason explorative and long-term development activities can be performed if the client so whishes. However, reimbursement payment may deter the implementation of new approaches and innovative solutions if these reduce contractors' time input and thereby their remuneration (Barlow, 2000). Reimbursement may therefore be coupled with incentive-based payment (e.g. gain/pain share agreement) in order to jointly reward cooperating actors for profits or other benefits resulting from innovative design solutions and effective adaptations (Barlow, 2000; Bajari & Tadelis, 2001). Eriksson and

Westerberg (2011) argue that incentive-based payment can enhance both short-term cost efficiency and long-term innovation, and thereby ambidexterity.

Collaborative tools

Although prior ambidexterity research has focused on formal hierarchical structures, also informal socialization issues and collaborative tools are important from an ambidexterity perspective (Jansen et al., 2006). Socialization, recognition and teambuilding activities improve the actors' connectedness (Jansen et al., 2006) and their generation of mutual tacit knowledge (Kristal et al., 2010). It helps individuals to think and act ambidextrously (Ghoshal & Bartlett, 1997) for which reason connectedness improves both exploratory and exploitative innovation (Jansen et al., 2006). Prior ambidexterity research has studied several collaborative tools. The use of joint IT systems facilitates ambidexterity (Gibson & Birkinshaw, 2004) since they can be used for exploitation purposes (e.g. automated billing and inventory management), explicitly focusing on enhancing efficiency, and for exploration purposes by enhancing collaboration in terms of gathering and exchanging information and new ideas across business units (Kristal et al., 2010). Furthermore, an overarching shared vision is an important integrating mechanism that facilitates ambidexterity by creating a common identity and motivating separate actors and groups to collaborate for the long-term prosperity of the overall system rather than to suboptimize small parts (Gibson & Birkinshaw, 2004; O´Reilly & Tushman, 2004; Jansen et al., 2008; O´Reilly & Tushman, 2008; Andriopoulos & Lewis, 2010). In order to enhance ambidexterity it is important that visions have a future oriented long-term oriented component (exploration), as well as an aspiration of the exploitation of current technologies and capabilities (Sidhu et al., 2004; O´Reilly & Tushman, 2008). A shared physical work space (i.e. joint office) enhance contextual ambidexterity by nurturing both cross-disciplinary work (diversity) and mutual understanding (cohesiveness) (Andriopoulos & Lewis, 2010).

Examples of collaborative tools utilized in construction projects are: developing joint objectives is vital in order to obtain a win-win situation (Crespin-Mazet & Ghauri, 2007; Swan & Khalfan, 2007), performing teambuilding activities is useful in terms of the socialization of partners (Bayliss et al., 2004; Crespin-Mazet & Ghauri, 2007), joint IT-tools enhance exploratory innovation (Gann & Salter, 2000) by facilitating communication and information sharing (Eriksson, 2008a; Woksepp & Olofsson, 2008), joint risk management is a useful way to deal with risks that are unforeseen or unquantifiable during the planning stage (Rahman & Kumaraswamy, 2004), and a joint project office on site in which all partners are located enhance communication through face-to-face encounters (Olsen et al., 2005). Although the use of these collaborative tools is low in traditional construction projects (Eriksson, 2008b), they should be an essential part of collaborative governance forms in which ambidextrous behaviors are demanded.

Proposition 3: Cooperative procurement procedures, including joint specification, partner selection based on multiple criteria, incentive-based payment, and collaborative tools, enhance ambidextrous project performance.

CONCLUDING DISCUSSION

In this paper organizational ambidexterity in the construction industry has been elaborated and discussed in terms of the exploration/exploitation paradox. Due to the project-based nature of the construction industry structural ambidexterity on firm and business unit level may not achieve desired ends. Hence, contextual ambidexterity at the project-level may be required in order to reap the benefits of an appropriate balance between exploration and exploitation. Earlier innovation studies within the field of construction management have highlighted the importance of inter-organizational cooperation in order to enhance innovation (Barlow, 2000; Dubois & Gadde, 2002; Widén & Hansson, 2007; Harty, 2008). Few earlier studies have discussed in more detail specific mechanisms that may enhance innovation. In this paper a procurement perspective has been adopted in order to discuss how cooperative procurement procedures may serve as mechanisms to achieve contextual ambidexterity in construction projects. This paper merely serves as a starting point for discussing organizational ambidexterity in the construction industry. Empirical investigations should be encouraged both in order to study if, when and why organizational ambidexterity is suitable in the construction industry and if so, how it may be achieved in real project settings.

Abstract
Sir John Egan's report on UK construction industry in 1998, Rethinking Construction, inspired a similar review in Singapore in 1999. The Construction 21 (C21) report has served as the blueprint for developing Singapore's construction industry. A series of interviews was carried out in late 2009 to investigate the implementation of the C21 report during the ten-year period. The aim was to ascertain the achievements and challenges, and the consequent changes in practices and procedures in the industry. A representative cross section of samples was taken to include policy makers, clients, consultants, professional bodies, and trade associations. The general perception was that considerable progress had been attained in the development of construction industry, although the achievements had not as much as had been intended in the C21 report. Although a range of progressive practices highlighted in C21 have been adopted in the industry, some of the initiatives in the recommendations in the report are still in progress and some have been launched but have not been pervasively used in the industry. Although Singapore has made much progress in developing its construction industry, the extent to which the industry reforms have fulfilled their original intentions is not completely clear. The impact of the initiatives on the way companies and practitioners work is also not clear. Hence, there is a need to revisit priorities and review the progress so far and map out general strategies for the future.

Keywords: Construction 21, change, construction industry development, industry perspective, Singapore.

INTRODUCTION

In 1998, Sir John Egan published his seminal report on the UK construction industry entitled *Rethinking Construction* (Egan, 1998). This was followed by similarly high-profile reviews of the construction industries in other countries, such as Singapore and Hong Kong, the reports on which were published in 1999 and 2001 respectively (Construction 21 Steering Committee, 1999; Construction Industry Review Committee, 2001). Each of the studies was initiated to address concerns in the local construction industry. For example, in Singapore, the

intention was to attain a radical transformation of construction performance through a planned series of change initiatives.

In Singapore, the Construction 21 (C21) committee put forth 39 recommendations under six strategic thrusts to help achieve the vision of the industry, which is "To be a world class builder in the knowledge age" (Figure 1). The strategic thrusts were: (i) enhancing the professionalism of the industry; (ii) raising the skills level; (iii) improving industry practices and techniques; (iv) adopting an integrated approach to construction; (v) developing an external wing; and (vi) a collective championing effort for the construction industry. The C21 study aimed to transform the construction industry in Singapore from a Dirty, Demanding and Dangerous (3D) to a Professional, Productive and Progressive (3P) industry. Hence, C21 seeks to upgrade all aspects of the construction industry, from processes (improving practices and techniques as well as adopting an integrated approach to construction) and players (professionalising the industry and raising skills levels of construction workers) to the products of the industry (improving construction quality) (Construction 21 Steering Committee, 1999).

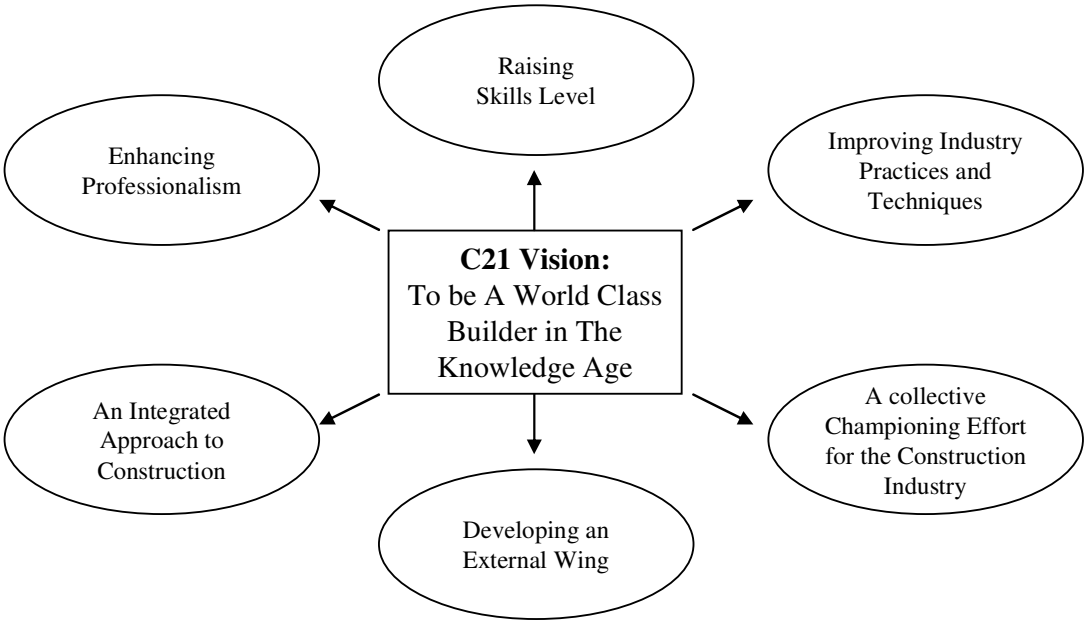

Figure 1*: The six strategic thrusts and vision of C21*
Source: Construction 21 Steering Committee, 1999

The C21 report has served as the blueprint for developing Singapore's construction industry. It has encouraged the adoption of a range of progressive practices and formal assessments, including Information and Communication Technology (ICT) adoption, greater consideration of buildability and quality during both the design and construction stages, and greater recognition of Continuing Professional Development (CPD). Construction and Real Estate Network (CORENET) is regarded by many as the most successful achievement of C21; it has led Singapore to be ranked the first in the world in the ease of doing business (International Finance Corporation, 2008).

Although most of the C21 recommendations have been implemented, by around the middle of the ten-year period set out for the implementation, the programme was losing some

momentum, with meetings to discuss progress becoming rather routine (Ang *et al.*, 2004). Some of the C21 initiatives and programmes have not succeeded. These include the promotion of Design and Build (D&B) and the intention to reduce the number of foreign workers in the construction industry by imposing stricter controls on the number of such workers (see Dulaimi *et al.*, 2003). As the programme was drawing to the end of its planned period of implementation, it was considered to be pertinent to assess its achievements and the continuing challenges facing the industry. The results of such an assessment would provide the basis for making proposals for enhancing the performance of the industry over the next decade.

This paper presents the results of a research project undertaken to examine the implementation of the C21 initiative in Singapore from 1999 to 2009. The study is founded on a review of the literature on industry development in Singapore (which formed the basis of a set of interview questions), and a series of interviews. Nine in-depth, face-to-face, interviews were conducted in late 2009 with 12 key people from the public and private sectors of the construction industry (Table 1).

INTERVIEWEE	POSITION	ORGANISATION TYPE
1A 1B	Director Deputy Director	Government
2	Executive Director	Consultancy firm
3	President	Professional body
4A 4B 4C	President and Chief Executive Officer (CEO) Executive Vice President Executive Vice President	Consultancy firm
5	Chairman	Consultancy firm
6	Past President	Professional body
7	General Manager	Developer
8	Executive Director	Trade association
9	Deputy Director	Government

Table 1: *Profile of interviewees.*

THE CONSTRUCTION 21 STUDY

The general perception from the interviewees was that each initiative under C21 has been followed up. There has been a major improvement, although a radical transformation as envisioned by C21 has not been achieved. According to Interviewee 1A, *"What had to be done, has been done. What was not undertaken back then in the initial stages (i.e. export promotion and research) has been done."* Interviewee 8 acknowledged, *"The report card on C21 would be a decent one because everything that can be done has been done. In many cases, they went beyond what was proposed."*

In terms of the transformation from a 3D to a 3P industry, in general, the interviewees agreed that the progress has been attained in the industry, but it had not been as much as had been intended in the C21 report. For example, the industry continued to depend on subcontracting and foreign workers. Interviewee 2 commented: *"Because of our system and dependence on foreign workers, you don't get the image of professionalism. Safety is still a concern because many foreign workers, who do not get proper training, do not understand dangers before they work on the site."* In Interviewee 4C's words, *"We are trying to achieve first world standards*

using third world workers." The reliance on subcontracting was not viewed as a problem; it has always pertained in Singapore, and is an integral part of the structure of the industry. The aspect which has been considered to be undesirable is the common phenomenon of multi-level subcontracting. Interviewee 4A noted, *"In Singapore, trade contractors do the bulk of the work. Hence, reform must go to that level, instead of focusing on the main contractors."* However, according to Interviewee 1A, the recent green initiatives have given opportunities for the industry to have a more positive image.

STRATEGIC THRUST 1: ENHANCING THE PROFESSIONALISM OF THE INDUSTRY

To achieve the vision to become a world class builder and to change the image of the 3D industry, the C21 report pointed out that the professionalism and capabilities of industry practitioners must be raised. The professional institutions have responded to the C21 recommendation by making CPD compulsory as a pre-requisite for renewing the practicing certificate. However, it is important to strike a balance. As Interviewee 2 explained, *"If you enforce it strictly, you may lose some members, but gain some respect as an institution."* Interviewee 6 noted that CPD may be more effective for certain professions than others; for example, it is more effective for architects than it is for quantity surveyors.

At the industry level, the development of CORENET has been influential in the business process reengineering of the construction industry. Furthermore, CORENET is inspiring similar developments in other countries. Singapore has been the top-ranked economy globally on the ease of doing business by the World Bank (International Finance Corporation, 2008). CORENET has been highlighted as one key reform that sped up the process for dealing with construction permits, reducing the time from 102 days to 38. Almost 99 percent of applications are now submitted electronically through the CORENET. According to Eastman *et al.* (2009), the Singapore effort in building code checking was the earliest, most mature and the farthest along. The interviewees agreed that CORENET has been the most significant achievement of C21.

C21 recommended that all contractors, including sub-contractors, be licensed to influence their standards and professionalism. To be licensed, firms must be financially sound, have good safety records, and employ qualified and experienced personnel to manage the firm and supervise its construction works. It took nine years after C21 before the contractor licensing scheme was launched. According to Interviewee 8, who was involved in the process of development and consultation, there had to be a lot of compromises along the way.

C21 recommended that an industry-wide code of conduct spelling out industry standards with regard to the working relationships among the various players be developed. The interviewees disclosed that the codes of conduct were drafted, but they have not been implemented because according to Interviewee 2, who was involved in the drafting process, the codes were too general and so they were considered to be unnecessary. Interviewee 6 noted that the development of the industry-wide code of conduct is very unreasonable. It is not possible to enforce it if there are no sanctions, while regulation should not go to that extent.

In summary, the professionalism of the industry has been improved. New awards have been created, incorporating key points from previous ones. There are now many new degree

programmes to meet the needs of the industry; however, a number of interviewees have expressed their concerns on the quality of the curriculum and graduates. CPD has become mandatory for some professionals in the industry. There is scope for further progress. Interviewee 4A noted, *"If you want professionalism, then you must downplay regulation, or have regulation with a lighter touch, and allow peer pressure to raise standards. We can say that professionalism has been achieved when the industry does the right thing without too many regulations."*

STRATEGIC THRUST 2: RAISING THE SKILLS LEVEL

Given its small geographical size, Singapore faces many physical limitations including the size of its population. The situation is worse in construction because, owing to the poor image of construction, the industry is unable to attract many Singaporeans. Thus, over 80 percent of the industry's workforce comprises foreign workers. There has been a set of initiatives and incentives to increase the proportion of skilled workers in the construction workforce. These include controls on the number of foreign workers; minimum training requirements for foreign workers before they are admitted into Singapore; and requirements for the employment of a resident engineer and a safety manager on each building project based on the value of projects.

The Man-Year Entitlements (MYE) system allows contractors to employ a maximum number of foreign workers for a specific project volume. To reduce reliance on foreign workers, the C21 report recommended that the MYE for projects should be tightened to 70 percent by 2005 and 50 percent by 2010, or earlier if practicable. The formula for calculating the MYE has since been adjusted a number of times in response to feedback from the industry (Ministry of Manpower, 2010). The interviewees agreed that MYE has not been an effective tool in addressing the supply of workers. Unexpected practices have developed, which gave an impression that the MYE is still at a comfortable level for the contractors.

The issue of foreign workers is the main concern for many interviewees. They highlighted the cultural differences, transient nature of the workers, hidden costs, skills, safety, and support from the government for the workers. There was a general feeling that the industry cannot do without foreign workers. Hence, the policies should be directed at integrating them into the industry. Currently, all incentives are intended to increase the number of locals joining the workforce. However, the interviewees felt that as it has been increasingly difficult to find Singaporeans who are willing to join the construction industry, the government should be more realistic and provide support for the foreign workers.

STRATEGIC THRUST 3: IMPROVING INDUSTRY PRACTICES AND TECHNIQUES

Enhancing Buildability

In Singapore, the concept of "buildability" is promoted for construction practitioners to take account of productivity during the design stage. The principles are: (i) standardisation – repetition of grids, sizes of components and connection details; (ii) simplicity – use of uncomplicated building construction systems and installation details; and (iii) single integrated elements – those that combine related components together into a single element that may be prefabricated in the factory. All new building projects with gross floor area

(GFA) of at least 2,000 sqm, are required to meet the minimum buildability scores. The total buildability score of a design is obtained by summing up the scores of the Structural System, the Wall System, and Other Buildable Design Features. The score is subject to a maximum of 50 points for the structural system, 40 points for the wall system, and 10 points for other buildable features. The maximum score that can be achieved is 100 points. The minimum buildability scores have been increased progressively over time. They were last adjusted with effect from 1 August 2008. The building designs were required to meet prescribed minimum buildability scores ranging from 60 to 77, depending on the building type. The C21 report noted that government intervention is required to achieve higher buildability.

The interviewees agreed that due to the increase in buildability scores, productivity has improved, but there is room for improvement. The policy on buildability has moved towards constructability. The most recent scheme to boost productivity is the Construction Productivity and Capability Fund (CPCF), which was launched in 2010 as part of the national drive to increase productivity. The government set aside S$250 million in the fund to help the construction industry to raise productivity. The fund, administered by the Building and Construction Authority (BCA), comprises incentive schemes to promote workforce development, technology adoption and capability development. It is still too early to assess the effectiveness of the schemes under the fund. The BCA has been actively promoting the schemes and the response from the industry has been encouraging.

Enhancing Maintainability

The C21 report recommended that a study be undertaken to devise a system that can be used to audit maintenance costs and produce manuals which give the design life and maintenance costs of components. A study, "Maintainability of Buildings" (NUS, 2005), an initiative of the BCA and the National University of Singapore (NUS),. aims to study the maintainability issues of various categories of buildings under tropical conditions. The research spearheads the incorporation of maintainability into processes right from the design stage by improving the knowledge of maintainability and setting maintainability benchmarks. The study developed a defects library, a materials manual, and a maintainability scoring system. Although the research results and findings have been disseminated through dialogue sessions, workshops, seminars, and publications, the interviews revealed that the results are not widely used in the industry.

Quality

The quality development programme is one of the BCA's key long-running initiatives. The Construction Quality Assessment System (CONQUAS) was developed to assess the quality of building work to provide a standardized, quantifiable, and systematic assessment system for grading the construction quality of a building (Construction Industry Development Board, 1995). CONQUAS sets out the standards for the various aspects of construction work and awards points for works that meet the standards. The points are then summed up to give a total CONQUAS score for the building project. Over the years, reviews have been carried out and key changes have been introduced to CONQUAS, considering industry concerns and end-user feedback. The average CONQUAS score has risen steadily (Figure 2). The C21 committee has set a target CONQUAS score of 79 by 2005 and 82 by 2010. In 2005, the average score was 80.6, above the target score of 79. In 2009, the average score reached 82, which was the target score to achieve by 2010. These figures are in line with the consensus among the interviewees that the quality of construction has improved.

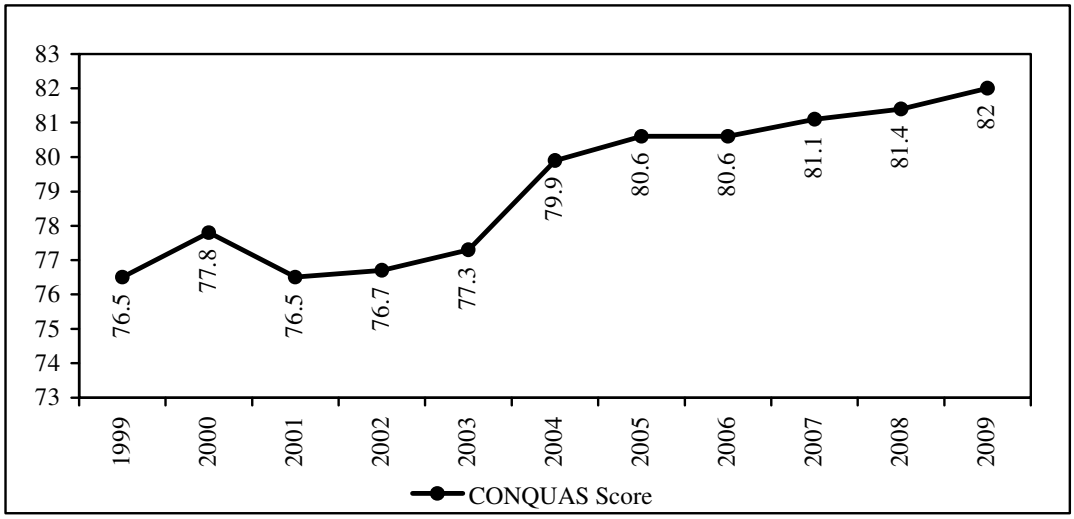

Figure 2: *Average CONQUAS score, 1999-2009*
Source: BCA (2002, 2006, 2008, 2010)

The formulation of a set of National Productivity and Quality Specifications (NPQS) was one of the recommendations of the C21 report. The NPQS is a set of standard specifications for building projects, which covers architectural, civil and structural, and mechanical and electrical works. NPQS aims to harmonise the specifications utilized in the building industry and provide a standard platform for achieving greater efficiency and quality in design and construction. Target users of the NPQS are developers, architects, consulting engineers, contracting companies, quantity surveyors, and suppliers y. It was launched in May 2004. The NPQS has not been pervasively used in the industry. Hence, there have been efforts to improve it. The NPQS is currently being revamped.

Health and Safety

The C21 report recommended the introduction of the Construction (Design and Management) Regulations after the enactment of the Occupational and Safety Health Act (OSHA) in 2000/2001. The new Occupational Safety and Health (OSH) framework was introduced on 10 March 2005. It was guided by three basic principles: requiring all stakeholders to eliminate or minimise the risks they create, instilling greater ownership of safety and health outcomes by industry, and preventing accidents through higher penalties for poor safety management (MOM, 2008). The Workplace Safety and Health Act (WSHA), which came into effect on 1 March 2006, is an essential part of the new framework. In the WSHA, general duties are prescribed for owners, occupiers, employers, designers, suppliers of machinery, equipment and hazardous substances, and individual workers. This is consistent with the principle of holding accountable those who create risks or have primary control over these risks (Joint MND-MOM Review Committee, 2005).

The MOM has been working closely with the Workplace Safety and Health (WSH) Council to improve WSH performance in Singapore. One area that they are working on is to develop the Construction (Design and Management) or CDM Regulations based on the UK's CDM Regulations. The regulations will require designers to work closely with contractors in thinking through safety management for the entire life-cycle of a project.

Implementing WSH 2018 for Construction Sector in Singapore (WSH Council, 2010) was published in April 2010 as part of the national WSH 2018 strategy. It sets the targeted outcomes, key strategies and initiatives to further enhance WSH standards in the construction sector and aims to guide all stakeholders to create a safer and healthier construction sector with a progressive and pervasive WSH culture. Its long-term goal is to achieve zero injury in the construction industry. Currently, the accidents in the construction sector by fatality rate and by injury rate are higher than those in other sectors (WSH Council, 2010).

The interviewees acknowledged the progress on the safety regulations. However, despite the extensive regulations on construction safety, Interviewee 2 believed that it is the mindset of the developers, project managers, and contractors that should be changed. Emphasis should also be placed on the lower levels, such as the supervisors and workers. Teo and Phang (2005) found that contractors understand the importance of a safety culture but do not have the right mindset or attitude towards implementing it. Interviewee 2 felt that Singapore construction still lags behind its comparable counterparts in terms of safety. He commented, *"In terms of safety, we are just two or three only on a scale of one to ten, considering where we've started from - zero."*

Stepping Up Research and Development

The C21 report recommended the establishment of a National Construction Research Institute (NCRI) to co-ordinate construction research and development (R&D) within five years after the publication of the report. The government's response to this recommendation was that it would consider it at a later stage. Hence, the proposed central body of construction research has not been set up. Research remains segregated in the industry. R&D activities are conducted separately or jointly by public agencies, companies and tertiary institutions. Research in construction has been encouraged by the Ministry of National Development (MND) Research Fund for the Built Environment, administered by the BCA under which S$50 million has been set aside for research during 2008-2013 (BCA, 2009).

Improving Construction Management

The C21 report recommended the development of a generic Construction Management System for all contractors and subcontractors and use appropriate incentive schemes to assist adoption of the system. In response to the recommendation, the Construction Productivity Benchmarking System (CPBS) was developed to help contractors to measure productivity and benchmark their performance against those of their competitors (*Framework*, 2001). CPBS is an IT toolkit comprising a smart card for identification of workers, Personal Digital Assistant (PDA) which acts as a tracking device and a desktop computer for generating reports. It enables contractors to analyse manpower usage, determine how activities are being performed on site, identify work patterns, as well as improve communication within the project team and with the head office. A web-based application for the Construction Management System was completed in 2004, but did not take off in the industry.

The C21 report also recommended the development of a pool of supervisors trained in proper site management and safety procedures to ensure high productivity and safety levels. The BCA Academy, the training arm of agency, offers certification courses for supervisors in the areas of precast concrete construction, waterproofing, and geotechnical instrumentation. It also offers safety courses for supervisors, on metal scaffold erection, formwork, co-ordination

of work, recognition of hazards in deep excavation temporary retaining structures, and general building construction.

The intention to minimise modifications to the standard forms of construction contracts for the private sector has not been realized. Many of the professional institutions has its own standard of contract. The interviewees agreed that there should be only one basic form. As Interviewee 4A noted, *"Everyone protects their own thing. That's all right but we need a uniform idea of what is a reasonable risk transfer."* Although there have been attempts under the umbrella of the Construction Industry Joint Committee (CIJC)t o unify the contracts in the, not much has been achieved. Interviewee 5 observed, *"It's a hugely end-user driven thing. Partly because there's no costing of the extra fees and other work. Our industry needs to mature to the point that architects and engineers must be allowed to charge for the extra work because of client's changing his mind."*

STRATEGIC THRUST 4: AN INTEGRATED APPROACH TO CONSTRUCTION

The construction industry is highly fragmented but the approach to construction is changing. The C21 report acknowledged that the development of more complex intelligent buildings, the demand by clients for greater responsiveness, guaranteed cost and delivery schedules of projects, and the push for greater efficiency, have increased the need to integrate the processes and roles of the various players. The C21 report recommended that BCA continue to promote D&B to private-sector developers.

The C21 report also recommended that the BCA undertake a comprehensive review of the Architects Act, Professional Engineers Act and Building Control Act to facilitate D&B arrangements. Following the amendments, with effect from 2003, D&B services can be offered by providing a single point of contact for the client. Moreover, the industry will have more choices of D&B arrangements. An architect or professional engineer can offer D&B without tying up with a builder's firm. Builders can offer D&B packages jointly with architects and professional engineers. Licensed corporations can also offer D&B services.

Despite the push from the government, there has not been much change in building projects. There seems to be lack of willingness of the parties involved in a D&B project to compromise. Among the issues cited are: the reluctance of architects to give away some of their 'traditional' control on projects (Interviewees 1A and 5); the small number of enlightened contractors which were willing to increase costs and let architects improve the design (Interviewee 4B); and the limited number of contractors which were capable of handling D&B projects (Interviewee 5). As reiterated by Interviewee 1A, D&B is used more on civil engineering projects than on building works. Interviewee 6 noted that D&B is only one type of many procurement methods, and it may not be appropriate for certain projects. In summary, the interviewees agreed that the use of D&B should be decided by the market; it should not be pushed by the government.

The interviewees agreed that the formation of multi-disciplinary firms which had been encouraged by C21 did not take off in the industry. They noted that some design firms have grown and added areas to their initial expertise, but they remain consultants. Similarly, contractors remain as they were. Consultants and contractors tie up in consortia to undertake some projects overseas (see below), but they do not form multi-disciplinary firms.

STRATEGIC THRUST 5: DEVELOPING AN EXTERNAL WING

One of the recommendations in the C21 report was that BCA should assist construction companies and consultancy firms to venture abroad. Despite the government's response which indicated that the emphasis should be given at a later stage and that BCA should focus on improving the domestic construction industry, the BCA launched an export promotion drive, which included the establishment of Export Digest, Export Link Services, workshops, seminars, overseas mission trips, and executive programmes (Framework, 2002, 2003a, 2003b, Pillars, 2008).

In general, Singapore-based architects have done quite well abroad. The contractors feel the need to go overseas, especially when there are fewer jobs in Singapore. In late 1990s and early 2000s, the depressed local market spurred firms on to seek opportunities abroad. From 2004 to 2009, except in 2008 when the global recession dampened construction demand, Singapore construction and engineering firms clinched more than S$2 billion worth of construction contracts each year (Figure 3). A number of consortia have been set up to pursue projects overseas. Several of these have been facilitated by the BCA.

Figure 3: *Construction exports, 2001-2009*
Source: BCA (2006, 2008, 2009, 2010)

STRATEGIC THRUST 6: A COLLECTIVE CHAMPIONING EFFORT FOR THE CONSTRUCTION INDUSTRY

The C21 report recommended that BCA should adopt the role of a champion agency for the construction industry and oversee the implementation of the C21 recommendations. The role of BCA as the champion agency in the efforts towards achieving the vision of C21 is significant, considering that BCA was appointed as the lead agency for 19 of the 39 recommendations set out on the C21 report. BCA has since steadily worked with the other relevant public agencies, professional institutions and trade associations, and universities to implement the recommendations.

The C21 report also recommended that BCA work in partnership with the CIJC to implement the C21 recommendations and develop the industry. Thus, the government encouraged and supported the formation of the Construction Industry Joint Committee (CIJC) in 2000 to formalise the co-operation among the key organisations in the construction industry. CIJC embraces clients, various design professionals, and contractors.

The interviews revealed that BCA has actively monitored and followed up on the list of C21 recommendations. BCA held quarterly meetings with CIJC to track the progress of the implementation, in addition to *ad hoc* meetings. Feedback sessions with the industry were also conducted. Within CIJC, each member institution was assigned specific C21 initiatives to spearhead. However, it is widely realised that CIJC has its limitations. It acts by consensus, which gives each body an effective veto on initiatives (Interviewee 3). It is a loose grouping of institutions (Interviewees 2 and 5). There is no real leadership; instead, there is a rotation of its president among the members every year (Interviewees 4A and 5). Each organisation tends to protect its own interests (Interviewee 7). The interviewees considered the CIJC important, and agreed that it needs to be strengthened.

CONCLUSIONS

The construction industry in Singapore has evolved since the publication of the C21 report a decade ago. There have been new regulations and initiatives that impacted on the industry's practices. In the past decade, the adoption of a range of progressive practices in Singapore has been encouraged by C21. CORENET has been one of the most successful initiatives. In addition, there has been greater consideration of buildability; widespread adherence to the construction quality programme; and greater adoption of CPD programmes. However, a decade after the publication of the C21 report, some of the recommendations have not been implemented. Industry-wide codes of conduct have been drafted, but they were considered to be rather too general. In the area of construction safety, Construction (Design and Management) Regulations were still in progress. Some of the C21 initiatives and programmes have not succeeded. They include the intention to reduce the number of foreign workers, MYE, maintainability study, NPQS, Construction Management System, standardisation of contracts, and multi-disciplinary firms.

The study reported on in this paper is based on interviews of some of the leaders of the industry in Singapore who were instrumental in the formulation, implementation and monitoring of C21. Their opinions were compared with the literature as well as the comments and views expressed by others in both the public and private sectors. The interviewees agreed that through C21, Singapore has made a considerable amount of progress in developing its construction industry. However, it is evident that more needs to be done in the future. The intended radical transformation of the industry has not been attained. After a decade, some of the underlying issues remain the same. The extent to which the industry reforms have fulfilled their original intentions is not completely clear. The impact of the initiatives on the way companies and practitioners work is also not clear. Hence, there is a need to revisit priorities and review the progress so far and map out general strategies for the future.

Considering the nature of the construction industry in Singapore, there will be continued reliance on subcontracting and foreign workers into the future. Thus, long-term solutions are needed. Improvement in quality must be accompanied by sustainability considerations. It is evident that the focus in construction industry development in Singapore will be on

improving productivity as part of the national, economy-wide drive. The government is also aggressive in promoting health and safety, and this will be another major consideration. In the area of IT, Building Information Modelling (BIM) will be used as a platform to facilitate the integration of knowledge in design, construction, and facilities management.

Abstract
This research explores the nature of relationship management on construction projects in Australia and examines the effects of culture, by means of Schwarz's value survey, on relationships under different contract strategies. The research was based on the view that the development of a sustainable supply chain depends on the transfer of knowledge and capabilities from the larger players in the supply chain through collaboration brought about by relationship management. The research adopted a triangulated approach in which quantitative data were collected by questionnaire, interviews were conducted to explore and enrich the quantitative data and case studies were undertaken in order to illustrate and validate the findings. The aim was to investigate how values and attitudes enhance or reduce the incorporation of the supply chain into the project. From the research it was found that the degree of match and mismatch between values and contract strategy impacts commitment and the engagement and empowerment of the supply chain.

Keywords: supply chain sustainability, relationship management, Queensland, culture, convergence.

INTRODUCTION

Relationship management is a system that provides a collaborative environment and a framework for all participants to adapt their behaviour to project (and longer term) objectives. It is about open communication which needs to be facilitated and nurtured. The, a 'sustainable supply chain' requires a clear relational strategy that takes into account individual values within the organisation structure (contract strategy in this case) and so empowers decision making, free communication and encourages relationship building.

Effective supply chain management enhances organisation performance and competitiveness through the management of operations across organisational boundaries (Giannakis, Croom, & Slack, 2004). Relational contracting approaches facilitate the exchange of information and knowledge and builds capacity in the supply chain, thus enhancing its sustainability. Relationship management also provides the conditions necessary for the development of collaborative and cooperative relationships. It is about open communication, sharing resources and experiences, exposing the 'hidden' risks in the project. However, subcontractors and suppliers are not empowered to attend project meetings or to have direct communication with project based staff (Dainty, Briscoe, & Millett, 2001). With this being a common phenomenon in the Australian construction industry, one might ask: what are the

barriers to implementation of relationship management through the supply chain? In other words, the problem addressed in this research is the engagement of supply chain through relationship management.

Relationship management is a business strategy. It is a system that provides a collaborative environment and a framework for all participants to adapt their behaviour to project objectives and allows for engagement with the supply chain. On the other hand, relational contracting is an approach. A relational contract tends to be of a fixed duration, with exchange of relations in light of opportunities for future cooperation among the contracting parties. After all, companies do not collaborate for the sake of collaboration. They would only engage in relational exchanges when the perceived benefits derived from these activities outweigh the cost incurred.

A contractual arrangement with strong relationship management, such as committed joint-venture or alliance, allows collaborative and cooperative attitude to develop between project participants. Project parties focus on the organisations' business future and aim for long-term success. The reason for this is a paradigm shift. Relational approaches assist and develop a collaborative and cooperative working environment where trust can be developed and this leads to community benefit and a sustainable supply chain.

Research Aim and Objectives

The aim of the research is to explore the association between relational contracting structures and processes and supply chain sustainability in the construction industry. The underlying principles which frame this research are relationship management, motivation values, culture and contract strategy. The objective of this research is to investigate perception of relationship management from a contractor's perspective and the impact of moving relational contracting down the value chain; thereby empowering and developing a sustainable supply chain.

Contract Strategy

Rowlinson defines contract strategy as being a subset of procurement systems (Walker & rowlinson, 2009; Rowlinson & McDermott 1998) and uses a typology consisting of seven key variables to uniquely define any particular contract strategy. One of the more important variables is organisation form and it is this dimension that is applied here in this research. Motivation values are context dependent and in construction the organisation form clearly distinguishes one project from another and, in some senses, demands more or less focus on relationship management as a consequence. For example, the degree of integartion inherently present in an organisation form can be represented in Figure 1 below. The common organisation strategies adopted in Australia in this research were:

Minor Works Contract (design then construct); Roadworks Performance Contract (RPC,design then construct); Road Construction Contract (RCC, design then construct); Road Construction Contract with Relationship Management (RCC(RM) design then construct); Design and Construct (design and construct); Early Contractor Involvement (ECI design and construct); Alliance (design, construct and maintain).

The number of such contract types in the research sample is shown below.

D&C (4)	Minor Works (8[a])	RPC (10)	RCC (10)	RCC (RM) (26)	ECI (10)	Alliance (30[a])

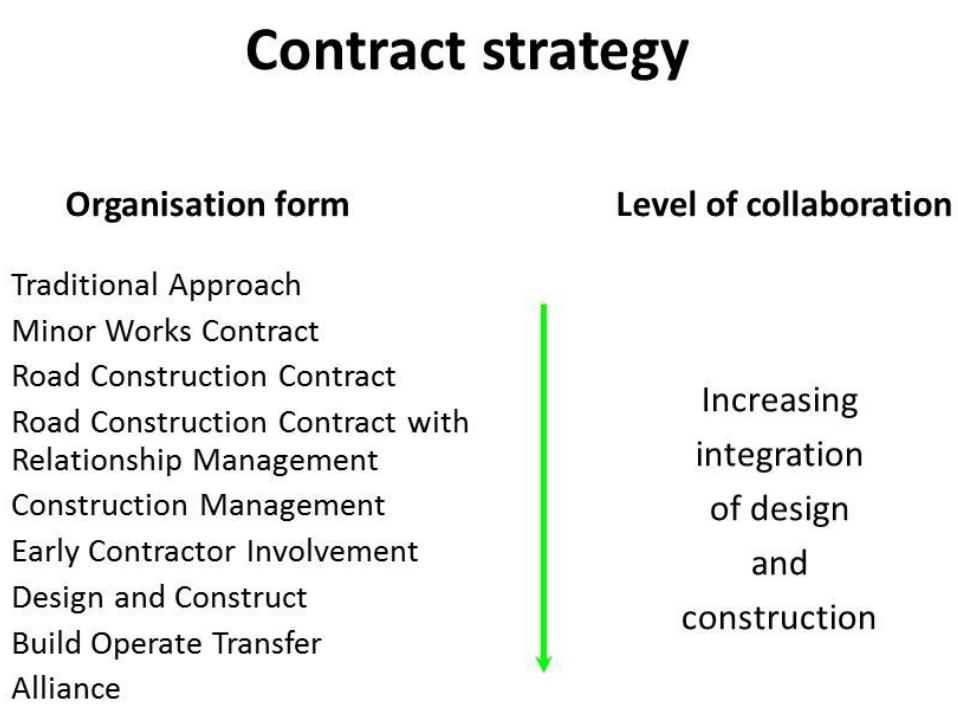

Figure 1: Contract strategy and collaboration potential

Relationship Management

There are many definitions of relationship management (RM). One of the most widely adopted definitions is Berry's description of RM as 'attracting, maintaining and – in multi-service organisations – enhancing customer relationships' (Berry, 1983, p.25). Grönroos (1996) describes RM as a process of managing the organisation's market relationships by which allows organisations to identify and establish, maintain and enhance and, when necessary, terminate relationships with customers and other stakeholders, at a profit so that the objectives of all parties involved are met through mutual exchange and fulfilment of promises (Grönroos, 2007) i.e. interactions and continuous improvement. Sheth's definition of RM reflects similar theme. Sheth (1994, p.2) describes RM as 'the understanding, explanation and management of the on-going collaborative business relationship between suppliers and customers' and companies must align their business processes to achieve higher level of efficiency and effectiveness when operating under a RM regime (Sheth & Sisodia, 2002). One common message is relationships are built on past behaviour and future promises.

In construction, the traditional hard-dollar procurement system can be seen to less suitable for today's complex construction environment, where rapid change and unanticipated decision situations are constantly encountered (Shirazi, Langford, & Rowlinson, 1996). One cause of this is that the construction industry is not unitary but comprises temporary multi-organisations (Murray, Langford, Hardcastle, & Tookey, 1999). While a pure mechanistic organisation form was appropriate for a completely stable environment (Winch, 2000a); for flexible and changing environments, an organic organisation form is much more suitable. The

project team changes its structure and organisation style in different phases of the project life cycle and hence is described as a 'living organism' (Sidwell, 1990). The project organisation is made up of members drawn from parent organisations. Sidwell also points out that all projects have a distinct life-cycle, the organisational forms change over time from chaotic to mechanistic to bureaucratic, depending on the project stage and the project team. For example, the consultant team tends to have a chaotic structure at the concept stage. Design and documentation is a more mechanistic process which then leads to the construction stage which involves heavy monitoring and a lot of bureaucracy. On the other hand, the contractor is likely to operate in an organic mode at the construction stage.
Relationship contracts are usually long-term, develop and change over time (Cheung & Rowlinson, 2007). Relationship management is a system that provides collaborative environments and frameworks for all project participants to adapt their behaviour to project objectives and allows for engagement of the supply chain. Relational approaches are particularly suited to the Australian culture, where open communications and direct confrontation are accepted and indeed preferred (Cheung, 2006a);such attitudes form a sound basis for relational approaches to be successful. This research seeks to explore the impact of values and attitudes on the success of the relationship management approach.

Key concepts for a successful relational contracting approach have been reported in recent studies (e.g. Cheung, 2006b; Dainty*, et al.*, 2001; Price, Bryman, & Dainty, 2004; Walker & Hampson, 2003). These studies identified empowerment, motivation, commitment, organisation structuring and culture as being significant in the implementation of a sound relational contracting approach to projects. Relational contracting approaches have received strong interest in the construction industry and the efficacy of relationship management in the client and contractor groups has been well documented. However, little research has been done in the supply chain context.

Studies suggest that relational approaches, such as partnering, alliances, framework agreements and relationship management, provide positive contributions to social, environmental and economic sustainability and help to satisfy client and stakeholder interests (Blau, 1963; MacNeil, 1978, 1985; Rousseau & Parks, 1993). In other words, relational contracts provide the means to achieve sustainable, on-going relationships in long and complex contracts by an adjustment process of a more thoroughly transaction specific, on-going, administrative kind (Kumaraswamy & Matthews, 2000). The essence of relationship management is also found in collaborative procurement. Collaborative procurement aims at engaging parties at all project stages; competitive bidding is no longer the only selection criterion for contractors and design consultants, as well as suppliers (Hughes*, et al.*, 2006). Also, some reliance is placed on the deliberate development of long-term working relationships which requires trust building. Another characteristic of collaborative procurement is the number of partners is limited. This is particularly crucial in countries such as the UK and Hong Kong, where multi-level subcontracting is a common practice.

The common aim of all relational contracts is to recognise and for strive mutual benefits and win-win scenarios between project parties in a long-term basis (Rowlinson & Cheung, 2003). Thus, relationship management places strong emphasises on collaborative relationships in the supply chain, proactive problem solving and open and honest communication between project parties; in other words, more collaborative working arrangements and sustainable practices. It is clear that relational contracting is predicated on a broader view of the procurement approach and requires clearly focussed contract strategies and strategic management; it implicitly incorporates supply chain engagement, essential if the performance indicators of

best value, community benefit and innovation are to be achieved. One of the main differences between relational contracts and traditional hard-dollar contracts is the problem solving mode where performance problems in relational contracts are solved in a more collaborative manner amongst project team members and senior management, without recourse to claims and litigation (Bresnen & Marshall, 2000a; Cheung, 2006b). In some cases, contractors would absorb extra costs in order to maintain good relationships with the client and increase the chances of gaining future business (Bresnen & Marshall, 2000a). After all, a partnering relationship between organisations is based on trust, dedication to common goals and an understanding of each other's expectations and values (Construction Industry Institute, 1991).

Commitment

Walker, Bourne and Rowlinson (2008) describe the connections between commitment and motivation using Allen and Meyer's theory (1990) and Maslow's theory (1970), as shown in 2. According to Maslow, human behaviour is controlled by both external and internal environments. Also, individuals have certain needs; these needs do not change in origin and are hierarchal in nature. One must satisfy lower level basic needs before recognises or pursues the next level in the hierarchy. As suggested by Walker *et al.* (2008), the strongest form of commitment is affective because it is 'want-to commitment' based on a motivation of self-actualisation and/or ego needs, and can move people to contribute beyond expectations.

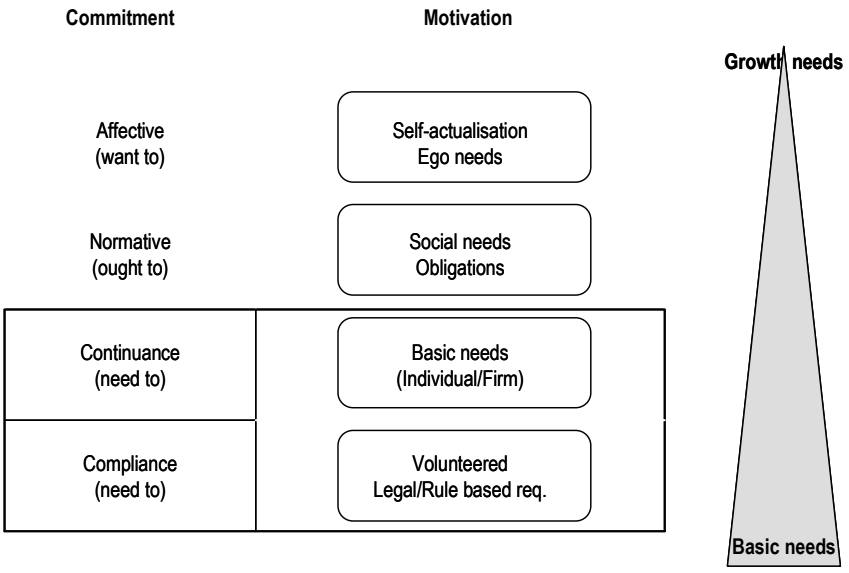

Figure 2: Commitment and Motivation
Source: Allen and Meyer (1996) and Maslow (1970) in Walker & Rowlinson, 2009

A relationship management approach cannot succeed if the collaborating organisations do not accept its ethos. Commitment is an important component of motivation (Meyer, Becker, & Vandenberghe, 2004). Hence, sharing values and being committed to the goals and objectives of the organisation is crucial in client, contractor and supply chain integration.

Values and Motivation

Cultures vary in their underlying values and attitudes (Wood, Wallace, & Zeffane, 2001). The way people think about such matters as achievement and work, wealth and material gain,

risk and change may influence how they view work and their experiences in organisations. Schwartz developed a value survey which examines individual motivational types of values and their goals. According to Schwartz (1992b), the meaning of a value can be inferred from its pattern of positive and negative associations with other values. Values '(1) are concepts or beliefs, (2) pertain to desirable end states or behaviours, (3) transcend specific situations, (4) guide selection or evaluation of behaviour and events, and (5) are ordered by relative importance' (Schwartz, 1992a, p.4). Thus, the meaning of a value is best captured by examining the structure of its relations with a comprehensive set of values thus providing insight into the development and consequences of a diverse range of behavioural attitudes and orientations, such as religious belief, political orientation and voting, social group relations, consumer behaviour, as well as the conceptualisation of human values across cultures. By comparing cultural value dimensions between different countries and regions/groups and, indeedworking teams and temporary multiorganisations, one can begin to understand the intercultural meanings in the project environment and so to establish effective relationships in project teams.

Relationship management is about a shared culture between organisations, where the motivation and attitude of the project participants is critical to success. Van de Ven and Ferry (1980) measure a whole series of organisational parameters including individual motivation, work processes and organisational structure. Winch *et al.* (1997) found autonomy at work, work coordination and work control along with job satisfaction, instrumental motivation and feedback as essential for enabling teamwork and individual motivation in construction projects. On the other hand, innovation, organisational commitment and motivation are strongly related (Khalfan & McDermott, 2006). Referring back to Figure , motivation is controlled by both internal and external environmental factors (Maslow, 1970) and is strongly associated with levels of commitment. It is important for construction organisations to be involved in the innovative procurement practices, such as relationship management, in order to take advantage of changes in markets. Financial reward might be a motivator for a client to build long-term relationships with other participants within the supply chain (Khalfan & McDermott, 2006). On the other hand, although money might be client's drive for relationship management, the supply chain might find further job opportunities and organisational competitiveness as attractive motivators for the initial buy-in

Motivation typology of Values

The motivation typology of values was measured with Schwartz Value Survey (SVS) (Schwartz, 1992b; Schwartz, 1994). Schwartz [Schwartz, 1992, 2005a] details the derivations of the ten basic values. For example, a conformity value was derived from the prerequisites of interaction and of group survival. For interaction to proceed smoothly and for groups to maintain themselves, individuals must restrain impulses and inhibit actions that might hurt others. A self-direction value was derived from organismic needs for mastery and from the interaction requirements of autonomy and independence. Each of the ten basic values can be characterized by describing its central motivational goal. The SVS measures values at both individual and cultural levels, using a 9-point Likert scale ranging from 1 to 7. Fifty-seven value items were clustered into 10 types of values using the statistical technique smallest-space analysis. The 10 values and their definitions are presented in 1 below.

Table 1: Definition of motivation values (adapted from Schwartz, 1994, p.22)

Motivational Types	Definitions
Power	Social status and prestige, control or dominance over people and resources
Achievement	Personal success through demonstrating competence according to social standards
Hedonism	Pleasure and sensuous gratification for oneself
Stimulation	Excitement, novelty and challenge in life
Self-direction	Independent thought and action – choosing, creating, exploring
Universalism	Understanding, appreciation, tolerance and protection for the welfare of all people and for nature
Benevolence	Preservation and enhancement of the welfare of people with whom one is in frequent personal contact
Tradition	Respect, commitment and acceptance of the customs and ideas that traditional culture or religion provide
Conformity	Restraint of actions, inclinations and impulses likely to upset or harm others and violate social expectations of norms
Security	Safety, harmony and stability of society, of relations, and of self

The 10 values are further grouped into four higher order value types: Self-Transcendence, Conservation, Self-Enhancement and Openness to Change, each containing two or three of the 10 values (3). Values under the same higher order value types are theorized to share similar meaning (Schwartz, 1994). For example, the value of benevolence is interrelated with universalism, conformity and tradition, constituting the higher-order value of self-transcendence. This value is considered to be opposed to and in tension with the value of self-enhancement; likewise openness to change and conservation.

Research approach

This research builds on the proposition that the values held by individuals will interact with their context, the type of contract strategy that they are working within, and thus affect motivation and performance and thereby supporting or interfering with the relationship management process by inducing either collaboration or conflict. Hence, the interaction of motivation values and contract strategy are investigated through statistical analysis of responses from individuals on 98 projects and the findings explained by reference to case studies and interviews undertaken during the study. Thus, the study has been triangulated but the data cannot be fully presented here due to space constraints.

The first step in the analysis was to check the scale reliability and validity, although Schwartz has argued (*op cit*) that his scale is universally applicable. The relationship between motivation values and contract strategy was then empically investigated and the results discussed with reference to the interviews and case studies.

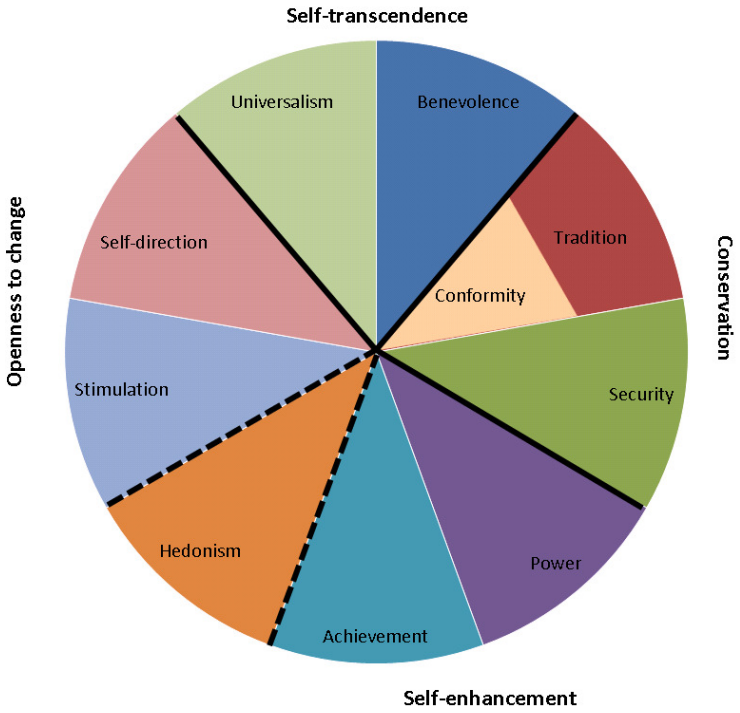

Figure 3: Value Types and Motivation Values (Schwartz, 1994)

Scale Reliability and Validity

Reliability analysis for the 10 motivation values was carried out. Out of the ten motivation values, *stimulation*, *tradition* and *security* have Cronbach's alpha less than 0.70, suggesting the items measured in these three values are not highly correlated and the value dimensions do not have high internal consistency.

Table 2: Scale Reliability and Validity - Motivation Values

Motivation Values	Cronbach's alpha	Motivation Values	Cronbach's alpha
Power	0.781	Universalism	0.786
Achievement	0.735	Benevolence	0.728
Hedonism	0.788	Tradition	0.597
Stimulation	0.627	Conformity	0.748
Self-direction	0.741	Security	0.619

Tables 2 & 3 and Figure 3 show the survey results of value dimensions of Australian construction professionals. The most important value for Australian construction professionals is *benevolence* (goodwill for work colleagues), followed by *self-direction* (independent thought and action), *achievement* (personal success) and *conformity* (self-restraint). Schwarz (2005a) states "Benevolence and conformity values both promote

cooperative and supportive social relations. However, benevolence values provide an internalised motivational base for such behavior. In contrast, conformity values promote cooperation in order to avoid negative outcomes for self." Hence, one might draw the conclusion that benevolence is an appropriate trait to display in promoting both relationship management and supply chain sustainability and that this appears to be a dominant value in the Australian construction profession sample. However, further analysis in relation to contract strategy is revealing.

Table 3: Mean, Median and Standard Deviation of Australian Professionals on the Subdimensions of the Schwartz Value Survey

	Mean	Median	Standard Deviation
Power	3.227	3.250	1.307
Achievement	4.791	5.000	.935
Hedonism	4.367	4.333	1.307
Stimulation	4.483	4.333	1.075
Self-direction	4.822	4.333	1.075
Universalism	4.434	4.375	.834
Benevolence	5.147	5.200	.723
Tradition	3.545	3.400	1.066
Conformity	4.739	4.750	1.020
Security	4.639	4.700	.866

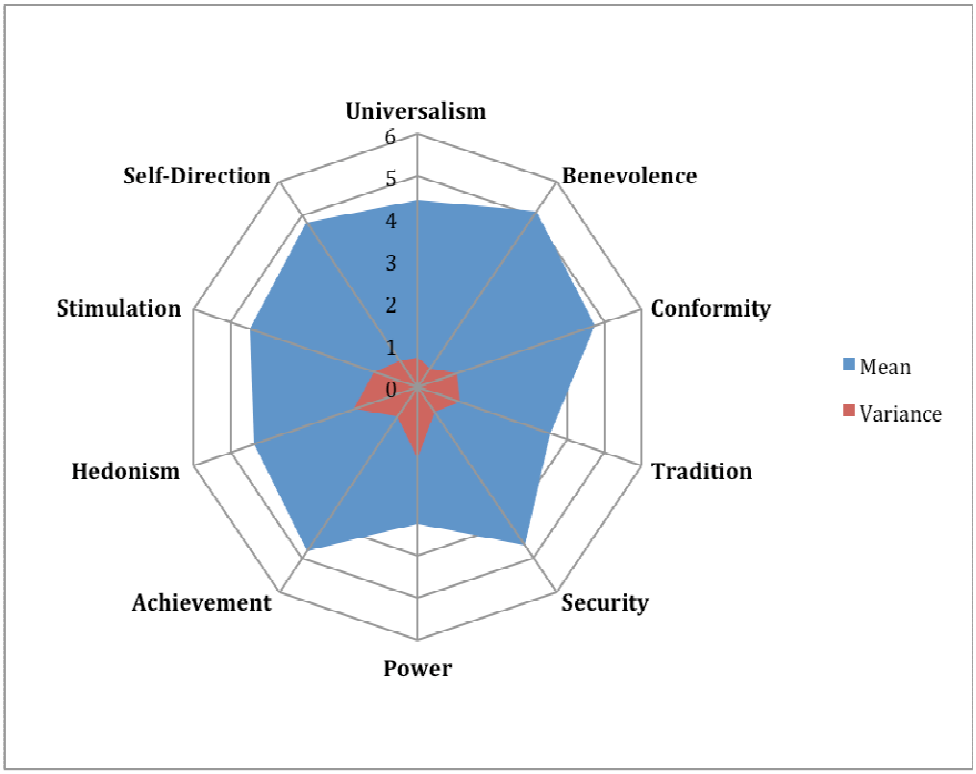

Figure 1: Australian Professionals' Value Dimensions

Motivation Values by Contract Strategy

Table 4 indicates that there is no significant variance difference in the mean motivation values, except *Self-Direction*, between each group.

Table 4: Test of Homogeneity of Variance - Motivation Values between Contract strategies

	Levene Statistic	df1	df2	Sig.
Security	.804	6	91	.569
Conformity	.482	6	91	.820
Tradition	1.336	6	91	.249
Benevolence	.178	6	91	.982
Universalism	.669	6	91	.675
Self-Direction	2.495	6	91	.028
Stimulation	.788	6	91	.582
Hedonism	.298	6	91	.937
Achievement	1.059	6	91	.393
Power	.604	6	91	.726

Results of ANOVA show how each of the motivation values varies with contract strategy as shown in Table 5. These result suggest that there is a significant difference in *Conformity* between different contract strategies (p<0.05). However, when sample sizes and variances are unequal, the Welch statistic is more powerful than the standard F or Brown-Forsythe statistics. The robust tests of equality of means suggest there is no significant difference in *Conformity*, but significant difference in *Self-direction* (p<0.05) between different contract strategies (Table 6). A post-hoc test was carried out to identify which groups are different. The test shows that RPC form is significantly different from ECI form, with a mean difference of -.980 and a p value of .037, with an *ES* of -.841. Self direction reflects independent thought and action and is exhibited in decisive actions such as choosing, creating and exploring

Table 5: Motivation Values by Contract strategies - ANOVA

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
Conformity	Between Groups	13.580	6	2.263	2.357	.037
	Within Groups	87.374	91	.960		
	Total	100.953	97			
Self-Direction	Between Groups	8.254	6	1.376	1.921	.086
	Within Groups	65.181	91	.716		
	Total	73.435	97

		Statistic[a]	df1	df2	Sig.
Conformity	Welch	2.353	6	22.049	.066
	Brown-Forsythe	2.399	6	40.095	.045
Self-Direction	Welch	2.851	6	22.179	.033
	Brown-Forsythe	2.060	6	43.773	.078

[a] Asymptotically F distributed.

Results on how *Self-Direction* may vary with contract strategy are shown in Table 7. Findings suggested there are significant differences in the degree of *Self-Direction* with different contract strategies (p<0.05). the post hoc test using Games-Howell reveals that professionals who work on RPC projects have significantly lower levels of self-direction than professionals who work on ECI projects. On the other hand, professionals from D&C, Minor Works, RCC, RCC (RM) and Alliance projects do not statistically differ in their level of self-direction.

Table 7: Motivation Values (Self-Direction) by Contract strategy

Motivation Value	**Contract strategy** (# of cases)							**ANOVA** (Welch)	
	D&C (4)	Minor Works (8[a])	RPC (10)	RCC (10)	RCC (RM) (26)	ECI (10)	Alliance (30[a])	df1, df2	F

Mean	5.45	4.95	4.34	4.88	4.58	5.32	4.89	6, 22.179	2.85[#]
S.D.	.37	.40	.59	.76	.79	.25	.49		

DISCUSSION AND CONCLUSIONS

The finding that the motivation value of self-direction is strongly correlated with ECI projects is interesting and fits in with the notion that ECI involves both high degrees of collaboration and exploration of alternatives at a stage in the project process where ideas can be "tossed around" and solutions developed. When this is combined with the motivational value of benevolence this provides an ideal context for collaborative working and inclusion of the supply chain. This proposition is backed up from the case study and interview data. That the converse relationship exists for RCP (hard dollar contracts) is then no surprise with the focus being on delivering a set product for a fixed price with no scope for exploration nor any perceived need to include the supply chain. This was again backed up from evidence in the interviews.

From the questionnaire survey it was found, but not reported in detail here, that project teams with strong inter-organisational influences, easy access to information, strong personal acquaintance and frequent group communication are found to have good understanding of organisational structuring and communication. Principal Contractors and project stakeholder groups generally exhibited medium to high levels of consensus. When disagreements arose, the most frequently used resolution method was by directly confronting the issues. As expected, the more often professionals directly confronted issues, the less likely professionals were to avoid or smooth over issues.

Professionals communicated by telephone conversation mostly, followed by face-to-face discussions. Quality of communication between Principal Contractors and project stakeholder groups was found to be highly satisfactory. Findings suggest that good communication quality and strong personal acquaintance result in high levels of agreement. There was an fair degree of agreement between Principal Contractor and project stakeholder groups.

Findings indicate that alliance and Early Contractor Involvement (ECI) projects achieve higher performance effectiveness at short-term as well as long-term levels than projects with either no or partial relationship management adopted as a management strategy. The motivation values of self direction and benevolence were to be found in such project teams and, taking a context dependent view, were instrumental in bringing about supply chain inclusion and, hence, the prospect of sustainability.

Out of the four most important values indicated by Australian construction professionals, no significant relationship was found between *benevolence* and any organisation variables. On

the other hand, *self-direction* related significantly with level performance effectiveness, particularly the longer term view of the company's strategic direction.

TOWARDS THE USE OF PROJECT ALLIANCE: JOINT DEVELOPMENT OF A TEAM SELECTION PROCEDURE AS AN EXAMPLE OF STEPS TAKEN

PERTTI LAHDENPERÄ
VTT Technical Research Centre of Finland
Finland
Pertti.lahdenpera@vtt.fi

Abstract

Project alliance is a relatively fresh project delivery method where the owner and service providers, the designer and the constructor, share the risks of the project in order to intensify their collaboration for the best of the project. Experiences from the model from "down under", where it has broken through, reached Finland some years ago. Since then, the Finnish Transport Agency (incl. its predecessors) has been intending to introduce the system in its transport infrastructure projects. The paper discusses related challenges and sheds light on an industry-wide joint effort and the progress made to date. In that respect, the development of the qualitative team selection process and criteria are presented in more detail. Moreover, the paper introduces the first two projects that are to apply the project alliance model: a rural rail renovation and an urban road tunnel construction one. The ambience generated by the efforts so far is promising, and it seems that all the parties look forward to taking up the practical work and seizing available benefits.

Keywords: project alliance, collaboration, selection criteria, shortlisting, competition

INTRODUCTION

Project alliance is a relatively fresh project delivery practice that has broken through especially in Australia and New Zealand. In project alliance the owner and service providers, the designer and the constructor, share the risks of the project and the payment to the service providers is tied to the overall success of the project. It is, first and foremost, a project delivery system for large, complex and risky projects. Success stories from the use of the project alliancing approach and news on related benefits reached Finland some years ago. Since then, various activities have been organised for the introduction of the delivery system also in Finland. *The Finnish Transport Agency* is the enthusiastic commissioner of the system and the first planned projects involve rail renovation and urban road tunnel construction that are about to start in the very near future.

This paper sheds light on the present state of the preparations for applying project alliance in Finland. After reintroducing the key ideas and principles of project alliance and how they reached Finland, the presentation focuses on the initial joint development between *the Finnish Transport Agency*, the industry and *VTT*. The development of qualitative team selection criteria is singled out for more detailed review as an example of steps taken so far. Finally, the paper proceeds towards the introduction of project alliance in practice by looking into the two transport infrastructure projects that are to be the first of this type in Finland. The procurement process for service providers has already started with one of the projects and will start later this year with the other.

AWARENESS OF PROJECT ALLIANCE

Features of project alliance

The concept of *alliance* refers generally to an association and agreement between actors aimed at integrating their goals and/or operations. An arrangement of the type made for a given project is called a *project alliance* or an *alliance contract* to distinguish it from so-called *strategic alliance* which is a collaborative arrangement covering several projects or other long-term activity.

More precisely, *project alliance* is a project delivery method based on a *joint contract* between the key actors to a project whereby the parties assume joint responsibility for the design and construction of the project to be implemented through a *joint organisation*, and where the actors *share* both positive and negative *risks* related to the project and observe the principles of information accessibility in pursuing close cooperation:

- *Joint agreement*. The tasks of an alliance include project planning and implementation tasks and (possibly) ones related to them and to the promotion of the project traditionally performed by the owner, which said actors are jointly responsible for. The parties enter into a single joint multi-actor contract instead of several bilateral contracts (different in spirit).
- *Joint organisation*. The alliance organisation comprises people from all partner organisations, including the owner's. Decisions on project implementation are taken jointly by the parties. The cost estimate covers all related tasks and persons. The project target cost is defined correspondingly and is consequently the total cost of the project.
- *Risk sharing*. Alliance partners share the risk of project implementation as concerns the bulk of both positive and negative risks. Thus, the reward of service providers is also based on the success of overall project implementation, not on their performance of their own tasks. The practice requires observing the principles of openness in cost monitoring.

In addition to these structural features, the collaborative features of trust, commitment and cooperation are of primary importance in project alliance (see e.g. DTF 2010).

The project alliance system evolved from the need to improve the implementation of demanding and risky investment projects. In a project involving much uncertainty due to, for instance, new technology and project conditions or interfaces, risk premiums and/or adversarial behaviour characteristics of traditional contracting would lead to an uneconomical result from the viewpoint of the owner. On the other hand, the alignment of the parties' objectives by joint risk-sharing in a project alliance arrangement, supplemented by a joint organisation and decision making, is supposed to improve the performance.

The rise of enthusiasm

The first few alliance-type construction projects were realised in Australia in the late 90's, and only a few years later the delivery system came to the Finns' notice in the connection of the reporting of international interviews on the procedures and performance of different road project delivery systems (Koppinen and Lahdenperä 2004, also Pakkala et al. 2007). Since then there has been growing interest for the model and the thing that finally set the wheels in motion was a fact-finding tour to Australia by a group of the former *Finnish Road Administration*'s representatives in the beginning of 2007. At that time, a real breakthrough in the use of project alliance had occurred in Australia and the number of cumulative experiences was already significant (cf. Anon 2009). So far, hundreds of projects have already been implemented by the project alliancing system. Except for very few social infrastructure projects, they have been civil engineering projects for road, rail and water infrastructure (Ross 2006, Anon 2009).

INITIAL DEVELOPMENT EFFORT

Joint development entity

The above mentioned fact-finding tour led to the launch of a sort of feasibility study on the application of project alliance in Finland (Lahdenperä 2009). The general challenge was to understand the possibilities of alliance-type procurement in increasing production efficiency, chart the procedural solutions for project alliances to the extent the approach has been used worldwide, evaluate the feasibility of the application of the procurement method in local Finnish (and European) culture and business and legal environment (e.g. Directive 2004b) and, particularly, develop project processes, procedures and ground rules to support the use of the project alliance in said application environment.

The development work built on a literature study and expert workshops. The several expert groups involved focused on different sections of the problem field. More precisely, there was a steering committee for the entire study and three separate subordinated thematic workgroups for cost estimation and the payment/incentive system, organisational and administrational issues, and selection process and criteria. The work of the last-mentioned group will be looked into in more detail below.

The groups consisted of a few dozen experts and practical actors from transport network owner organisations (the then *Finnish Road Administration* and *Finnish Rail Administration*) as well as numerous companies offering corresponding design and construction services. The groups met regularly to comment on and direct development work and ideate new procedural solutions. Several dozen such workshops and meetings were conducted during the one year team work period (the 2008 calendar year), and the time spent attending them corresponds to a few person-months of labour.

Workshop activity was speeded up by literature surveys and presentations as well as procedural constructions prepared in advance by researchers. Although an attempt was made to utilise existing knowledge to the fullest, the research approach is rather constructive as a whole due to the scope and multiformity of the problem. The aim is to test the workability of solutions through later application and further development. The wide participation in the development project also prepared and committed the markets so as to allow launching pilot or actual alliance projects as soon as possible.

All in all, development work focused on process engineering and basic contractual solutions that form a starting point for later preparation of project documentation. The workability of project alliance which stresses cooperation also requires heavy investment in cultural and management issues, which were excluded from the initial development work reported here.

Selection process and criteria development

The workgroup on the selection process and criteria met ten times during the year in an attempt to adapt the existing model to the target market. The legal praxis concerning competitive tendering in public procurement was, however, found a special challenge which is why it was considered that the implementer selection procedure that is based on competence (or quality) only, i.e. the most common one in Australia at the time, could not be introduced as such. On the other hand, there was the desire to avoid heavy competition involving design and total pricing. A comparison method applied early on that stresses competence while also considering (partial) price was thus heavily weighted in the work.

According to the general guidelines for government procurement, price should – roughly speaking – carry a weight of clearly more than one third when using relative weighting of criteria although, in the case of service procurement, exceptions are allowed (Hytönen and Lehtomäki 2007). The joint view of participating experts and practical actors is that price should generally carry a weight of no more than one fourth or so in project alliance. This is because better overall economy is pursued by putting together the best possible team of versatile know-how already at the stage when the implementation solution still can be influenced and improved. It also makes for more profound evaluation of qualitative factors than is the norm with other procurement methods.

Another impact of the European legal environment on the shaping up of the selection process was that when using the negotiated procedure or the competitive dialogue, at least three candidates must be invited to the tendering process unless there are fewer suitable candidates (Laki 2007a). Tender phase workshops are so laborious that it is generally not justified to invite more than that minimum number.

The development of qualitative selection criteria, on the other hand, started on a slightly more independent basis. A global survey (Lahdenperä and Sulankivi 2001) carried out a few years earlier offered a good starting point since it comprised all thinkable qualitative criteria for the selection. Through reclassification, combination and elimination the set of criteria summarised below was created. The material from the survey was also complemented with alliance-specific issues drawn from actual alliance owners' requests for proposals (e.g. VicRoads 2006).

The development of actual qualitative selection criteria was also constrained by the local environment. Courts are known to have intervened in cases where clear enough distinction has not been made between reducing the number of candidates and tender evaluation as concerns suitability criteria. Thus, qualitative criteria must evolve between these phases from evaluating qualifications toward evaluation of project-specific procedures although in the case of project alliance evaluation during both phases focuses on quite similar issues.

SELECTION PROCESS AND CRITERIA

Selection process

The procedure of competitive selection is established for the early involvement of service providers through a collaborative approach. Service provides are selected as a team; in other words, designers and builders are not selected separately and matched. According to the model, selection takes place through elimination of candidates and a subsequent two-phase tendering process: the qualitative tender precedes the workshops that are part of evaluation, followed by submission of tender price data. The price is made up of unit prices, overhead rates and other components as appropriate in each case (although the issue is too multifaceted to be discussed here). Then, selected service providers develop the project and its designs in cooperation with the owner before the actual target cost is set and the parties are ready to finally commit to the implementation of the project in question.

The phases of this process are shown in the middle of Figure 1. The elements on the left represent the key inputs of each phase and those on the right are the key results from the phases or a characterisation of follow-up work.

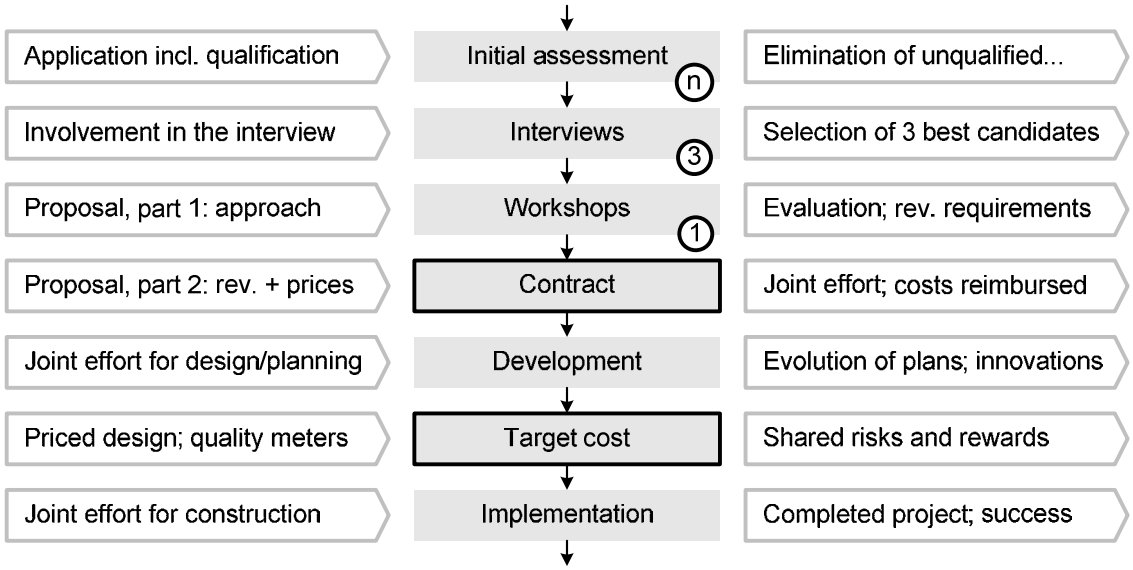

Figure 1: *Selection process with key input and output characteristics.*

Selection criteria

Overview

Different phases of the selection process for the implementer of the alliance contract use different criteria: at first minimum criteria concerning candidates are applied, followed by elimination (or shortlisting) criteria, and lastly tender evaluation criteria (Figure 2, Table 1). The meeting of minimum criteria (A) is evaluated on the basis of the request to participate, and that of elimination criteria (B) on both the request to participate and interviews. Tender evaluation has two phases. First, Part I of the written tender (C1–C3), submitted before the workshops are conducted, and the workshop performance of the tenderer's project group (C4) are assessed. After the workshops, Part II of the tender including price data (C5) is submitted as well as other information required by the specification of the call for tenders. The criteria are examined in more detail by phases below.

Verification of qualification

Application of minimum criteria ensures that candidates have the basic qualifications for successful implementation of the construction project in question. Minimum requirements include, for instance, that candidates have a transparent financial monitoring system suitable for cooperation as well as the required experience from design management and organising and implementing of projects involving design (Table 1, Section A). Candidates that meet the minimum requirements qualify and are invited to interviews organised by the owner. Candidates that fall short of the minimum requirements are rejected.

Reducing the number of candidates

Candidates meeting the minimum requirements are ranked according to their merits, initially on the basis of the requests to participate they submitted to the owner (Table 1, Section B). Candidates are also invited to interviews intended to clarify things already expressed in writing in the request to participate. On the basis of the interviews and the request to participate, the three best candidates are selected for the next round. These candidates receive the project's call-for-tenders material. The criteria used at this stage are the candidates' competence and technical capacity, proof of successful projects and planned project organisation.

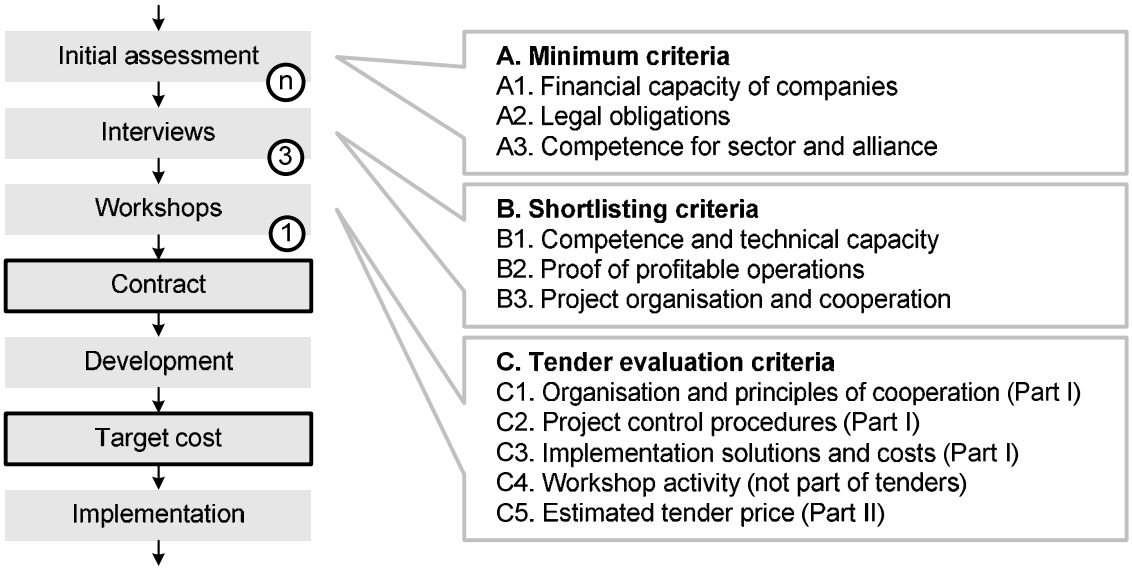

Figure 2: *Selection criteria headings combined with process phases.*

Selection of best tenderer
Evaluation of offers divides into two phases. The issues of the qualitative Part I (Table 1, Sections C1–C3) and workshop performance (Section C4) are evaluated first. At this phase, emphasis is on the suggested organisation and operating culture, project management procedures and implementation solutions and costs. After the selection workshop, the second part of the written tender, which contains the issues of Part I of the tender dealt with in the workshop and updated to the extent necessary, as well as Part II of the tender, that is, certain price data (Section C5), are submitted. The candidate that submits the most advantageous tender from the overall economic point of view is selected for negotiations.

Although both of the latter two phases of selection focus on the evaluation of the competence of actors, the general principle is that each selection criterion is used only in one phase of the selection process and the elimination-phase evaluations and corresponding scores of candidates are not considered as such at the tender evaluation phase. Naturally, the original project report (Lahdenperä 2009) describes in much more detail the process phases and tasks, selection criteria and the proof required by the owner of meeting the criteria.

THE WAY FORWARD

Pilot projects

Some time has now passed since the completion of the initial feasibility study described above. Appropriate transport infrastructure investment projects in which the model could have been applied were not found immediately thereafter. One reason for that was the need to immediately expedite some major projects as a part of the financial stimulus package launched to diminish the adverse effects of the global debt crisis. Although project alliance is generally the choice for demanding, urgent projects, it was not considered appropriate for those projects due to the significant amount of preparatory work and educational efforts that the first project of its kind would have required.

Table 1: *Selection criteria for service providers in project alliance.*

Selection phase >	Verification of qualification	Elimination of candidates		Selection of consortium	
Basis of evaluation >	Request to participate	Request to participate	Candidate Interviews	Tender (Parts 1 & 2)	Selection workshops
Selection criteria					
A. Minimum criteria

• Technical approach to project implementation				●	●
• Budget critique				●	●
C4. Workshop activity (not part of tenders)					
• Commitment, attitude and cooperation of team					●
C5. Calculated tender price (Part II)				●	

An additional challenge was posed by the reorganisation of the owner bodies. *The Finnish Road Administration* and *the Finnish Rail Administration* were the owners involved in the earlier development, who soon thereafter merged with *the Finnish Maritime Administration*. Since the beginning of 2010 all three have operated as *the Finnish Transport Agency* (except for branch offices of the earlier *Road Administration* that are currently under *the Centres for Economic Development, Transport and the Environment*). *The Finnish Transport Agency* is a government agency operating under the jurisdiction of *the Ministry of Transport and Communications* and it is responsible for the maintenance and development of the transport system overseen by the government.

The search for the first projects where project alliance could be applied has finally produced a plan to adopt it at least in the two following forthcoming projects:

- *The Lielahti-Kokemäki rail section*. The section extends from the western boundary of the City of Tampere nearly 100 km towards the west. It is a replacement investment required by the decades old railway superstructure. Renovation of the superstructure to meet the standards of modern technology is a basic requirement for increasing the rail speed and axle loads of the section. In need of renovation are the rails, sleepers, crushed stone and gravel layers of the beds and switches. The project with a total cost of nearly €100 million also includes renovation of electrical, information and safety equipment as well as repair of bridges, culverts and platform areas.
- *The Tampere lakeshore road*. Arterial road 12 serves as a major entry road to the city as well as a through road for long distance traffic. Its current traffic volume is 30,000–45,000 vehicles/day and the road gets jammed regularly during commuting hours. Moreover, the 2+2 lane bypass road splits up the city. The aim is to bury part of the lakeshore road in two 2.3 km tunnels of three lanes in each direction, to widen the rest of it (along 3 km), and to connect it to the surrounding traffic network by graded interchanges. Besides the city infrastructure, the tunnels will also pass under the Tammerkoski Rapids, which traverse the city, at 20 metres below the river bed. The project is estimated to cost nearly €200 million.

The first rail project is by nature more of a normal reinvestment carrying no extraordinary risks or difficulties although it is a demanding project. Thus, it may not be ideal for implementation through project alliance. Yet, it was considered suitable as the first pilot project that would increase our experience since it might be too risky to start experiment with the most difficult projects. The road project is, by contrast, a challenging one. Tunnelling works involving all the junctions, temporary traffic arrangements and the stakeholder issues related to urban development surely pose a challenge.

The foreseeable future

As concerns the rail project, procurement of service providers for the planning and implementation of the project started in December 2010 by the publication of a procurement notice (Finnish 2010). In Finland procurement notices are to be submitted for publication on the free, electronic *Hilma* information system at *www.hankintailmoitukset.fi* as determined by *the Ministry of Employment and the Economy*. The aim is to select a project team in early autumn 2011 to start joint development of the emerging project alliance. Actual implementation would, thus, take place from 2012 to 2015. The road project will follow less than a year behind. Some uncertainty still exists about the road and urban plans becoming legally valid (at the time of writing in January 2011). Yet, the optimistic presumption is that the process can be expedited and it will catch up with the rail project so that the 3-year road construction project can also be launched in autumn 2012.

In connection with the preparation work related to service procurement for the rail project, two full day briefing and/or workshop events involving the industry were organised prior to the publication of the procurement notice in order to inform companies and discuss the procedures to be applied in the project. That prepared and committed companies to the forthcoming call and also gave valuable feedback to the owner.

To date, there are no signs that the selection criteria to be used in this project would essentially differ from those condensed in the paper. Naturally, the elaborateness and diversity of the practical criteria influence their format. However, the process differs more. Only a maximum of five teams can be selected for the actual shortlisting phase and two teams

for the subsequent competition phase involving price components and preceding the selection of the best team. The latter option is possible because the general law on public procurement (that requires at least three teams; Laki 2007a) does not apply to the rail sector whose procurements are controlled by a different law on special services sectors (Laki 2007b, Directive 2004a). The actual shortlisting phase including interviews takes places only after the candidate teams have submitted their proposals, and the workshops concern only the best two. This modification, for its part, illustrates the many possibilities for organising the alliance team selection. There is no 'one size fits all' process for all projects and situations.

The pricing arrangement will also differ from that of the feasibility study report (Lahdenperä 2009; not dealt with here). Although lawyers were involved in the initial development, only more recent legal consultations have encouraged the owner to depart from the use of the calculated/comprehensive tender price estimate as a selection criterion, and the price component is likely to be represented only by certain more restricted items (e.g. fee percentage). Therefore, the proper legal praxis concerning competitive tendering in public procurement, that was said to have been found a special challenge earlier, has not been established yet. Finland seems to have been more conservative (so far) in the application of the European directive and its economically most advantageous criterion than some other countries governed by the same directive.

Due to the simplified approach and the lack of price information at the time of selection, it is also not possible to apply the two-stage target-cost arrangement drafted in the feasibility study either. Yet, it is a concept (cf. Lahdenperä 2010) that needs to be examined further before it can be introduced in actual contracts. An effort to that effect is, however, likely to be included in the R&D project just about to start aimed at supporting the development of pilot project practices and more long-term alliancing solutions in general.

Final remarks

All in all, the aim is to take the further steps needed and utilise the project alliance model in Finland in the very near future. The key governmental transport infrastructure owner has committed itself to the model and the effort will be supported by considerable R&D efforts. Naturally, many practical challenges must still be met as we deal with indicative launch-phase views in this paper and its background material. It is also likely that views on the presented solutions will evolve as experiences are gained; as they have until now.

Anyway, the journey towards a more collaborative and, presumably, more innovative and efficient project protocol has started and you will soon be hearing more about Finnish project alliance solutions and experiences. Thus, stay tuned and be prepared for good news. Provided, of course, that the news from the other edge of the globe are true and the benefits can be seized to the same extent by the local stakeholders.

Abstract
International construction projects are mostly known with poor cost performance. Their large sizes, multi-party environments, along with unfamiliarity of foreign firms with host country conditions create high chances of cost overrun and delay which lead to disagreements, claims and failures. Factors that result in cost overrun usually occur in the form of a chain of causally dependent events, each of which are either under the responsibility of one party, or shared among different project participants according to the related contract clauses. The diversity of the factors, namely global, country, company and project specific factors, increases the complexity of negotiation process between the project participants when cost overrun and delays occur in international projects. The major idea in this research is that cost overrun depends on causal relations between various risk sources (namely, risk paths) and sources of vulnerability that interfere with these paths. Using the data of 166 international construction projects and utilizing Structural Equation Modeling (SEM), a Risk-Path Model that represents the interactions among different risk and vulnerability paths is identified. In this paper, through a comprehensive case study, the complex risk emergence pattern in a real construction project is demonstrated.

Keywords: vulnerability, risk assessment, structural equation modeling.

INTRODUCTION

International construction projects are mostly known with poor cost performance [6, 7, 15]. Sources of cost overrun occur in the form of a chain of causally dependent events, each of which are either under the responsibility of one of the project parties, or shared among the parties based according to the related contract clauses. The diversity of these factors, namely global, country, company and project specific factors, is the other fact increasing the complexities of cost overrun negotiations, analysis, and estimations in international projects [13, 15, and 21]. Prediction of possible cost overruns and the influencing events, and formulating adequate mitigation and preventive strategies necessitate a comprehensive, proactive and systematic risk management process in international construction projects [4, 13, and 21]. Risk modelling is a critical step of risk management, however, as Han et al. [13] state, traditional methods are not adequate for modelling of diverse risks and complex interactions among risks in overseas projects. Cost-influencing risks should be identified in a way that is compatible to their emergence pattern in real construction projects, instead of

being studied as independent factors. The major idea in this research is that risk factors occur in the form of *interactive risk paths*, and that early identification, and documentation of such interactive causalities may enhance the accuracy of early estimates, and decrease the conflicts during negotiations over the occurred overruns. In this paper, utilizing Structural Equation Modeling (SEM), a Risk-Path Model that represents the interactions among different risk and vulnerability factors is presented and a detailed case study is discussed to demonstrate how the proposed model can be used to identify risk paths in international construction projects.

BACKGROUND AND LITERATURE REVIEW

Interrelations among risk factors

Various checklists, taxonomies and databases are developed to facilitate identification of factors affecting cost performance of construction projects. However, since cost overruns are affected by a combination of interdependent risk factors rather than sole effects of independent risks [9, 13, and 14], examining the interactions among different risk factors is necessary in real construction projects. Interactions among different risk factors and how these factors lead to cost overrun have widely discussed in literature. For example, Burati et al. [5] argued that adverse changes during design and construction phases are the main causes for further reworks which will finally lead to considerable cost overruns. Design changes are considered as the sources of cost overrun by other researchers like Sempel et al. [17]. Factors like design errors, increase in the scope of the work, and adverse weather conditions are also mentioned as main sources of cost overrun, which by itself is identified to be one of the major sources of claims. Investigating the causes of cost deviations in construction projects, Akinci and Fischer [1] have examined a number of possible causalities. For example, increase in the scope of the project is claimed to affect project cost overrun through increase in unit cost of work. Also, the ambiguities associated with project scope and client objectives are stated to lead to scope changes which are one of the main causes of cost overrun. Moreover, vague contract clauses are claimed to result in some disputes one of the outcomes of which will be cost escalations. Factors like, unknown geological conditions and bad weather conditions are considered as the main causes of changes in productivity and work quantity which will lead to delays and subsequent cost increases. As country specific factors, country economic conditions are stated to cause increases in unit cost rates that will lead to project cost overrun. In their cross-impact model, Han and Diekmann [12] have demonstrated a number of causalities affecting project cost performance. For example, low design quality is considered to lead to redesigns and subsequent scope increase and schedule deviations which will cause cost overruns. As country factors, political conditions are considered to affect government acts and regulations which may lead to variations in contract conditions and subsequent scope changes. Country economic conditions are assumed to affect the availability of the resources which will impact labour productivity and project cost performance. Country economic conditions are also considered to affect cost performance through inflations. Company related factors, such as managerial capabilities and resources, are considered to lead to delays and subsequent cost overruns. Makulsawatudom et al. [16] have studied the causes of low productivity as one of the reasons of time and cost overruns in construction projects. Factors such as lack of material, incomplete drawings, poor communication, inception delays, reworks, etc. are considered as the parameters directly affecting productivity. As a comparable study, Alinaitwe et al. [2] have identified lack of skills, reworks, poor construction methods, poor communications, inaccurate drawings, bad weather conditions, etc. as the major factors leading to decrease of productivity and subsequent time and cost overruns. Zou et al. [21] have considered factors such as design changes, disputes, price fluctuation of materials, and incomplete documents as the factors that

directly affect cost overrun some of which will have also effects on time overruns and decrease in quality of work. According to Alnuaimi et al. [3], client related factors, lack of national information, lack of experiences and skills, and country related factors are those leading to occurrence of change orders which will cause plan revisions and additional works that will subsequently result in time and cost overruns and disruptions. Sun and Meng [18] have identified factors such as inadequate managerial skills and experiences, bad weather conditions, unknown geological conditions, change in availability of resources, change in material cost, etc. as the causes of changes in construction projects. They mentioned extra works, rework, time loss, design revisions, decrease in productivity, etc. as the effects of occurred changes.

Problem Determination

In order for a realistic and accurate identification of risk scenarios and prediction of probable cost deviations, all of the aforementioned interrelations should be taken into account simultaneously. However, it is highly difficult, if not impossible, to consider all these dispersed interrelations without a systematic approach and a comprehensive risk model. Few studies have emphasized the importance of inclusive risk models that incorporate possible interactions, and the counter-effects among influencing factors. Han and Diekmann [12] argued that the existing risk models and analysis methods are inadequate since they are not realistic reflections of complex nature of existing risks in international construction projects. They propose the utilization of Cross Impact Analysis (CIA) method as an appropriate technique for analyzing the conditional probabilities of occurrence of various interrelated risk variables affecting project cost under high uncertainties. The integrated risk management system developed by Han et al. [13] is one of the most noticeable efforts in this regard. The notion of *risk path* is mentioned in this research and a scenario-based checklist that includes various causalities among risks throughout different stages of the project was developed. The SEM-based prediction model developed by Kim et al. [14] should be mentioned as one of the most recent efforts in this regard. The prediction capability of the SEM model, which comprises of a network of interrelated factors affecting project cost performance, is compared with that of ordinary regression analysis and Neural Networks. SEM is identified to show higher prediction performance mainly due to the fact that it considers the interrelations and complexities of the real case.

RESEARCH METHODOLOGY

This study is part of a larger research project whose ultimate objective is to develop a Multi Agent System (MAS) for simulation of argumentation-based negotiations among project parties, and for generation of a risk-sharing platform for the occurred cost overrun. At initial steps of the research, in order to develop the conceptual framework of the research, a number of case studies were conducted and cognitive maps demonstrating the risk emergence pattern of these projects were drawn. Examining these cognitive maps, the Vulnerability-Risk framework of the research and the notion of *risk paths* were generated [8]. Risk and vulnerability factors were identified and documented in a Vulnerability-Risk ontology-based database using data related to 75 international construction projects conducted by Turkish contractors in foreign countries [11]. A cost estimator agent is currently under development by means of Case Based Reasoning (CBR). In order to generate an independent agent supporting negotiator agents' arguments, a risk model comprising of a network of interactive scenarios was developed using SEM [10] . In this model, a total number of 82 vulnerability and risk factors are included as the model's observed variables. Using special features of SEM, 28 latent factors are identified to be indicated by these observed variables. The final

SEM-based Risk-Path Model includes a total of 36 interactive risk-path scenarios each of which deriving from one of the vulnerability sources inherent in project environment. Data related to 166 international construction projects are used for development of this model. The cross-impacts among risk paths are all estimated in a way that all are mutually significant at 5% level, and the whole model fits the data adequately.
SEM-based Risk-Path Model mitigates the aforementioned shortcomings of current risk models in that it possess a comprehensive and lifecycle look to the risk emergence pattern of projects by incorporating vulnerabilities, risk sources, risk events and risk consequences. Moreover, apart from considering causal relations among diverse risk factors, it includes the complex interactions among diverse risk-path scenarios. In this paper, a case study project will be given to demonstrate application of the SEM-based Risk-Path Model.

CASE STUDY

Overview of the project

A Bulgarian based company has awarded a contract for replacement and reconstruction of part of its power station. The scope of the project is defined as construction of circulating fluidized bed (CFB) boiler for an industrial power plant in Bulgaria. In 2006, as one of the subcontractors of this project, a Turkish company was engaged by the major contractor under four separate contracts. The first contract is the "Purchase Contract for the Delivery of Equipment and Steel Structure Fabrication and Delivery to the Site". This contract included manufacturing and delivery of steel structures, structural and miscellaneous steel, for Boiler Building, Silo Building, and for Crusher Building. The second contract is the "Subcontract for the Delivery of Erection works for Boiler Steel Structure". This contract included erection of steel structures, structural and miscellaneous steel, for Boiler Building, Silo Building, and for Crusher Building. The third contract is the "Subcontract for the Delivery of Boiler Erection". This contract included the erection of the boiler mechanical equipments/ components in accordance with the provided technical description. And finally, the fourth contract is an umbrella agreement entered into, in order to coordinate the three aforementioned contracts which are linked to each other. The total contract amount comprising of three initial contracts has been estimated about 7.5 million euro. The payment type of all contracts was lump sum. The works contracted to the Turkish company mainly included the fabrication of structural steel at a factory located at Turkey, followed by the delivery of fabricated material to the project site, and finally, erection of the boiler steel structure and the boiler itself.

In order to examine the initial vulnerabilities of the project, the problems and risks faced, and the occurred risk scenarios throughout the lifecycle of the project, one of the managers directly involved in all phases of the project, and in all of the claim preparation stages, was interviewed in separate sections.

Overview of the company

The firm under study is a Turkish company specialized in giving services in construction and steel structure fabrication. Since its establishment, the company have conducted diverse construction projects like power plants, refineries and petrochemical plants and civil works for both Turkish and international clients. In terms of fabrication, different products, ranging from heavy steel structures to many kinds of equipments, are being fabricated at the Steel Construction and Machinery Factory owned by the company.

The project that is going to be studied in this paper is the first experience of the company in Bulgaria. Although the technological complexity and the size of the project can be considered to be relatively low when compared with other projects conducted by the company in both domestic and overseas markets, the company faced lots of cost and time overruns, and numerous disagreements occurred among project parties. This project is used for examining the emergence pattern of risks that may affect performance of international construction projects.

Vulnerabilities of the project

Vulnerability sources representing the capacities, capabilities and characteristics of each project's environment are believed to trigger the occurrence of future risk scenarios. The vulnerability sources identified in previous stages of this research [8] and included in a Risk-Path Model [10] are examined for this project.

Design Problems:

This factor is mentioned as one of the most important and effective vulnerability sources of the project. The structural design of various elements of the project was contracted to another company located in a third country. The designer company, the manufacturing unit, and the erection team had to work in a highly coordinated manner since the design was not complete when the fabrication of the elements and the erection of the structures started. The drawings issued by the designer were to be sent to fabrications unit according to a predefined schedule. Then, the manufactured elements were to be sent to construction site in Bulgaria for montage and erection of the structure in accordance to the planned schedule. However, due to the lack of skills and experiences of the designer company in similar projects, and because of high levels of details and different types included, vast amounts of delays occurred in submissions of the drawings. These delays affected the planned schedules of both the manufacturing and the construction works. Due to the specific physical condition of the site (will be discussed in detail in subsequent sections of the paper), most of the activities have to be done in a finish-to-start pattern. That is, less parallel activities existed and most of the construction works had to be stopped in the case of significant delays in delivery of elements and equipments. Incomplete designs, late drawing submissions, the significant time losses in construction process of the project (approximately 1 year in some parts), and the loss of construction productivity, were some of the major subjects of the further disputes.

Existence of lots of design errors was the factor that affected the performance of the project more than late submissions. The structural elements were mostly unique, possessing different dimensions, shapes and technical specifications. Therefore, the elements fabricated based on such incorrect drawings became useless for other parts of the structure most of the time. The sudden escalation of steel price caused the additional costs of such wastes to substantially increase. The Turkish company faced problems like significant cost increase, negative cash flows, several reworks, decrease in productivity, and lots of time loss. For example, each type of the steel beams had holes and welds in different places with different dimensions that errors in specifying them correctly led to some additional work items such as 1) Additional holes were added, 2) Holes were removed, 3) Welds were added, 4) Weld were removed, 5) Dimensions were changed, and 6) Details were added.

Design revisions, most of which were sudden and without early notice, is the other factor having led to reworks, productivity losses, decrease in work quality, and further cost overruns.

Adverse Site Conditions:

One of the other most important vulnerability factors mentioned by the company representative is physical boundaries and working conditions prevailing the construction site of the project. The erection area at the project site was surrounded from three of its sides with the existing buildings. The erection works had to be started from the back side of the boiler unit which was adjacent to the existing building and had to be carried out from backward to the front direction. Moreover, the access to the erection area was only possible from the front side due to buildings surrounding other sides. The limited access and dangerous position of the erection area eventually imposed certain technical priorities and restrictions related to the erection process. Such physical limitations made the construction process very sensitive to the sequence of the activities. For example, the erection of some portions of 4^{th} floor could not be started before the lifting of coal gallery, otherwise the coal gallery could never be lifted to its final position since there was existing building adjacent to it, which had made the lifting process impossible. The other example for the tasks having been affected by adverse site condition was the placement of the elements like supports for the coal and limestone silos that had to be placed on the beams of the 2^{nd} floor. In the case that the steel structure erection was carried out without the installation of these supports, these silos could not be placed due to access limitations to the back side of the area. The Turkish company was only responsible for the erection, and the material supply of such supports and silos was under the responsibility of another company located in a third country. The procurement and delivery of such materials faced significant delays due to unexpected harsh sea storm. This caused substantial time loss in construction process since the erection had to be stopped until the installation of the supports. Also, the access limitations of the erection site limited the lifting radius of the tower crane. This caused difficulties in subsequent phases of erection in lifting of some bigger or heavier elements. Therefore, a mobile crane was hired. This brought about additional costs and some time losses due to problems like unavailability of crane and certified local operator, and also erection time of the crane. It is claimed that, although the occurred delays in supply and delivery of the material by either supplier party or the manufacturing unit would have probably caused time losses in erection process even if there had not been any site constraints, the finish-to-start relations of the activities resulted from the backward erection of the elements, and from access limitations, have significantly intensified the idle times.

Country Related Conditions:

Newly joined to European Union, Bulgaria was subject to lots of sudden and substantial changes in its laws and regulations. The first one was the visa requirement. Acquisition of visa for Turkish workers became obligatory. This resulted in significant delays in the supply of manpower from Turkey. The lack of local skilled manpower and certified technicians in some areas intensified this problem. According to the company's representative, this fact affected the construction productivity and quality of the work. For example, the company faced difficulties in finding a skilled operator for the newly hired mobile crane. This led to some idle times of the crane, and to delays in erection process. Finally, in order to prevent further losses, the company employed some uncertified workers resulting in conflicts with health and safety inspectors. Other notified problem was high levels of bureaucracy, especially in custom procedures that caused significant delays in the procurement of materials and equipment which were mostly outsourced from other countries. Lack of local material and equipment were other notified country related vulnerabilities of the project.

Contractor Related Vulnerabilities:
Besides the drawing errors, revisions and supplier delays, lack of coordination and poor communication among the erection team and manufacturing unit were other factors that affected the manufacturing process, supply and delivery of the structural elements, and erection process. For example, there were elements having been sent to the site long before their prerequisite parts were fabricated. Lack of managerial skills of contractor is the other notified vulnerability. Poor planning was one of the most important vulnerability that apart from its effects on project time and cost performances, caused the company to face difficulties in gathering the necessary documents for supporting their arguments in raised claims. Poor quality management for both manufacturing and erection parts can be considered as the other managerial vulnerability of the contractor. For example, there were some unnoticed differences among some fabricated beams and their specifications in the design drawings. Such quality deviations led to reworks and time losses. The site organization and management team of the contractor changed frequently throughout the project. The company representative believes that this factor mostly affected the productivity of the erection team. Contractor's lack of experience with client, and with the general conditions of the country is other contractor related vulnerabilities mentioned by the company representative.

Unexpected Events:
Harsh and extreme weather conditions are mentioned as the most important unexpected events in this project. Unpredictable and exceptionally high speed of the wind during July and August months forced contractor to stop erection with cranes due to health and safety issues. Also, the erection process of the top floors had to be stopped for several weeks since their construction was postponed to winter's freezing months because of delays, especially due to the design related delays.

Client's high level of bureaucracy, negative attitude, and technical, managerial and organizational incompetency are client related vulnerabilities, and strict quality, and strict health and safety requirements are the vulnerabilities of the project mentioned by the interviewee.

Application of the SEM-based Risk-Path model
The identified SEM-based Risk-Path Model [10] comprises of 36 interactive risk-path scenarios each deriving from one of the project vulnerabilities. Using the prediction capability of SEM models, the magnitudes of the future risk factors and the probable risk paths can be estimated by inserting the known severities of the vulnerability sources as the inputs of the model.

For the project studied in this paper, the most significant vulnerabilities are mentioned above. The interviewee is asked to rate the severity of these critical vulnerabilities, and the others included in the model, in a 5 Likert scale: Very Low (1), Low (2), Medium (3), High (4), and Very High (5).
Based on these values, and using the estimated path coefficients, the probable magnitudes of risk factors, and the level of project cost overrun are estimated. Figure 1 shows all the 36 interactive risk paths, the inserted severities of the vulnerability sources, and the estimated magnitudes of the risk and cost overrun factors. This gives an overall picture of the complex risk emergence pattern of the project. The total effect of each of the 36 risk-path scenarios will be the product of coefficients of all paths underlying that scenario. Multiplying the total effect of the scenarios with the severity levels of their initiator vulnerability sources, the

impact of different vulnerabilities on the cost overrun will be calculated. Ranking these impacts, the most effective risk-path scenarios for the project will be obtained. Table 1 shows the risk-path scenarios, their impacts on project cost overrun, and the most critical ones for the project under study.

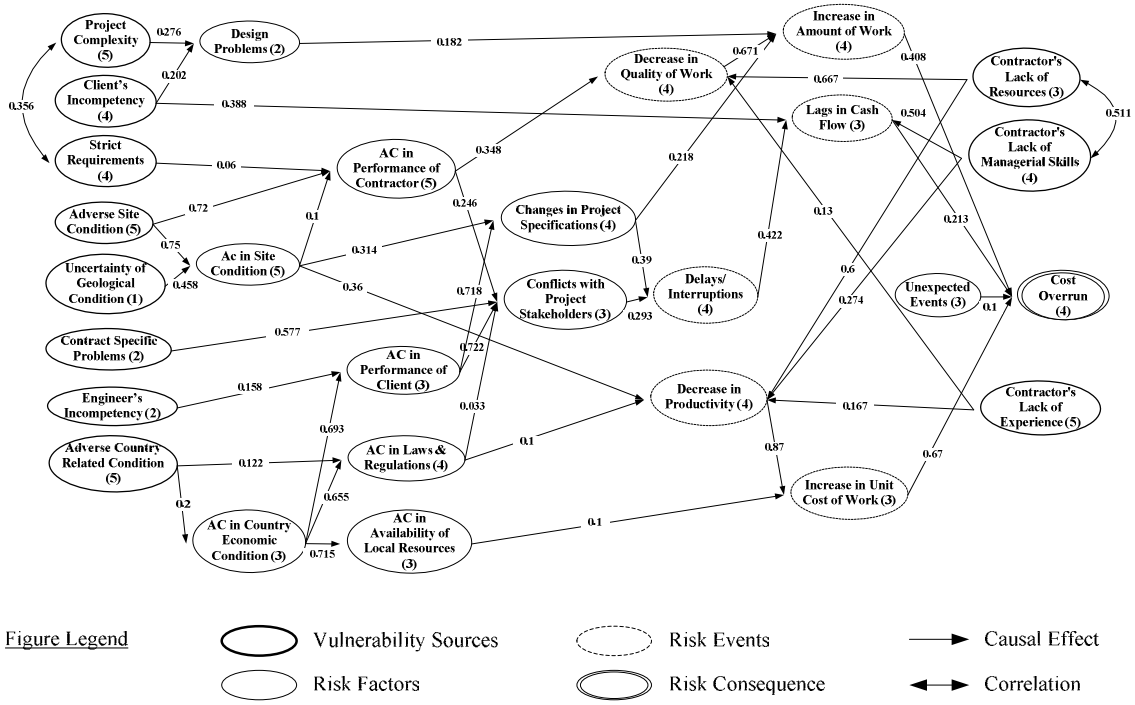

Figure 1: *Risk-Path Model for the case study*
Note: A) Values in parenthesis are inserted or estimated magnitudes of the vulnerability/risk factors in 5 scales. B) All paths are mutually significant at 5% level.

Discussion of findings
Figure 1 shows the general risk structure and the emergence pattern of the possible risk-path scenarios for the case study project. Such a comprehensive risk map gives a wider and more realistic view about the future when compared to that of common risk checklists. For example, as mentioned by company's representative, *adverse site condition* was one of the main vulnerabilities of the project the severity of which was known from the beginning of the project. If the company had considered the direct and indirect impacts of this source on other areas like *quality decreases*, *specification changes*, *delays*, *etc*., and at the same time the subsequent effects of these events, more effective strategies may have been made, and more realistic cost and time planning may have been possible. On the other hand, the influence of alternative mitigation strategies can be traced not only on a specific risk and possibly on its outcomes, but also on the whole network of interrelated risks. The statement of "*missed opportunity*", mentioned by Ward [19], being generated from the ignorance of such interdependencies, refers to the existing gap of various risk checklists that are improper in clarifying the effects of any response strategy on the whole system of risks. Moreover, the probable magnitudes of diverse risk factors, their cross-impacts on each other, and their impacts on project cost overrun are estimated (Figure 1 and Table 1). A total of 36 general risk-path scenarios are considered. Based on the specific conditions of different projects,

these paths may have different impacts on project cost overrun, and hence, different scenarios may become critical.

***Table 1**: Risk-path scenarios and their impacts on project cost overrun for the case study project*

Note: A) All impacts are standardized estimates. B) Highlighted paths are the most effective scenarios.

In the Power Plant Reconstruction project, the standardized impacts of each risk-path scenario are estimated (Table 1) based on the severity levels of project vulnerabilities reported by the interviewee and discussed before through the paper. The total impacts of the vulnerability sources (i.e. the sum of the impacts of each scenario deriving from the vulnerability) are also reported in this table. The highlighted scenarios are the most effective ones deriving from each source. Also, the highlighted total impacts indicate the highest total impacts on project cost overrun, belonging to sources like adverse site condition, contractor's managerial incompetency, unexpected events, contractor's lack of resources, contractor's lack of experience, client incompetency, and adverse country conditions. Although some conclusions can be made by comparing the prediction results of the Risk-Path Model with the details discussed in the case study section, the identified paths and the predicted magnitudes were consulted with the company representative to ensure their compatibility with what happened in real project. All the identified critical risk paths were confirmed by the interviewee to be effective scenarios in the project.

According to company representative, the complex and interrelated nature of the occurred events was one of the factors having made the identification of responsible parties, and determination of their contribution rate on the raised overruns, a tedious task resulting in lots of time/cost consuming disagreements. According to the related clauses of the binding contract, each of the risk factors forming the project Risk-Path Model is under the responsibility of one of the project parties, or is shared among them based on their contribution to its occurrence. It is believed that integrating the identified risk paths with contract clauses will provide project parties with a supporting tool to facilitate their negotiations over the occurred cost overruns. Having knowledge about their approximate fault rate in the occurred scenarios will assist negotiators in determination of their reservation values, in getting ideas about the reasonable offers, and in forecast of the counter-offers during the negotiation process.

CONCLUSIONS

This paper reports a detailed case study for examining the complex risk emergence pattern of an international construction project. The results of the case study illustrates that incomplete design, errors in drawings, and sudden and frequent revisions have been some of the major problems of the project causing lots of time, cost, and productivity loss. Restrictions in accessibility of different construction areas and adverse site conditions were other main sources of poor time and cost performance in the project. Country, contractor, and client related vulnerabilities were other important fragility sources for the case under study. The results of the case study show that these vulnerabilities have caused a number of interrelated risks. In order to examine the discussed risk emergence pattern of the project in a systematic way, the Risk-Path Model developed in previous stages of this research is applied. Knowing the severities of project vulnerabilities, which are the most certain knowledge sources at early stages, the probable magnitudes of risk factors, and possible risk-path scenarios and their impacts on project cost overrun were predicted. The results of the Risk-Path Model are identified to be highly compatible with what have happened in the real project. Finally, it should be noted that, the aim of this case study is not to test the reliability of the model and predictive capability, but it is to demonstrate that how the proposed model may be used to assess risk paths in international construction projects.

Abstract
While heated discussions have been directed towards various innovative procurement systems such as PPP, PFI, and BOT that carry the great expectation to help materialise the projects and deliver value to the society, a procurement system named agent-construction system (ACS or in Chinese Dai Jian Zhi) is being prevailing in China's public procurement. This research aims to examine ACS by relating them to China's particular Political, Economics, Social, Technological, Environmental, and Legal (PESTEL) background. It is found that the ACS is promising in procuring public projects owing to two merits: (a) clearly defined right and responsibilities; and (b) appropriate allocation of resources and risks amongst parties involved. The research is particularly useful when governments worldwide are searching for innovative procurement approaches to help deliver public projects and services. It also sheds light on how to devise an innovative procurement system. A word of caution, nevertheless, is that readers should not follow this "good practice" slavishly. One ought to truly understand the essence of procurement innovation and devise suitable innovative procurement systems in a given PESTEL setting.

Keywords: Procurement innovation, Agent-Construction System, Construction procurement, China

INTRODUCTION

In the course of procuring public construction projects, no matter whether it is in socialist or capitalist countries, or whether it is in developing or developed worlds, there have been widespread problems discovered. Particularly in China, though its construction industry has made significant development owing to its strong economic growth and unprecedented urbanization plan, several problems have been frequently mentioned, such as cost overrun, late delivery, delay of payment, low efficiency, overstaffed organizations and/or corruption (Yan, Yan, & Yin, 2009; Yin & Yan, 2006; Zhang, 2008). To address these problems, governments worldwide are searching for innovative procurement approaches that can help procure projects in a more efficient way and thus truly deliver values to the society. The often-discussed innovative procurement methods may include, inter alia, Build-Operate-Transfer (BOT) first introduced in Turkey, Private Finance Initiatives (PFI) initially put forward by UK government, and Private-Public-Partnership (PPP) that has been ubiquitously discussed around the world.

It is generally observed that there are two trends in these innovative procurement approaches. Firstly, public procurement is shifting from traditional state-led approaches to partnering between public and private sectors, expecting that the private sector can be more active in improving efficiency and delivering value (Egan, 1998, Winch, 2000). Secondly, integrated approaches were adopted to reduce the problems of fragmentation and discontinuity by which the construction sector has long been plagued (Anderson et al., 2000). Together with the trends is the systems view to construction procurement which emphasizes a procurement system including elements such as contract strategy, culture (e.g. trust and institutions), and finance, should deserve more attention of the construction and project management fraternity (Rowlinson, 1999).

With the success of the procurement systems in some mega projects, they have been introduced to other economies for procuring new projects. However, “one size does not fit all”; a procurement system growing from a certain Political, Economics, Social, Technological, Environmental, and Legal (PESTEL) background may not be of full applicability to other economies with different PESTEL settings. Adopting them slavishly may cause loss or even failure of a project. The big issue is thus to devise innovative procurement systems that are suitable for a given PESTEL setting and should truly deliver value to the society. On the other hand, notably in China, an Agent-Construction System (ACS or in Chinese *Dai Jian Zhi*) is widely adopted in the procurement of public projects, for example, the Beijing 2008 Olympic Games projects. It is intriguing to examine why the ACS became the most widespread procurement approach and what are the implications to procurement innovation that can help procure projects in a more efficient way.

The aim of this research is to shed light on procurement innovation by skeptically examining the ACS and relating it to China’s particular PESTEL background. The rest of this paper is structured into three sections. Firstly, research design and methods are described – this is comprised of extensive literature review and interviews with practitioners. Secondly,

discussions are conducted to deepen the understanding of the ACS in terms of its history, strengths and weaknesses. Of particular importance is to project the procurement systems into China's PESTEL background. Research findings are presented in this section. Finally, key conclusions are drawn together.

RESEARCH METHODOLOGY

The principle underlying in this research is that a procurement system should be examined skeptically in terms of its suitability to a certain PESTEL setting. This principle is an extension of the systems view to construction procurement contributed by Rowlinson (1999). This investigation thus adopts PESTEL as an analytic framework. PESTEL analysis, standing for Political, Economics, Social, Technological, Environmental, and Legal, is a framework of macro-environmental factors used in the environmental scanning component of strategic management. It also gives an overview of the different macro environmental factors that a procurement system has to take into consideration.

Bearing in mind the PESTEL framework, the authors investigate various sources by using a literature survey in order to truly understand the ACS in China. There are three prevailing books (Zhang, 2008; Yin and Yan, 2006; Hou, 2006) about the ACS. The understanding of the ACS was enhanced by a body of articles published on different journals but being organized under a Project Manager Union (2010) website. Archived papers, presentations and in particular keynote speeches by governmental officers in the First National Summit on "Agent-Construction System: theories and practices" provide very useful literature for this study. The search of the literature was further enhanced by using a CNKI database for research papers. All the literature on the ACS is in Chinese. This presents a possibility that information will be lost in the translation but it also provides a chance for cross referencing by perusing them in two languages. The literature survey has projected the procurement system into China's PESTEL background, which is changing rapidly, though in various speed.

The second stage of this research adopts interview as the main method for investigating the ACS in China. Interviews allow for an in-depth interpretation of the comparisons. Three interviews have been conducted. Somehow, these took place over a long period with the first one being conducted in December of 2009 with the vice president of an international construction company and the last one in December of 2010 with a government officer in charge of audit of government-invested projects including those adopted the ACS. Each interview lasted 40–60 minutes and the transcriptions are used to cross validate the understanding from the previous literature survey. The data from the literature survey and interviews is to be analyzed in the next section.

ANALYSES, DISCUSSIONS, AND FINDINGS

General PESTEL Background for public project procurement in China

In order to effectively understand the Agent-Construction System (ACS), it is necessary to relate the system with China's PESTEL background. China is known as a socialist country adopting a Marxism-Leninism ideology. Based on this ideology, a centrally planned economy system has been adopted and there was no private sector. Since 1978 when the country adopted an "open-door" policy, the economy has been reformed from the traditional planned economy to a market economy. Lu (2009) used the spectrum as shown in Fig. 1 to illustrate the transition of the economy systems. Yang (2004) also effectively summarize that all the significant affairs taken place in China since 1978 can be understood by putting them into two spectrums similar to Fig. 1, one for political reform and the other for economy. It can be seen from the spectrum that gradually economic activities and factors of production are configured by the market as "the invisible hand" instead of a central plan. The zigzag of the curve represents its struggling with two briefs of "plan (state planning)" and "market (incentive-based competition)", which were traditional labeled as "socialism" and "capitalism" respectively. Whilst Western economists argue that these two are not natural partners, it is generally accepted in China that "government planning and market regulating are two integral parts of the socialist market economic system". It should allow the market to allocate factors of production and to increase efficiency while the central planning is indispensable in ensuring healthy development of the whole economy. Although the market economy is now dominant, the whole economy system still has a strong "planning" culture. For example, the economic goals have been achieved through its "Five-Year Plans", which are a series of economic development initiatives shaped by the Central Committee and National Congresses to map strategies for economic development, set growth targets, and launch reforms. Currently, it is in the 12th "Five-Year Plans" (2011-2015). As a result of the economy reform, China's GDP grows at an average rate of about 10%, reaching a GDP of $4.99 trillion in nominal term in 2009, becoming the world's second largest economy after the United States.

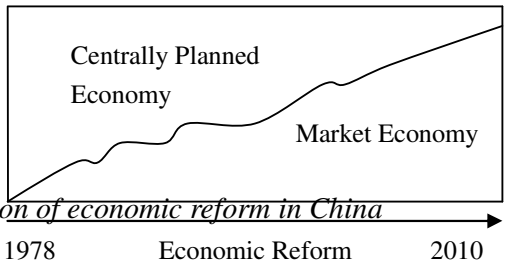

Figure 1: *An illustration of economic reform in China*

Intertwined with the political and economic development is its unprecedented urbanization in China. Urbanization has been the major drivers of China's GDP growth over the past decades and it will become even more so over the next 20 years. According to the UN World Urbanization Prospects (UN, 2009), the level of urbanization in China is 46.1, with a population of 620million living in urban areas, while this level will be 73.2 in 2050 and the urban population will be 1 billion. A McKinsey report (2009) forecasted that 1 billion people

will live in China's cities even early in 2030, and 5 billion m^2 of road will be paved, 170 mass-transit systems could be built, and 40 billion m^2 of floor space will be built in 5 million buildings by 2025. These resonate with China's fixed-asset investment on property, roads, and other infrastructures to sustain the economic growth as well as the urbanization ambition. For example, in 2009, the total fixed-asset investment was 22,486 billion Yuan (NBS, 2010). Although the government investment system is in transition, for example, in 2004, a regulation named *Decision on Reforming the Government Investment System* was promulgated by the Chinese State Council, the government is still dominant in both the public spending and the procurement of government-invested facilities driven by the urbanization. Normally, there are two types of government-invested projects: (i) non-profit-making, for example, urban roads, schools, hospitals, libraries, museums, government offices(These are called institutional buildings in Hong Kong), and (ii) profit-making utilities, i.e. water, gas, sewage facilities, tolling roads, bridges and tunnels, etc.

In the face of the ambitious urbanization plan, Chinese government is keen to introduce innovative procurement systems that can help materialize the huge demand of public projects. Various writers (e.g. Liu, 2001; Zhang, 2007) summarized a genealogy of the typical government public procurement systems as follows:

(a) Self-build model, in which the end users (i.e. a university, or a hospital), more precisely, their long-standing project organizations, are in charge of the construction projects. They define project scopes, apply for budget from the government, and procure the project by themselves;

(b) Government construction commanding units model, in which a temporary governmental unit was set up to command the budgeting and construction of a given project, e.g. a road committed by a local government. The project will be transferred to the end users after completion.

(c) State-owned construction enterprises model, in which the State-owned enterprises are in charge of the construction of a project. For example, for Ministry of Railway (MOR), Ministry of Transportation (MOT), Ministry of Construction (MOC), they had their own construction bureaus which later were transformed to state-owned construction enterprises in charge of specific types of projects (i.e. railway, road infrastructure, and residential buildings).

Later, the market-oriented economy reform introduced competition. The competitive bidding and tendering has changed the system of construction project financing from traditionally government-free allocations to loans from commercial banks, and changed the project procurement system from traditional government assignments to competition through the tendering process as occurs in international practice (Shen and Song, 1998). But for the public projects, the government is still dominant in financing and procurement, mainly through the National Planning Commission, although it was renamed to the National Development and Reform Commission (NDRC). Public clients are remaining as various state-owned organizations; the construction commanding units model is still seen every now and then (e.g. Shanghai Expo 2010) while for some profit-making public projects, a Legal

Person system (e.g. Water Affairs Group Limited; Road and Bridge Corporations) is adopted as a legal entity to be responsible for the profit and loss of the projects. The state-owned construction firms were pushed into a competitive market and became real companies that are responsible for their own gains and loss. The above procurement systems, with a label of the planned economy, have been changed with the transition of the whole economy system. More diversified procurement systems appeared, for example:

(d) Legal person model, in which a project company will be set up as a legal entity, usually a qualified and authorized organization, to take charge of the procurement and also operation of the construction project.

(e) Governmental investment and development companies. This model is not significantly different from the Model (d) above but this one should be responsible for the financing of a project thus return of investment is of high concern.

(f) Government procurement center model, in which a government procurement center is established to be in charge of procuring a project which will be transferred to the end-users after its completion.

With a closer investigation, it can be summarized that the above models have actually struggled to streamline the relationships between government (as both a market regulator and a client), project contractors (state-owned or private enterprises), and end-users (often the public sector). Typical relationships between the parties underlying in different procurement systems can be seen in Fig. 2. The relationships could be underlying in any government investment project in any economy but this is more important as an issue in China which adopted a socialist economy. It is believed that the unclear relationships are the main causal factor for problems in public procurement. For example, budget overrun is widespread as a result of enlarging project scope by end users; quality is poor as no professional construction management is in place; rent-seeking in these relationships leads to misconduct and corruptions. The Agent Construction System (ACS) and the exotic systems such as PPP, PFI, and BOT, etc were introduced under this particular PESTEL background.

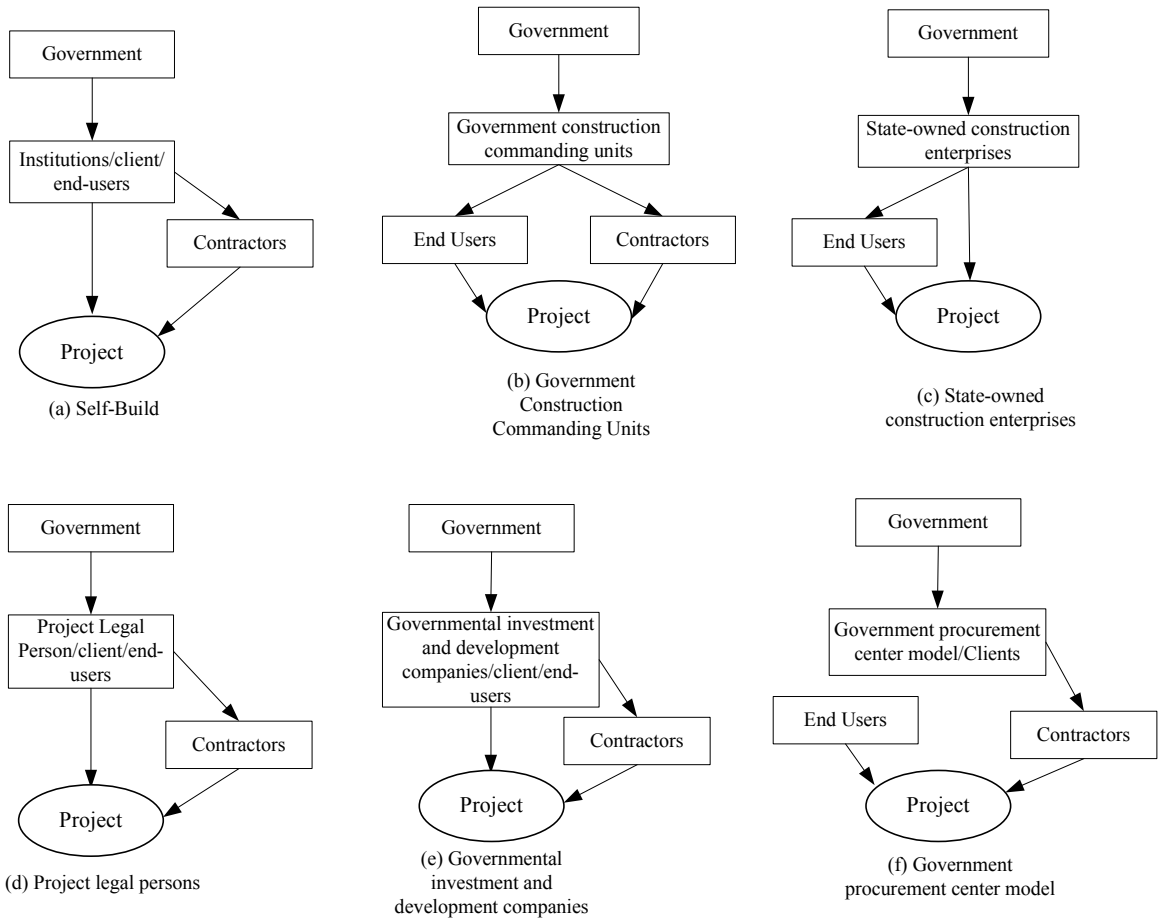

Figure 2: *The relationships of government, contractors, and end-users in various public procurement systems*

Agent-Construction System (ACS or Dai Jian Zhi)

It is generally agreed that the ACS was firstly trialed in Xiamen in 1993 and formally introduced in 2004 when the Chinese State Council issued a regulation named *Decision on Reforming the Government Investment System*. The term firstly appeared in the *Decision* in which it was stated that for procuring government-invested non-profit-making projects, professional construction management units are selected through competitive bidding and tendering to conduct the construction projects, to control project cost, quality, and time, and to turn over the projects to the future users or operators after they are successfully constructed. Similarly, the relationships in an ACS is illustrated in Fig. 3.

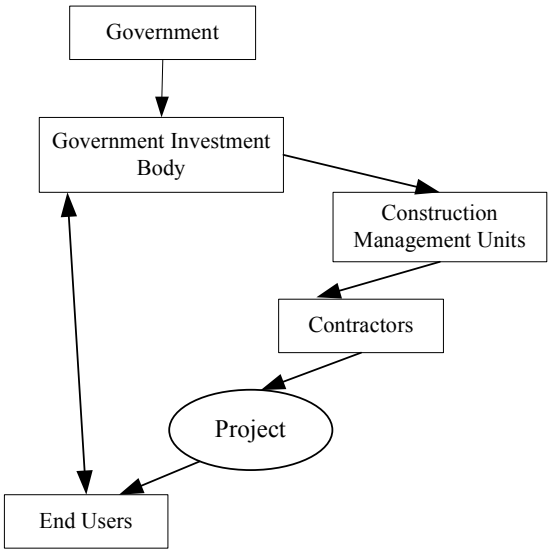

Figure 3: *The relationships of government, construction agents, contractors, and end-users in the Agent-Construction System*

By comparing Fig. 3 with Fig. 2, a major difference observed is that the construction management units (CMUs) are selected as an agent of the government investment body, through competitive bidding and tendering, to conduct a certain or all stages of construction projects, i.e. feasibility study, design, contracting, construction and handover after completion, meanwhile to strictly control project cost, quality and time. The ACS, therefore, is considered by many researchers as the construction management system originated in the U.S. This view places an emphasis on that the CMUs, with more professional knowledge than the government investment body or end-users, can help overcome the problems in procuring public projects. There is another view considering that the ACS can overcome the problems by streamlining the relationships amongst the parties. After the project was completed, it will be transferred to end-users, who applies for a project from the very beginning, while has no intervention during the execution of the project. All the details of rights and obligations are required to be clearly specified in an agent-construction contract, and so are the risk sharing mechanism and dispute solving approaches. Through this way, it is hoped that budget overrun can be reduced as end-users cannot enlarge project scope any more, and quality can be improved by introducing the CMUs. The latter view emphasizes a clear definition of rights and obligations of various parties that are involved in a public projects. Both views are correct while more analyses are needed to clarify the many ambiguities in the ACS.

The *Decision* only addresses a general principle (Yan et al., 2009) while applicable procurement systems are subject to detailed elaborations by individual provinces, autonomous regions and municipalities. For example, the government investment body could be Provincial Development and Reform Commissions (PDRC) themselves (e.g. in Beijing), or their authorized institutions (i.e. in Shanghai Chengtou Corporation as a professional industrial investment group company engaged in the construction and operation of the city's

infrastructure facilities), or ender users (i.e. the model in Chongqing). According to Zhang (2008), the last mode should not be regarded as the ACS. In addition, the professional CMUs could be professional project management companies which are complete legal entities, or government specially-set institutions which are extended government executive arms (e.g. Bureau of Public Works in Shenzhen). Actually, the latter form is not significantly different from the model (f) governmental procurement center as illustrated in Fig. 2. With different combinations of government investment bodies and CMUs, a wide variety of procurement systems which are generated and all claimed to be ACS. Yin (2008) summarized there are three models of ACS in China: Beijing Model with Beijing DRC as the investor and professional CMUs as the construction agent, Shanghai Model with project investment corporation and professional CMUs, and Shenzhen Model with government as the investor and Works Bureau as the agent.

During the course, there emerge various forms of ACS that respectively embody some features and strengths/weakness of emerging procurement modes such as BOT, PFI, EPC, or BT, which are more familiar to the construction and project management fraternity. Some state-owned companies, with their relatively strong financing, architecture, engineering, and construction capabilities, acted as the government's agent in procuring projects. Instead of operating for a certain years as BOT does, the projects will be completely purchased back by the government after 2 to 5 years. This model is reported as successful to create a win-win situation by complementing with each other using each party's strengths. It also reduces each party's weaknesses while introducing a risk sharing mechanism that is critical to the success of public construction projects.

Although there is no consensus on what the ACS is, it has become a widespread procurement system in China. According to Yan et al. (2009), by the end of 2008, 45 out of totally 47 regions including provinces, municipalities and special provincial-level cities in the mainland China have issued their guidelines on how to conduct the ACS in line with the *Decision.* In many regions, the ACS has been made as a mandatory system while in some others the system is promulgated with greater flexibility when procuring government-invested non-profit-making public projects. According to Yin (2008), by the end of 2005, there were 153 completed, 164 ongoing, and 85 planned projects adopting the ACS. The Beijing 2008 Olympic Games projects also adopted this procurement system. The discussions of the pros and cons of the system have been prolific. All these provide a good standing point to compare the ACS and PPP in China.

The ACS and Procurement Innovation

Hughes et al. (2006) suggest that to define procurement, the following six aspects of procurement must be defined at the same time:

1) ownership, initiation and funding, e.g. owner-financed, public sector-financed, developer financed, PFI;
2) selection method, e.g. negotiation, partnering, frameworks, selective competition, open competition;

3) price basis, e.g. work and materials as defined by bills of quantity, whole building, a fully-maintained facility, performance;
4) responsibility for design, e.g. architect, engineer, contractor, in-house design teams;
5) responsibility for management, e.g. client, lead designer, principal contractor, JV; and
6) amount of sub-contracting, e.g. 0-100%.

Innovation could be taken place in one or more aspects as listed above. Furthermore, the combination of these aspects provides a wide range of innovative procurement options. Their work provides a framework for analyzing the ACS as a procurement innovation here.

Ownership, initiation and funding: The adoption of ACS has not changed the fact that the public sector is still dominant in initiating, funding, and owning non-profit-making public projects. Unlike some governments which are suffering from lack of fund, Chinese government is relatively rich due to closely monitored fiscal policy and high saving rate of Chinese people. This mainly explains why PPP, PFI, BOT are not really popular in China. This ACS actually tries to streamline the relationships between investors, owners, professional management units, and contractors so as to overcome the problem of budget overrun.

Selection method: The ACS clearly stated that competitive bidding and tendering will be adopted in the selection of construction agents. However, this has not been fully implemented in some forms of ACS, for example, the Shenzhen model, similar to many other things, which copied from Hong Kong. Further studies to investigate the effectiveness of a similar system in two different PESTEL settings are envisaged.

Responsibilities for design and management: The ACS is much superior to other procurement systems for shifting the responsibilities for design and management to professional CMUs. As shown in Fig. 2, the part of responsibilities was traditionally assumed by government or its executive arms, which are not necessarily professional in design and management of public projects. Instead of managing individual projects, government was liberated by the system and can focus on regulating efficient market rules. It is through professional design and management that the problems of budget overrun, poor quality, and delayed delivery are expected to be reduced.

Price basis and sub-contracting: In the ACS, the issues were left to the professional CMUs with several principles. For providing the professional services, the construction agent will receive a service fee plus some incentive schemes.

Risk sharing mechanism: While has not been mentioned in Hughes et al.'s work, risk and reward allocation is critical for the success of an innovative procurement system. The ACS, particularly for the form similar to BT, creates a win-win situation by reasonably considering the risks bored by each party. It is noteworthy that instead of 30 years as PFI promises, 2-5 years is a reasonable period that the risk associated with the PESTEL background, changing in a high speed, can be handled by both the governments and the construction agents.

CONCLUSIONS

In the face of widespread problems in public project procurement such as cost overrun, low quality and delayed delivery, governments worldwide are searching for innovative procurement systems that can help procure projects in a more efficient way and thus truly deliver values to the society. The ACS is reported as successful in China's particular Political, Economics, Social, Technological, Environmental, and Legal (PESTEL) background, although its many weaknesses are yet to be eliminated. The innovations of the ACS are lying in two aspects: (a) clearly defined right and responsibilities; and (b) appropriate allocation of resources and risks amongst parties involved.

The ACS reported herein can be treated as a "good practice" in project procurement that may provide valuable reference to readers. A word of caution, nevertheless, is that readers should not follow this "good practice" slavishly. The main proposition of this paper is that one ought to truly understand the essence of procurement innovation and devise suitable innovative procurement systems in a given PESTEL setting. Further research is suggested to investigate a national guideline on the ACS, the service fee for the construction agents. But if aiming to provide more references to other economies in procuring public projects, research may be directed to devise a more thoughtful risk sharing mechanism that takes into consideration each party's strengths, weaknesses, rights, responsibilities, and rewards respectively.

Nevertheless, a word of caution is that readers should not follow one specific "good practice" slavishly. One ought to truly understand the essence of procurement innovation and devise suitable innovative procurement systems in a given PESTEL setting.

Abstract

In situation of contractors competing to finish a given project with the least duration and cost, acquiring the ability to improve the project quality properties seems essential for project managers. Evolutionary Algorithm (EAs) have been applied as suitable algorithms to develop the multi-objective Time-Cost trade-off Optimization (TCO) and Time-Cost-Resource Optimization (TCRO) in the past few decades ; however, by improving EAs, the Shuffled Frog Leaping Algorithm (SFLA) has been introduced as an algorithm capable of achieving a better solution with faster convergence. Furthermore, considering splitting in execution of activities can make models closer to approximating real projects. One example has been used to demonstrate the impact of SFLA and splitting on the results of the model and to compare with previous algorithms. Current research has elucidated that SFLA improves final results and splitting allows the model find suitable solutions.

Keywords: Optimization, Multi-objective SFLA, Splitting, Leveling, Construction Management

INTRODUCTION

Project control plays an important role for contractors for scheduling, cost analysis and resource evaluation. The time and cost of projects are related to each other and considered in Time-Cost trade-off problems. From the researchers' point of view, developing highly efficient and robust

algorithms to solve highly complex Time-Cost trade-off problems is still a challenging subject (Afshar et al. 2009). On the other hand, the challenge in resource leveling problems is to make the resource requirements as uniform as possible and to force resource utilization to conform to a desired, predetermined resource distribution in order to meet the project milestones (Senouci and Eldin 2004). In addition, resource availability constraints may postpone activity start time, extend activity duration, and hence prolong the total project duration (LU and Lam 2008).

One of the factors that has significant impact on completed time and cost of project is delay. Delays are acts or events that extend the time necessary to finish activities under a contract (Stumpf 2000). If a project is delayed beyond its due date, a financial penalty is incurred by the contractor (Vaziri et al 2007). Delays during execution of projects can happen at the start of each activity or during activities. Delays at the start of activity change the initiation from early start to late start. If an activity is placed on Critical Path Method (CPM) or delay duration is longer than total float, then delay postpones project duration. We call it "splitting allowed" if delay happens during activity execution. It effects on total duration of activity, however, the active duration of activity will not be varied.

Accordingly, the key question is how to allocate resources to activities while taking into account splitting, in order to finish the project within budget and on time from the standpoints of contractors, sponsors, and the project client.

RESEARCH BACKGROUND

In an attempt to reduce processing time and improve the quality of solutions, particularly to avoid being trapped in local optima, Evolutionary Algorithms (EAs) have been introduced during last decade (Elbeltagi et al. 2005). EAs are stochastic search methods that mimic natural biological evolution and social behavior of species. One of the most important criteria of EAs is their capability of speed convergence to obtain a global optimized solution. Based on Elbetlagi's work (2005), the best solutions of TCO problems have been received by the Shuffled Frog Leaping Algorithm (SFLA). SFLA presented by Eusuff and Lansey (2003) is a meta-heuristic iterative method inspired from the memetic evolution of a group of frogs when seeking for food (Huynh 2009). In the SFLA, the virtual frogs are periodically shuffled and reorganized into new memplexes in a technique similar to that used in the Shuffled Complex Evolution algorithm (SCE) in order to ensure global exploration. The results demonstrated that SFLA produced better results than the Genetic Algorithm (GA) in terms of effectiveness and efficiency for all problems.

SHUFFLED FROG LEAPING ALGORITHM

Instead of using genes in GA, SFLA uses memes to improve spreading and convergence ratio. Meme (pronounced 'meem') is a contagious information pattern that alters human/animal behavior. The actual contents of a meme, called memotype, are analogous to the genes of a chromosome (Eusuff 2004). The main difference between a gene and a meme is related to its transmission ability. Genes can only be transmitted from parents or a parent in the case of asexual reproduction to offspring. Memes can be transmitted between any two individuals (Eusuff 2006). SFLA, in essence, combines the benefit of the local search tool of Particle Swarm Optimization (PSO) and the idea of mixing information from parallel local searches, to move toward a global solution which is called a Shuffled Complex Solution (SCE). The philosophy behind SCE is to treat the global search as a process of natural evolution (Duan et al 1992). On the other hand, PSO simulates a social behavior, such as bird flocking, to a promising position for certain objectives in a multidimensional space (Kennedy and Eberehart 1995). A population of particles is randomly initialized with position and velocities. The particles are improved according to the following equations:

$$\nu_i(t+1) = w*\nu_i(t) + c_1*r_1*(P_i(t)-X_i(t)) + c_2*r_2*(P_g(t)-X_i(t)) \quad (1)$$

$$X_i(t+1) = X_i(t) + \nu_i(t+1) \quad (2)$$

where w=inertia coefficient, which has an important role in balancing a global (a large value of w) and local search (a small value of w); c_1 and c_2=constants ; r_1 and r_2 =uniform random numbers in [0,1]; P_i=best position vector of particle *i* so far ("personal" best); P_g=best position vector of all particles so far (global best); $X_i(t)$ =current position vector of particle *i*; and $\nu_i(t)$=current velocity of particle *i*.

The whole population of frogs is distributed within a different subset called a memeplex. Each memeplex is considered a different culture of frogs, performing an independent local search. After a defined number of memetic evolutionary steps, frogs are shuffled among memeplexes, enabling frogs to interchange messages among different memplexes and ensuring that they move to an optimal position, similar to particles in PSO. The local search and the shuffling processes continue until defined convergence criteria are satisfied (Eusuff 2006). Figure 1 demonstrates the flowcharts of the SFLA. (See Eusuff-2004-for a comprehensive review of SFLA algorithm)

TIME-COST-RESOURCE OPTIMIZATION MODEL WITH ACTIVITY SPLITTING ALLOWED

Each frog in the TCRO model consists of *p*4* memes, in which *p* is the number of activities. Selected option and early start date can be placed as values of two first memes for each activity. After fixing CPM for each frog, Total Float (TF) and Free Float (FF) are calculated for each meme and are placed as values of the next two memes for each activity. In cases of splitting

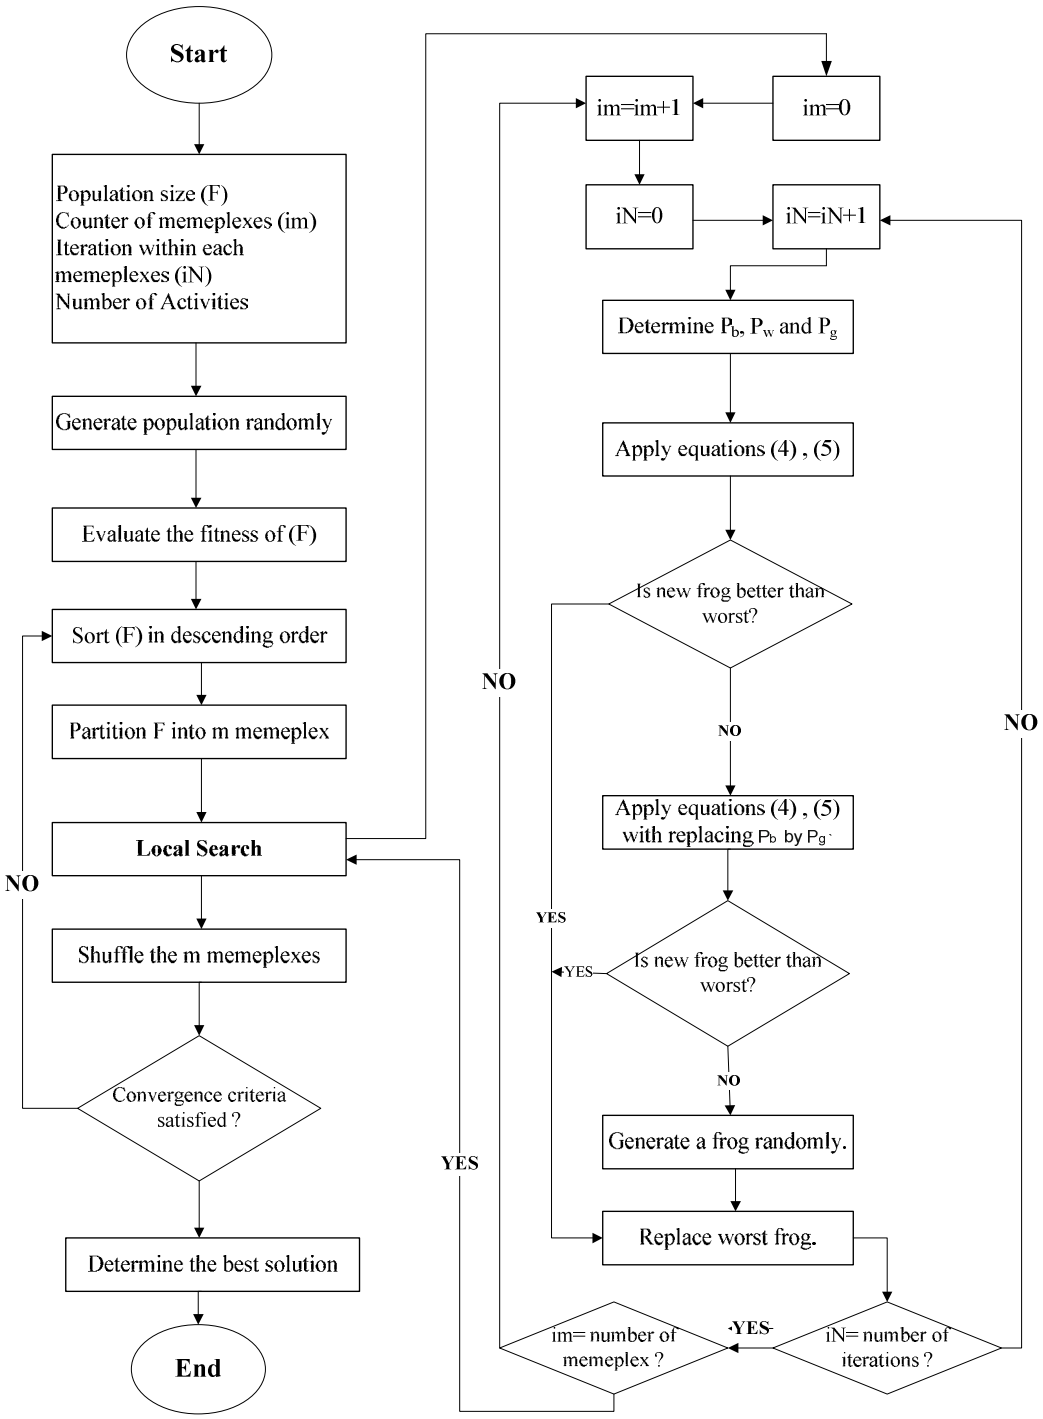

Figure 1. *The flowcharts of the SFLA*

allowed, these values will be used to optimize objective functions. The sequence of memes should be consistent with the order of activities in priority relations between activities. Each frog contains the information of one project based on the different chosen option of activities. Six main parameters are estimated for each frog.

- Critical path for estimating total duration of project execution;
- Total time of project;
- Total cost of project;
- Moment of resources;
- Logical parameter which shows validity of Daily Resource Limit (DRL) condition;
- Activities of project in which splitting has been applied to optimize objective functions;
- The binary parameters should display the active duration of each activity based on the selected option.

OBJECTIVE FUNCTIONS

The objective functions of the TCRO model are formulated to simultaneously minimize total project time and cost along with leveling and allocating of resources to different activities. (Zharaie and Tavakolan 2009). Based on Hegazy (1999), three resource moments have been applied based on the goal of the project manager in utilizing resources.

1. In order to reduce of fluctuations in utilizing resources (M_1):

$$M_1 = Min\left(\sum_{j=1}^{m}\sum_{i=1}^{n} r_{ij}^2\right) \tag{3}$$

Where r is the resource utilized in day i; and m and n are total number of resources and days required for project execution, respectively.

2. In order to release the resources in the least possible time (M_2):

$$M_2 = Min\left(\sum_{j=1}^{m}\sum_{i=k}^{n} (r_{ij} \times (i - k_j))\right) \tag{4}$$

Where k_j is the start time of using each resource.

3. In order to reduce fluctuations of resources utilization and release of resources in the least possible time (M_3):

$$M_3 = Min\left(\left(\sum_{j=1}^{m}\sum_{i=1}^{n} r_{ij}^2\right) + \left(\sum_{j=1}^{m}\sum_{i=k}^{n} (r_{ij} \times (i - k_j))\right)\right) \tag{5}$$

One of the above mentioned resource allocation objectives and the two following objectives of minimizing total time and total cost of project are the three objective functions of the optimization model:

$$M_4 = Min\ Z_c \tag{6}$$

$$M_5 = Min\ Z_t \tag{7}$$

CONSTRAINTS OF THE MODEL

The main constraint of the model considered is the fact that the structure of the model is related to the dependencies between activities. In other words, the relationships of the activities cannot be changed in a network of activities. Since we have only "Finish to Start" relationships between activities, the following constraint precludes the situation that the successor has started before the predecessor is finished by considering TF and FF of all activities in one frog.

$$(TF_p - FF_p - m + 1)^* \lambda_{km} + \lambda_{p(Dp+FFp+m)} + \lambda_{p(Dp+FFp+m+1)} + \ldots + \lambda_{p(Dp+TFp)} \leq (TF_p - FF_p - m + 1) \tag{8}$$

where $m=1,2, \ldots, TF_p - FF_p$.

Another important constraint that should be considered in the model is the Daily Resource Limit (DRL) condition. Where resources are allocated, the logical parameter should be considered in order to level resources. Considering splitting for noncritical activities gives the model more flexibility to optimize Pareto front solutions. Based on Son and Mattila's research (2004), the binary optimization model must reflect the duration constraint for each activity.

EXAMPLE

In order to demonstrate the effectiveness of SFLA on the TCO and TCRO models with splitting allowed, one example is adapted from Zheng and Ng (2005). It contains seven activities. The daily indirect cost of this project is considered to be \$1500, the same as prior research on this example. In total, 80 options have been considered for seven activities of the project. As Tables 1 and 2 show, 7 required resources with fixing unit costs (ranges from \$50 to \$4000) and defined number of options during construction have been considered for different activities of project.

RESULTS OF EXAMPLE

SFLA applied on this example demonstrates improvement of results of the TCO and TCRO model. For local exploration, the parameters of c_1 and c_2 in the equation (1) are set to 2. The value of inertia weight w is stipulated at 0.5. Results are evaluated in both splitting allowed and

not allowed. Before applying splitting, results of TCO and TCRO are compared with the previous works in terms of non-dominated solutions and processing time of convergence. The

Table 1: *Details of Example*

Activity Description	Activity Number	Precedent Activities	No. of Options	Types of Required Resources
Site preparation	1	-	11	7
Forms and rebar	2	1	11	4
Excavation	3	1	19	4
Precast concrete girder	4	1	9	7
Pour foundation and piers	5	2,3	9	7
Deliver PC girders	6	4	11	7
Erect girders	7	5,6	10	7

Table 2. *Different options for the first activity in Example*

Option No.	Duration	Number of Required Resources							Total Cost($)
		R1	R2	R3	R4	R5	R6	R7	
1	14	3	2	1	1	1	0	0	23000
2	15	3	2	1	0	1	2	0	21900
3	16	3	2	0	1	0	1	2	20800
4	17	3	2	0	0	1	1	0	19700
5	18	3	1	1	0	1	2	4	18600
6	19	3	1	1	0	0	0	0	17500
7	20	3	1	0	0	1	2	0	16400
8	21	2	2	0	0	0	1	2	15300
9	22	2	1	1	0	1	1	0	14200
10	23	2	1	0	1	0	0	2	13100
11	24	2	0	0	2	2	0	0	12000

results demonstrate that the least cost and fewest resource moments are decreased by SFLA. In addition, the processing time to obtain a final solution is improved by 25%, however, only least time and cost solutions are decrease in the TCRO model and resource moments solutions have not been changed by SFLA. The processing time is improved by 22% in TCRO model.

The other objective of selecting this example is comparing results when splitting is applied in the model. In order to apply splitting in activities, the values of TF and FF of each meme can be used. The results demonstrate that the time and cost are decreased by 6% and 0.4% respectively in TCO model and 6% and 0.3% in TCRO. The same procedure can be seen in resource moments solutions. They are improved by 0.07% to 1.8% by applying splitting in SFLA in both TCO and TCRO models. Compared to cases without splitting, the processing time increases in both models. It should be noted that every results in this example is considered with an unlimited resource condition. Table 3 shows the complete results of this example.

Table 3. *The results of Example*

Model		Algorithm	Splitting	Pop. Size	Min Time	Min Cost	Minimum Resource Moment among the pareto solution			Average of Processing time (min)
							M_1	M_2	M_3	
Zheng et al. 2004		GA	Not Allowed	5	66	236,500	-	-	-	-
Zahraie & Tavakolan (2009)	TCO model	NSGA-II	Not Allowed	250	65	226,350	8,539	98,120	41,057	12
TCO model		SFLA	Not Allowed	250	64	226,300	8,535	98,050	40,522	9

TCRO model		SFLA	Allowed	500	64	226,850	4,601	53,361	12,068	18

CONCLUSION

SFLA has been used as appropriate tools to obtain the best solutions with the least total time and cost by evaluating unlimited possible options. One of the problems of previous research is that assumptions make them unrealistic in comparison with actual construction projects. On the other hand, delay events during execution of activities have an important impact on total time and cost of projects. Therefore, the authors attempt to make the model better approximate real projects by considering splitting during execution of activities.

The example is adapted from Zheng and Ng (2005) to compare non-dominated solutions of SFLA by applying splitting to previous works in GA and NSGA-II. Results in both TCO and

TCRO models demonstrate improvement of solutions, convergence ratio, and the processing time to reach the optimum solution. It confirms that SFLA improves results, by comparing results before applying splitting. Moreover, splitting permits the model to become more flexible in finding the least time and cost and the fewest resource moments. Since in this case, we do not have any limit for resources, the impact of splitting on concepts of time-cost trade off and resource allocation has been investigated. The values of improvement demonstrate that splitting has significant impact on final results.

Abstract
In almost 20 Years since Latham published the interim report 'Trust and Money' in which he asserted that there was too little of either in the UK construction industry, has anything changed? This paper addresses issues of what trust is, how it is created and its fragility, and progresses to examine how trust operates in the construction industry. The second major thread, money, is examined in the context of the economics and financing of construction projects and organisations in an era in which globalisation of the finance industry has occurred as well as global and local crises in that industry and many countries economies. Market emphases and process changes have occurred at several levels, continuing existing trends but also spawning new ones. A key question, which is examined as the underpinning, central theme of this paper, is that although structural changes and procedural changes are highly evident, what has changed in behaviour within the industry, why, and with what consequences regarding trust and money?

Keywords: behaviour, construction, finance, globalisation, projects, trust.

INTRODUCTION

Money has always been a vital consideration for construction projects. Emperors in ancient China endured financial restrictions in constructing the Great Wall and the Forbidden City; Christopher Wren endured and overcame financial shortfalls in the construction of the new St. Paul's Cathedral, Sydney Opera House and the Channel Tunnel both vastly exceeded their budgets and securing the additional finance required proved hugely problematic and left notable legacies! A further complication was articulated by Denning LJ who identified cash flow as the 'life blood of the construction industry'. Indeed, it may be argued that the profession of Quantity Surveying, in its various guises and contexts, developed out of a desire to achieve financial control in the industry.

Trust has changed as processes and procedures have altered and relationships between people have responded. The industrial revolution seems to have been a watershed with a rapid transition from craft guilds' masters and journeymen transacting on reputation and trust amongst relatively few persons who conducted small numbers of transactions with the individuals well known to each other and the community, to numerous transactions amongst persons largely unknown to each other. A direct result was the increase in use and importance of contracts to govern relationships and enforcement of the terms of agreements. Thus, trust became replaced by (legally enforceable) assurance.

In December 1993, the interim report of the 'Latham' review of UK construction industry procedures was published under the title of 'Trust and Money' (Latham, 1993), forcefully asserting that there was not enough of either in the UK construction industry. The full report was published in 1994 which, although much more 'glossy' and detailed concerning payment terms and practices and the call for 30% improvement in productivity, much of the message regarding trust and various aspects on money was obscured (Latham, 1994). Nonetheless, the 'Latham Report' has had significant impact through consequent legislation (Housing Grants, Construction and regeneration Act 1996), promotion of 'partnering' in construction, outlawing 'pay-when-paid' terms, and promotion of the New Engineering Contract (NEC). Effects have reached far beyond the shores of UK.

Construction projects operate as informal joint ventures where both individual and aggregate performance is determined by behaviour of interdependent actors in the coalition; Sherman (1992) finds that '…one third of strategic alliances failed due to lack of trust among trading partners'. Thus, this paper examines the major issues of trust and money raised by Latham (1993) to determine their underpinnings in theory and practice and what has occurred in the (UK) construction industry to address those issues.

> I tell this tale, which is strictly true,
> Just by way of convincing you
> How very little, since things mere made,
> Things have altered in the building trade.
>
> (Kipling, 2011)

HUMAN BEHAVIOUR

The general behavioural assumption in many social sciences is of ultimate self-interest (e.g., Dawkins, 2006). Under that assumption, individuals behave to maximise their own satisfaction and firms behave to maximise their own profits – more appropriately, profitability. However, the severence of ownership and management in modern corporations and the recognised importance of growth of the firm has modified the single objective assumption to be replaced by the objective of maximising growth, subject to a minimum profit constraint (Baumol, 1959).

Even in highly developed Western capitalist market economies, grounded in very individualistic societies (see Hofstede, 2001), there is increasing evidence that such assumed behaviour by individuals and firms is not universal (e.g., Etzioni, 1988; Perrow, 1986). Not only do firms, of necessity, examine and respond to the demands of powerful stakeholders, their activities are increasingly subject to legislative constraints (health and safety, environmental protection, etc.). However, despite the evolution of apparently altruistic behaviour, including citizenship behaviour, corporate social responsibility (CSR) / performance (CSP), and greening/sustainability, a strong core of adherence to self interest remains (Friedman, 1970; Coase, 1937; Williamson, 1985).

Thus, human behaviour comprises a blend of motivators/drivers – self interest through utility maximisation (which tends to be highly materialistically oriented) and morality through the operation of ethics to give regard to the welfare of others. Resultant behaviour is dependent upon personality, culture and social institutions together with the context of the particular situation as perceived by the actor(s).

Commonly, personality is analysed through the 'big five' personality traits (Costa and McCrae, 1988) of Extroversion, Agreeableness, Conscientiousness, Emotional stability (Neuroticism), and Intellect or openness to experience. Traits describe what people are like, while values refer to what people consider to be import and, thence, the goals they endeavour to pursue (Roccas, Sagiv, Schwartz and Knafo, 2002).

Culture constitutes the social context in which activities occur. Culture is a group construct, commonly defined as 'the collective programming of the mind which distinguishes one category of people from another' (Hofstede, 1994). Culture is analysed at the levels of the society (national) and the organisation; organisational culture is acknowledged to be embedded in the national culture. Hofstede's five dimensions of national culture are Power Distance, Collectivism/Individualism, Masculinity/Femininity, Uncertainty Avoidance, and Long-Termism / Short-Termism; the six dimensions of organisational culture are: Process – Results Orientation, Job – Employee Orientation, Professional – Parochial, Open – Closed System, Tight – Loose Control, and Pragmatic – Normative (see Hofstede, 2001).

Both Denison (1997, 2009) and Cameron and Quinn (1999) employ competing values frameworks to model organisational cultures. In Denison's (1997, 2009) model, flexibility and stability are juxtaposed along one dimension with organisational focus – internal juxtaposed to external – on the other dimension. The resultant quadrants comprise mission, consistency, involvement and adaptability. In Cameron and Quinn's (1999) model, 'flexibility and discretion' is juxtaposed to 'stability and control' on one dimension with 'internal focus and integration' and 'external focus and differentiation' juxtaposed on the other. The resultant model comprises four quadrants, each denoting a type of organisational culture – Clan, Adhocracy, Market, Hierarchy.

Handy (1985) suggests a typology of organisational cultures. Power culture is depicted as a web with the major power at the centre, emphasising control over subordinates and external agents (suppliers etc., and nature). A role culture focuses on functions/professions which provide support to top management; emphasis is on rules, hierarchy and status through legality, legitimacy and responsibility. In a task culture, jobs or projects are the major foci; an organisation is regarded as a net (as in a matrix organisation); structures, functions, and activities are evaluated in respect of their contributions to achievement of the organisation's objectives. In a person culture, people interact and cluster freely and emphasise meeting the needs of members of the organisation through consensus. Handy considers that the main factors influencing which organisational culture develops are: goals and objectives, history and ownership, size, technology, environment, and people. Williams, Dobson and Walters (1989) advance categories of 'Power', 'Role', 'Task', and 'People' which correspond to Handy's (1985) typology.

Hall and Hall (1990) employ the concept of high context / low context to analyse cultures. In a high-context culture, there are many contextual elements that help people to understand messages, behaviour and other manifestations of the culture. Meaning must be derived from the message itself and the prevailing circumstances/situation – much intuition is necessary together with a thorough understanding of both the language and the society. In a low-context culture, very little is taken for granted. Thus, much more content is needed but the resultant message is precise and explicit in its meaning and so, there is a low chance of misunderstanding; thus, people can be quite confident to interpret messages at 'face value', although such direct and obvious expression can be offensive to people from high context cultures.

Hall and Hall's second dimension concerns how people perceive time along a dimension of monochromic / polychromic. Monochronic time means doing one thing at a time, often in a

predetermined sequence. In more complex situations (such as a construction project), it requires careful planning and scheduling to be carried out and is usually assumed/adopted in 'time management'. Monochronic people tend to be low context (high content). In Polychronic perceptions of time, human interaction is valued over time itself and material things. That generates a low concern for 'getting things done' – they get done, 'in their own time'. Polychronic people tend to be high context.

'Organizational Climate is a relatively enduring quality of the internal environment of an organization that (a) is experienced by its members, (b) influences their behaviour, and (c) can be described in terms of the values of a particular set of characteristics (or attributes) of the organization.' Tagiuri and Litwin, 1968: 27). Hence, the climate of an organisation distinguishes it from other, similar organisations. As organisational climate both reflects and shapes the work-experiences shared by members of an organisation, it indicates their perceptions about autonomy, trust, cohesion, fairness, recognition, support, and innovation and so, leads relative homogeneity amongst members through recruitment and retention.

Norms of acceptability and rules of human behaviour are often embodied in social institutions. Those institutions comprise both formal and informal organisations, including governments, firms, professional institutions, friendship groups. Social institutions include meta-organisations, such as an industry, and systems of organisations, such as an economy. Further types of social institutions are not organisations but are important influences on society and its constituents, such as a religion, and a language.

All those primary variables of human behaviour, group and individual, combine to determine actual behaviour in any given context/situation. Naturally, the variety of mixes of influence of the behavioural determinants lead to very different behaviours by people in a given situation – understanding, tolerance and consideration (towards others) are, therefore, important features of human interactions, together with subjective assessments of how others will behave proactively and reactively.

TRUST

Trust, the antithetical compliment of risk, is always an element in the decision to engage in a (business) relationship. Generally, trust is defined as 'Confidence in or reliance on some quality or attribute of a person or thing, or the truth of a statement.' (OED, 2009) or, in relationships, trust may be considered to be adequate confidence (on the part of the subject actor/participant) that the other participant(s) will not cheat – that the other will not behave to cause detriment to the actor. Perhaps the most widely employed definition is '…willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party' (Mayer, Davis and Schoorman, 1995). Thus, trust is an ***expectation*** of future behaviour rather than a certainty and so, incorporates a probability of betrayal (Zaheer, McEvily and Perrone, 1998). Trust may be unidirectional or mutual.

Trust may be classified in several alternative ways. For initial, or individual, encounters between actors, dispositional trust is appropriate (do the actors intuitively regard others to be trustworthy or are they cautious, wary of others and so, take precautions for their self-protection?). Additionally, trust may be based on the reputation of the other (reputational trust), which, then, operates to modify dispositional trust. For recurring encounters, trust may be based on experience (of others generally and of the particular others) – experiential trust. Trust may relate to individuals and to organisations (through their agents) – interorganisationally and between organisations and individuals (see, e.g., Lau and

Rowlinson, 2009). Bachmann (2001) classifies trust as relating to people (personal trust), institutions (as organisations) and the system (technical, political, social,economic and legal).

Zaheer *et al*. (1998) suggest that concepts of trust comprise components of predictability, reliability and fairness – which relate to others and their performance, both process and (especially) outcomes. Further, in addition to trust in the system, they consider the human facets of trust as cognition, behaviour and emotion (affect).

In a social context, trust is categorised as generalised (relating to trust exhibited by members of that society in its broad context) or particularised (between members of small communities who know each other and with strong social controls). Further, Arrow (1972) considers calculative (instrumental) trust which depends upon rational self-interest, whilst Bachmann (2001) finds that behaviour is determined by beliefs and knowledge rather than by explicit calculations regarding gains/losses.

Convergent interests between actors fosters trust (conversely for distrust). Further, continuing relationships leads to relational trust arising from experience of interactions between the particular actors. Interorganisational trust concerns the extent to which members of an organisation hold a collective view regarding the trustworthiness of the other organisation(s) (Zaheer *et al*., 1998). Hence, organisational culture and climate impact on perceptions of trustworthiness and trust behaviour between organisations.

Yamagishi and Yamagishi (1994) distinguish trust and (performance) assurance in that if one actor trusts another because the former has some provisions in place so that the latter has an incentive to cooperate, then that situation is one of assurance; trust exists when an actor believes that the other has an incentive to 'cheat' but does not do so – perhaps because of goodwill.

Hagen and Choe (1998) note that, '…a trust relationship in business involves an expectation of cooperation but not an expectation of altruism'. 'The Chinese system of networked transactions…is relatively uncodified, and it is based on trust and long standing personal connections' (Boisot and Child, 1996). Thus, social institutions give rise to differing levels of trusting behaviour through the required behavioural norms (and limits) and sanctions for transgressors (who are caught); those institutions also impact on trustworthiness of individuals and organisations and, hence, on apparent dispositional trusting behaviour.

'The relationship…in Japan is not built primarily on trust, but on the mutual interdependence enshrined in the agreed-upon rules of the game' (Womack, Jones and Roos, 1990:155). That is afforded more general applicability by Hagen and Choe (1998) who state that '…the institutionalized industry practices that we call 'institutional sanctions' in the context of societal sanctions, are key determinants of interfirm cooperation', as manifested as the deterrent based trust in Japanese industry.

Although trust and distrust are commonly viewed as opposite ends of a single dimension, that may not be appropriate (Lewicki, McAllister and Bies, 1998). Given that many business relations are multi-faceted, '…relationship partners might trust each other in certain aspects, not trust each other in other respects, and even distrust each other at times.' (ibid). That finding suggests the contingent nature of relationships together with the importance of culture and perceptions of cultures in determining behaviour. Likewise, trust comprises components of amount and scope (realms of trust and ways of trusting) (Rousseau, Sitkin, Burt and Camerer, 1998). Those aspects arise because, usually, relationships are multifaceted and those facets may be treated seapartely.

Thus, interorganisational relationships are complicated and, for each major componemt, amounts and types of trust and distrust are likely to differ.

Uncertainty and trust are the two primary constructs which affect relationships and their institutional arrangements (Sheth and Parvatiyar, 1992). Bachmann (2001) views trust and power as means for social control within business relationships. Those concerns are commonly manifested in the criteria for selection of participants and the establishment of safeguards against opportunistic behaviour; thereby increasing *ex ante* costs in the venture (Williamson, 1985). However, Baiden, Price and Dainty (2006) find that, in the usual processes employed for selecting participants on a construction projects, the vastly dominant criteria continue to be price and perceived technical expertise – the ability of participants to integrate and cooperate to deliver the project effectively and efficiently remains, largely, ignored.

MONEY

Traditionally, beyond a barter economic system, money is a system of tokens used to facilitate exchange, usually as coins and banknotes (narrow quantifications) but now includes significant extensions to include bank deposits and credit (broad quantifications). Today, even cash is not directly exchangeable for underpinning precious metal (gold) as the vast majority of the world's money supplies are 'fiduciary issue' – i.e., backed only by confidence (in governments and economies). Consequent potential problems due to ensuing fragility of modern money have been clearly demonstrated through recent (global) financial crises.

Money performs four major functions: a medium of exchange; a store of wealth; a unit of account; and a standard of deferred payment. People and organisations require (demand) money to effect transactions (whether cash or via credit), as a 'safety net' (precaution) for unforeseen expenditures (solvency and liquidity), and for speculations (as in much property development). On the supply side, at the macro level, an economy's money supply (the total amount of money in the economy and its rate of change) is regulated by government or, as in UK, the central bank. The money supply is controlled via (short term) interest rates plus open market operations, special deposits, reserve ratios and other means of control of 'money creation' by the banks. Normally, monetary control is used in conjunction with instruments of fiscal policy to effect management of the economy by government.

In construction, money is required to meet revenue (short term) expenditures (direct/prime costs) and for investment (long term). Those types of finance are obtained from different sources and, internally, are managed by different sections of the organisation. No finance (money) is free; its price is the rate of interest (real, foregone, or 'shadow'). A market (nominal) rate of interest, within the competitive market environment, has three components – inflation (simplistically assumed to affect everything equally), time/liquidity preference, and risk. People have liquidity preference and are risk averse – both to varying degrees but each requiring compensation through the rate of interest.

Cash flow models of projects are well known and are used to assist organisations to determine their financing requirements and costs. However, given the risk distributions and returns available, coupled with the widespread emphasis on capital price competition for work allocation, much effort is devoted to 'financial engineering' and power ploys for enhancement of own, individual profitability.

'The increased uncertainty of economic activity increases the information impactedness of parties and consequently increases the potential for opportunism in economic exchange' (Korczynski, 2000), thereby reducing potential trust and, consequently, performance of the processes involved – as in UK construction.

CONSTRUCTION (IN UK) SINCE 1983

Construction in UK is in the third phase of its contribution to the socio-economy. Having gone through emphasis on infrastructure provision and on new building, now repair, maintenance, and refurbishment dominate. Construction is also subject to privatisation, concerning both the public sector as client and as a supplier of construction realisation work. An important structural and systemic change is the (universal) adoption of total subcontracting for the execution of construction operations with 'main contractors' becoming, *de facto*, management contractors.

In 2007, the output of the UK construction industry contributed over 8% of gross domestic product (GDP) at market prices and almost 54 % of gross domestic fixed capital formation (GDFCF), which, itself, contributed over 16 % of GDP. The output was mainly produced by over 192,000 private contractors, which provided employment for almost 1.3 million people, of which ¾ million were operatives. Insolvencies of construction companies and partnerships, constituted over 14 % of the total but bankruptcies of individuals, self employed persons, etc. in construction had experienced a steady decline to only 3.5 % of the total (Office for National Statistics, 2009a; 2009b.)

The mix of output, by type of work, (2007) was about 58% new work (includes refurbishment etc.) and 42% repair and maintenance. Of the new work, just over 10% was infrastructure, 34.5% was housing (82.5% private), 21.5% private commercial and 7% private industrial; public housing and non-housing comprised almost 21% of total new work. Of the total repair and maintenance work (housing and non-housing), 67% was done by the private sector (Office for National Statistics, 2009a).

During the third quarter of the twentieth century the public and private sectors each commissioned about 50% of construction output. Given that (most) construction is a producer good, with stock far dominating annual (new) supply and that construction is a relatively independent industry regarding its inputs and outputs (expenditure on construction is 'postponable', at least in the short term), the operation of the Keynesian multiplier, coupled with successive governmental attempts at management of the economy, the industry was subject to cycles of 'boom and bust' (whether intentional or otherwise is contested – see, e.g., Hillebrandt, 2000: 23-28), the effects being magnified by the accelerator principle. Thus, turbulence forces in the environment over many years have shaped the industry culture of opportunistic behaviour.

Prior to Latham, a raft of reports presented analyses of facets of the industry and recommendations to enhance its performance; since Latham, the incidence of further such reports, with consequent initiatives for change, has intensified (see, e.g., Murray and Langford, 2003; Constructing Excellence, 2009). Essentially, Latham (1994) provided the foundations on which subsequent reports have built, notably, Egan (1998) but what remain largely omitted is the fundamental message of Latham (1993).

Latham (1994) articulated the impetus for 'partnering', asserting that such practices could achieve 30% saving in cost within five years(!) plus the significance of the client role; in respect of finance and cash flow, 'pay when paid' terms, extensive delays in making payments and 'bid shopping' were condemned. Four years later, Egan (1998), drawing on experiences in production industry and major construction clients, strongly advocated 'lean' production for the industry. Egan's perspective and performance change targets are shown in figure 1. Subsequently, additional reports etc. have developed the outputs of Latham and Egan – not just in UK but internationally; some countries have reinforced their desires for change with legislation.

Figure 1: *Achievements of UK Construction following Egan (source: Constructing Excellence, 2009:7)*

Constructing Excellence (2009) provides some salutary views on 'partnering': '…many so-called partners still seek to avoid or exploit risk to maximise their own profits, rather than find ways to share risk and collaborate genuinely so that all can profit…Companies who say that they partner will still seek to retain profit for themselves and pass risk down the supply chain…'. Further, '…we cannot assess how far the improvements in, say, profitability are attributable to favourable economic conditions…as opposed to process efficiency…'.

CIOB (2010) report a survey investigating what CIOB members of the UK construction industry regard as important issues in procurement. Amongst the issues are that clients are not sufficiently knowledgeable, 'suicide bidding' (leading to adversarial, opportunistic behaviour), and cover pricing. KPMG (2010) Global construction survey finds that margins are very tight, financing remains a big challenge for clients, competition is extensive, and 'red tape' is increasing. In accord with the findings of CIOB (2010), KPMG (2010) note that '…39 percent of the larger organizations said they were reducing prices to near break-even…Some are hopeful of making up such shortfalls further down the line through change orders and greater internal efficiency, and by demanding lower sub-contractor pricing'.

DISCUSSION

Mayer et al. (1995) develop a model of trust in which a trustor examines a potential trustee's technical ability, benevolence, and integrity to determine that trustee's trustworthiness which is, then operationalized into trust by the trustor, as moderated by the trustor's propensity to trust. Thus, trust occurs between actors and depends on purpose, context and time. Trust may occur between individuals and organisations but only the potential for trust, as in propensity to trust, seems to be applicable to a society as a generic feature/dimension. That conceptualisation, raises concerns over whether and, if possible, how Latham's assertion of too little trust within and relating to the construction industry may be addressed.

Literature suggests that there is a fairly strong relationship between interorganisational trust and performance, relating to interorganisational exchanges, negotiations, and conflict (Zaheer *et al.*, 1998); the longer relationships have endured, the greater the trust is likely to be. However, a caution involves 'contractual trust', which is assurance rather than trust *per se* and may be appropriately considered as reliance which operates as '…institutionalised standards to reduce potential risks…manifested in legal agreements…' etc. (Jiang, Henneberg and Naudé, 2010). Reliance, implies dependence – which seems a more appropriate

conceptualisation of relationships between participants in the realisation of construction projects, while relationships with other stakeholders may be more trust oriented.

'…when contingencies arise, such as unexpected costs…or unanticipated design changes, high levels of interorganizational trust enable the parties to address the contingencies without resort to legalistic remidies…the parties will tend to direct their efforts toward determining how best to reach mutually beneficial solutions' (Zaheer *et al*., 1998). However, due to the nature of the temporary multi organisations (TMOs), which are assembled bespokenly for each project, Korczynski,'s (2000) finding is apposite, 'In situations of power imbalance there is a temptation to enforce cooperation through power rather than trust'. That finding is reinforced by Bachmann (2001), 'In the British…business system, the risk of trust often seems intolerably high, and businessmen in many situations can find good reasons to consider their sources of power'.

Duarte and Davies (2004) note a positive relationship between trust and cooperation (although the causal relationship sequencing is contested), reduced conflict and increased commitment; they also discuss the empirical results which indicate satisfaction to be a consequence of trust. That perspective is detailed by Kwon and Suh (2004) '…a firm's trust in its supply chain partner is highly associated with both sides' specific asset investments (positively) and behavioural uncertainty (negatively). It is also found that information sharing reduces the level of behavioural uncertainty, which, in turn, improves the level of trust. A partner's reputation in the market has a strong positive impact on the trust-building process, whereas a partner's perceived conflict creates a strong negative impact on trust….the level of commitment is strongly related to the level of trust.'

Those findings support 'relational contracting' in its various guises. Unfortunately, empirically based findings regarding behaviour in the UK industry (e.g., Baiden, *et al*., 2006) demonstrate absence of the fundamentals and emphasis on uses of power for self-gain.

The issues of lack of trust and consequent behaviour spawn financial problems for the industry – the extensive uses of market power to allocate work and drive down prices, low profitability prompting investment difficulties, including securing finance to supply projects, opportunistic behavious to reduce costs and enhance cash flows, etc. The resultant risk distributions and performance concerns exacerbate the self-reinforcing cycle such that clients have problems in securing finance for construction too and so, prompt the cycle further. Indeed, major clients who have extolled the mutual virtues of partnering to construction have been found to practice in their own industries the very behaviours which they condemn in construction!

CONCLUSIONS

Construction is an important but relatively independent industry which may serve to enhance the turbulence of its activities. Given risk aversion, it is hardly surprising, therefore, that the industry operates opportunistically for its self-protection and survival of individual firms as well as having strong preference for the *status quo* and reluctance to invest. The industry, in addition to its many well-known caricature descriptors, may also be denoted as being suspicious and wary of suggested initiatives, hence, not prepared to trust and of questionable trustworthiness – both applying inwardly and outwardly.

By definition, the culture of the industry is deeply ingrained and very difficult to change – and that, only in the long term through enduring means which convince participants to change. Latham's concerns for trust and money, and the many reports and initiatives subsequently, have failed to address the fundamentals as well as the more superficial

behavioural cycles involving trustworthiness, trust behaviour, performance and finance. Indeed, it seems that research is required to identify the cycle and its cause-effect linkages as, only with such understanding, can real opportunities for improvement change be identified.

Abstract

The Public Procurement Act (Act 663) 2003 was introduced in Ghana to streamline the anomalies in public procurement. The objective of the law is to promote fairness, transparency and ensure that public procurement is non-discriminatory. The implementation of the Public Procurement Act 2003 (PPA) has been quiet challenging coupled with a number of inefficiencies. The aim of this study is to observe and compare the extent to which selected public procurement entities have complied with the processes and requirements of the Law during the year 2008. The entities were chosen from the Ashanti and Brong Ahafo regions of Ghana. Structured questionnaire and face-to-face interviews were used to obtain data for this study. The overall compliance levels in the Ashanti and Brong Ahafo Regions lies at 19.58% and 17.8% respectively. This indicates low compliance levels of public entities. The study confirms that the Public Procurement Act 2003 (Act 663) is observed to proffer solutions but not without challenges. In the pursuit to improve compliance with the Act the study recommends that public entities recruit procurement personnel and organize intensive and regular procurement training for the personnel handling public procurement especially in the area of procurement processes.

Keywords: Ghana, Public Entities, Public Procurement, Public Procurement Act, Compliance

INTRODUCTION

In Ghana, the Public Procurement Act (Act 663) 2003, was enacted to harmonize public procurement processes in the public service, secure judicious, economic and efficient use of state resources, and furthermore, ensure that public procurement is fair, transparent and non discriminatory (Ministry of Finance, 2001). This new Act, was constituted after years of foul play and abuse as far as procurement was concerned in the country. This necessitated a thorough review of the existing procurements regulations. The enactment of the law in 2003 further

ensured that modern trends in procurement was adopted to bring about the much needed sanity to local procurement system which had been flawed by bad procurement practices such as corruption and other malfeasances (Osei-Tutu *et al*., 2010).

In Ghana, public procurement accounts for 50%-70% of the national budgets (after personal emoluments), 14% of GDP and 24% of imports. Implicitly, public procurement therefore has both social and economic impact on the country (World Bank, 2003a).

Assessment of Public Procurement Entities

Increasing the effectiveness, efficiency and transparency of procurement systems is an on-going concern of governments and the international development community. All countries have recognized that increasing the effectiveness of the use of public funds, including funds provided through official development assistance (ODA) requires the existence of an adequate national procurement system that meets international standards and that operates as intended.

The regular and continuous assessment of procurement entities in countries of their national procurement systems with regard to their compliance with the procedures, rules and regulations setup in the Public Procurement Laws has been embraced worldwide.

The baseline indicator assesses the strengths and weakness of National Procurement Systems. The indicator covers the legal and regulatory instruments from the highest level (national law, act, regulation, decree, etc.) down to detailed regulation, procedures and bidding documents formally in use. These indicators can be broken down into eight sub-indicators which are individually scored. These are: Scope of application and coverage of the legislative and regulatory framework, Procurement Methods, Advertising rules and time limits, Rules on participation, Tender documentation and technical specifications, Tender evaluation and award criteria, Submission, receipt and opening of tenders and Complaints (OECD-DAC/World Bank, 2006).

Performance indicators includes: Implementing regulation that provide defined processes and procedures not included in higher-level legislation, Model tender documents for goods, works, and services, Procedures for pre-qualification, Procedures suitable for contracting for services or other requirements in which technical capacity is a key criterion, User's guide or manual for contracting entities and General Conditions of Contracts (GCC) for public sector contracts covering goods, works and services consistent with national requirements and, when applicable, international requirements (OECD-DAC/World Bank, 2006).

For a public entity in a developing country to conduct procurement performance assessment, there are numerous challenges that are encountered. Notably among them are: i) there are many ways of measuring that may be in use, ii) most measures are irrelevant iii) there is no way of standardizing the measurements and iv) conducting performance measurement is costly (Kakwezi & Nyeko, 2010) .

Performance/Compliance of Procurement Entities

The Public Procurement Authority in its review in 2006 identified the weakness in the public institutions that need urgent attention. These are: Lack of qualified procurement personnel, incorrect interpretation and application of some provisions of the procurement Act, slow pace in regularizing the Draft Regulations, lack of clear procedures for Emergency Procurement, lack of Training Avenues or Institutions, poor Record Management (scattered files), poor handling of Suppliers' Complaints, poor Procurement Planning, Mobilization & Implementation, poor Contract Management and high cost of Advertisement (PPA, 2007).

Country Procurement Assessment Report (CPAR), prepared by a team of Government officials, World Bank and donor staff, and national consultants, reveals substantial inefficiency in public procurement and concludes that the principle of "value for money" is not achieved. This is true for both governments financed and donor financed procurement. The main findings of the 2002 Country Portfolio Performance Review of World Bank projects also reviewed slow project implementation and disbursement among other factors due to, a large extent of inadequate procurement planning, non-transparent procurement procedures and poor contract management. A review in 2002 of 132 works contracts which constitute an important part of public expenditure indicated that about 84% incurred cost-overruns of up to 30% of the initial amount (World Bank, 2003b). Similar findings of public procurement weaknesses were recorded in the 1996 Country Procurement Assessment Report (World Bank, 1996).

Successive waves of management and financial reforms have, inter alia, focused on improving public procurement efficiency, effectiveness and outcomes (Calendar & Matthews, 2002). Requirements for greater performance produce a refocusing of procurement management away from accountability for compliance through rule-bound codified processes (McCue & Pitzer, 2000) towards accountability for outcomes.

Public Procurement Law and Implementation Challenges

In most developing countries, the procurement function is transitioning from a clerical non strategic unit to an effective socio-economic unit that is able to influence decisions and add value (Knight et al, 2007). Developing countries in one way or another have reformed their public procurement regulations. The reforms have not been limited to regulations only; they have included public procurement process, methods, procurement organizational structure, and the workforce. The reforms have been as a result of joint efforts with various development partners like the World Bank, International Trade Centre, WTO, and UNCTAD varying from country to country.

In addition, public procurement is faced with the challenges imposed by a variety of environmental factors (external factors) such as market, legal environment, political environment, organizational and socio-economic environmental factors. Regardless of the effort by the central government and its related agencies and the acknowledgement that the procurement department is capable of adding value to the organization, still a large number of the internal customers act on their own and more frequently bypass the procuring department

(Schiele & McCue, 2006). This problem requires establishment of clear procurement procedures and performance standards. Performance when adopted will provide the decision-makers in the procurement department with unbiased and objective information regarding the performance of the procurement function (Knudsen, 1999).

Several countries have instituted reforms in their public procurement processes (Hunja, 2003). This is aimed at purging the public procurement sectors, encouraging competition, transparency, efficiency and ensuring accountability. These reforms have not come without difficulties (Hunja, 2003). The challenge include poor dissemination of the procurement law (Azeem, 2003), lack of proper training for the managers of the procurement process (Forgor, 2007).

The Country Procurement Assessment Report of Ghana in 2003 revealed that most Ministries, Departments and Agencies (MDAs) and District Assemblies (DAs) staff responsible for procurement were not procurement-proficient, even though they have been trained. The report contended that, application of the PPA and the Standard Tender and Contract Documents will not be successful without broad training and "refresher" programs and encouragement of officials in charge of procurement. In view of this, the PPA initiated a training programme in 2007 throughout the country with the aim to build the capacity of personnel responsible for the management of procurement in various institutions. This exercise unfortunately could not be sustained due to financial difficulties thereby leaving most Procurement Managers completely ignorant in the application of the law.

Building the capacity of service providers has been identified as one of the success factors of public procurement reforms. Many bidders are limited in various capacity issues including: lack of basic knowledge in the law, inadequate capacity to appreciate the standard tender documents, poor access to tender information and insufficient technical and managerial skills to be competitive in the tendering process (ODPP, 2007).

Political interference with the procurement process is also a big challenge to the implementation process and public procurement reforms. A good number of politicians think that they have the right to intervene in the procurement procedures thereby leading to a capricious procurement decisions (World Bank, 2004b).

The lack of career development path and low salaries of procurement personnel also militates against procurement reforms implementation (World Bank, 2003a). Poor records keeping (World Bank, 2003a), (ODPP, 2007) and delays in payment of contractors and suppliers have also been cited as some of the crucial factors that challenges the procurement reforms implementation (Azeem, 2007).

Corruption and Inefficiencies in Public Procurement

It is vital to make a distinction between instances of corruption and cases of inefficiency or lack of competence. While these problems occasionally go hand-in-hand, and some solutions are helpful in all areas, there are also trade-offs. For example, choosing to speed up a Procurement process might condense its transparency, making it very efficient but more prone to corruption. Moreover, it is important to realize that there is no single solution to the problem. Procurement processes need to be permanently monitored. Supervision and control play a key role since good

rules are necessary but not always enough to curb corruption. It is also important to have clear and publicly available procedures and to have regular audits by external parties.

Also, the 2009 Corruption Perception Index (CPI) released by Transparency International (TI) shows Ghana not making progress in the fight against corruption through passing of legislations. The country maintained its 2008 score of 3.9 in the 2009 CPI report. Ghana's score in the Transparency Internationals report, points to the fact that corruption is still deeply rooted in the country's procurement process (Transparency International, 2009). For example, a 2002 internal audit report revealed significant procurement irregularities in some of the major hospitals in Ghana.

There is a knowledge gap on how the procurement assessment can contribute to improved performance of the procurement function in developing countries. Only when the procurement function is well planned, that it is easy to identify areas where it is performing well, and where there is need for improvement (Kakwezi & Nyeko, 2010). Organisations which do not have performance means in their processes, procedures, and plans experience lower performance and higher customer dissatisfaction and employee turnover (Artley & Stroh, 2001, Amaratunga & Baldry, 2002 and CIPS Australia, 2005).

Thus the objective of the study was to find out the level of compliance of public procurement entities in Ghana with the Procurement Law, which was instituted to address some of these observed anomalies.

RESEARCH METHODOLOGY

The methodology for assessment of national procurement systems jointly developed by the Organization for Economic Co-operation and Development (OECD)/Development Assistance Committee and World Bank has been adopted in this research.

The methodology presented herein includes a numeric scoring with defined criteria that will enable the monitoring of indicators providing a qualitative scoring of the procurement system in place in procurement entities.

The indicators are intended to provide harmonized tools for use in the assessment of procurement systems. Although the indicators are designed for use in the assessment of the central government or national procurement system in a country, they can be adapted for use in sub national or agency level assessments. There are two parts of the indicators: baseline indicators (BLIs) that deal with the formal and functional features of the existing system; and compliance/performance indicators (CPIs), that deal with monitoring performance data to determine level of compliance with the formal system. The CPI's associated with the baseline indicators have been adopted since the authors intend to determine the level of compliance with the Procurement Law.

The suggested Compliance/Performance Indicators (CPIs) used has been summarized in Table 1 below. The CPIs help identify those areas where compliance or performance is weak. Based on review of the CPI data, analysis and findings were recorded.

The authors adopted four main Compliance Areas in the study. Indicators that designated compliance were also used. Specific information or records that designated the indicators were also identified and rated on a scale of 0 – 5; "0" rating indicates absence of the required information whilst "5" indicates that the information available is satisfactory.
The analysis was carried out by aggregating the statistics obtained from the rating. In all instances, a minimum of 20 contracts were sampled to enable subsequent analysis. Analysis of the data helped to determine the degree of compliance, measured in terms of percentage, within a given compliance area. Obtaining a 100% would imply that the entity fully complies with requirements of the procurement law in the particular area.

Four main compliance areas were adopted for determination of the compliance levels. Compliance levels in the areas were assessed based on certain indicators, which were used as sub-criteria for assessing the four main compliance areas adopted. Specific information were included in the questionnaire to aid in the assessment of the indicators. In developing countries, Ghana not being an exception, data on the baseline information are not available. Hence, the authors restricted themselves to assessing compliance levels based on the four main compliance areas.

Sampling Procedure and Data Collection

A purposive sampling was adopted for the survey. The study purposively targeted public entities in the categories of local government, education and health as representation of procurement activities of the regions for the financial year 2009. The simple method of calculating averages was employed in the computations. The ratings of the performance under each procurement area were done by the authors using a predetermined key Compliance Indicators (KCI's). In all a total key of 85 and 61 entities were assessed in both Ashanti and Brong-Ahafo Regions respectively.

Main Compliance Areas	**Key Compliance Indicators**	**Information rated on a scale of 0-5**
MANAGEMENT SYSTEMS	Effectiveness of Leadership	• Training programme(s) in place • Seeking technical support from the body with oversight role • Carrying out internal procurement auditing • Good record keeping
	Human Resource Development	• Having Staff with professional procurement qualification • Putting internal auditors in place and giving them procurement training • Evaluation of performance of procurement staff
	Monitoring and Control Systems	• Putting proper payment systems in place for every contract • Capturing procurement transactions in Cash budgets • Putting in place quality control mechanisms for contracts • Effective use of available procurement information dissemination systems
	Compliance with ethics and regulatory framework	• Appropriate use of procurement plans and contract documents • Use of Standard Tender Documents (STD) and Manuals • Use of right procurement methods • Anti-corruption measures put in place
	Complaints system, structure and sequence	• Fairness and transparency in resolution of cases within the terms established in the legal framework
INFORMATION AND COMMUNICATION	Procurement Information searching and Dissemination	• Awareness of use procurement website, procurement internal notice boards and newspapers • Capacity to use and using the procurement information dissemination systems

COMMUNICATION	Interaction with the marketplace	• Having knowledge of and interacting with the marketplace • Interacting with all procurement stakeholders
PROCUREMENT PROCESSES	Procurement Planning	• Having an adequately defined procurement plan • Posting plan on the net
	Procurement Publicity	• Advertising tender invitations • Sending information for placement in procurement bulletin • Using internal notice boards to display procurement information
	Bid Preparation and Invitation	• Use of STDs • All bid documents containing same evaluation criteria • Stating reasonable date and time for bid opening
	Submission, opening and evaluation of bids	• Stating date, time and venue for bid submission • Stating date, time and venue for bid opening • Having secured tender box in place • Having tender opening register • Keeping minutes of bid opening including all opening records • Evaluating tenders in accordance with tendering requirements
	Award of Contract	• Notifying Winner of Contract • Publicizing contract awards • Notifying losers of bid
CONTRACT MANAGEMENT	Project Planning and Mobilization	• Taking Works Programme from executers • Taking Advance payment Guarantees for advance payments made
	Project Implementation and Supervision	• Preparation of project monitoring reports • Organization of project progress meetings • Comparing and analysing planned progress against actual
	Inspection and Inventory control	• Preparation of Handing over certificates • Preparation of completion or delivery reports • Use of appropriate stock control record system
	Disposal	• Forming the required membership of Board of survey • Keeping minutes of meetings of Board of survey • Keeping records of items disposed

Table 1: *Rating of Compliance Indicators*
Source: Adopted from World Bank/OECD/DAC, 2004

Structured questionnaire were used to obtain the data required for determining the compliance levels in all the compliance areas. To obtain further data on the actual practices and challenges encountered in applying the procurement law, the key personnel members responsible for procurement were engaged in face-to-face interviews for all the entities.

ANALYSIS AND DISCUSSION OF RESULTS

The aggregated compliance levels of all the entities obtained under the main compliance areas are as presented in tables 2 and 3 below:

MAIN COMPLIANCE AREAS	LOCAL GOVERNMENT (%)	HEALTH (%)	EDUCATIONAL (%)	OVERALL (%)
MANAGEMENT SYSTEMS	35.00	31.58	15.56	27.38
INFORMATION AND COMMUNICATION	20.54	10.53	1.39	10.82
PROCUREMENT PROCESS	37.50	23.95	5.83	22.43

CONTRACT MANGEMENT	41.07	9.21	2.78	17.69

Table 2: *Compliance level of Public entities in Ashanti Region*

MAIN COMPLIANCE AREAS	LOCAL GOVERNMENT (%)	HEALTH (%)	EDUCATION (%)	OVERALL (%)
MANAGEMENT SYSTEMS	22.61	22.67	28.18	24.49
INFORMATION AND COMMUNICATION	8.69	18.33	18.64	15.22
PROCUREMENT PROCESS	17.39	10.67	5.91	11.23
CONTRACT MANAGEMENT	45.65	11.67	3.41	20.24

Table 3: *Compliance level of Public entities in Brong Ahafo Region*

In both regions, compliance levels observed were very low as indicated by the percentages obtained in tables 2 and 3. The procurement entities had comparatively better procurement management systems in place when compared to the other three main compliance areas. However, the compliance levels of all the three sectors were below average as none was able to attain 50% in all the four main compliance areas.

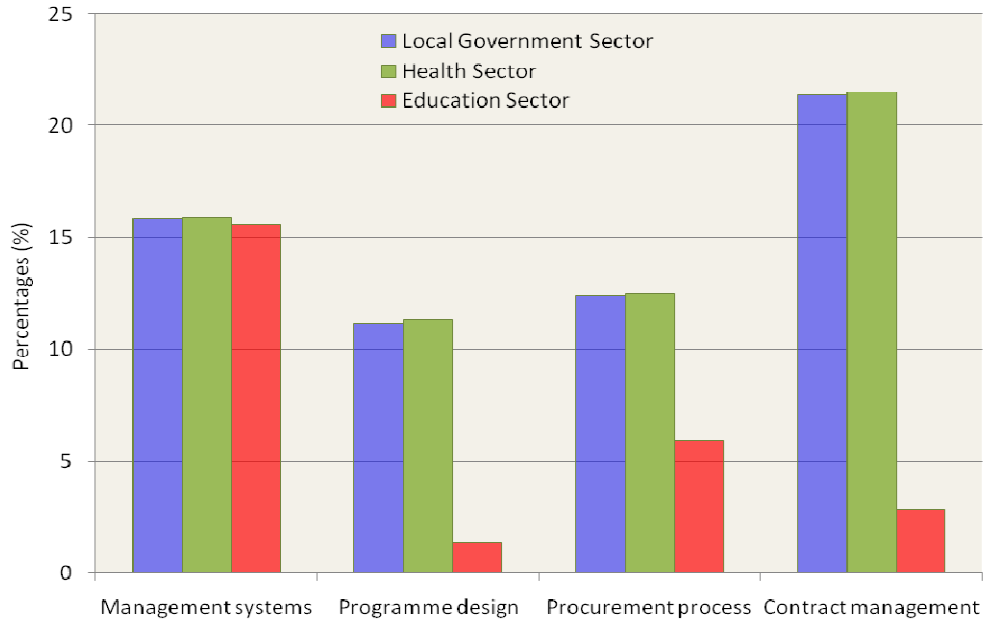

Figure 1*: Compliance level of the three sectors (Ashanti Region)*

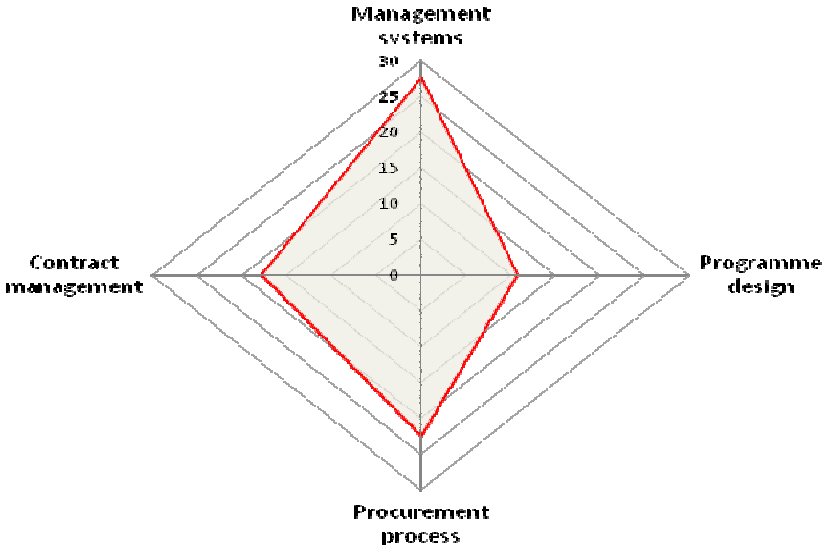

Figure 2: *Compliance levels under the Four Main Compliance Areas (Ashanti Region)*

Overall Compliance Level

The local government sector had a comparatively higher compliance figures as compared to the other sectors. The personnel at the Metropolitan, Municipal, and District Assemblies (MMDAs) are well familiar with contract management as most of the government construction projects are executed through the local government. Some supply contracts such as supply of school tables and chairs are also executed through the district assemblies. Contracts involving construction of hospital buildings are occasionally executed through the MMDAs.

Overall Compliance Level

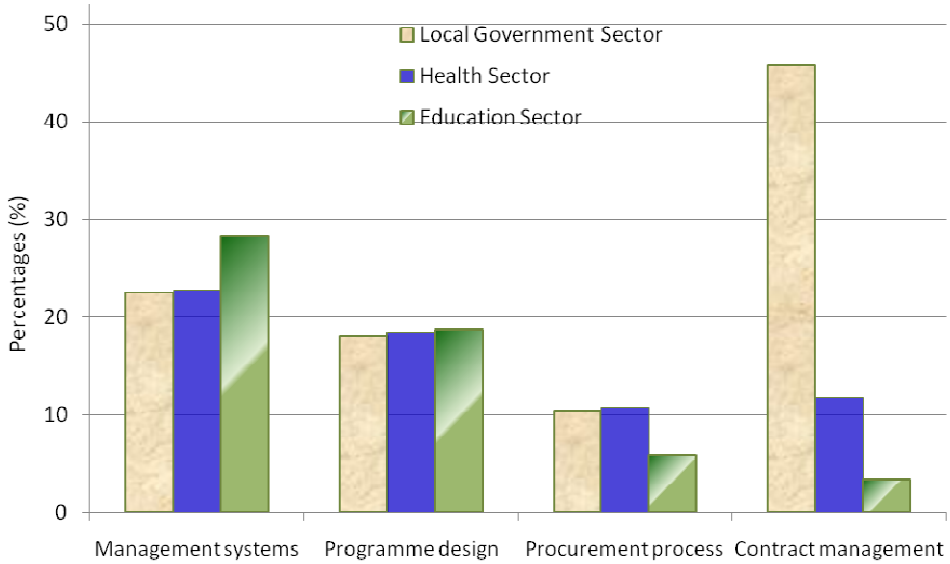

Figure 3: *Compliance level of the three sectors (Brong Ahafo Region)*

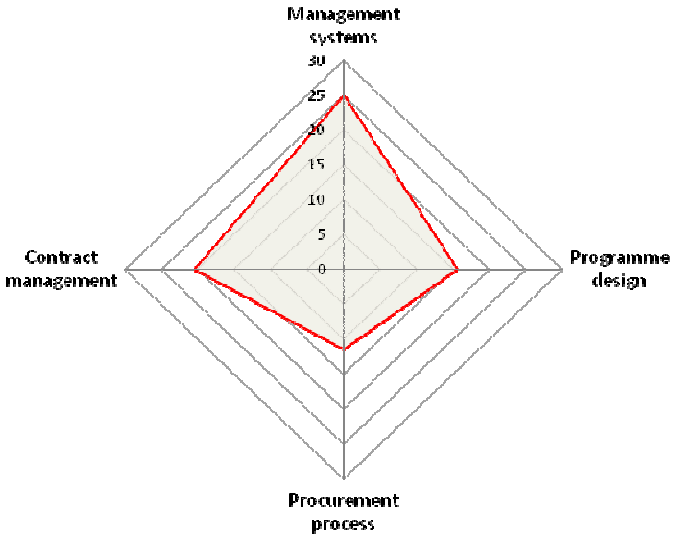

Figure 4: *Compliance levels under the Four Main Compliance Areas (Brong Ahafo Region)*

Moreover, it was found out that most of the staff members under the local government sector had the opportunity of participating in the first organized procurement training by the PPA. Hence, most of the procurement staff members are more familiar with contract management procedures resulting in better compliance level. This notwithstanding, the compliance level for this sector is found to be below average.

The health sector complied relatively better than the education sector (see figs.1 and 3). This is due to the fact that, most of the procurement undertaken by the schools (mostly second cycle and few tertiary institutions) dealt with the supply of low value procurement (perishables like tomatoes, okro, etc). In most cases personnel available were not procurement-proficient. This was evident where heads and their accountants and matrons double as procurement officers one time or the other. The procurement staff in most of the second cycle institutions complained of difficulty in following required procurement processes when dealing with such kind of procurements. This is evident by the compliance levels of 5.83% and 5.91% obtained by the education sectors in the Ashanti and Brong Ahafo regions respectively. Suggestions about developing peculiar procurement guidelines for the second cycle institutions came up in most cases.

Generally, the compliance levels of the entities under the area of procurement information and communication were on the lower side as overall percentages obtained fell at 10.28% and 15.22% for the Ashanti and Brong Ahafo regions respectively. This is probably due to the absence of access to Internet facilities in most of the district capitals. Also the authors identified that due to the absence of regular procurement training for staff of most of the procurement entities, there was lack of know-how with regards to the use of the Internet to post plans, retrieval of procurement information and other standard documents from the Internet and even the use of internal notice boards to disseminate procurement information.

Figures 2 and 4 indicate the overall compliance levels obtained by the entities with respect to the four main compliance areas. The average overall compliance level of entities in the Ashanti and Brong Ahafo regions were 19.58% & 17.80% respectively.

Under each of the four main compliance areas are key compliance indicators. Improving the management system in a public entity requires effective leadership i.e. putting in place training programs and seeking regular technical support from apex bodies. It was observed that there was lack of continuous staff capacity improvement in the procurement processes. For instance, it was found out that most of the staff in charge of procurement were not procurement proficient and have little or no knowledge of the existence of standard tender documents to be used for a given procurement as required by the Procurement Law.

Compliance with the public procurement Act, is anchored on how entities are able to conform with the outlined processes in the Act. There is a general outcry about the delays in the award of contract due to lengthy procurement processes. It is observed that, most entities are unable to award contracts on time due to inadequate planning of the procurement processes. World Bank, (2002) intimated that "misapplication of the procurement procedures and delays is as a result of uneducated procurement staff.

Generally, low compliance with some of the processes including notifying successful bidder, publicizing contract awards, notifying unsuccessful bidders, using internal notice boards to display procurement information and the use of standard tender documents is attributed to inadequate capacity of procurement personnel. In March 2005, The Paris Declaration on Aid Effectiveness highlighted the need to develop the procurement capacity of developing nations (OECD, 2005). Training of procurement managers in public entities should be on top of the agenda in the bid to ensure compliance with the law.

Contract management recorded a very low compliance level. It was observed that most entities take contract management for granted and thus are not enthusiastic at the contract management stage as compared to the award stage. There is a complete lack of information on ongoing contracts. Reports expected from procurement managers like project implementation and supervision reports, project monitoring reports, delivery reports, keeping of records of items disposed of and the use of appropriate stock control record system were generally not adequate in most of the institutions surveyed.

CONCLUSIONS

Based on the four main compliance areas adopted in this paper, the overall compliance levels in the Ashanti and Brong Ahafo Regions lie at 19.58% and 17.8% respectively. The study confirms the low level of compliance as indicated in earlier reports by the World Bank and the Public Procurement Authority. This paper affirms these findings and concludes that there is generally low compliance with the Public Procurement Act 663. The Local government sector however had higher compliance level compared to the other sectors. The Education sector has relatively low compliance level which is attributed to the kind of supplies this sector deals with. It was discovered that the sector deals with perishables and also lack storage facilities to encourage bulk purchase, hence the poor compliance level. The paper argues that the generally poor compliance with the law is due to lack of procurement proficient personnel to man public procurement, lack of resources to purchase in bulk, lack of understanding of the law, lack of Internet facilities to facilitate accessing of information from PPA and also to post adverts and procurement plans.

It is recommended that specific procurement guidelines tailored to suit the nature of procurement commonly carried out in the second cycle institutions should be developed to enable smooth compliance, frequent assessment of all entities, engaging of procurement professionals by all entities and encouraging entities to organize in-house procurement training to specifically address their peculiar needs.

The study confirms that the Public Procurement Act 2003 (Act 663) is observed to proffer solutions but not without challenges. It pencils out weaknesses and threats of the various sectors. In the pursuit to improve compliance with the Act the study recommends that public entities have to recruit procurement personnel and organize intensive and regular procurement training for the personnel handling public procurement especially in the area of procurement processes.

The paper has implications for policy makers in an attempt to strategize to improve the overall compliance level with the public procurement law. Complete conformance to the recommendations of this paper would guarantee maximum adherence to the law, enhance efficiency in Public Procurement, increase public confidence in the procurement process, the protection of public resources and grant equal opportunity for all. Though, the paper admits that its findings cannot be generalized due to the limited nature of the sample size, it also believes that the recommendations can be benchmarked to improve on the compliance level in the nation as a whole.

Abstract
In most literature integrated contracting and procurement is assumed to result in more innovative solutions as a result of the intended process integration. This paper explores Design Build Finance Maintain Operate (DBFMO) cases in the Netherlands on resulting innovations focusing on maintenance and energy-use. It is assumed that in DBFMO contracts innovations on these aspects are of direct benefit for the contractor and thus the most easy to detect.
Two DBFMO office projects were compared with five traditionally build office projects. Applied research methods are explorative interviews with clients and contractors about DBFMO-contracting, case-studies focusing on maintenance costs and energy-use calculations and expert interviews with contracting parties.
Within the DBFMO cases four design choices can be considered to be innovations on maintenance and energy use. Out of the expert interviews it has been identified that four design choices of the two DBFMO cases are new solutions directly related to the way the projects were procured. The innovations detected in the case studies can be considered as the successful transfer of knowledge between departments of one contractor that would have worked independently in case of a traditional procured project.

Keywords: DBFMO, PFI, PPP, innovation, maintenance, energy-use, performance specifications

INTRODUCTION

Bundling design, construction, maintenance and operations (DBFMO) is strongly advocated by the Dutch government to improve the performance of the construction industry. The overarching term for this construction organization is Public Private Partnership (PPP) or Private Finance Initiative (PFI).
In the discussion on the benefits of these projects, the private financing is often seen as a

condition to execute the projects with assumed large advantages for public clients. Besides this several other benefits are often assumed, with regard to these project types as listed by Blayse and Manley (2004), Akintoye et al.(2005) and Leiringer (2006): lower project cost (Haynes and Roden, 1999), shorter construction time (Tiffin and Hall, 1998), competitive advantage (Lemos et al., 2003), higher overall quality of the end product (Regeringskansliet, 2000) and benefits accruing from letting the private sector be innovative in its solutions (Construction Industry Council, 1998).

Conditions for better DBFMO project outcomes

In the PPP literature some arguments are presented for the supposed conditions to achieve innovations within DBFMO projects compared to traditional projects. The first one is the integration of activities and therefore a more collaborative environment. Secondly, the demand of the client is described in performance specifications (output specifications). The third argument is the possibility of optimizing through long life cycle commitments. The last argument is about the risk transfer from public to private parties. These issues will be further discussed, because they appear not to be as obvious as they might look at first sight.

The first argument is about the collaborative environment. One provider (mostly a contractor) is responsible for the delivery of several activities over a relatively long period (20-30 years). Therefore a common view is that this could lead to better collaborative working between the different disciplines involved. In practice a special unit (special purpose vehicle) is established which is concerned with the bidding. This special unit will not execute the work themselves, but is subcontracted to other departments within or outside the providers company, like construction and maintenance. Leiringer et. al. (2009) present a case study of a large construction firm that works with PPP projects. The case study clearly illustrates how managers responsible for service operations struggle in having any real impact on key design and construction decisions. Even within PPP projects there might be struggles between the construction department and the departments responsible for operations like maintenance and facilities management. The different activities are often subcontracted separately by the special purpose vehicle, resulting fragmented interests and non-collaborative working as in traditional projects.

The most common way to formulate the accommodation demand within PPP projects is by performance specifications. Whereas the traditional approach focuses on detailed description of the building, the performance approach only focuses on performances in relation to a certain use. A provider can therefore choose solutions that are able to deliver the performance in the most efficient way (e.g. Sexton and Barrett, 2005). In a publication of the Dutch Regieraad Bouw (2005) it is claimed that formulating the demand in performance specifications is an important stimulant for letting a provider be innovative in choosing a solution. However, Leiringer (2006) suggests that due to the performance approach a provider will likely choose a solution that fits best to the existing knowledge and available techniques within their organization instead of choosing new or unique innovative solutions.

The third argument is about the possibility to optimize on life cycle costs due to longer commitments. In case of DBFMO projects multiple activities of the construction process are outsourced for a longer period to one contractual partner, namely the special purpose vehicle and the demand is formulated in performance specifications. The focus within DBFMO projects is more on the use in form of accommodation services and less on the physical building as a product delivered at a certain moment in time. Due to the longer obligations it can be suggested that a DBFMO provider focuses more on life-cycle costing by optimizing

initial investments and operational costs. Leiringer et. al (2009) claim in their case study that there is little contact between the maintenance and construction department and therefore the possibility to influence the design is minimal: “Such decisions remain dominated by an institutionalized mindset that prioritizes traditional cost cutting over any consideration of through-life operational value”.

The last argument is about the risk transfer from the public side to private parties. This can be beneficial to a public client because the chances for budget overruns are smaller (HM_treasury, 1999). Whether a larger risk transfer to private parties will lead to innovative solutions is questionable (Leiringer, 2006). Especially the development and application of innovative solutions entails additional risk, therefore the doubt in the previous mentioned reasoning seems logical.

It might be concluded that there are different opinions and types of reasoning whether or not a DBFMO provider will be innovative in its solutions to deliver the accommodation services asked for.

This study is focused on finding empirical evidence for innovations on maintenance and energy-use in DBFMO office projects in comparison with traditional office projects. The main research question is: Can innovations be detected in case a DBFMO construction organization is applied instead of a traditional construction organisation? Two DBFMO cases in the Netherlands are explored on resulting innovations focusing on maintenance costs and energy-use. It is assumed that in DBFMO contracts innovations on these aspects are of direct benefit for the contractor and thus the most easy to detect.

THEORETICAL FRAMEWORK

First the context of DBFMO projects is discussed. The second part explains how innovations on maintenance and energy-use can be defined and how they can be measured. In the last part the conceptual model used within this research is described.

DFBMO context

When a DBFMO construction organization is applied, the client is demanding an accommodation service instead of a building delivered as a product at a certain moment in time. Within a predetermined performance specification a client buys, usable space or functionality for a certain period. This is in sharp contrast with the traditional construction organization where an amount of square meter floor area is bought as a building. A provider of a DBFMO project delivers the accommodation services through a model consisting of process parts and physical parts. The process parts consist of different activities that have to be performed during the contract period like designing, building, maintaining and operating the physical parts.

Based on decomposition models for design decision making, as described by for instance Prins (1992) and Leupen (2005), in the theoretical framework a building is decomposed in physical parts in terms of single components, component compositions) and ensembles. Components and their aggregations must have meaning in terms of usage, construction and/or their life-cycle, and as such are meaningful for design decisions as well as maintenance and operations.

The influence that can be exercised on the initial investment and operational costs is the highest in the design phase. According to Kohnstamm and Regterschot (1996) the influence in design phase is 30% for the investments costs and 65% for the operational costs. However these figures that often can be found in the literature do not make clear in which proportions the different costs per activity (design, build, operations) are represented. Evans et al. (1998) give the ratio 1:5:200, where 1 represents the cost for construction, 5 the costs for maintenance and building operations and 200 the business operating costs. However this ratio seems to be highly questionable, because no data can be found in the original study on which the numbers are based (Hughes et al., 2004). One generic ratio seems also debatable because every structure or building is (relative) unique. A building as a whole is unique due to a one-off composition of spaces, materials and products. At a lower level e.g. building materials or construction methods a building often is relatively less unique. E.g. a floor finishing will not differ that much between buildings.
The process parts were not investigated within this research, because it is not clear how the process parts influence exactly the design decisions and whether they stimulate innovations. So it is assumed that all the supposed advantages of the integrated process parts have to work out on the physical parts of the structure (components, component compositions and ensembles).

Innovation on maintenance and energy-use
The term innovation is in many ways ambiguous and its wide applications has led to many definitions depending on how innovation as a phenomenon gets meaning in a variety of contexts. Definitions can be found in for instance Rogers and Schoemaker (1971), Slaughter (1998), Kleinknecht (2000), Aa and Elfring (2002) and, Garcia and Calantone (2002). Most of the definitions found contain uniqueness of new developed inventions in terms of products, markets, systems and technology combinations. In case of determining project based innovations on DBFMO construction projects these definitions aren't applicable and can't be made operational.

In order to get a better understanding of innovations from a maintenance and energy-use point of view, explorative interviews were held with staff members of a large construction firm, an architect's firm and a client who were involved in DBFMO projects. In total 11 people were asked the following questions: (1) How to define innovation on maintenance and energy-use within a context of DBFMO projects? And (2) how to detect and to measure innovations on maintenance and energy-use in case of DBFMO projects? Ten respondents stated on the first question that innovations are mostly seen as the application of life-cycle costing. The application of products and solutions that in a traditional setting are considered to be too expensive, can be seen as innovative. The majority of the interviewees answered on the second question that innovations can be detected in the design process in terms of low life-cycle cost solutions and on the physical parts of the structure due to the uniqueness of product choices and materials.
Based on the outcomes of the explorative initial study innovation on maintenance and energy-use is defined as: A better performance compared to similar traditional build projects on maintenance and energy-use by developing and applying new and improved products and solutions on the physical parts components, component compositions and/or ensemble level, which are integrated into a structure and delivering accommodation services at an agreed level for a predetermined period.
Innovation according to this definition is not a goal on itself, but has to contribute value to the accommodation services. Innovation is measured via the so-called object method. This means that innovations themselves are investigated and not the company that creates the

innovations (Archibugi and Sirilli, 2001). The possible innovations are classified into project bounded and project unbounded innovations, due to the 'relative' unique nature of structures and buildings.

Conceptual model

As argued before it might be assumed that by both the integration of the process activities design, build, maintain and operate as well a the open solutions space by specifying the demand in performances, a provider of DBFMO constructions can offer accommodation services in a more efficient way especially in terms of life-cycle optimizations. If the structure is performing better on maintenance and energy-use by developing and applying new and improved products and solutions on the physical parts in comparison to traditional projects, it is an innovation within the context of this research. This has been visualized in a conceptual model, as depicted in Figure 1.

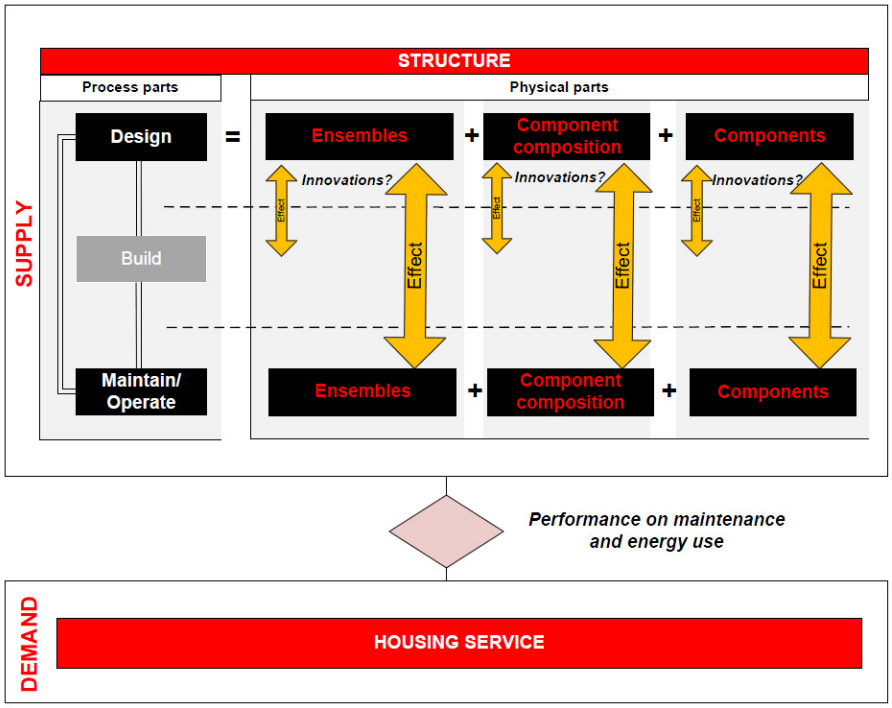

Figure 1: *Conceptual model*

RESEARCH METHODOLOGY

The research is focused on finding empirical evidence for the assumption that DBFMO projects stimulate innovations within maintenance and energy-use on the physical parts of a structure. A qualitative case study method was adopted as part of an engagement with a construction company, which has executed a large number of PPP projects in the Netherlands. This company is a leading PPP contractor at the Dutch market and has provided the data that was needed to conduct this research. The case study research consists of two components. First the 'better performance' on maintenance and energy-use had to be

determined. Second the solutions were assessed in order to determine if the better performing solutions could be classified as innovations according to the applied definition.

Case studies

In this research two DBFMO projects from a large contractor in the Netherlands are investigated. These two cases are compared with the traditional projects by means of long-term maintenance plans and expected energy consumption in order to identify possible innovations. The traditional projects were selected based on criteria for their properties in terms of comparability. Data of the traditional projects was received from maintenance consulting firms and facility management organizations. In Table 1 the different characteristics of the cases and projects studied as well as the methods used for data retrieval are shown.

Maintenance costs data-analysis

In order to determine a –potential- better performance on maintenance long-term maintenance plans of two DBFMO projects were compared with long-term maintenance plans of traditional projects.

Comparing buildings on maintenance costs is difficult due to the unique nature of buildings as a whole. “Every building is affected by its location, height, composition, energy consumption and a plethora of other differentiation points – all of which make each building unique” (Hughes et al., 2004). When a building is decomposed to smaller parts e.g. elements, the uniqueness is more relative. Maintenance costs are generally found in practice, related to a classification in elements. The maintenance costs were not re-classified and aggregated to components, component compositions and ensembles. Besides practical reasons for not doing this, it was not a necessity because the cost analysis is used to get an idea where possible innovations on components or their aggregations could be found. Also according to the applied definition it might be assumed that components and their aggregations are project specific and cannot easily be compared.

According to Daly et al. (2003) a number of factors have a strong influence on the maintenance costs. To compare different buildings on maintenance costs the following factors are identified, see Table 2 and Table 3. These factors wee used, given the characteristics of the two DBFMO cases, for the selection of traditional build projects getting comparative data and to correct the data by differences in building characteristics.

Project size	> 10.000 m2
Floors	Indicative
Quality maintenance	Quality (Conditieniveau) equal to or higher than the traditional projects

Table 2: *Factors that must be equal*

Gross floor area	Cost and consumption is expressed per m2 GFA
Price level	Corrections using the BDB index
Consideration period	Equeal consideration period
Operating time	Corrections if possible

Table 3: *Factors that must be corrected*

A long-term maintenance plan is in essence an activity planning where dissimilar sequences of costs are modelled for a certain period. In the different maintenance plans different types of maintenance are identified. In the analysis the following types of technical maintenance are taken into account: preventive maintenance, corrective maintenance and replacements. In order to compare different sequences of costs the net present value was calculated, due to the time value of money. Besides the net present value the nominal value was calculated. The nominal value does not take time influences and price increases into account. The net present value method seems suitable because identical project lives are taken into account in the comparison. The maintenance costs are shown per element in €/m2 gross floor area (GFA).

Within structural maintenance the elements floor finishing and ceiling finishing are good comparable because they are almost equal to the gross floor area of a building. Elements like façade finishing and roof finishing can result into disturbing outcomes due to different shape factors. An example of the disturbing effect of shape differences in buildings on the maintenance cost for roof finishing is shown in Table 4. When the maintenance costs are calculated per m2 GFA, building one seems to be the most cost efficient. When the costs are calculated per roof surface the costs are equal, due to different building typologies. Building one is a high rise typology and building two can be seen as low rise typology.
For the building services the following elements seem to be comparable: heat generation, cold generation, ventilation and lighting.

Influence shape factors	**Building 1**	**Building 2**
GFA	50.000	12.000
Roof surface	1.000	2.400
Maintenance cost roof per year	€ 6.500	€ 15.600
Maintenance costs per m2 GFA	**€ 0,13**	**€ 1,30**
Maintenance costs per m2 roof	**€ 6,50**	**€ 6,50**

Table 4: *Influence of shape factors on maintenance cost per m2/GFA*

Energy-use analysis

The energy consumption of a building is also related to a number of factors, which are mostly unique per building. In the research the energy performance is expressed in consumption per Mega Joules instead of costs. Energy costs are affected by the oil price which can give a disturbing effect in a comparison. According to a publication of SenterNovem (2007) the

following factors can be distinguished that influence the energy consumptions in buildings: function, project size, year of construction and the operating time. With regard to energy consumption the use of gas and electricity were taken into account and are diverted into the unit Mega Joules (MJ) per year per m2 gross floor area.

Innovations?

Indications from the previous analysis of a better performance by lower maintenance costs of elements or lower energy use were discussed by means of expert interviews. The interviews (seven in total) have been held with staff who where involved in the design phase of the DBFMO cases. Per better performing element on maintenance costs or a better performance on energy consumption the interviewees have been asked the following questions: (1) Is the motivation for the application direct or indirect?; in other words is the design solution focused on reducing maintenance costs and/or energy-use, or is it a secondary advantage? (2) Can the applied solution be seen as innovative as defined in this research? (3) Is the solution project bounded or project unbounded? This framework of analysis has been visualized in Figure 2.

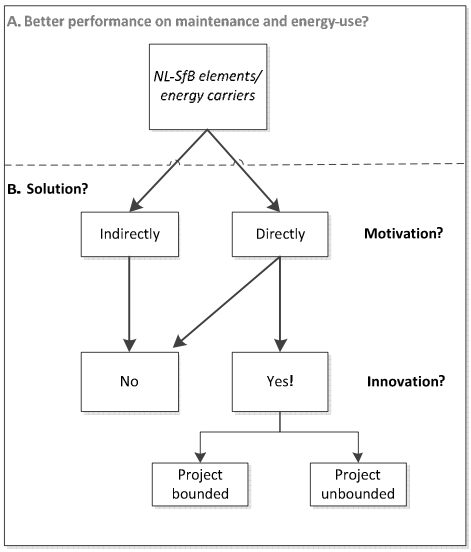

Figure 2: *Analysis framework for the expert interviews*

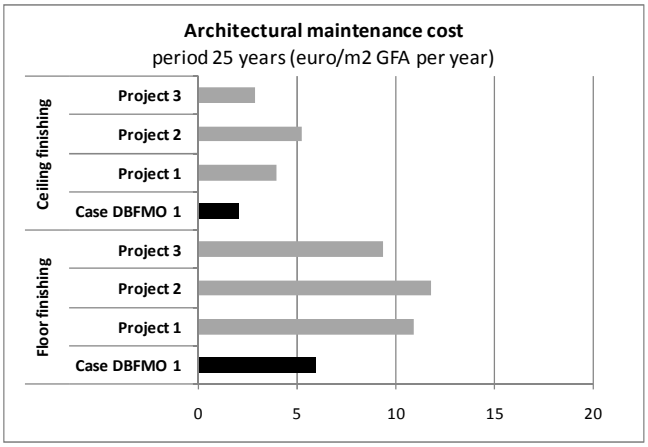
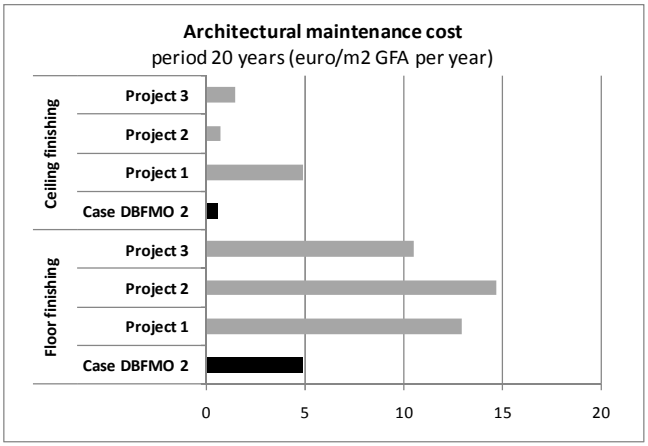


5. FINDINGS



The findings are presented by type of analysis: maintenance costs, energy-use and expert interview, and by case.

Maintenance costs performance

For case one only the structural (architectural) maintenance costs could be analysed because the cost data for the building services maintenance was not available. The values shown in Figure 3 are nominal values because the net present values showed a similar trend as the nominal values. The absolute values as shown in the graphs are fictitious, the relative differences are real.

The graphs show significant lower cost levels for the DBFMO cases.

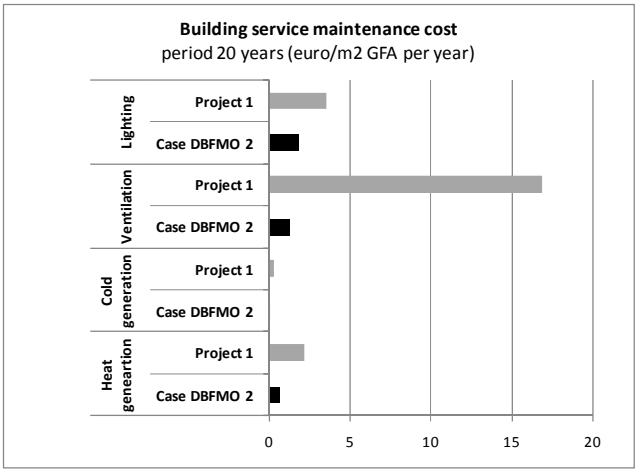


Figure 3: *Maintenance costs performance of the case studies*

Energy-use analysis

It was not possible to compare the energy consumption at element level because the data was only available per energy carrier (gas and electricity).

Figure 4 shows that the DBFMO cases are performing better than the traditional cases even without corrections for longer opening hours for the DBFMO cases.

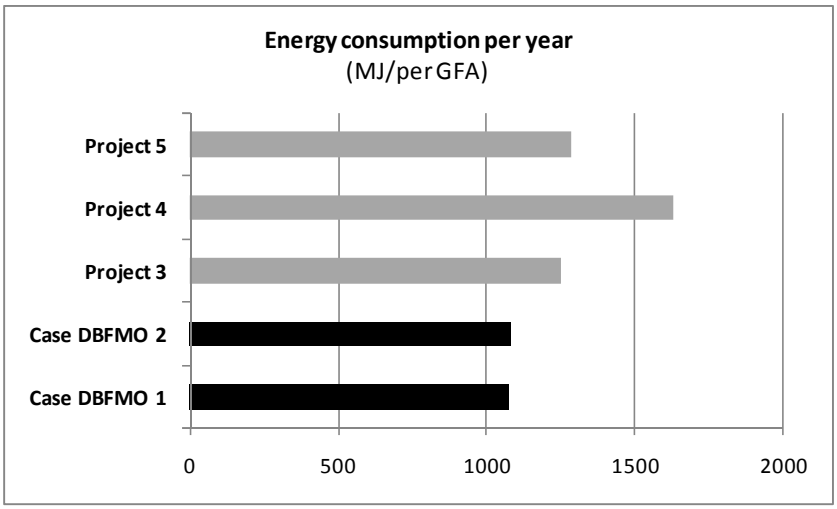

Figure 4: *Energy-use as analysed within the cases*

Expert interviews

In the interviews with experts the results of the data analysis were discussed, including the researchers ideas on innovations found within the cases according to the constituted definition within this research. The analyses of these interviews have resulted in the following findings.

Innovation on maintenance

Floor finishing: Carpet is the dominant floor finishing in the two DBFMO cases. In case one a carpet tile is applied. During the design phase a specific carpet tile was developed by the architect, contractor and supplier, resulting in seven different tiles differing in colour, weaving and pattern. The tiles are randomly produced, packed and mounted in the structure. Because of these special developed carpet tiles it is less visible when a single tile has to be replaced. The new tile does not stand out as a new tile in a 'carpet' with the old tiles. Therefore fewer replacements are expected to take place during the operational phase. This solution can be seen as an innovation on the ensemble because this solution has been developed and improved the use of a carpet tile. The carpet tile itself is not an innovation; the pattern that is developed that only works when seven or more tiles are placed together, can be seen as an innovation.

Ceiling finishing: The solution for the ceiling as applied in the DBFMO cases have an indirect link with maintenance. The choice for a climate sealing in case DBFMO 1 is based on energetic considerations. The advantage for the maintenance can be considered as indirect. The ceiling finishing for case DBFMO 2 is also based on energetic considerations and therefore it is not an innovation on maintenance.

Heat generation/cold generation: In case DBFMO 2 a heat pump is applied to warm and cool the structure. Out of the analysis a better performance can be discerned. However the interviewees refute this outcome. The heat pump is according to a number of interviewees more expensive on maintenance than a traditional heat system but has energetic advantages. In contrast with the data analysis the interviewees cannot see any advantages with regard to maintenance. Therefore the heat pump cannot be seen as an innovation on maintenance.

Ventilation: The choice for the ventilation concept of case DBFMO 2 is driven by a maintenance point of view. The fresh air is blown in the room via a raised floor and the exhaust air is collected in the room and exhausted via a central duct. This solution entails no ventilation ducts within the office spaces. Less ventilation ducts means less maintenance. The contractor and advisors developed this design solution in the design phase. Therefore this solution can be seen as an innovation on maintenance.

Lighting: Due to lower lighting level demand less lighting elements are installed, which are compensated with individual desk lights. Interviewees could not explain the better performance that came out of the maintenance costs analysis. It can be argued that less base lighting result in less maintenance. However interviewees argue that this is compensated by the extra individual desk lightning. So this aspect can't be seen as an innovation on maintenance.

Innovation on energy-use
Façade concept: The façade concepts of both DBFMO cases are not commonly applied solutions. First the façade concept of case DBFMO 1 will be explained. This case is in essence a renovation project. The existing structure was posing a problem for the transportation of exhaust air within the building and large thermal bridges were present. In order to overcome these two design issues, a double skin façade is applied to reduce the thermal bridges and to transport fresh and exhaust air in the façade. The individual elements cannot be seen as innovations. However, the solution as a whole is an innovation on ensemble level, which enables a reduction in energy consumption. The façade concept of case DBFMO 2 is specially developed with regard to sun influences. The façade consists of a fin, which differs in length and height to optimize sun radiation and light entry in all seasons of the year. In this way a reduction of energy consumption is expected because less heating, cooling and lighting has to be applied. This second façade concept can also be seen as an innovation on ensemble level.

Heat/cold generation: In both DBFMO cases the heat and cold generation is produced by a heat pump. This system can generate more efficiently heat or cold in relation to traditional heating systems. Interviewees conclude that it is a fairly normal system within offices. Therefore this is not classified as an innovation within the context of this research.

CONCLUSION AND DISCUSSION

Within the DBFMO cases four design choices can be considered to be innovations on maintenance and energy-use (two per case). See Figure 5. The design choices perform better on maintenance costs or energy use than the traditional projects selected for comparison. The four design choices on the physical parts are applied new and improved products and solutions related to the way the project was procured (DBFMO) and how parties involved collaborated to provide qualitative solutions.

Figure 5: *Innovations on maintenance and energy-use (www.mvsa.nl (2011) and Strukton (2008))*

The conceptual model, where a classification of design choices is introduced in components, component compositions and ensembles proved to be useful to identify innovations. For example, the carpet tile floor finishing itself is not an innovation and is done for decades. However, using the conceptual model the use of carpet tiles could be analysed as an innovation on ensemble level.. The pattern of the tiles is developed in collaboration between architect, the tile supplier and the maintenance specialist. Together they found a concept of seven tiles, which visually worked satisfactory after random replacement of tiles. The floor finishing contributes to the overall architectural expression of the interior of the building, and is aiming to reduce maintenance costs substantially over time. The ventilation concept is an innovation on component composition level. In this solution less components are used, because the raised floor is used to transport fresh air. In this way less maintenance costs are expected due to less applied components that require maintenance. Both façade concepts of the cases are innovations on ensemble level aiming to minimize energy consumption, but also contributing significantly to the architectural expression of the exterior. A larger case environment is needed to strengthen the applicability of this method for identifying innovations on project level.

Considering the findings of the research the DBFMO construction organization has a positive influence on the development of innovations on maintenance and energy-use. A number of conditions are described in the introduction that could be of influence on an innovative environment of DBFMO projects: the collaborative environment, the use of performance specifications, optimising life-cycle costing and risk transfer between public and private partners. Which relations exist between the conditions and the innovations is not explicitly investigated in this research, although some explanations are found based on the expert

interviews held after the data analysis. The innovations found in the case studies can be considered as the successful transfer of knowledge between departments that would have worked independently in case of a traditional procured project. Besides innovations found on the physical parts, other small incremental innovations on service delivery by the DBFMO-contractor were mentioned in interviews, dealing with the conditions of life-cycle costing and performance specifications, e.g. monitoring the condition of building components in-situ.

In the research only two DBFMO cases were investigated due to limited number of DBFMO projects in the Netherlands, making the conclusions difficult to generalize for all DBFMO projects. In general the conditions of DBFMO projects shape an innovative environment.

The performance data of the DBFMO cases on maintenance costs and energy-use is based on expected results, as the delivery dates were too recent for reliable actual cost data. The data used are provided by the contractor, which has made the calculations of the maintenance costs and energy-use on the basis of the preliminary designs. In this research it has been assumed that this data should reflect the real costs rather accurately, because risk-averse parties like the contractor in case are liable for these expected costs over up to two decades. The maintenance data and expected energy-use performance is calculated based on confidential data sets, therefore the validity could not be determined.

Comparing buildings on costs in general is rather problematic due to their unique character. It was not possible to get identical projects with regard to the case characteristics. In terms of case selection often the researchers were faced with limited available data on life-cycle costs, long-term maintenance plans and energy consumption performance. Instead of comparing buildings as a whole it proved possible to compare a number of elements. The maintenance costs and energy consumption analysis was about detecting possible innovations and not to compare similar solutions on cost or energy consumption efficiency.. However, on their contribution to the total life-cycle cost performance conclusions cannot be drawn.

Further research should be conducted on three areas: (1) The contributing issues why exactly innovations are arising in this type of construction organization; (2) The study has to be repeated with more cases and should be based upon actual cost data and real energy performance data for better validity; (3) A new study could focus more on the life-cycle cost efficiency of whole projects related to innovations detected.

CHAIN COLLABORATION BETWEEN A HOUSING CORPORATION AND TWO GENERAL CONTRACTORS, THE FIRST STEPS

J.S.J. KOOLWIJK
Delft University of Technology, Faculty of Architecture
Julianalaan 134, 2628 BL Delft, The Netherlands
j.s.j.koolwijk@tudelft.nl

Abstract
Several housing corporations in the Netherlands have realized they cannot do it alone if they want to renovate their housing stock faster, cheaper and with a higher quality. More and more of these corporations are forming strategic alliances with contractors and other partners to reach these goals. They are applying principles of supply chain integration and lean on the total process of the building lifecycle, under the umbrella concept of Chain Collaboration (Ketensamenwerking in Dutch).
This article draws from active research executed on two projects which started in 2010 and are still under development. It focuses on the definition and design phase and describes the approach applied to implement the chosen strategies.

Keywords: supply chain integration, lean, strategic alliance, housing corporation

1. INTRODUCTION

Under pressure of the current credit crunch and a decreasing need for new homes the coming ten to fifteen years, housing corporations (HC's) in the Netherlands are facing a market where higher quality at a lower price is requested by home buyers and tenants (Wal van der, Arts & Beijer, 2009). The cost HC's make for the production and maintenance of their houses will have to decrease dramatically in order to keep houses affordable (De Wildt and Luijkx, 2011). Faced by these challenges the HC's are looking for ways to produce more value to the end user at a lower price level.

In order to produce more value at a lower price level, HC's are abandoning the traditional design-bid-build approach. HC's are exploring different strategies, most of them under the umbrella concept of Chain Collaboration (*Ketensamenwerking* in Dutch).

The HC subjected to research in this case is applying the following strategy:

- integrating supply chains, with main contractors, subcontractors and suppliers;
- forming strategic alliances and alliance culture;
- applying lean principles and tools in the definition, design and realization phases.

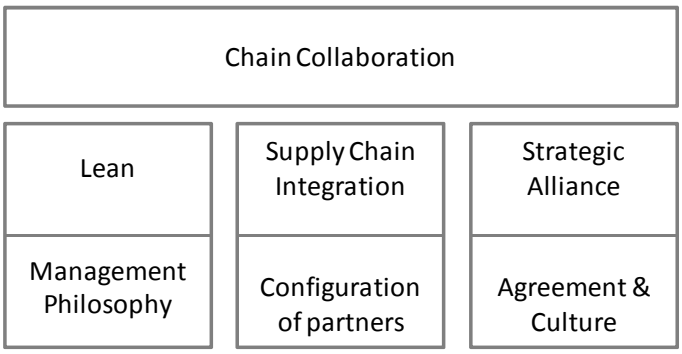

Figure 1: *Strategies part of Chain Collaboration*

In this article two cases of one Dutch HC are presented. The cases consist of two strategic alliances formed by one HC with two different general contractors. The general contractors also forms strategic alliances themselves with several subcontractors.

One alliance is formed for large maintenance projects of low rise houses. The other alliance is formed for the upgrading of apartments so they become more suitable for the elderly (55+). The research is done by action research and focuses primarily on the definition and design phase.

2. METHODOLOGY

This article draws from active research done during the formation of two strategic alliances between a HC, two main contractors and several subcontractors which started in 2010 and is still ongoing. The main goal of these alliances is, by the integration of the supply chains, to develop a faster and cheaper maintenance and upgrading process for existing houses.

This project consists out of two parts. The first part focuses on the definition and design phase. The second on the realization phase. This paper focuses primarily on the first part. Within this part, the traditional process is re-designed to converge to the main goal.

The development of each strategic alliance is managed by two change agents. One agent form the HC and one from the general contractor. Each of the two alliances has its own agents. The change agents work directly under the board of their company.
The change agents are guided by a team consisting out of two consultants and one researcher (the author). The development of the alliances is monitored for two hours a week during the guiding-sessions for a full year. A logbook of these sessions has been kept for ex-post research.

The researcher is actively involved in the process under study in order to identify, promote and evaluate problems and potential solutions. As stated by Fellows and Liu (2008) active research ‘is where the research actively and intentionally endeavors to effect a change in a system. Knowledge is used to effect the change which then creates new knowledge about the process of change and the consequences of change (as well as the change itself). In programmes of action research, the usual cycle of scientific research (problem definition – design – hypothesis – experiment – data collection –analysis – interpretation) is modified

slightly, by purpose of the action rather than by theoretical bases, to become 'research question – diagnosis – plan – intervention – evaluation', the 'regulative cycle'.

The main research question for this project is: How should the process of the definition and design phase be redesigned in order to (1) incorporate the know-how of the several alliance partners and (2) filter out the waste, in terms of lean, from the definition and design phase?
The method applied to diagnose the situation is value stream mapping (VSM) (Hines and Rich, 1997). At first the 'current state' of the (traditional) definition and design phase, together with the underlying process characteristics (lead time, process time,etc), was defined. This was done by the guiding team together with the change agents, the projectmanagers of the HC and general contractor, architects and other advisors. For both alliances a current state has been described.
Based on this value stream map possible interventions for filtering out waste and the integration of alliance-partner knowledge where identified. At the time of writing this article, the possible interventions where defined, but not fully developed.

In the follow up, which falls outside of the scope of this paper, the initiatives will be further developed in smaller teams and implemented into the process following a standard DMAIC-method (define, measure, analyse, improve, control). When an initiative is implemented, a new process map can be drawn up making the future state (or new current state). After this, new initiatives can be defined and developed, and the cycle starts again. The use of the VSM is further explained in chapter 4.

3. STRATEGY APPLIED BY THE HOUSING CORPORATION

This section will describe the three strategies used for the development and implementation of Chain Collaboration as presented in the first paragraph.

3.1 Supply chain management and relations

The supply chain has been defined as 'the network of organizations that are involved, through upstream and downstream linkages, in the different processes and activities that produce value in the form of products and services in the hands of the ultimate customer' (Christopher 1992). Instead of looking at just the next entity, the concept of Supply Chain Management (SCM) looks across the entire supply chain and aims to increase transparency and alignment of the supply chain's coordination and configuration, regardless of functional or corporate boundaries (Cooper and Ellram 1993). According to Koskela and Vrijhoef (1999) the actors in the supply chain are dependent on each other for implementing the supply chain methodology successfully.

Supply chain relations are often described in terms of the level of integration, interconnectedness, or interdependence among trading partners within the chain (Lockamy and Smith, 2000). The level of partnership is, for example, identified by Cooper et al. (1997) and Tyndall et al. (1998). They identified four levels of partnership.
At the lowest level, the trading partners rely on what Tyndal et al. (1998) calls open market negotiations characterized by arm's length transactional business practices. The competitive imperatives, not management initiatives, determine the nature of the relationship.
In the next level Tyndall et al. (1998) trading partners formalize their cooperation. They construct specialized transactional processes that better serve their needs. To secure the benefits, partners enter into long term agreements and they commit to sharing information

about the volume and timing of product and service. This to further reduce uncertainty in their relationship.
The third level of partnership aims to create relationships rich enough to support joint efforts to simplify supply chain operations. Coordinated efforts are deployed to, for example, reduce inventories or the amount of transaction.
The fourth level is where partners reach the collaboration stage. In this stage partners engage in joint efforts to develop and improve products and in joint efforts to enhance the value and satisfaction provided by customers. In this stage, management devotes considerable energy to building trusting supply chain relationships and to negotiating equitable arrangements for sharing the risks and rewards of supply chain improvements.

According to Handfield and Nichols (2002) integrating a supply chain, as in level 4, represents a major change in the way companies do business. In creating integrated supply chains, companies must rethink how they see their customers and suppliers. They must concentrate not just on their own profits, but also on how to maximize the success of all organizations in the supply chain. When the organizations involved focus on these goals, they may discover the need to re-design the entire structure of their supply chains.

3.2 Strategic alliance agreement

Arrangements that counteract adversarial relationships with each other are needed to enlarge the magnitude of Supply Chain Management (Koskela and Vrijhoef,1999). Similar conclusions can be drawn from Khalfan and McDermott (2006) which conducted multiple case studies on long term framework arrangements applied in construction.
In this case the partners are aiming for a level 3-4 of supply chain relation (see paragraph 3.1 for explanation) where a contractor and subcontractors become involved in the early design stages of a project. The strategic alliance agreement between the HC, general contractors and sub-contractors therefore forms the fundament for the collaboration effort.

There are many definitions of ‘partnering’ and ‘alliancing’ (Barlow et al., 1997). The strategic alliance subjected to research in this case is a long term contractual agreement between the client, general contractor and several strategic partners (suppliers and subcontractors). According to Doz and Hamel (1998) such an alliance would be called a non-equity alliance.
The features of this strategic alliance are that the collaborators work together on multiple (housing) projects, towards joint goals, sharing parts of the projects risks and profits. The joint goals in this case are to produce more value to the end user at lower cost and at a higher speed. The performance is measured through performance indicators. An aligned development process, unanimous decision making, open book accounting, a fair payment, and trust are the basis of the arrangement.

The compensation model the partners are developing for these alliances is target costing based on a cost-plus pricing system. There are several approaches possible. For further reading about these approaches, the author suggests to read Lockamy and Smith (2000). The Target Costing approach falls outside the scope of this paper.

3.3 Lean

Koskela (1992) states that the traditional way of managing is essentially based on a conversion view on production, whereas Supply Chain Managment is based on a flow view of production. The conversion view suggests that each stage of production is controlled independently whereas the flow view focuses on the control of the total flow of production (Koskela, 1992).
There is a large toolbox of methods available to analyze various issues in order to integrate and improve the performance of the supply chain (Vrijhoef and Koskela 1999). For this case the lean philosophy and tools where used for the redesign, control and improvement of the supply chain.

Lean manufacturing is a generic process management philosophy derived mostly from the Toyota Production System (TPS) and identified as "Lean" in the 1990s. The term was first coined by John Krafcik in a 1988 article, "Triumph of the Lean Production System," published in the Sloan Management Review (Holweg, 2007).

Lean stresses a supply chain perspective, seeing the internal production operations as a part of a value stream from the sub-suppliers to the end customer (e.g. Rother & Shook, 1998; Jones & Womack, 2002). This perspective fits the highly fragmented AEC industry (Arbulu & Tommelein, 2002).
Lean considers the expenditure of resources for any goal other than the creation of value for the end customer to be wasteful, and thus a target for elimination. Working from the perspective of the customer who consumes a product or service, "value" is defined as any action or process that a customer would be willing to pay for.

The first step in lean is to understand what value is. The second step is to understand what activities and resources are absolutely necessary to create that value. Once this is understood, everything else is waste. According to Monden (1993) waste can be categorized into:

- non-value adding
- necessary but non-value adding
- value adding

The original Toyota seven wastes are defined by Shingo in 1989 (see table 1 below).

The seven forms of waste	
Overproduction	Producing more than is needed or before it is needed
Motion	Any wasted motion to pick up parts, stack parts, wasted walking
Correction	Rework or Repair
Waiting	Any non-work time, waiting for tools, supplies, drawings, parts, etc.
Processing	Doing more work than is necessary
Inventory	Maintaining excess inventory
Conveyance	Wasted effort in transferring goods etc.

Table 1: *the seven forms of waste (Shingo, 1989)*

Many other wastes have been added since Shingo defined the first seven (Bicheno and Holweg, 2009).

For many, Lean is the set of "tools" that assist in the identification and steady elimination of waste. As waste is eliminated quality improves while production time and cost are reduced. Examples of such tools are Value Stream Mapping, Five S, Kanban (pull systems), and poka-yoke (error-proofing). In this case Value Stream Mapping has been used to diagnose the situation and to plan further action.

4. METHOD FOR DIAGNOSES: VALUE STREAM MAPPING

The method used in this case to assess and redesign the activities and resources, in order to create value is value stream mapping (VSM).

VSM was created by practitioners at Toyota to "make sustainable progress in the war against muda" ('muda' is the Japanese word for 'waste') (Rother and Shook 1998). VSM includes creating a map of the complete value adding (and nonvalue adding) process, from conception of requirement back through to raw material source and back again to the consumer's receipt of product. A current-state map of in-company value streams then serves as the basis for developing future-state maps that leave out wasted steps while pulling resources through the system and smoothing flow (Arbulu and Tommelein, 2002). In a CS-map all steps that are performed to complete the work as it is operating in todays environment as well as the issues and performance (metrics) of the process are mapped. The difference between the current state and potential future states provides a road map to start the implementation of performance improvements.

A value stream perspective should look across individual functions, activities, departments, and organizations, and focus on system efficiency rather than local efficiency within any one of these (Arbulu and Tommelein, 2002).

When setting up a VSM, a product family has to be defined and then map its current-state value stream before analyzing production data and metrics. A product family is a group of products or services that pass through similar process steps. In this case two product families of this HC where defined:

- large maintenance projects of low rise houses which where build in the 70's and 80's;
- (rather small) upgrading of existing apartments from the 70's and 80's so they become more suitable for seniors (55+).

Although every project in construction has its own dynamics and characteristics, the projects that are part of this 'product family' can be seen as comparable. The data is gathered through VSM-workshops with the change agents, the project managers of the HC and general contractors, architects and other advisors, all having experience with projects belonging to these product families. The data gathered therefore provide approximate durations instead of measured durations.

The scope of the VSM (current state) is restricted to the HC and it's first tier suppliers who are involved in the definition and design phase of a traditional project. This paper presents a current state maps of both projects and considerations for supply chain performance improvement (interventions).

5. CASE ANALYSIS

This section will describe the VSM's of two cases that have been produced through the VSM workshops.

5.1 Case 1: Large maintenance project of low rise houses

Using VSM the current state (CS) of the definition and design phase was drawn (see figure 2).

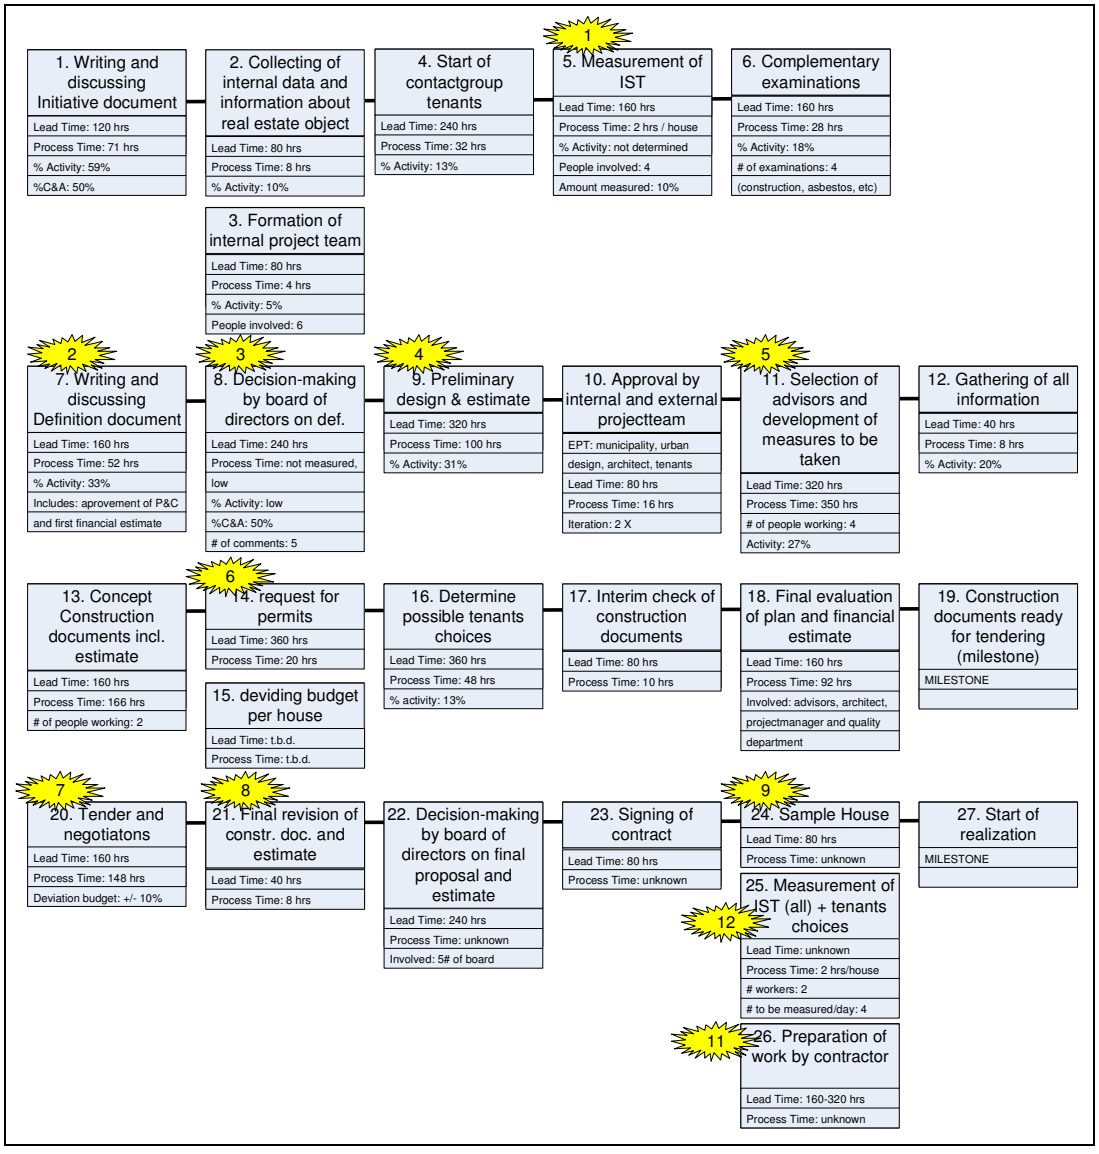

Figure 2: *Current state map of a large maintenance project*

The CS starts with the initiative document in which the projectmanager defines the global goals and targets of the project. With this document the projectmanager acquires a budget for the development of the design en research of the situation. From the initiative document the

global process steps are analysis (measurement IST, examinations), design development, permits, tender and negotiations to start of realization (see figure 2).

When looking at the CS waste becomes visible and possible initiatives (see figure 2, bursts) from the view of Chain Collaboration, can be defined:

- The percentage of activity in comparison to lead time on almost every steps is low. A lot of time in the overall process is going to waste as a result of waiting. Waiting for decisions, approval, meetings and documents. For every step further research should be done to minimize, at least, waiting time.
- The percentage complete and accurate (%C&A) for more than one step is 50%. This means one out of two of these steps have to be redone, resulting in extra waiting time and work. Further investigation what causes this low percentage of complete and accurate is needed.
- The decision-making by the board processes in general take a large amount of time (approx. 6 weeks per decision). One major cause for the delay is that project managers have to hand in their project plans 4-6 weeks before the board meeting. The responsibility for taking decisions could also be transferred to the head of the department when the project is still within scope and budget. This could lead to much faster decision-making process.
- The decision by the board, for most projects, are taken for one project at a time, while there are multiple ongoing projects which belong to the same product family. Combining projects can save time.
- There are steps that seem to be double. The measurement of the IST is done in step 6 and step 25. For a traditional design-bid-build project, this is understandable due to the split between design and realization, but within an alliance where client, designers and contractors work together it looks like one step to many.
- The tendering of the projects takes five weeks (step 21 and 22) when all goes well and the tender price is within budget. Step 22 represents a revision of the construction documents as a result of this tendering step. When working in an alliance, developing the design and estimates together, these steps should become obsolete. A process like Target Value Design (*The American Institute of Architects*, 2004), or another Target Costing mechanism, has to be implemented.

The initiatives are presented in the next figure (3, see next page), making a first idea for a future state map.

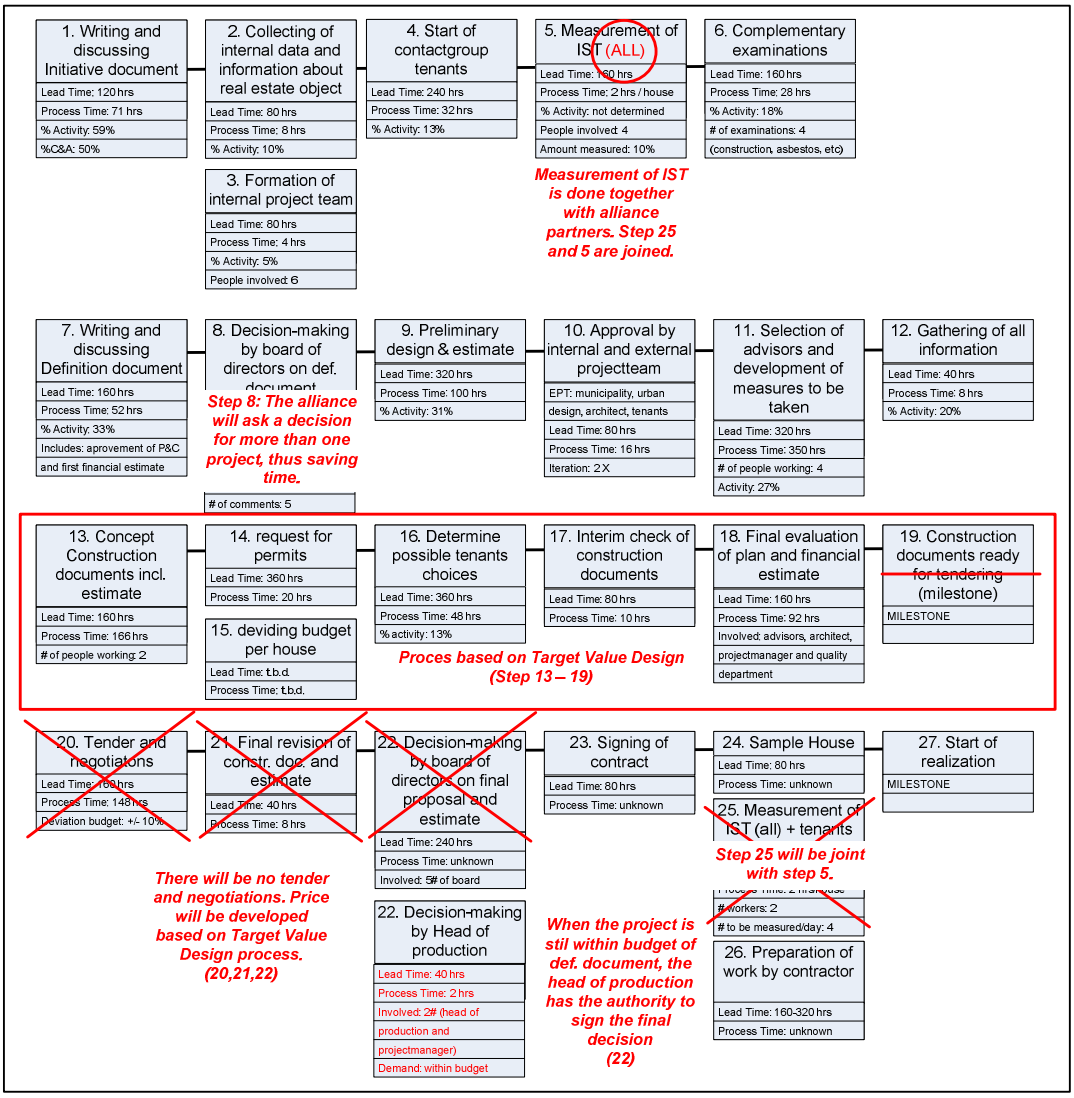

Figure 3: *First idea for the future state map of a large maintenance project*

5.2 Case 2: Upgrading of existing apartments

Using VSM the current state (CS) of the definition and design phase of the upgrading of existing apartments was drawn (see figure 4, next page). At the time of writing this article, the metrics for this project where not fully developed yet, therefore they are not presented.

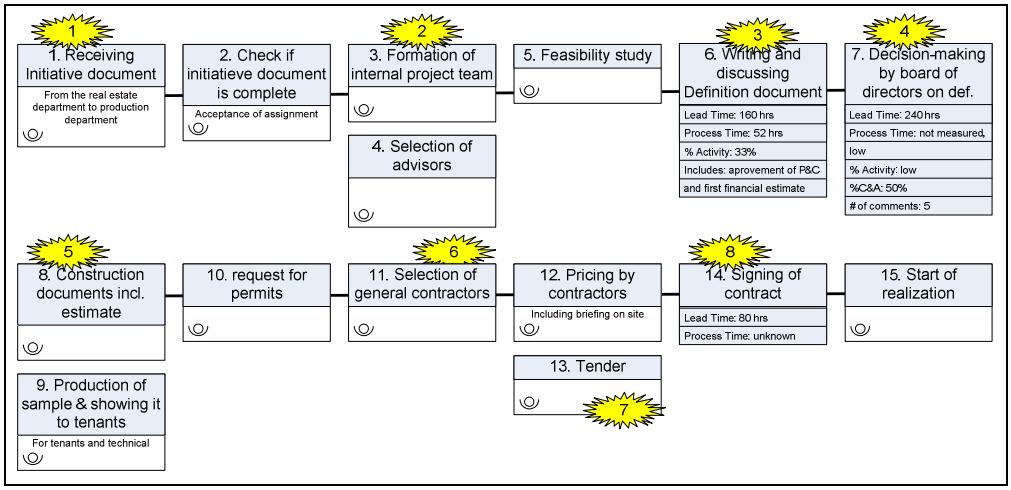

Figure 4: *Current state map of an upgrading of existing apartments project*

The CS map of the upgrading projects is shorter than the CS op a large maintenance project. This is due to the lower level of complexity of these projects.

The CS starts with the initiative document in which the projectmanager defines the global goals and targets of the project. The initiatieve document forms the assignment for the projectleader of the production department. This projectleader checks if the document is complete. When the project is accepted the projectleader sets up an internal team and selects advisors for a feasibility study. Based on the feasibility study the projectleader writes definition document on which the board decides. When the board approves the construction documents are produced and a sample is produced for testing. When the permits are requested, possible contractors are selected. These contractors can start pricing the project. After the tender one contractor is awarded the project and the project start.

When looking at the CS waste becomes visible and possible initiatives (see figure 4, bursts) from the view of Chain Collaboration, can be defined:

- Every projects starts with an initiative document (step 1). Part of this document is a program (an analysis of current situation and possible actions plus estimates). The program is drawn up for every single project. This initiative (burst 1) contains the development of a standard program document. Based on this program, all projects (25) can be analyzed and roughly estimated. This will be done by the advisors, general contractor and subcontractors which are part of the Chain Collaboration. By using this standardized program and the knowledge of the Chain Collaboration partners the speed and accuracy of the analysis will become much higher than current practice.
- The steps 3 and 4, formation of an internal project team and the selection of advisors (and possible contractors), will be eliminated due to Chain Collaboration.
- The writing of a definition document can be shortened using the standardized program (step 6).
- The decision-making by the board (step 7) can be shortened and multiple projects can be decided on instead of one which is current practice.
- The construction documents (step 8) can be simplified, only defining the information that is needed.

- Due to Chain Collaboration the general contractor is already selected. The selection step (11) can be deleted from the current map.
- There will be no tender (step 13).
- The signing of the contract will be replaced by a final check on the price and documents. The boards will sign a standard project agreement.

The initiatives are presented in the next figure (5), making a first idea for a future state map.

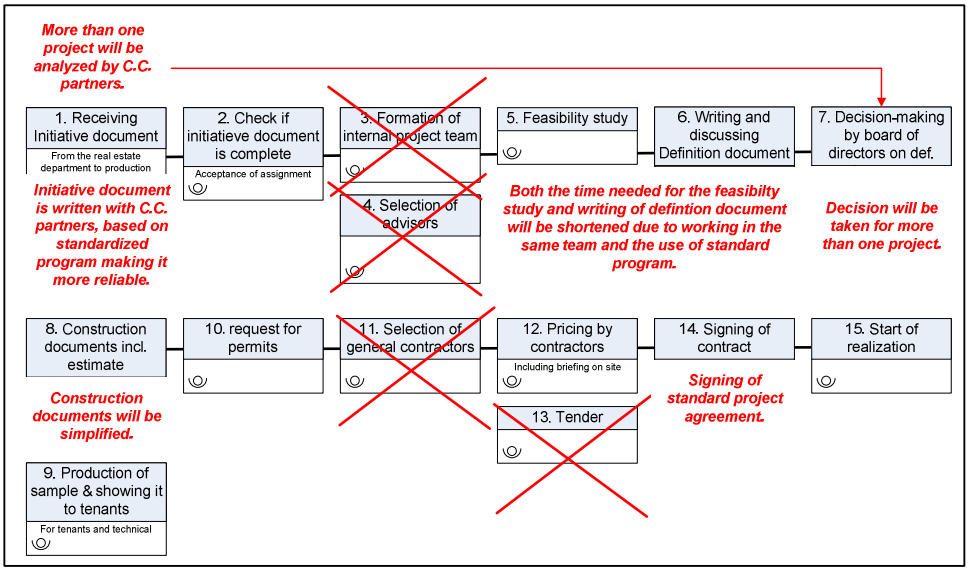

Figure 5: *First idea for the future state map of of an upgrading of existing apartments project*

6. CONCLUSIONS AND FINAL REMARKS

It seems that the combination of strategies, applied by the HC under the umbrella concept of Chain Collaboration, makes it possible not only to filter out waste from the traditional (design-bid-built) way of working by the use of lean principles, but also to alter the complete development and design phase. The reason for this is mainly the formation of a strategic alliance. The strategic alliance makes it possible to:

- research and develop (invest) a more efficient way of working;
- work as one integrated supply chain based on one joined process;
- utilize contractor's knowledge on design, construction and costs in the early stages of design, this making the whole process more predictable;
- filter out non-value adding steps (tender, negotiations, revisions of documents);
- join steps because the justification for two separate steps has disappeared;
- make steps simpler and less time consuming.

This first step in this Chain Collaboration effort looks very promising, but it's also clear that the future will tell us if the several initiatives can be implemented and what their effect will be. Only then can the actual performance be measured.

Parallel to this development are many other aspects that have to be tackled which have not been part of this paper. Personal issues, issues between team members, another way of working, mixing cultures, etc can all become bumps along the way. Next to this, the 'pattern

of payoff' and 'the shadow of the future' (Axelrod et al., 1985) will pay an important role in keeping the alliance working.

APPROACHES TOWARDS A SMART & SPEEDY IMPROVEMENT OF THE IN SERIES DEVELOPED POST WAR HOUSING STOCK

ANKE VAN HAL, LEONIE VAN DER STEEN & EEFJE VAN DER WERF
j.d.m.vanhal@tudelft.nl

Abstract
One third of the current housing stock in The Netherlands dates from the sixties and seventies and a large part of these dwellings are fairly similar (because they were built in series). There is a high need for smart and speedy renovation methods, to improve technical, energy and cost efficiency of renovation projects as well as to limit inconveniences to residents. A considerable number of professionals in the Netherlands currently are making a combined effort to improve these methods and their implementation, in an initiative called Smart & Speedy ('Slim & Snel' in Dutch). This article describes this initiative, some results till now and an inspiring already realized renovation project that illustrates the goal of the Smart & Speedy approach.

The large part of all Dutch houses is built after World War II. Almost a third between 1960 and 1980 (VROM,2009b). The calculated economical lifespan of dwellings in the Netherlands is fifty years. However, in practice houses stand much longer. Even before the economic crisis in the Netherlands only 0,25% of existing homes were replaced every year. Based on this information existing houses are expected to last six to eight times their economic life span (Van Hal, 2008).

In general, the quality of these houses is very low as a result of the shortage of both building materials and experienced constructors in the years of their construction (Andeweg 2009). Also, due to the increase of welfare of the population and many technical developments the use of dwellings and the wishes regarding living quality have changed a lot (Vreeze, 2001). Improving these houses in a smart and speedy way to make them more attractive for today's residents, has already been an issue high on the agenda of the government, housing associations and other parties of the supply chain, for a long period of time.

Figuur 1: Samenstelling woningvoorraad (Blijie, 2009)

Figure 1: *Compilation of the housing stock (Blijie, 2009).*

THE IMPORTANCE OF A FOCUS ON ENERGY EFFICIENCY

In the Netherlands one third of the CO_2 emissions, amounting to over 60 million tons per year, is related to energy usage in buildings. 53% of this emission is caused by the housing stock (Ecofys 2005). The energy efficiency of homes built before 1975 is lower than realized in housing stock built more recently. To a large extent this is due to the fact that legislation on energy efficiency was only implemented after 1975. Before there were no norms that prescribed insulation and the installation of high yield condensation boilers. Due to the fact that many homes were built in the period between 1945 and 1970, a large part of the total housing stock has a relatively low quality in terms of energy efficiency.

For a long period of time most energy reducing initiatives were focused on new housing. However, as a result of the crisis of 2008-2011 in the Dutch construction industry the focus changed from new housing toward the existing housing stock. In a short time energy efficiency in the existing housing stock became a big issue (Nieboer, Van Hal , Dulski, 2011). Due to the rise of the energy prices the living costs of residents increase as well. Figure 2 shows that the energy costs have been doubled since 2000.

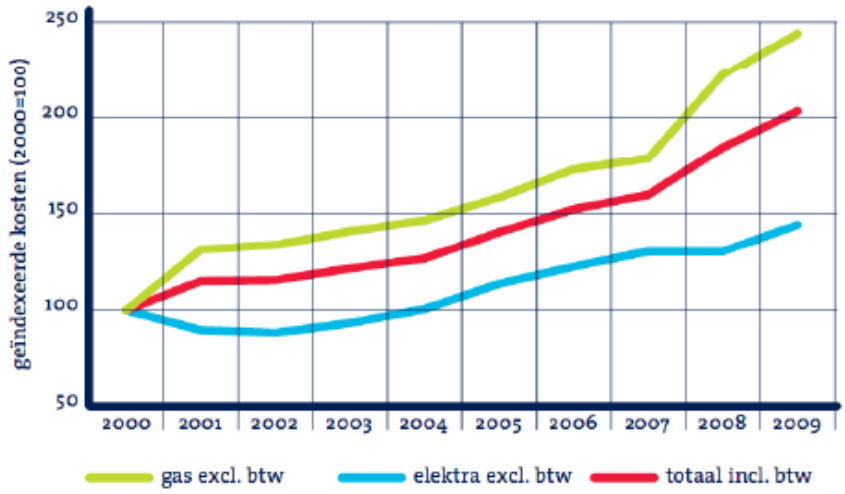

Figure 2: *Developments for energy costs of households since 2000 in the (Luijten, 2010).*

SOCIAL HOUSING

The Netherlands is unique because of the large percentage of social housing: 32 percent (between 2.2 and 2.3 million homes) of the total housing stock. With over 4.1 million homes the owner-occupied dwellings cover 55.9% of the total housing stock in the Netherlands (CBS, 2010). Over the past five years there has been a shift towards the owner-occupied market (CBS, 2010). Virtually all social housing (more than 99 percent) is procured and managed by social housing associations, which are private organizations operating under a range of public regulations that aim to ensure that a number of social tasks, such as housing lower-income households, are fulfilled. Large housing associations manage over 100,000 houses, whereas the majority of the housing associations manage less than 5,000, making the operational scope and influence of housing associations wide ranging. The remaining half percent of the social housing stock is owned by municipalities (Nieboer, Van Hal , Dulski, 2011).

Housing associations in the Netherlands are taking the energy challenge seriously. They signed an ambitious agreement with the government in which they promised to lower the energy use of their housing stock within a short period of time. The agreement was signed by the national association of housing associations AEDES.

It is the aim of the Smart & Speedy initiative to improve the large part of the housing stock built in series. To make an effective start on a broad scale the project is (at least initially) primarily focused on dwellings owned by housing associations.

THE CONCEPT OF THE SMART & SPEEDY PROJECT

Several parties have been approaching building and construction differently for quite some time. For these relatively small parties, it is difficult to really make a difference in the field. Housing associations, looking for suppliers and constructors, are cautious and often do not dare to opt for a new party on the market, especially not when that party operates differently to the usual. Often, after a long period of preparation and many meetings, they still chose a traditional party.

By joining forces and operating on a large scale, the project Smart & Speedy wants to bring movement to this static situation. The aim is to obtain concepts for serially built housing of the sixties and seventies that may reduce energy use by at least 45% at an affordable rate and without much hinder for the residents. One of the conditions is that the residents will not need to leave their house for longer than five days, whilst the preference goes to avoiding necessary vacation entirely.

The project consists of several elements that intertwine; a network, a field program and an extensive research program. Members from the construction chain that are involved with the sustainability of housing of the sixties and seventies, but also financial experts and parties from the energy field, work together in this network. Currently more than 20 companies are involved. The network members pay a fee per year for three years and thus create a joint capital that enables oriented research and the development of activities.

The network is involved on many fronts, for example as sounding board for the field segment of Smart & Speedy. This part is financed by the government and is part of the Energy Jump Program (EnergieSprong) of the SEV (Stuurgroep Experimenten Volkshuisvesting). Through field experiments the SEV aims to greatly increase energy reduction in the built environment. In the field program, Smart & Speedy realizes four projects, each with a minimum of 400 houses. These projects will start within a year and be completed within 3 years, but more importantly, will create concepts that may be repeatedly applied to comparable housing in other parts of the country.

The field program is experimental in the sense that in a totally new manner, consortia of rivaling market parties, in cooperation with the (coalition of) awarding corporations, develop supply ánd demand. Currently housing associations are approached and requested to take part and soon the search for supplying consortia will also start. They will be challenged so that they do not come forward with a solution that consists of piling measures such as double glazing and extra insulation, but with an integrated concept that may be applied to a large part of the housing of the sixties and seventies. The SEV provides an intensive process management to ensure these solutions become reality.

Of course, realizing these ambitions in the field is not just a technical issue. On the contrary. Besides the conservative reaction of awarding authorities already mentioned, there are more reasons that prevent ambitious plans from becoming reality. Therefore, preliminary to the field program, an extensive research was started with the aim to chart all possible opportunities and obstacles. Each opportunity and obstacle is displayed as a knob that may be turned, resulting in a concept with the working title ‘the control panel’. Who and when should turn which knob which way, differs per situation. These situations are charted as scenarios. During the program the results will be calibrated yearly.

Finally, three institutes of knowledge are connected to Smart & Speedy; Nyenrode Business University , Delft University of Technology (TUD) and Hogeschool Utrecht (University of applied sciences Utrecht). It is intended that a PhD candidate will monitor the whole project. Graduation students will focus on parts of the project.

BOTTLENECKS AND OPPORTUNITIES

The willingness of housing associations to invest in energy reduction used to be low. The interest among housing associations in the first years of the century was limited because of

low demand from residents and expected high costs of energy reducing measures. The introduction of the energy labels in 2008 may have changed the picture. Van Hal et al (2009) conducted an explorative study to see if this supposition is right. They made an inventory of the potential financial benefits of energy reducing investments, resulting or not in a higher energy label. They also conducted a survey of 15 housing associations to assess the impact of these benefits on the willingness of housing associations to invest in energy reduction.

The survey about the willingness of housing associations showed that they agree upon the urgency of the matter: energy reduction is necessary and is a task for housing associations. Compared with the first part of the decade the opinion of housing associations changed.

Van Hal et al conclude that housing associations are willing to invest in energy reduction. However, there are three obstacles for housing associations to do so:

- the 'split incentive' problem. When housing associations invest in energy reduction, they have to carry the load of the investment, the costs. The benefits - lower energy costs and more comfort - land with the residents. (When the majority of the residents do not agree with the investments they do not have to pay a higher rent (see below).) The split incentive problem is also related to the problem that the energy performance has a relatively small weight in the Dutch rent setting system.
- the diverging development of rents and energy costs. The energy costs are growing much faster than rents and are not leveled off by the housing allowance.
- the requirement that 70% of the tenants of an estate have to agree with investments and corresponding rent increase. If they do not agree the investments are possible but the increase in rent cannot be enforced.

Several housing associations tried, in creative ways, to avoid these obstacles. For example by starting an energy company, by investing in a long turn relationship with their tenants (tenants do support the initiatives of a housing association more easily if the relation is based on trust), by investing without a rent increase (in those cases the rent will only be raised after moving of the tenants) and several other initiatives. However; a definitive solution has not bene found yet. There are still a number of obstacles to remove to reach the goal of an energy efficient housing stock (Flier, v.d. and Van Hal, 2010).

Recent discussion amongst the members of the network Smart & Speedy show the same results. In this network one of the main concerns is related with the willingness of residents to cooperate and pay the raise of rent that goes with the energy efficient retrofitting. For years there have been attempts to get Dutch citizens enthusiastic to invest in improving the energy efficiency of their homes. Looking back, one can only conclude that the results are disappointing this far. A lot of money has been invested in information campaigns and specific motivational programs, but the overall results are minimal. Herein the Dutch are not unique. The American environmental psychologist Dough McKenzie-Mohr already stated in 1999 the example of an electricity company in California in his book 'Fostering Sustainable behavior'. This company had spent more money on advertising about the benefits of an energy-saving system in a specific type of dwelling, than the costs would have been had they implemented the system in the dwellings for free. In the Netherlands there are no official figures in this field, but it is not inconceivable that a comparable situation sometimes arises here.

An important cause seems the fact that too little is learned from earlier experiences. It is difficult to find projects whose effects have been analysed on the basis of a thorough benchmark and a final study. Developers of campaigns just do 'what seems sensible'. Partly due to this, project descriptions from years ago show strikingly few differences with descriptions of present projects, despite the fact that they were not successful. Another reason for the repeated mistakes seems to be the fact the main focus with the startup and realization of Dutch motivation campaigns often stays limited to the technique and financial consequences. Knowledge of the behavior of the target groups (fields of study such as psychology, sociology, behavior-economy and marketing) was usually not considered (Boerbooms, Diepenmaat, Van Hal, Kansrijke aanpakken, 2010).
The Smart & Speedy initiative shows the following elements to be of great importance too:

- The ratio of sold and rented houses
- The specific circumstances of the renovation project (kind of neighborhood, technical condition, etc..)
- Energy prices
- Public opinion regarding sustainability topics
- Policy of the national government
- European regulation
- Employment rate in the building industry
- Pull or Push market
- Market demand
- Vision of the construction industry on cooperation (willingness to cooperate)

Research carried out for the Smart & Speedy initiative has resulted in determining the following main focuses for action: cost reduction, meeting the needs of the residents, increasing the interests of housing associations, improvement of the position of the supply side, optimization of the effectiveness of governmental influences, development and optimization of effective technology, improvement of cooperation, a focus on the neighborhood scale too, and improvement of communication.

PROMISING APPROACH: THE CASE OF ROOSENDAAL

In neighborhood the Kroeven in Roosendaal 264 dwellings are being renovated in a way that can be described as smart and speedy. The project is realized according to the 'passive house' principle. This project is unique because in the Netherlands traditional rental terraced houses are never renovated to passive house level on this scale. Furthermore, besides the high energy ambition, the project is spectacular as the whole renovation is realized in occupied state, for which a relative fast realization and rigid planning are necessary.
In conjunction with the residents' committee, the choice was made to renovate to passive-house level as a response to the fast rising energy prices. Since the first plan to renovate these houses normal maintenance had been put off. Unfortunately, it had taken years before the project was started. This diminished the residents' trust in the housing association, making it difficult to get the required 70% approval. In the end, the necessary approval was obtained by a guarantee for the coming five years that the rent increase will be compensated by the decrease in energy costs.

In the passive-house concept, optimal insulation is used in combination with the sealing of chinks causing the dwelling to have a maximal heat demand of 25 kWh/m^2 (against 65 kWh/m^2 for a newly built dwelling). In this project, this leads to a decrease in average use of natural gas from 2500 m^3 to 700 m^3. The energy label of the houses improves from an F/G label to A++. Two approaches are used for the renovation of the houses. The first 110 dwellings are renovated in a more traditional way on the outside as well as on the inside. The installation systems needed for a passive house are installed separately. The other approach makes use of prefab elements and one integrated passive house heating and ventilation system.

The second approach, with prefab elements, leads to higher quality, shorter construction time, no delays and less complaints of inconvenience. In this renovation method the outer cavity wall is removed first. Next, the ground floor is insulated. On the fifth day the door frame, the window frames and the roof are removed and replaced with new prefab façade and roof elements. These elements are already provided with windows and a solar boiler. The total renovation takes no more than fifteen days. The tenants are given the option to include an internal renovation of their dwelling. If the kitchen or bathroom are old, they can be replaced during the renovation. Additionally, the residents can choose convenience improvements, like a larger bathroom or a luxurious kitchen, in exchange for a rent increase.

In spite of the improvement in quality and the short turnaround, the reactions of the residents are not always favorable. At the start of the project, some of the tenants are dissatisfied when they do not qualify for a free new kitchen or bathroom, when others do. During the renovation there are complaints about the workmen working inside the house, not tied to any specific job. The renovation is a large infringement of the residents' privacy.

However, there is a different between the two renovation approaches. The approach with the prefab elements takes no more than fifteen days. This seems to be the maximum amount of time people can bear with this inconvenience. The more traditional approach takes four to five weeks. This causes a lot more complaints about the duration of the renovation. When the renovation is done, the residents are not always satisfied with their 'new' dwelling. They have to get used to using new heating strategies and to the lingering warmth. Some complain that the dwelling is too warm and there is some distrust of the new (mechanical) ventilation system regarding the indoor air quality.

CONCLUSIONS

There is a great urgency to refurbish the existing serial built housing stock in a smart, speedy and energy efficient way. New approaches, strategies and more extensive implementation are necessary which ask for a combined effort of stakeholders. Bottlenecks to realize these renovation projects in practice have to be tackled. Apart from speeding up technical and process innovation (and sharing knowledge) expanding the possibilities for financing energy efficient renovations is crucial. One of the main issues is to address the split incentive phenomena. To be able to do so, in the Netherlands also cooperation of residents is of major concern. One of the main bottlenecks is the lack of enthusiasm amongst residents. Meeting the needs of residents should be the number one concern of all parties involved.
